}
```

Viewing Amazon CloudWatch metrics for an integration

Once an integration completes, you can see these Amazon Cloudwatch metrics generated in your account for each Amazon Glue job run:

CloudWatch metrics namespace: "Amazon/Glue/ZeroETL"

Metrics dimensions:

- `integrationArn`
- `loadType`
- `tableName`

Metric names:

- `InsertCount` - number of records inserted in the target Iceberg table.
- `UpdateCount` - number of records updated in the target Iceberg table.
- `DeleteCount` - number of records deleted from the target Iceberg table.
- `IngestionSucceeded` - count 1, if the ingestion succeeded for the integration.
- `IngestionFailed` - count 1, if the ingestion failed for the integration.
- `LastSyncTimestamp` - timestamp until which source has been synced to target.

Managing event notifications with Amazon EventBridge

Zero-ETL integrations use Amazon EventBridge to manage event notifications to keep you up-to-date regarding changes in your integrations. Amazon EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. In this case, the event source is Amazon Glue. Events, which are monitored changes in an environment, are sent to EventBridge from Amazon Glue automatically. Events are delivered in near real time.

EventBridge provides an environment for you to write event rules, which can specify actions to take for specific events. You can also set up targets, which are resources that EventBridge can send an event to. A target can include an API destination, an Amazon CloudWatch log group, and others. For more information about rules, see [Amazon EventBridge rules](#). For more information about targets, see [Amazon EventBridge targets](#).

To capture all Zero-ETL notifications, create an Eventbridge rule which matches the following:

```
{
  "source": [{
    "prefix": "aws.glue-zero-etl"
  }],
  "detail-type": [{
    "prefix": "Glue Zero ETL"
  }]
}
```

The following table includes zero-ETL integration events, with additional metadata:

Customer-facing detail type	Explanation
Amazon Glue Zero ETL Ingestion Completed	Individual execution for an entity has completed successfully.
Amazon Glue Zero ETL Ingestion Failed	Individual execution for an entity has completed unsuccessfully (either with a client or system error).
Amazon Glue Zero ETL Integration Resynced	Integration has been RESYNCED.
Amazon Glue Zero ETL Integration Failed	Integration status has changed to FAILED due to an error.
Amazon Glue Zero ETL Integration Needs Attention	Integration status has changed to NEEDS_ATTENTION due to an error.
Amazon Glue Zero ETL Ingestion In Progress	Individual execution for an entity has made partial progress towards completion.

Limitations

The following are general limitations of or considerations about zero-ETL integrations:

- Resource properties have a one-to-one relationship with the corresponding resource. Consequently, all integrations created using that resource must adhere to the singular resource property. Modifying a resource property will therefore impact all integrations associated with that resource.

- Table properties have a one-to-one relationship with the corresponding table or object within a resource. As a result, all integrations that process the same table to or from the same resource must adhere to the singular table property.
- You cannot rename a column at the source. If a column is renamed then there is no guarantee that the schema detection will be accurately done by Amazon Glue and the repercussions on the integration are undefined.
- The following consideration applies to how the integration works with Amazon Lake Formation managed tables: By default, you use the IAM/Amazon Glue policy to manage your table and databases.
- If you want to use Amazon Lake Formation to manage the table creation in that database, you need to make sure that the role is given sufficient Lake Formation permissions to create, modify and delete the table and database.
- The zero-ETL summary page does not contain any metrics at this time.

The following are source-specific limitations of zero-ETL integrations:

- Zero-ETL integrations with an SAP OData source supports entities starting with EntityOf. The ability to override the primary key is currently supported only for SAPOData EntityOf objects. Once this property has been set, it cannot be modified.
- Zero-ETL integrations from Amazon DynamoDB to Amazon SageMaker Lakehouse (via S3) support a maximum DynamoDB table size of 50TB.
- The source DynamoDB table must be encrypted with either an Amazon-owned or customer-managed Amazon KMS key. Amazon managed encryption is not supported for the source DynamoDB table.
- SAP OData works using a delta token, where the combination of an OAuth client plus an entity, or basic authentication plus an entity, can have only a single delta token. Avoid using the same entity in two different integrations with the same client.
- The following Salesforce entities or fields are unsupported for use in a zero-ETL integration with a Salesforce source.

```
AccountChangeEvent, AccountContactRoleChangeEvent, AccountHistory, AccountShare,

Amazon Glue Data Quality

Amazon Glue Data Quality allows you to measure and monitor the quality of your data so that you can make good business decisions. Built on top of the open-source DeeQu framework, Amazon Glue Data Quality provides a managed, serverless experience. Amazon Glue Data Quality works with Data Quality Definition Language (DQDL), which is a domain specific language that you use to define data quality rules. To learn more about DQDL and supported rule types, see [Data Quality Definition Language \(DQDL\) reference](#).

For additional product details and pricing, see the service page for [Amazon Glue Data Quality](#).

Benefits and key features

Benefits and key features of Amazon Glue Data Quality include:

- **Serverless** – There is no installation, patching or maintenance.
- **Get started quickly** – Amazon Glue Data Quality quickly analyzes your data and creates data quality rules for you. You can get started with two clicks: “Create Data Quality Rules → Recommend rules”.
- **Detect data quality issues** – Use machine learning (ML) to detect anomalies and hard-to-detect data quality issues.
- **Improvise your rules** – with 25+ out-of-the-box DQ rules to start from, you can create rules that suit your specific needs.
- **Evaluate quality and make confident business decisions** – Once you evaluate the rules, you get a Data Quality score that provides an overview of the health of your data. Use Data Quality score to make confident business decisions.
- **Zero in on bad data** – Amazon Glue Data Quality helps you identify the exact records that caused your quality scores to go down. Easily identify them, quarantine and fix them.
- **Pay as you go** – There are no annual licenses you need to use Amazon Glue Data Quality.
- **No lock-in** – Amazon Glue Data Quality is built on open source DeeQu, allowing you to keep the rules you are authoring in an open language.
- **Data quality checks** – You can enforce data quality checks on Data Catalog and Amazon Glue ETL pipelines allowing you to manage data quality at rest and in transit.
- **ML-based data quality detection** – Use machine learning (ML) to detect anomalies and hard-to-detect data quality issues.

- **Open language to express rules** – ensures that data quality rules are authored consistently and simply. Business users can easily express data quality rules in a straightforward language that they can understand. For engineers, this language provides the flexibility to generate code, implement consistent version control, and automate deployments.

How it works

There are two entry points for Amazon Glue Data Quality: the Amazon Glue Data Catalog and Amazon Glue ETL jobs. This section provides an overview of the use cases and Amazon Glue features that each entry point supports.

Data quality for the Amazon Glue Data Catalog

Amazon Glue Data Quality evaluates objects that are stored in the Amazon Glue Data Catalog. It offers non-coders an easy way to set up data quality rules. These personas include data stewards and business analysts.

You might choose this option for the following use cases:

- You want to perform data quality tasks on data sets that you've already cataloged in the Amazon Glue Data Catalog.
- You work on data governance and need to identify or evaluate data quality issues in your data lake on an ongoing basis.

You can manage data quality for the Data Catalog using the following interfaces:

- The Amazon Glue management console
- Amazon Glue APIs

To get started with Amazon Glue Data Quality for the Amazon Glue Data Catalog see [Getting started with Amazon Glue Data Quality for the Data Catalog](#).

Data quality for Amazon Glue ETL jobs

Amazon Glue Data Quality for Amazon Glue ETL jobs lets you perform *proactive* data quality tasks. Proactive tasks help you identify and filter out bad data *before* you load a data set into your data lake.

[Video: Introducing Amazon Glue Data Quality for ETL Pipelines](#)

You might choose data quality for ETL jobs for the following use cases:

- You want to incorporate data quality tasks into your ETL jobs
- You want to write code that defines data quality tasks in ETL scripts
- You want to manage the quality of data that flows in your visual data pipelines

You can manage data quality for ETL jobs using the following interfaces:

- Amazon Glue Studio, Amazon Glue Studio notebooks, and Amazon Glue interactive sessions
- Amazon Glue libraries for ETL scripting
- Amazon Glue APIs

To get started with data quality for ETL jobs, see [Tutorial: Getting started with Data Quality](#) in the *Amazon Glue Studio User Guide*.

Comparing data quality for the Data Catalog to data quality for ETL jobs

This table provides an overview of features that each entry point for Amazon Glue Data Quality supports.

Feature	Data quality for the Data Catalog	Data quality for ETL jobs
Data sources	Amazon S3, Amazon Redshift, JDBC sources compatible with the Data Catalog, and transactional data lake formats such as Apache	All data sources supported by Amazon Glue, including custom connectors and third-party connectors.

Feature	Data quality for the Data Catalog	Data quality for ETL jobs
	Iceberg, Apache Hudi, and Delta Lake. Amazon Lake Formation managed OTF formats are also supported with some limitations. Amazon Athena views that are cataloged in Amazon Glue Data Catalog are not supported. Please see Supported source types .	
Data Quality rule recommendations	Supported	Not supported
Author and run DQDL rules	Supported	Supported
Auto scaling	Not supported	Supported
Amazon Glue Flex support	Not supported	Supported
Scheduling	Supported when evaluating Data Quality rules and via Step Functions.	Supported when using Step Functions and workflows.
Identifying records that failed data quality checks	Not supported	Supported
Integration with Amazon Eventbridge	Supported	Supported
Integration with Amazon Cloudwatch	Supported	Supported
Writing data quality results to Amazon S3	Supported	Supported

Feature	Data quality for the Data Catalog	Data quality for ETL jobs
Incremental data quality	Supported via pushdown predicates	Supported via Amazon Glue bookmarks
Amazon CloudFormation support	Supported	Supported
ML-based anomaly detection	Not supported	Supported
Dynamic rules	Not supported	Supported

Considerations

Consider the following items before you use Amazon Glue Data Quality:

- Data quality rules can't evaluate nested or list-type data sources. See [Flatten nested structs](#).

Terminology

The following list defines terms that are related to Amazon Glue Data Quality.

Data Quality Definition Language (DQDL)

A domain-specific language that you can use to write Amazon Glue Data Quality rules.

To learn more about DQDL, see the [Data Quality Definition Language \(DQDL\) reference](#) guide.

data quality

Describes how well a dataset serves its specific purpose. Amazon Glue Data Quality evaluates rules against a dataset to measure data quality. Each rule checks for particular characteristics like data freshness or integrity. To quantify data quality, you can use a *data quality score*.

data quality score

The percentage of data quality rules that pass (result in true) when you evaluate a ruleset with Amazon Glue Data Quality.

rule

A DQDL expression that checks your data for a specific characteristic and returns a Boolean value. For more information, see [Rule structure](#).

analyzer

A DQDL expression that gathers data statistics. An analyzer gathers data statistics that can be used by ML algorithms to detect anomalies and hard-to-detect data quality issues over time.

ruleset

An Amazon Glue resource that comprises a set of data quality rules. A ruleset must be associated with a table in the Amazon Glue Data Catalog. When you save a ruleset, Amazon Glue assigns an Amazon Resource Name (ARN) to the ruleset.

data quality score

The percentage of data quality rules that pass (result in true) when you evaluate a ruleset with Amazon Glue Data Quality.

observation

An unconfirmed insight generated by Amazon Glue by analyzing data statistics gathered from rules and analyzers over time.

Limits

Amazon Glue Data Quality service limits:

- You can have 2,000 rules in a ruleset. If your rulesets are larger, we recommend splitting into multiple rulesets.
- The size of the ruleset is 65KB. If your rulesets are larger, we recommend splitting into multiple rulesets.
- Amazon Glue Data Quality collects statistics when you create a rule or analyzer. There is no cost associated with storing these statistics. However, there is a limit of 100,000 statistics per account, and these statistics will be retained for a maximum of two years.

Release notes for Amazon Glue Data Quality

This topic describes features introduced in Amazon Glue Data Quality.

General availability: new features

The following new features are available with the general availability of Amazon Glue Data Quality:

- The ability to identify which records failed data quality checks is now supported in Amazon Glue Studio
- New data quality ruletypes such as validating referential integrity of data between two data sets, comparing data between two datasets, and data type checks
- Improved user experience in the Amazon Glue Data Catalog
- Support for Apache Iceberg, Apache Hudi and Delta Lake
- Support for Amazon Redshift
- Simplified notification with Amazon EventBridge
- Amazon CloudFormation support for creating rulesets
- Performance improvements: caching option in ETL and Amazon Glue Studio for faster performance when evaluating data quality

Nov 27, 2023 (Preview)

- ML-powered anomaly detection capabilities are now available in Amazon Glue ETL and Amazon Glue Studio. With this, you can now detect anomalies and hard-to-detect data quality issues
- [Dynamic Rules allows you to provide dynamic thresholds \(ex: RowCount > avg\(last\(10\)\)\)](#)

Mar 12, 2024

- DQDL improvements
 - [Support for Keywords like NULL, BLANKS, WHITESPACES_ONLY](#)
 - [Options to specify how Amazon Glue Data Quality must handle Composite rules](#)
 - [ColumnValues rule type will not allow NULL values to pass during comparisons](#)
 - [Support for NOT operator in DQDL](#)

June 26, 2024

- DQDL improvements

- DQDL now supports [where clause](#) so that you can filter data before applying DQ rules

August 7, 2024

- Anomaly Detection and Dynamic Rules are now generally available

Nov 22, 2024

- [Complex composite rules allows you to author more complex business rules with nested support](#)
- New rule types for managing data quality for your files
 - [FileFreshness](#)
 - [FileSize](#)
 - [FileUniqueness](#)
 - [FileMatch](#)
- Default data quality checks in Visual ETL jobs

Dec 6, 2024

- Amazon Glue Data Quality now supports Amazon SageMaker AI LakeHouse tables and Amazon Lake Formation managed Iceberg, Delta and HUDI tables in Amazon Glue ETL 5.0.

Jul 7, 2025

- Amazon Glue Data Quality; now supports Amazon S3 Tables, RMS, Lakehouse and Amazon Lake Formation managed Iceberg tables in Amazon Glue Data Catalog.

Nov 21, 2025

- Amazon Glue Data Quality now supports rule labeling for enhanced reporting. You can organize and analyze data quality results more effectively by querying results by specific labels to identify failing rules within particular categories, count rule outcomes by team or domain, and create focused reports for different stakeholders. For more information, see [Labels](#).

- Amazon Glue Data Quality now supports Constants in DQDL, allowing you to define constant values and reference them throughout your script. This helps prevent issues related to query size limits when working with large SQL statements. For more information, see [Constants](#).

Anomaly detection in Amazon Glue Data Quality

Case for Machine Learning in Data Quality

Engineers manage hundreds of data pipelines simultaneously. Each pipeline can extract data from various sources and load it into the data lake or other data repositories. To ensure high-quality data is delivered for decision-making, they establish data quality rules. These rules assess the data based on fixed criteria reflecting the current business state. However, when the business environment changes, data properties shift, rendering these fixed criteria outdated and causing poor data quality.

For example, a data engineer at a retail company established a rule that validates daily sales must exceed a one-million-dollar threshold. After a few months, daily sales surpassed two million dollars, rendering the threshold obsolete. The data engineer could not update the rules to reflect the latest thresholds due to a lack of notification and the effort required to manually analyze and update the rule. Later in the month, business users noticed a 25% drop in their sales. After hours of investigation, the data engineers discovered that an ETL pipeline responsible for extracting data from some stores had failed without generating errors. The rule with outdated thresholds continued to operate successfully without detecting this issue.

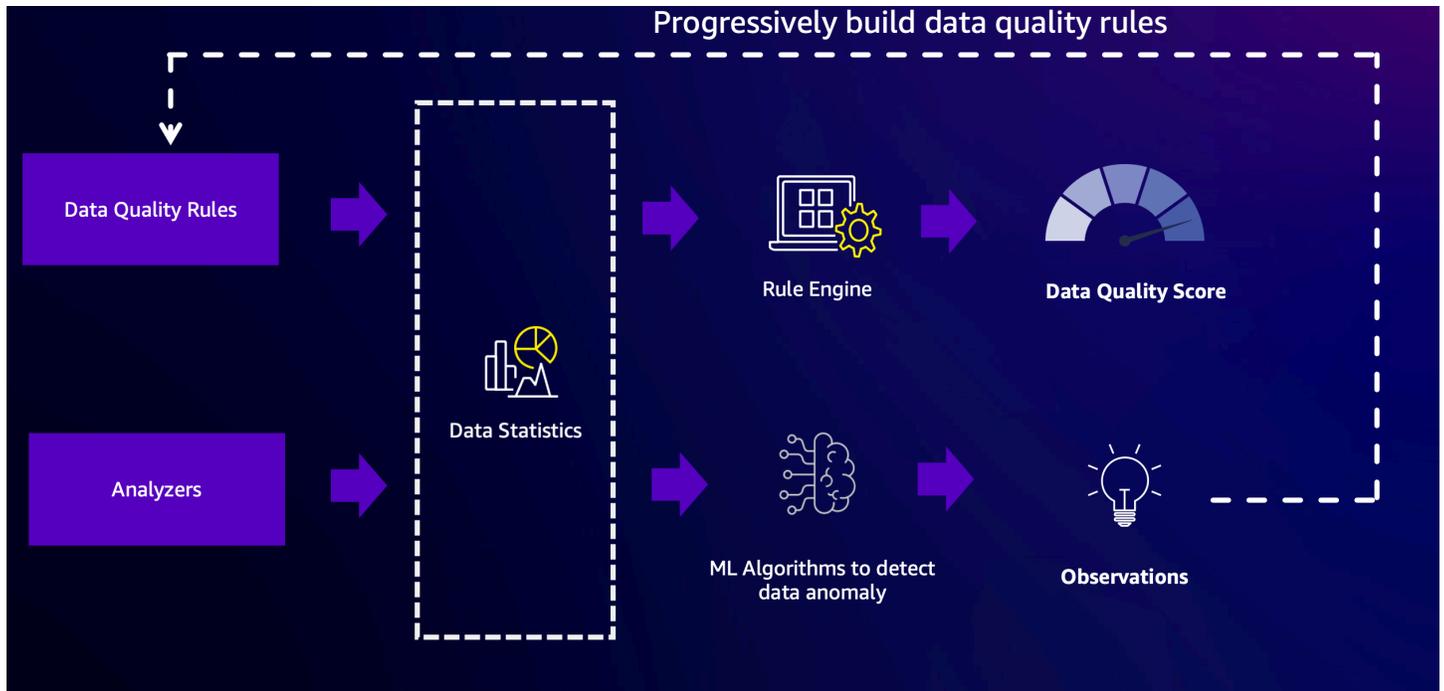

Alternatively, proactive alerts that can detect these anomalies could have enabled users to detect this issue. Moreover, tracking seasonality in business can highlight significant data quality problems. For instance, retail sales may be highest on weekends and during the holiday season while relatively low on weekdays. Divergence from this pattern may indicate data quality issues or shifts in business circumstances. Data quality rules cannot detect seasonal patterns as this requires advanced algorithms that can learn from past patterns capturing seasonality to detect deviations.

Finally, users find it challenging to create and maintain rules due to the technical nature of the rule creation process and the time involved to author them. As a result, they prefer exploring data insights first before defining rules. Customers need the ability to spot anomalies with ease, enabling them to proactively detect data quality issues and make confident business decisions.

How it works

Note

Anomaly detection is only supported in Amazon Glue ETL. This is not supported in Data Catalog-based data quality.

Amazon Glue Data Quality combines the power of rule-based data quality and anomaly detection capabilities to deliver high-quality data. To get started, you must first configure rules and analyzers, and then enable anomaly detection.

Rules

Rules – Rules express the expectations for your data in an open language called the Data Quality Definition Language (DQDL). An example of a rule is shown below. This rule will be successful when there are no empty or NULL values in the `passenger_count` column:

```
Rules = [
  IsComplete "passenger_count"
]
```

Analyzers

In situations where you know the critical columns but may not know enough about the data to write specific rules, you can monitor those columns using Analyzers. Analyzers are a way to gather data statistics without defining explicit rules. An example of configuring Analyzers is shown below:

```
Analizers = [  
  AllStatistics "fare_amount",  
  DistinctValuesCount "pulocationid",  
  RowCount  
]
```

In this example, three Analyzers are configured:

1. The first Analyzer, `AllStatistics "fare_amount"`, will capture all available statistics for the `fare_amount` field.
2. The second Analyzer, `DistinctValuesCount "pulocationid"`, will capture the count of distinct values in the `pulocationid` column.
3. The third Analyzer, `RowCount`, will capture the total number of records in the dataset.

Analyzers serve as a simple way to gather relevant data statistics without specifying complex rules. By monitoring these statistics, you can gain insights into the data quality and identify potential issues or anomalies that may require further investigation or the creation of specific rules.

Data statistics

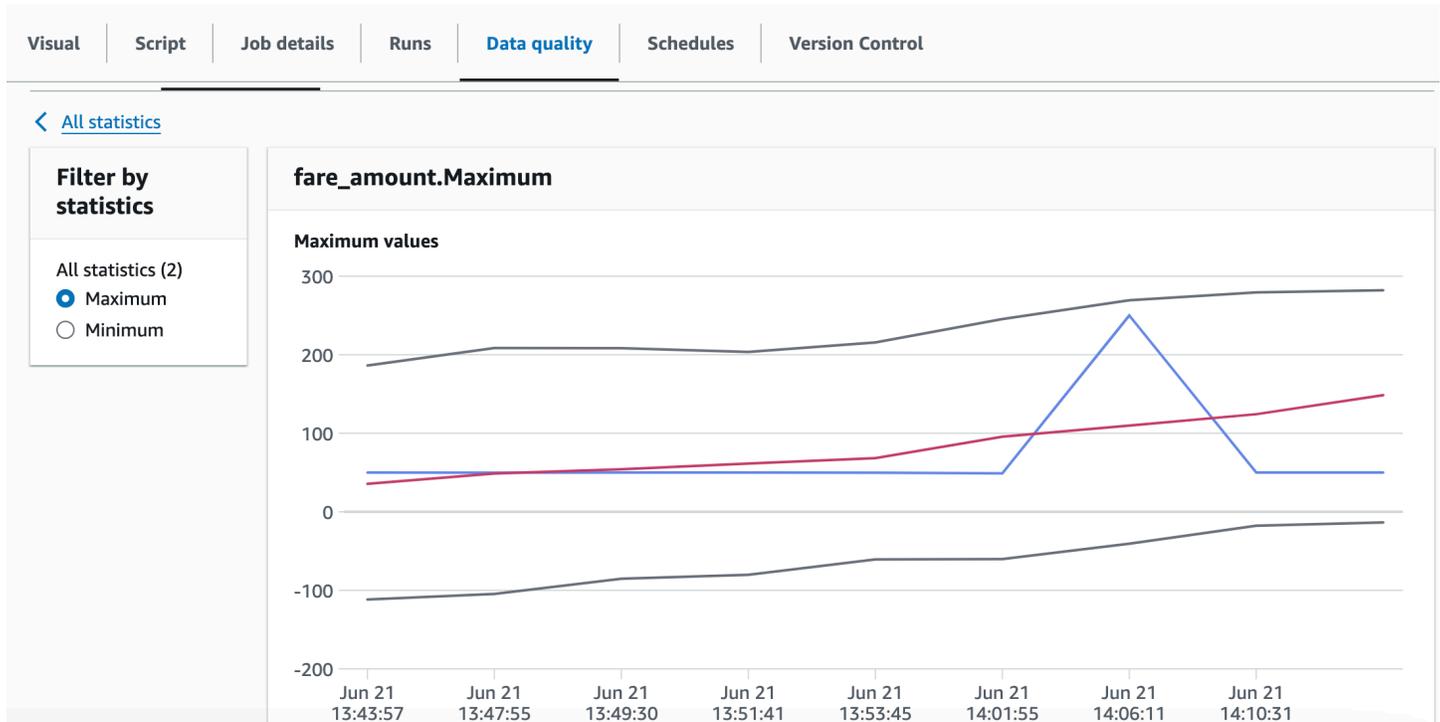

Both Analyzers and Rules in Amazon Glue Data Quality gather data statistics, also known as data profiles. These statistics provide insights into the characteristics and quality of your data. The collected statistics are stored over time within the Amazon Glue service, allowing you to track and analyze changes in your data profiles.

You can easily retrieve these statistics and write them to Amazon S3 for further analysis or long-term storage by invoking the appropriate APIs. This functionality enables you to integrate data profiling into your data processing workflows and leverage the collected statistics for various purposes, such as data quality monitoring, anomaly detection.

By storing the data profiles in Amazon S3, you can take advantage of the scalability, durability, and cost-effectiveness of Amazon's object storage service. Additionally, you can leverage other

Amazon services or third-party tools to analyze and visualize the data profiles, enabling you to gain deeper insights into your data quality and make informed decisions about data management and governance.

Here is an example of data statistics stored over time.

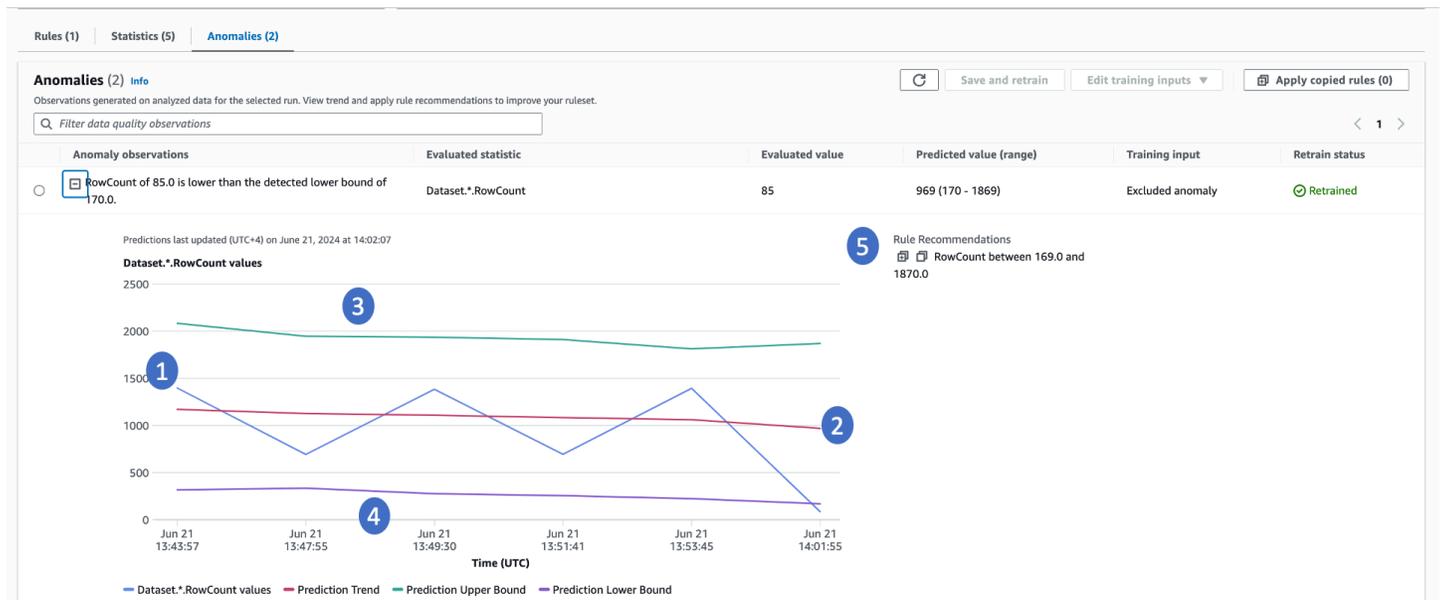

Note

Amazon Glue Data Quality will gather statistics only once, even if you have both **Rule** and **Analyzer** for the same columns, making the statistics generation process efficient.

Anomaly Detection

Amazon Glue Data Quality requires a minimum of three data points to detect anomalies. It utilizes a machine learning algorithm to learn from past trends and then predict future values. When the actual value does not fall within the predicted range, Amazon Glue Data Quality creates an Anomaly Observation. It provides a visual representation of the actual value and the trends. Four values are displayed on the graph below.

1. The actual statistic and its trend over time.
2. A derived trend by learning from the actual trend. This is useful for understanding the trend direction.
3. The possible upper bound for the statistic.
4. The possible lower bound for the statistic.
5. Recommended data quality rules that can detect these issues in the future.

There are a few important things to note regarding Anomalies:

- When anomalies are generated, data quality scores are not impacted.
- When an anomaly is detected, it is considered normal for subsequent runs. The machine learning algorithm will consider this anomalous value as input unless it is explicitly excluded.

Retraining

Retraining the anomaly detection model is critical to detect the right anomalies. When anomalies are detected, Amazon Glue Data Quality includes the anomaly in the model as a normal value. To ensure the anomaly detection works accurately, it is important to provide feedback by acknowledging or rejecting the anomaly. Amazon Glue Data Quality provides mechanisms both in Amazon Glue Studio and APIs to provide feedback to the model. To know more, refer to the documentation on setting up [Anomaly Detection in Amazon Glue ETL pipelines](#).

Details of the Anomaly Detection algorithm

- The Anomaly Detection algorithm examines data statistics over time. The algorithm considers all available data points and ignores any statistics that are explicitly excluded.
- These data statistics are stored in the Amazon Glue service, and you can provide Amazon KMS keys to encrypt them. Refer to the Security Guide on how to provide Amazon KMS keys to encrypt the Amazon Glue Data Quality statistics.
- The time component is crucial for the Anomaly Detection algorithm. Based on past values, Amazon Glue Data Quality determines the upper and lower bounds. During this determination, it considers the time component. The limits will differ for the same values over a one-minute interval, an hourly interval, or a daily interval.

Capturing seasonality

Amazon Glue Data Quality's anomaly detection algorithm can capture seasonal patterns. For example, it can understand that weekday patterns differ from weekend patterns. This can be seen in the example below, where Amazon Glue Data Quality detects a seasonal trend in the data values. You don't need to do anything specific to enable this capability. Over time, Amazon Glue Data Quality learns seasonal trends and detects anomalies when these patterns break.

Cost

You will be charged based on the time it takes to detect anomalies. Every statistic is charged 1 DPU for the time it takes to detect anomalies. Refer to [Amazon Glue Pricing](#) for detailed examples.

Key considerations

There is no cost to store the statistics. However, there is a limit of 100,000 statistics per account. These statistics will be stored for maximum of two years.

Configure IAM permissions for Amazon Glue Data Quality

This topic provides information to help you understand the actions and resources that you an IAM administrator can use in an Amazon Identity and Access Management (IAM) policy for Amazon Glue Data Quality. It also includes sample IAM policies with the minimum permissions you need to use Amazon Glue Data Quality with the Amazon Glue Data Catalog.

For additional information about security in Amazon Glue, see [Security in Amazon Glue](#).

IAM permissions for Amazon Glue Data Quality

The following table lists the permissions that a user needs in order to perform specific Amazon Glue Data Quality operations. To set fine-grained authorization for Amazon Glue Data Quality, you can specify these actions in the `Action` element of an IAM policy statement.

Amazon Glue Data Quality actions

Action	Description	Resource types
<code>glue:CreateDataQualityRuleset</code>	Grants permission to create a data quality ruleset.	<code>::dataQualityRuleset/<name></code>
<code>glue>DeleteDataQualityRuleset</code>	Grants permission to delete a data quality ruleset.	<code>::dataQualityRuleset/<name></code>
<code>glue:GetDataQualityRuleset</code>	Grants permission to retrieve a data quality ruleset.	<code>::dataQualityRuleset/<name></code>
<code>glue:ListDataQualityRulesets</code>	Grants permission to retrieve all data quality rulesets.	<code>::dataQualityRuleset/*</code>

Action	Description	Resource types
glue:UpdateDataQualityRuleset	Grants permission to update a data quality ruleset.	::dataQualityRuleset/<name>
glue:GetDataQualityResult	<p>Grants permission to retrieve a data quality task run result. This IAM action also provides permissions to the following APIs:</p> <ul style="list-style-type: none"> • BatchGetDataQualityResult • ListDataQualityStatistics • ListDataQualityStatisticAnnotations 	::dataQualityRuleset/<name>
glue:ListDataQualityResults	Grants permission to retrieve all data quality task run results.	::dataQualityRuleset/*
glue:CancelDataQualityRuleRecommendationRun	Grants permission to stop an in-progress data quality recommendation task run.	::dataQualityRuleset/*
glue:GetDataQualityRuleRecommendationRun	Grants permission to retrieve a data quality recommendation task run.	::dataQualityRuleset/*
glue:ListDataQualityRuleRecommendationRuns	Grants permission to retrieve all data quality recommendation task runs.	::dataQualityRuleset/*
glue:StartDataQualityRuleRecommendationRun	Grants permission to start a data quality recommendation task run.	::dataQualityRuleset/*

Action	Description	Resource types
<code>glue:CancelDataQualityRulesetEvaluationRun</code>	Grants permission to stop an in-progress data quality task run.	<code>::dataQualityRuleset/*</code>
<code>glue:GetDataQualityRulesetEvaluationRun</code>	Grants permission to retrieve a data quality task run.	<code>::dataQualityRuleset/*</code>
<code>glue:ListDataQualityRulesetEvaluationRuns</code>	Grants permission to retrieve all data quality task runs.	<code>::dataQualityRuleset/*</code>
<code>glue:StartDataQualityRulesetEvaluationRun</code>	Grants permission to start a data quality task run.	<code>::dataQualityRuleset/<name></code>
<code>glue:PublishDataQuality</code>	Grants permission to publish data quality results.	<code>::dataQualityRuleset/<name></code>
<code>glue:GetDataQualityModel</code>	Grants permission to retrieve Data Quality Model.	<code>::dataQualityRuleset/<name>, ::job/<name></code>
<code>glue:GetDataQualityModelResult</code>	Grants permission to retrieve Data Quality Model Results.	<code>::dataQualityRuleset/<name>, ::job/<name></code>
<code>glue:PutDataQualityStatisticAnnotation</code>	Grants permission to add annotations to Statistics. This IAM action also provides permissions to the following APIs: <ul style="list-style-type: none"> <code>BatchPutDataQualityStatisticAnnotation</code> 	<code>::dataQualityRuleset/<name>, ::job/<name></code>

Action	Description	Resource types
<code>glue:PutDataQualityProfileAnnotation</code>	Grants permission to put annotations to all Statistics in a Profile.	<code>::dataQualityRuleset/<name></code> , <code>::job/<name></code>

IAM setup required for scheduling evaluation runs

IAM permissions

To run scheduled Data Quality evaluation runs, you must add the `IAM:PassRole` action to the permissions policy.

Amazon EventBridge Scheduler required permissions

Action	Description	Resource types
<code>iam:PassRole</code>	Grants permission for IAM to allow the user to pass the approved roles.	ARN of the role used to call <code>StartDataQualityRulesetEvaluationRun</code>

Without these permissions the following error occurs:

```
"errorCode": "AccessDenied"
"errorMessage": "User: arn:aws:sts::account_id:assumed-role/AWSGlueServiceRole is not
authorized to perform: iam:PassRole on resource: arn:aws:iam::account_id:role/service-
role/AWSGlueServiceRole
because no identity-based policy allows the iam:PassRole action"
```

IAM trusted entities

The Amazon Glue and Amazon EventBridge Scheduler services need to be listed in the trusted entities in order to create and run a scheduled `StartDataQualityEvaluationRun`.

JSON

```
{

]
```

Example IAM policies

An IAM role for Amazon Glue Data Quality needs the following types of permissions:

- Permissions for Amazon Glue Data Quality operations so that you can get recommended data quality rules and run a data quality task against a table in the Amazon Glue Data Catalog. The example IAM policies in this section include the minimum permissions required for Amazon Glue Data Quality operations.
- Permissions that grant access to your Data Catalog table and the underlying data. These permissions vary depending on your use case. For example, for data that you catalog in Amazon S3, the permissions should include access to Amazon S3.

Note

You must configure Amazon S3 permissions in addition to the permissions described in this section.

Minimum permissions to get recommended data quality rules

This example policy includes the permissions you need in order to generate recommended data quality rules.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGlueRuleRecommendationRunActions",
      "Effect": "Allow",
      "Action": [
        "glue:GetDataQualityRuleRecommendationRun",
        "glue:PublishDataQuality",
        "glue:CreateDataQualityRuleset"
      ],
      "Resource": "arn:aws:glue:us-east-1:111122223333:dataQualityRuleset/*"
    },

```

Getting started with Amazon Glue Data Quality for the Data Catalog

This getting started section provides instructions to help you get started with Amazon Glue Data Quality on the Amazon Glue console. You'll learn how to complete essential tasks such as generating data quality rule recommendations and evaluating a ruleset against your data.

Topics

- [Prerequisites](#)
- [Step-by-step example](#)
- [Generating rule recommendations](#)
- [Monitoring rule recommendations](#)
- [Editing recommended rulesets](#)
- [Creating a new ruleset](#)
- [Running a ruleset to evaluate data quality](#)
- [Viewing the data quality score and results](#)
- [Using preprocessing queries](#)
- [Supported source types](#)
- [Related topics](#)

Prerequisites

Before you use Amazon Glue Data Quality, you should be familiar with using the Data Catalog and crawlers in Amazon Glue. With Amazon Glue Data Quality, you can evaluate quality for tables in a Data Catalog database. You also need the following:

- A table in the Data Catalog to evaluate your data quality ruleset against.
- An IAM role for Amazon Glue that you supply when you generate rule recommendations or run a data quality task. This role must have permission to access resources that various Amazon Glue Data Quality processes require to run on your behalf. These resources include Amazon Glue, Amazon S3, and CloudWatch. To view example policies that include the minimum permissions for Amazon Glue Data Quality, see [Example IAM policies](#).

To learn more about IAM roles for Amazon Glue, see [Create an IAM policy for the Amazon Glue service](#) and [Create an IAM role for the Amazon Glue service](#). You can also view a list of all Amazon Glue permissions that are specific to data quality in [Authorization for Amazon Glue Data Quality actions](#).

- A database with at least one table that contains a variety of data. The table used in this tutorial is named `yyz-tickets`, with the table `tickets`. This data is a collection of publicly available information from the City of Toronto for parking citations. If you create your own table, make sure that it's populated with a variety of valid data to get the best set of recommended rules.

Step-by-step example

For a step-by-step example with sample datasets, see the [Amazon Glue Data Quality blog post](#).

Generating rule recommendations

Rule recommendations make it easy to get started with data quality without writing code. With Amazon Glue Data Quality, you can analyze your data, identify rules, and create a ruleset that you can evaluate in a data quality task. Recommendation runs are automatically deleted after 90 days.

To generate data quality rule recommendations

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Tables** in the navigation pane. Then choose the table that you want to generate data quality rule recommendations for.

3. On the table details page, select the **Data quality** tab to access Amazon Glue Data Quality rules and settings for your table.
4. On the **Data quality** tab, choose **Add rules and monitor data quality**.
5. On the **Ruleset builder** page, an alert at the top of the page will prompt you to start a recommendation task if there are no rule recommendation runs.
6. Choose **Recommend rules** to open the modal and input your parameters for the recommendation task.
7. Choose an IAM role with access to Amazon Glue. This role must have permission to access resources that various Amazon Glue Data Quality processes require to run on your behalf.
8. After the fields are completed according to your preferences, choose **Recommend rules** to start the recommendation task run. If recommendation runs are in progress or completed, you can manage your runs in this alert. You might need to refresh the alert to view the status change. Completed and in-progress recommendation task runs appear in the **Run history** page that lists all recommendation runs for the past 90 days.

What the recommended rules mean

Amazon Glue Data Quality generates rules based on the data from each column of the input table. It uses the rules to identify potential boundaries where data can be filtered to maintain quality requirements. The following list of generated rules includes examples that are useful for understanding what the rules mean and what they might do when applied to your data.

For a full list of the generated Data Quality Definition Language (DQDL) rule types, see [DQDL rule type reference](#).

- `IsComplete "SET_FINE_AMOUNT"` –The `IsComplete` rule verifies that the column is filled in for any given row. Use this rule to tag columns as non-optional in data.
- `Uniqueness "TICKET_NUMBER" > 0.95` – The `Uniqueness` rule verifies that the data within the column meets some threshold of uniqueness. In this example, the data that populates any given row for "TICKET_NUMBER" was determined to be at most 95% identical in content to all other rows, which suggests this rule.
- `ColumnValues "PROVINCE" in ["ON", "QC", "AB", "NY", ...]` – The `ColumnValues` rule defines valid values for the column, based on existing column contents. In this example, the data for each row is a 2-letter license code plate for a state or province.

- ColumnLength "INFRACTION_DESCRIPTION" between 15 and 31 – The ColumnLength rule enforces a length restriction on a column's data. This rule is generated from the sample data based on the minimum and maximum recorded lengths for a column of strings.

Monitoring rule recommendations

When data quality rule recommendations are running, the **Add rules and monitor data quality** page displays information and additional actions that you can take in the top bar.

When rule recommendations are in progress, you can choose **Stop run** before the recommendation task is complete. While the task is in progress, you will see the status, **in progress**, and the date and time when the run started.

When the rule recommendations are complete, the rule recommendation bar displays the number of rules recommended, the status of the last recommendation run, and the date and timestamp when it finished.

You can add the recommended rules by choosing **Insert Rule Recommendation**. To view previously recommended rules, select a specific date. To run a new recommendation, choose **More actions**, and then choose **Recommended rules**.

Set default settings by choosing **Manage user settings**. You can set the default path for Amazon S3 to store rulesets or to set up a default role to run the Data Catalog.

Editing recommended rulesets

Because Amazon Glue Data Quality generates rules based on existing data that you have available, you might see some unexpected or undesirable rules in the automated suggestions. In order to get the most out of the recommended rulesets, you need to evaluate and modify them. For this step of the tutorial, you take the rules generated in the previous step and adjust them to enforce more restrictive qualities on some data. You also relax other rules to ensure that correct, unique data can be added later.

Edit a suggested ruleset

1. In the Amazon Glue console, choose **Data Catalog**, and then choose **Databases tables** in the navigation pane. Choose the table `tickets`.
2. On the table details page, choose the **Data quality** tab to access Amazon Glue Data Quality rules and settings for the table.

3. In the **Rulesets** section, select the ruleset generated in [Generating rule recommendations](#).
4. Choose **Actions**, and then choose **Edit** in the console window. The ruleset editor loads in the console. It includes an editing pane for your rules and a quick reference for DQDL.
5. Remove line 2 of the script. This relaxes the requirement that the database size is constrained within a certain number of rows. After the edit, your file should contain the following on lines 1–3:

```
Rules = [
  IsComplete "TAG_NUMBER_MASKED",
  ColumnLength "TAG_NUMBER_MASKED" between 6 and 9,
```

6. Remove line 25 of the script. This relaxes the requirement that 96% of recorded provinces are ON. After the edit, your file should contain the following from line 24 to the end of the ruleset:

```
ColumnValues "PROVINCE" in ["ON", "QC", "AB", "NY", "AZ", "NS", "BC", "MI", "PQ",
  "MB", "PA", "FL", "SK", "NJ", "OH", "NB", "IL", "MA", "CA",
  "VA", "TX", "NF", "MD", "PE", "CT", "NC", "GA", "IN", "OR", "MN", "TN", "WI",
  "KY", "MO", "WA", "NH", "SC", "CO", "OK", "VT", "RI", "ME", "AL",
  "YT", "IA", "DE", "AR", "LA", "XX", "WV", "MT", "KS", "NT", "DC", "NV", "NE",
  "UT", "MS", "NM", "ID", "SD", "ND", "AK", "NU", "GO", "WY", "HI"],
ColumnLength "PROVINCE" = 2
]
```

7. Change line 14 to the following:

```
IsComplete "TIME_OF_INFRACTION",
```

This *strengthens* the requirement on the column by limiting the database to only tickets that contain a recorded time of infraction. You should always consider tickets without a recorded time of infraction to be invalid data in this dataset. This is different than situations where partitioning or transformation might be more appropriate for further data use or inspection to determine a quality rule.

8. Choose **Update Ruleset** at the bottom of the console page.

Creating a new ruleset

A ruleset is a group of data quality rules that you evaluate against your data. In the Amazon Glue console, you can author custom rulesets using Data Quality Definition Language (DQDL).

To create a data quality ruleset

1. In the Amazon Glue console, choose **Data Catalog**, choose **Databases**, and then choose **Tables** in the navigation pane. Select the table `tickets`.
2. Open the **Data quality** tab.
3. In the **Rulesets** section, choose **Create ruleset**. The DQDL editor launches in the console. It has a text area for direct editing, and a quick reference for DQDL rules and the table schema.
4. Start adding rules to the text area of the DQDL editor. You can either write rules directly from this tutorial, or use the **DQDL rule builder** feature of the data quality rules editor.

Note

How to use the DQDL rule builder

1. Select a rule type from the list, and select the plus sign to insert example syntax into the editor pane.
2. Exchange the placeholder column names with your own column names. Column names from the table are available in the **Schema** tab.
3. Update the expression parameter as you see fit. For a full list of expressions that DQDL supports, see [Expressions](#).

As an example, the following rules are constraints for data validation of the `ticket_number` column in the `tickets` table. To add the following rules, use the DQDL rule builder or directly edit your ruleset:

```
IsComplete "ticket_number",  
IsUnique "ticket_number",  
ColumnValues "ticket_number" > 9000000000
```

5. Provide a name for your new ruleset in the **Ruleset name** field.
6. Choose **Save ruleset**.

Evaluating data quality across multiple datasets

You can set up data quality rules across multiple datasets using `ReferentialIntegrity` and `DatasetMatch` rulesets. `ReferentialIntegrity` checks to see if data in the primary dataset is present in other datasets.

To add a reference dataset, choose the **Schema** tab and then choose **Update reference tables**. You will be prompted to select a database and a table. You can add the table and then set up data quality rules. Rule types like `AggregateMatch`, `RowCountMatch`, `ReferentialIntegrity`, `SchemaMatch`, and `DatasetMatch` support the ability to perform data quality checks across multiple datasets.

Running a ruleset to evaluate data quality

When you run a data quality task, Amazon Glue Data Quality evaluates a ruleset against your data and calculates a data quality score. This score represents the percentage of data quality rules that passed for the input.

To run a data quality task

1. In the Amazon Glue console, choose **Data Catalog**, choose **Databases**, and then choose **Tables** in the navigation pane. Select the table tickets.
2. Choose the **Data quality** tab.
3. In the **Rulesets** list, select the ruleset that you want to evaluate against the table. For this step, we recommend using a ruleset that you've written or modified already rather than generated rules. Choose **Run**.
4. In the modal, choose your IAM role. This role must have permission to access resources that various Amazon Glue Data Quality processes require to run on your behalf. You can save the IAM role as the default or modify it by going to the **Default Setting** page.
5. Under **Data quality actions**, choose whether you want to **Publish metrics to Amazon CloudWatch**. When this option is selected, Amazon Glue Data Quality publishes metrics that indicate the number of rules that passed and the number of rules that failed. To take action on metrics stored this way, you can use CloudWatch alarms. Key metrics are also published to Amazon EventBridge for you to set up alerts. For more information, see [Setting up alerts, deployments, and scheduling](#).
6. In **Run Frequency**, choose run on demand or schedule the ruleset. When you schedule a ruleset, you're prompted for a task name. The schedule will be created in Amazon EventBridge. You can edit your schedule in Amazon EventBridge.

7. To save the data quality results in Amazon S3, select a **Data quality results location**. The IAM role that you previously selected for this task must have write access to this location.
8. Under **Additional Configurations**, enter the **Requested number of workers** that you want Amazon Glue to allocate for your data quality task.
9. You can optionally set up a filter at the data source. This helps you reduce the data that you're reading. You can also use a filter to run incremental validations by selecting partition information and passing them as parameters via API calls. To improve performance, you can provide a partition predicate.
10. Choose **Run**. You should see your new task in the **Data quality task runs** list. When the **Run status** column for the task shows as **Completed**, you can view the quality score results. You might need to refresh your console window for the status to update correctly.
11. To view the column for the data quality result details, choose the "+" icon to expand the ruleset. The results show you the rules that passed and failed in the evaluation, and what triggered the rule failure.

Viewing the data quality score and results

To see the latest run on all created rulesets

1. In the Amazon Glue console, choose **Tables** in the navigation pane. Then choose the table that you want to run a data quality task for.
2. Choose the **Data quality** tab.
3. The **Data quality snapshot** shows a general trend of runs over time. The last 10 runs over all rulesets are displayed by default. To filter by ruleset, select the desired one from the dropdown list. If there are less than 10 runs, all the completed runs that are available are displayed.
4. In the **Data quality** table, each ruleset with its latest run (if there is one) is shown, along with the score. Expanding the ruleset displays the rules that are in that ruleset, along with the rule results for that run.

To see the latest run on a particular ruleset

1. In the Amazon Glue console, choose **Tables** in the navigation pane. Then choose the table that you want to run a data quality task for.
2. Choose the **Data quality** tab.

3. In the **Data quality** table, choose on a specific ruleset.
4. On the **Ruleset details** page, choose the **Run history** tab.

All of the evaluation runs for this particular ruleset are listed in the table within this tab. You can see the history of the scores and the status of the runs.

5. To see more information about a particular run, choose the **Run ID** to go to the **Evaluation run details** page. On this page, you can see specifics about the run and more details about the status of individual rule results.

Using preprocessing queries

Amazon Glue Data Quality supports preprocessing queries that allow you to transform your data before running data quality checks. This feature enables you to:

- Create derived columns for data quality validation.
- Filter data based on specific conditions.
- Perform calculations or transformations for quality checks.
- Validate relationships between columns.

Note

This feature is only supported in APIs and is not supported via the console.

Using preprocessing queries with the CLI and SDK

Recommendation runs

The following examples show how to use preprocessing queries with recommendation runs.

Amazon CLI:

```
aws glue start-data-quality-rule-recommendation-run \  
  --data-source '{"DataQualityGlueTable": { \  
    "DatabaseName": "mydatabase", \  
    "TableName": "mytable", \  
    "PreProcessingQuery": "SELECT sepal_length, sepal_width, petal_length, petal_width, \  
class, (sepal_length + sepal_width) as sepal_total FROM `mydatabase.mytable`" \  
  }'
```

```

}}' \
--role "arn:aws:iam::123456789012:role/GlueDataQualityRole" \
--created-ruleset-name "my-ruleset-with-preprocessing"

```

Java SDK:

```

StartDataQualityRuleRecommendationRunRequest request = new
StartDataQualityRuleRecommendationRunRequest()
    .withDataSource(new DataSource()
        .withDataQualityGlueTable(new DataQualityGlueTable()
            .withDatabaseName("mydatabase")
            .withTableName("mytable")
            .withPreProcessingQuery("SELECT sepal_length, sepal_width, " +
                "(sepal_length + sepal_width) as sepal_total " +
                "FROM `mydatabase.mytable`"))
        .withRole("arn:aws:iam::123456789012:role/GlueDataQualityRole")
        .withCreatedRulesetName("my-ruleset-with-preprocessing");

glueClient.startDataQualityRuleRecommendationRun(request);

```

Ruleset evaluation runs

The following examples show how to use preprocessing queries with ruleset evaluation runs.

Amazon CLI:

```

aws glue start-data-quality-ruleset-evaluation-run \
--data-source '{"DataQualityGlueTable": { \
  "DatabaseName": "mydatabase", \
  "TableName": "mytable", \
  "PreProcessingQuery": "SELECT order_id, amount, (tax + shipping) as total_fees FROM \
`mydatabase.mytable`" \
}}' \
--role "arn:aws:iam::123456789012:role/GlueDataQualityRole" \
--ruleset-names ["my-ruleset"]

```

Java SDK:

```

StartDataQualityRulesetEvaluationRunRequest request = new
StartDataQualityRulesetEvaluationRunRequest()
    .withDataSource(new DataSource()

```

```
.withDataQualityGlueTable(new DataQualityGlueTable()  
    .withDatabaseName("mydatabase")  
    .withTableName("mytable")  
    .withPreProcessingQuery("SELECT order_id, amount, " +  
        "(tax + shipping) as total_fees " +  
        "FROM `mydatabase.mytable`"))  
.withRole("arn:aws:iam::123456789012:role/GlueDataQualityRole")  
.withRulesetNames(Arrays.asList("my-ruleset"));  
  
glueClient.startDataQualityRulesetEvaluationRun(request);
```

Considerations when authoring preprocessing queries

When writing a preprocessing query:

- The table reference must be formatted as ``databaseName.tableName`` using backticks.
- The query must be a valid SELECT statement.
- Column names in the query output will be used for data quality rules.

The following example shows a preprocessing query:

```
SELECT  
    sepal_length,  
    sepal_width,  
    petal_length,  
    petal_width,  
    class,  
    (sepal_length + sepal_width) as sepal_total  
FROM `mydatabase.mytable`
```

Limitations

- The query must reference the table using backticks and the full ``databaseName.tableName`` format.
- Maximum query length is 51,200 characters.
- The query must return at least one row of data.
- All columns referenced in your ruleset must be present in the query output.

Supported source types

* Amazon S3 tables and SageMaker Lakehouse support in Amazon Glue Console is not supported. Currently, Amazon S3 table and SageMaker Lakehouse Data Catalog Recommendation Runs and Data Catalog Data Quality Evaluation runs are only supported via the CLI.

Other known limitations

- Delta Lake Symlink Tables: Not supported for Amazon Glue Data Quality recommendation runs or Data Catalog Data Quality evaluation runs.
- Amazon S3 Table Asset publishing in SageMaker Unified Studio: Currently, publishing Amazon S3 Tables as Assets in SageMaker Unified Studio is unavailable; visualizing Amazon S3 Table Data Quality runs is unavailable from SageMaker Unified Studio as a result.

Evaluating data quality with Amazon Glue Studio

Amazon Glue Data Quality evaluates and monitors the quality of your data based on rules that you define. This makes it easy to identify the data that needs action. In Amazon Glue Studio, you can add data quality nodes to your visual job to create data quality rules on tables in your Data Catalog. You can then monitor and evaluate changes to your datasets as they evolve over time. For an overview of how to work with Amazon Glue Data Quality in Amazon Glue Studio, see the following video.

The following are the high-level steps for how you work with Amazon Glue Data Quality:

1. **Create data quality rules** – Build a set of data quality rules using the DQDL builder by choosing built-in rulesets that you configure.
2. **Configure a data quality job** – Define actions based on the data quality results and output options.
3. **Save and run a data quality job** – Create and run a job. Saving the job will save the rulesets that you created for the job.
4. **Monitor and review the data quality results** – Review the data quality results after the job run is complete. Optionally, schedule the job for a future date.

Benefits

Data analysts, data engineers, and data scientists can use the Evaluate Data Quality node in Amazon Glue Studio to analyze, configure, monitor, and improve the quality of data from the visual job editor. The benefits of using the data quality node include the following:

- **You can detect data quality issues** - You can check for issues by creating rules that check characteristics of your datasets.
- **It's easy to get started** - You can start with pre-built rules and actions.
- **Tight integration** - You can use data quality nodes in Amazon Glue Studio because Amazon Glue Data Quality runs on top of the Amazon Glue Data Catalog.

Evaluating data quality for ETL jobs in Amazon Glue Studio

In this tutorial, you get started with Amazon Glue Data Quality in Amazon Glue Studio. You will learn how to:

- Create rules using the Data Quality Definition Language (DQDL) rule builder.
- Specify data quality actions, data to output, and the output location of the data quality results.
- Review data quality results.

To practice with an example, review the blog post [Getting started with Amazon Glue Data Quality for ETL pipelines](#).

Step 1: Add the Evaluate Data Quality transform node to the visual job

In this step, you add the Evaluate Data Quality node to the visual job editor.

To add the data quality node

1. In the Amazon Glue Studio console, choose **Visual with a source and target** from the **Create job** section, and then choose **Create**.
2. Choose a node that you want to apply the data quality transform to. Typically, this will be a transform node or a data source.
3. Open the resource panel on the left by choosing the "+" icon. Then search for **Evaluate Data Quality** in the search bar and choose **Evaluate Data Quality** from the search results.
4. The visual job editor shows the **Evaluate Data Quality** transform node branching from the node you selected. On the right side of the console, the **Transform** tab is automatically opened. If you need to change the parent node, choose the **Node properties** tab, and then choose the node parent from the dropdown menu.

When you choose a new node parent, a new connection is made between the parent node and the **Evaluate Data Quality** node. Remove any unwanted parent nodes. Only one parent node can be connected to one **Evaluate Data Quality** node.

5. The Evaluate Data Quality transform supports multiple parents so you can validate data quality rules across multiple datasets. Rules that support multiple datasets include ReferentialIntegrity, DatasetMatch, SchemaMatch, RowCountMatch, and AggregateMatch.

When you add multiple inputs to the Evaluate Data Quality transform, you need to select your "primary" input. Your primary input is the dataset that you want to validate data quality for. All other nodes or inputs are treated as references.

You can use the Evaluate Data Quality transform to identify specific records that failed data quality checks. We recommend that you choose your primary dataset because new columns that flag bad records are added to the primary dataset.

6. You can specify aliases for input data sources. Aliases provide another way to reference the input source when you're using the ReferentialIntegrity rule. Because only one data source can be designated as the primary source, each additional data source that you add will require an alias.

In the following example, the ReferentialIntegrity rule specifies the input data source by the alias name and performs a one-to-one comparison to the primary data source.

```
Rules = [  
  ReferentialIntegrity "Aliasname.name" = 1  
]
```

Step 2: Create a rule using DQDL

In this step, you create a rule using DQDL. For this tutorial, you create a single rule using the **Completeness** rule type. This rule type checks the percentage of complete (non-null) values in a column against a given expression. For more information about using DQDL, see [DQDL](#).

1. On the **Transform** tab, add a **Rule type** by choosing the **Insert** button. This adds the rule type to the rule editor, where you can enter the parameters for the rule.

Note

When you're editing rules, ensure that the rules are within the brackets and that the rules are separated by commas. For example, a complete rule expression will look like the following:

```
Rules= [  
  Completeness "year">0.8, Completeness "month">0.8  
]
```

This example specifies the parameter for completeness for the columns named 'year' and 'month'. For the rule to pass, these columns must be greater than 80% 'complete', or must have data in over 80% of instances for each respective column.

In this example, search for and insert the **Completeness** rule type. This adds the rule type to the rule editor. This rule type has the following syntax: `Completeness <COL_NAME> <EXPRESSION>`.

Most rule types require that you provide an expression as a parameter in order to create a Boolean response. For more information on supported DQDL expressions, see [DQDL expressions](#). Next, you'll add the column name.

2. In the DQDL rule builder, choose the **Schema** tab. Use the search bar to locate the column name in the input schema. The input schema displays the column name and data type.
3. In the rule editor, click to the right of the rule type to insert the cursor where the column will be inserted. Alternately, you can enter in the name of the column in the rule.

For example, from the list of columns in the input schema list, choose the **Insert** button next to the column (in this example, **year**). This adds the column to the rule.

4. Then, in the rule editor, add an expression to evaluate the rule. Because the **Completeness** rule type checks the percentage of complete (non-null) values in a column against a given expression, enter an expression such as `> 0.8`. This rule checks the column if it's greater than 80% complete (non-null) values.

Step 3: Configure data quality outputs

After creating data quality rules, you can select additional options to specify data quality node output.

1. In **Data quality transform output**, choose from the following options:
 - **Original data** – Choose to output original input data. When you choose this option, a new child node “rowLevelOutcomes” is added to the job. The schema matches the schema of the primary dataset that was passed as input to the transform. This option is useful if you just want to pass the data through and fail the job when quality issues occur.

Another use case is when you want to detect bad records that failed data quality checks. To detect bad records, choose the option **Add new columns to indicate data quality errors**. This action adds four new columns to the schema of the “rowLevelOutcomes” transform.

- **DataQualityRulesPass** (string array) – Provides an array of rules that passed data quality checks.
 - **DataQualityRulesFail** (string array) – Provides an array of rules that failed data quality checks.
 - **DataQualityRulesSkip** (string array) – Provides an array of rules that were skipped. The following rules cannot identify error records because they're applied at the dataset level.
 - AggregateMatch
 - ColumnCount
 - ColumnExists
 - ColumnNamesMatchPattern
 - CustomSql
 - RowCount
 - RowCountMatch
 - StandardDeviation
 - Mean
 - ColumnCorrelation
 - **DataQualityEvaluationResult** – Provides “Passed” or “Failed” status at the row level. Note that your overall results can be FAIL, but a certain record might pass. For example, the RowCount rule might have failed, but all other rules might have been successful. In such instances, this field status is 'Passed'.
2. **Data quality results** – Choose to output configured rules and their pass or fail status. This option is useful if you want to write your results to Amazon S3 or other databases.
 3. **Data quality output settings** (Optional) – Choose **Data quality output settings** to reveal the **Data quality result location** field. Then, choose **Browse** to search for an Amazon S3 location to set as the data quality output target.

Step 4. Configure data quality actions

You can use actions to publish metrics to CloudWatch or to stop jobs based on specific criteria. Actions are only available after you create a rule. When you choose this option, the same metrics

are also published to Amazon EventBridge. You can use these options to [create alerts for notification](#).

- **On ruleset failure** – You can choose what to do if a ruleset fails while the job is running. If you want the job to fail if data quality fails, choose when the job should fail by selecting one of the following options. By default, this action is not selected, and the job completes its run even if data quality rules fail.
 - **None** – If you choose **None** (default), the job does not fail and continues to run despite ruleset failures.
 - **Fail job after loading data to target** – The job fails and no data is saved. In order to save the results, choose an Amazon S3 location where the data quality results will be saved.
 - **Fail job without loading to target data** – This option fails the job immediately when a data quality error occurs. It does not load any data targets, including the results from the data quality transform.

Step 5: View data quality results

After running the job, view the data quality results by choosing the **Data quality** tab.

1. For each job run, view the data quality results. Each node displays a data quality status and status detail. Choose a node to view all rules and the status of each rule.
2. Choose **Download results** to download a CSV file that contains information about the job run and data quality results.
3. If you have more than one job run with data quality results, you can filter the results by date and time range. Choose *Filter by a date and time range* to expand the filter window.
4. Choose a relative range or absolute range. For absolute ranges, use the calendar to select a date, and enter values for start time and end time. When you're done, choose **Apply**.

Automatic Data Quality

When you create a Amazon Glue ETL job with Amazon S3 as the target, Amazon Glue ETL automatically enables a Data Quality rule that checks if the data being loaded has at least one column. This rule is designed to ensure that the data being loaded is not empty or corrupted. However, if this rule fails, the job will not fail; instead, you will notice a reduction in your data quality score. Additionally, Anomaly Detection is enabled by default, which monitors the number of columns in the data. If there are any variations or abnormalities in the column count, Amazon Glue

ETL will inform you about these anomalies. This feature helps you identify potential issues with the data and take appropriate actions. To view the Data Quality rule and its configuration, you can click on the Amazon S3 target in your Amazon Glue ETL job. The rule's configuration will be displayed, as shown in the provided screenshot.

The screenshot displays the Amazon Glue console interface for configuring a Data Quality rule. The top navigation bar includes tabs for Visual, Script, Job details, Runs, Data quality, Schedules, and Version Control. The main area shows a visual workflow with three nodes: 'Data source - S3 bucket Amazon S3', 'Transform - Aggregate Aggregate', and 'Data target - S3 bucket Amazon S3'. The 'Data target' node is highlighted, and the configuration panel on the right is open. The configuration panel includes sections for 'S3 Target Location', 'Data Catalog update options', 'Partition keys - optional', and 'Check data quality'. A warning message at the bottom left states 'Nodes are misconfigured'.

You can add additional data quality rules by selecting **Edit data quality configuration**.

Aggregated Metrics

You may require aggregated metrics such as number of records that passed, failed, skipped at a rule level or at the ruleset level to build dashboards. In order to get the Aggregated Metrics and Rule Metrics for each rule, first, enable Aggregated Metrics by adding the `publishAggregatedMetrics` option to your `EvaluateDataQuality` function.

The possible options for `additional_options` `publishAggregatedMetrics` are `ENABLED` and `DISABLED`. As an example:

```
EvaluateDataQualityMultiframe = EvaluateDataQuality().process_rows(
    frame=medicare_dyf,
    ruleset=EvaluateDataQuality_ruleset,
    publishing_options={
        "dataQualityEvaluationContext": "EvaluateDataQualityMultiframe",
        "enableDataQualityCloudWatchMetrics": False,
        "enableDataQualityResultsPublishing": False,
    },
    additional_options={"publishAggregatedMetrics.status": "ENABLED"},
)
```

If not specified, the `publishAggregatedMetrics.status` is `DISABLED` by default and the `ruleMetrics` and aggregated metrics would now be computed. This feature is currently supported in Amazon Glue Interactive Sessions and in Glue ETL jobs. This is not supported in Glue Catalog Data Quality APIs.

Retrieving aggregated metrics results

When `additionalOptions` `"publishAggregatedMetrics.status": "ENABLED"`, you can get the results in two places:

1. `AggregatedMetrics` and `RuleMetrics` are returned through the `GetDataQualityResult()` when providing the `resultId` where `AggregatedMetrics` and `RuleMetrics` include:

Aggregated Metrics:

- Total rows processed
- Total rows passed
- Total rows failed
- Total Rules Processed
- Total Rules Passed
- Total Rules Failed

2. AggregatedMetrics is returned as an additional data frame and RuleOutcomes data frame is augmented to include RuleMetrics.

Example implementation

The following example shows how to implement aggregated metrics in Scala:

```
// Script generated for node Evaluate Data Quality
val EvaluateDataQuality_node1741974822533_ruleset = ""
  # Example rules: Completeness "colA" between 0.4 and 0.8, ColumnCount > 10
  Rules = [
    IsUnique "customer_identifier",
    RowCount > 10,
    Completeness "customer_identifier" > 0.5
  ]
""

val EvaluateDataQuality_node1741974822533 =
  EvaluateDataQuality.processRows(frame=ChangeSchema_node1742850392012,
    ruleset=EvaluateDataQuality_node1741974822533_ruleset,
    publishingOptions=JsonOptions("""{"dataQualityEvaluationContext":
  "EvaluateDataQuality_node1741974822533", "enableDataQualityCloudWatchMetrics":
  "true", "enableDataQualityResultsPublishing": "true"}"""),
    additionalOptions=JsonOptions("""{"compositeRuleEvaluation.method":"ROW","observations.scope":
  "publishAggregatedMetrics.status": "ENABLED"}""))

println("-----ROW LEVEL
  OUTCOMES-----")
val rowLevelOutcomes_node = EvaluateDataQuality_node1741974822533("rowLevelOutcomes")

rowLevelOutcomes_node.show(10)

println("-----RULE LEVEL
  OUTCOMES-----")

val ruleOutcomes_node = EvaluateDataQuality_node1741974822533("ruleOutcomes")

ruleOutcomes_node.show()

println("-----AGGREGATED
  METRICS-----")

val aggregatedMetrics_node = EvaluateDataQuality_node1741974822533("aggregatedMetrics")
```

```
aggregatedMetrics_node.show()
```

Sample results

Results are returned as follows:

```
{
  "Rule": "IsUnique \"customer_identifier\"",
  "Outcome": "Passed",
  "FailureReason": null,
  "EvaluatedMetrics": {
    "Column.customer_identifier.Uniqueness": 1
  },
  "EvaluatedRule": "IsUnique \"customer_identifier\"",
  "PassedCount": 10,
  "FailedCount": 0,
  "SkippedCount": 0,
  "TotalCount": 10
}
{
  "Rule": "RowCount > 10",
  "Outcome": "Failed",
  "FailureReason": "Value: 10 does not meet the constraint requirement!",
  "EvaluatedMetrics": {
    "Dataset.*.RowCount": 10
  },
  "EvaluatedRule": "RowCount > 10",
  "PassedCount": 0,
  "FailedCount": 0,
  "SkippedCount": 10,
  "TotalCount": 10
}
{
  "Rule": "Completeness \"customer_identifier\" > 0.5",
  "Outcome": "Passed",
  "FailureReason": null,
  "EvaluatedMetrics": {
    "Column.customer_identifier.Completeness": 1
  },
  "EvaluatedRule": "Completeness \"customer_identifier\" > 0.5",
  "PassedCount": 10,
  "FailedCount": 0,
  "SkippedCount": 0,
}
```

```
"TotalCount": 10
}
```

Aggregated Metrics are as follows:

```
{ "TotalRowsProcessed": 10, "PassedRows": 10, "FailedRows": 0, "TotalRulesProcessed":
  3, "RulesPassed": 2, "RulesFailed": 1 }
```

Data Quality rule builder

With the Data Quality Definition Language (DQDL) rule builder, you can create data quality rules to evaluate your data. Start by selecting a rule type, and then specify the parameters in the rule editor. The rule editor also shows you any errors and warnings as you create rules.

The [DQDL guide](#) provides comprehensive documentation on how to construct rules using the DQDL syntax, built-in rule types, and examples.

Evaluate Data Quality node

When you're working with the **Evaluate Data Quality** transform node and the DQDL rule builder, you can expand the working space.

- To expand the **Transform** tab to fill the entire screen, choose the expand icon in the upper-right hand corner of the node details panel.
- To expand the DQDL rule editor, choose the << icon to expand the rule editor and collapse the **Rule types** and **Schema** tabs.

The screenshot displays the Amazon Glue Studio interface for configuring a data quality rule. The visual editor on the left shows a workflow starting with two data sources: 'employees' and 'customers'. These feed into a central 'Transform - Evaluate Data Quality' node. This node then branches into two 'Transform - SelectFrom' nodes, which output to 'rowLevelOutcomes' and 'ruleOutcomes' respectively. These outcomes are then written to data targets: 'Amazon S3' and 'AWS Glue Data Catalog'.

The right-hand panel shows the configuration for the 'Evaluate Data Quality' transform. It includes a 'Name' field, 'Node parents' (employees and customers), and 'Aliases for referenced data sources'. The 'Input sources' section shows 'employees' as the primary source and 'customers' as a secondary source. The 'Helper' section shows a list of rule types, including 'AggregateMatch', 'ColumnCorrelation', 'ColumnCount', 'ColumnDataType', and 'ColumnExists'. The 'Schema' tab is active, showing a custom SQL rule:

```

1 Rules = [
2   ReferentialIntegrity "employeeNumber" "customers
3     salesRepEmployeeNumber" between 0.6 and 0.7,
4   RowCount > 1000,
5   CustomSql "select count(*) from primary" between 10 and 200
]

```

At the bottom, the 'Data quality transform output info' section is visible, with the 'Original data' checkbox checked.

Components

There are 26 rule types that are built into Amazon Glue Studio. Each rule type has a description and examples of how they can be used.

Data quality rule types

Amazon Glue Studio provides built-in rule types for ease in creating a rule. For more information on rule types, see [DQDL rule type reference](#).

Schema

The **Schema** tab displays the column names and data type from the parent node. Schemas from multiple nodes are displayed. You can view the input schema, search by column name, and insert the column into the rule editor.

Evaluate data quality [Info](#)

Evaluate data quality by defining your data quality rules and actions

Data quality rules [Info](#)

Add rules using DQDL (Data Quality Definition Language)

The screenshot shows the "DQDL rule builder" interface. On the left, there is a sidebar with "Rule types (18)" and a "Schema" tab highlighted. Below this is a search bar and a list of input schema items: "year int", "month int", "day int", and "fl_date string", each with a "+" button. The main area is a code editor showing a DQDL rule:

```
1 Rules= [  
2   Completeness"year">0.8  
3 ]
```

 The status bar at the bottom indicates "Ln 1, Col 1", "Errors: 0", and "Warnings: 0".

Rule editor

The rule editor is a text editor where you can write and edit rules. If you select a rule type from the DQDL rule builder, the rule type is added to the rule editor. You can then specify parameters, add rules, and edit rules as needed by modifying the text. Amazon Glue Studio validates the rules in the rule editor and displays errors and warnings if there are any.

Errors and warnings

If a rule doesn't follow the DQDL rule syntax, the rule editor shows several visual indicators that there is an error:

- The rule editor displays an error icon and red color on the line with the error.
- The rule editor displays the number of errors next to the red error icon.
- When you choose the line with the error, descriptions of the error and location (line and column) are displayed at the bottom of the rule editor.

Ln 1, Col 1 h is null

Data quality actions

By default, this action is not selected and the job will complete its run even if the data quality rules fail.

Choose between the following actions. You can use actions to publish results to CloudWatch or stop jobs based on specific criteria. Actions are only available after you create a rule.

- **Publish results to CloudWatch** – When you run a job, add the results to CloudWatch.
- **Fail job when data quality fails** – If data quality rules fail, the job will also fail as a result.

Data quality transform output

- **Original data** – Choose to output original input data. This option is ideal if you want to stop the job when quality issues are detected.
- **Data quality metrics** – Choose to output configured rules and their pass or fail status. This option is useful if you want to take a custom action.

Data quality output settings

Set the data quality result location by specifying the Amazon S3 location as the data quality output target.

Configuring anomaly detection in Amazon Glue ETL jobs

To begin with anomaly detection in Amazon Glue Studio, open a Amazon Glue Studio job and click on the **Evaluate Data Quality Transform**.

By enabling this feature, Amazon Glue Data Quality will analyze your data over time to detect anomalies. It provides valuable data statistics and observations about your data, allowing you to take action on any identified anomalies.

Review the [Anomaly Detection](#) documentation to understand the inner workings of this feature.

Enabling anomaly detection

To enable anomaly detection in Amazon Glue Studio:

1. Choose the **Data Quality** node in your job, then choose the **Anomaly detection** tab. Toggle to turn on **Enable Anomaly Detection**.

Ruleset editor | **Anomaly detection** [New](#)

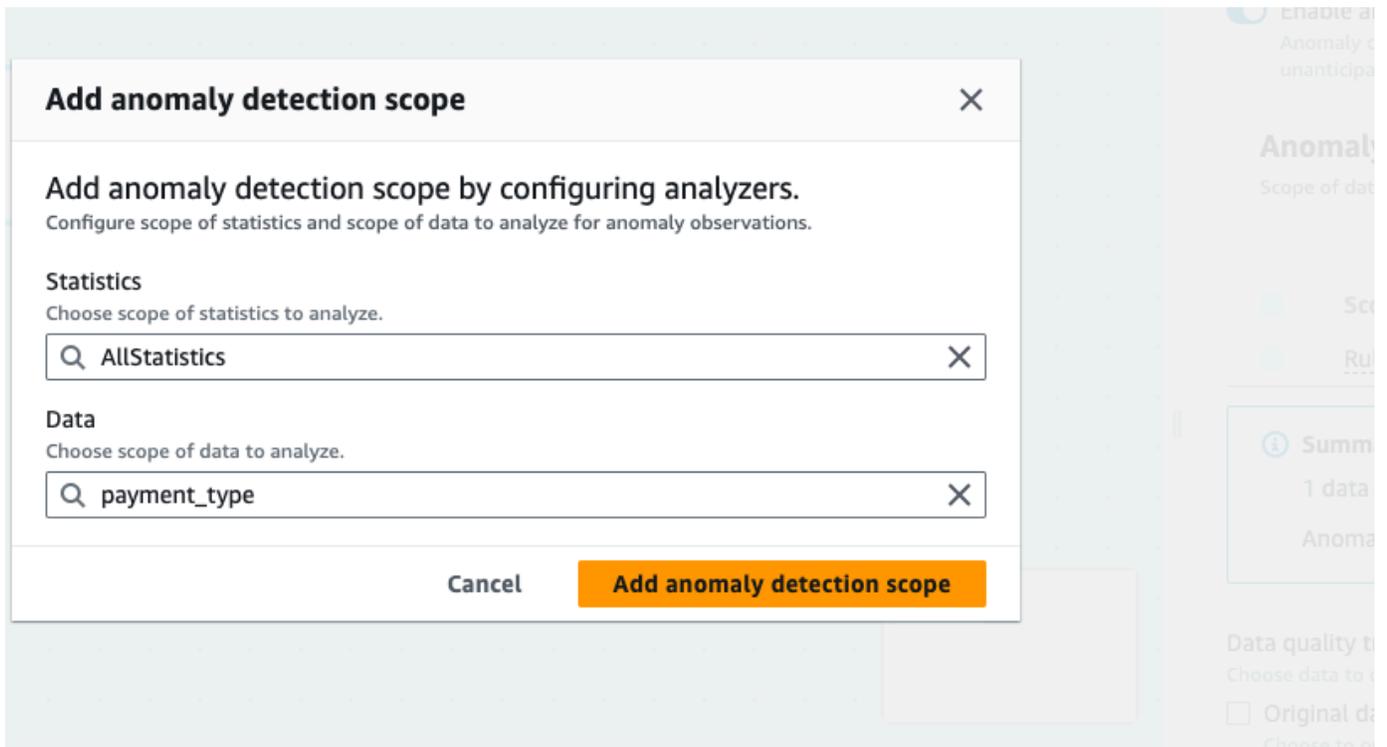

Enable anomaly detection [Info](#)
 Anomaly detection leverages machine learning algorithms to analyze statistics collected by rules and analyzers, allowing us to detect unanticipated and hidden data quality issues. Enable detect anomalies to generate observations on your data during a job run.

Anomaly detection scope (0) Actions ▼ Add analyzer
 Scope of data statistics configured to be analyzed for anomalies.

Scope of statistics	Scope of data	Source
<p>No anomaly detection configuration No configuration to display.</p>		

Summary
 0 data quality rule(s). 0 analyzers.
 Anomaly detection enabled on data statistics from rules and analyzers.

2. Define the data to monitor for anomalies by choosing **Add analyzer**. There are two fields that you can populate: Statistics and Data.
 - **Statistics** are information about your data's shape and other properties. You can choose one or more statistics at a time, or choose **All statistics**. Statistics include: Completeness, Uniqueness, Mean, Sum, StandardDeviation, Entropy, DistinctValuesCount, UniqueValueRatio and more. Refer to the [Analyzers](#) documentation for more details.
 - **Data** is the columns in your dataset. You can choose all columns or individual columns.

3. Choose **Add anomaly detection scope** to save your changes. After you've added analyzers, you can see them in the **Anomaly detection scope** section.

You can also use the **Actions** menu to edit your analyzers, or choose the **Ruleset editor** tab and edit the analyzer directly in the ruleset editor notepad. You will see the analyzers that you saved under any rules that you've created.

```
Rules = [  
  
]  
  
Analyzers = [  
    Completeness "id"  
]
```

Once the updated ruleset and analyzers are configured, Amazon Glue Data Quality continuously monitors incoming data streams. It can signal potential anomalies through alerts or job stops, depending on your settings. This proactive monitoring helps ensure data quality and integrity throughout your data pipelines.

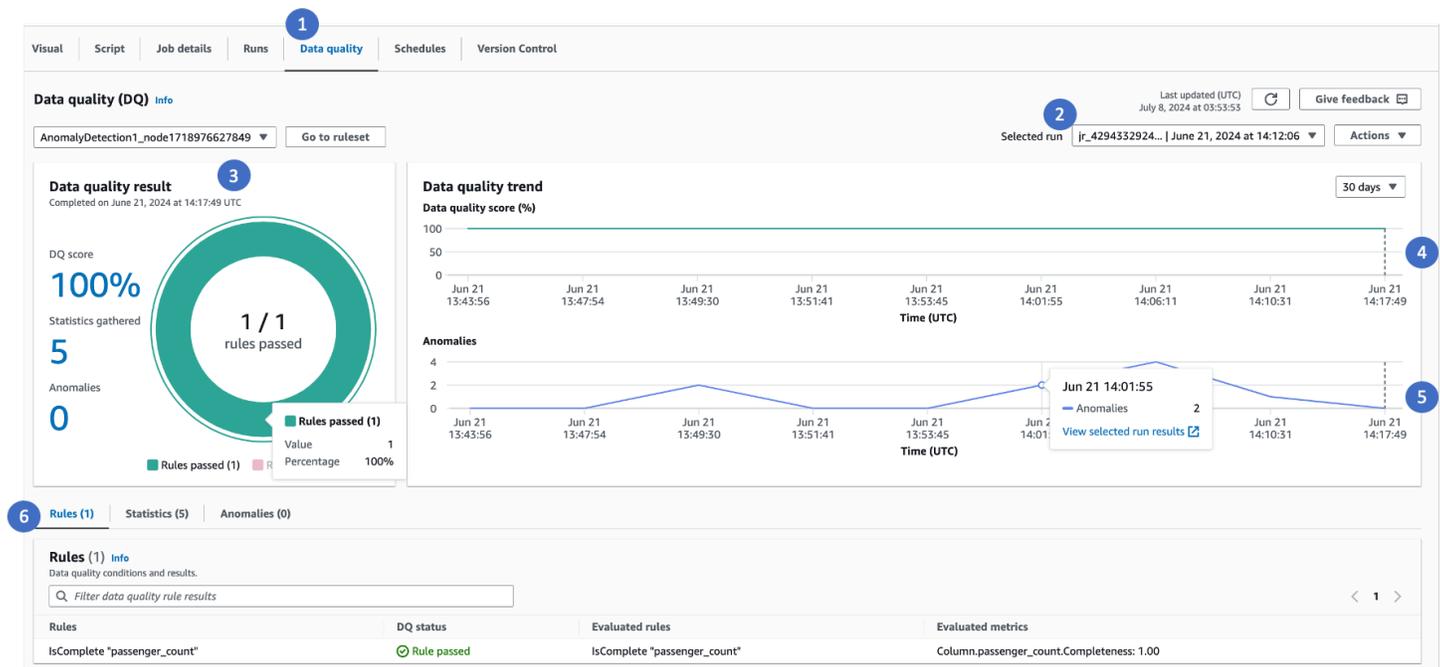

In the next section, you will learn how to effectively monitor anomalies identified by the system. You'll also learn how to view and analyze the data statistics gathered by Amazon Glue Data Quality. Additionally, you'll understand how to provide feedback to the machine learning model that powers the Anomaly Detection feature. This feedback loop is crucial for improving the model's accuracy and ensuring it can effectively detect anomalies that align with your specific business requirements and data patterns.

Viewing data quality scores and anomalies

In this section, we will explore the data quality dashboard and different functionalities that it provides.

Visualize and understand high level data quality metrics and trends

Once your job is successful, choose the **Data Quality** tab to view data quality scores and anomalies.

The following components in the Data quality tab provide useful information.

1. Choose the **Data Quality** tab to view data quality metrics.
2. Select a specific job run ID to view the Data Quality score.
3. This pane shows three important information. You can choose each to navigate to specific tables to view anomalies, data statistics or rules.

- Data Quality score when rules are configured.
 - Number of statistics gathered by Rules and Analyzers.
 - Total number of anomalies detected.
4. This trend chart shows how data quality is trending over time. You can hover over the trend and go to a specific time when data quality scores have deteriorated.
5. Anomaly trends over time will show you the number of anomalies detected over time.
6. Tabs:
- Rules Tab is the default tab that shows list of all the rules and status. Evaluated Rules is useful in case of dynamic rules to view the actual value the rule was evaluated to.
 - Statistics Tab lists all the statistics, allowing you to view the metrics and the trends over time.
 - Anomalies tab shows the list of anomalies that were detected.

Viewing anomalies and training anomaly detection algorithm

Data quality result
Completed on June 21, 2024 at 14:06:11 UTC

DQ score: **100%**

Statistics gathered: **5**

Anomalies: **4**

Rules passed (1) | Rules failed (0)

Data quality trend
Data quality score (%)

Anomalies

Anomalies (4) Info
Observations generated on analyzed data for the selected run. View trend and apply rule recommendations to improve your ruleset.

Anomaly observations	Evaluated statistic	Evaluated value	Predicted value (range)	Training input	Retrain status
<input type="checkbox"/> RowCount of 1391.0 is higher than the detected upper bound of 969.0.	Dataset*.RowCount	1391	68 (0 - 969)	Included anomaly	Retrained

Dataset*.RowCount values

Rule Recommendations: RowCount <= 969.0

Call outs for the image above:

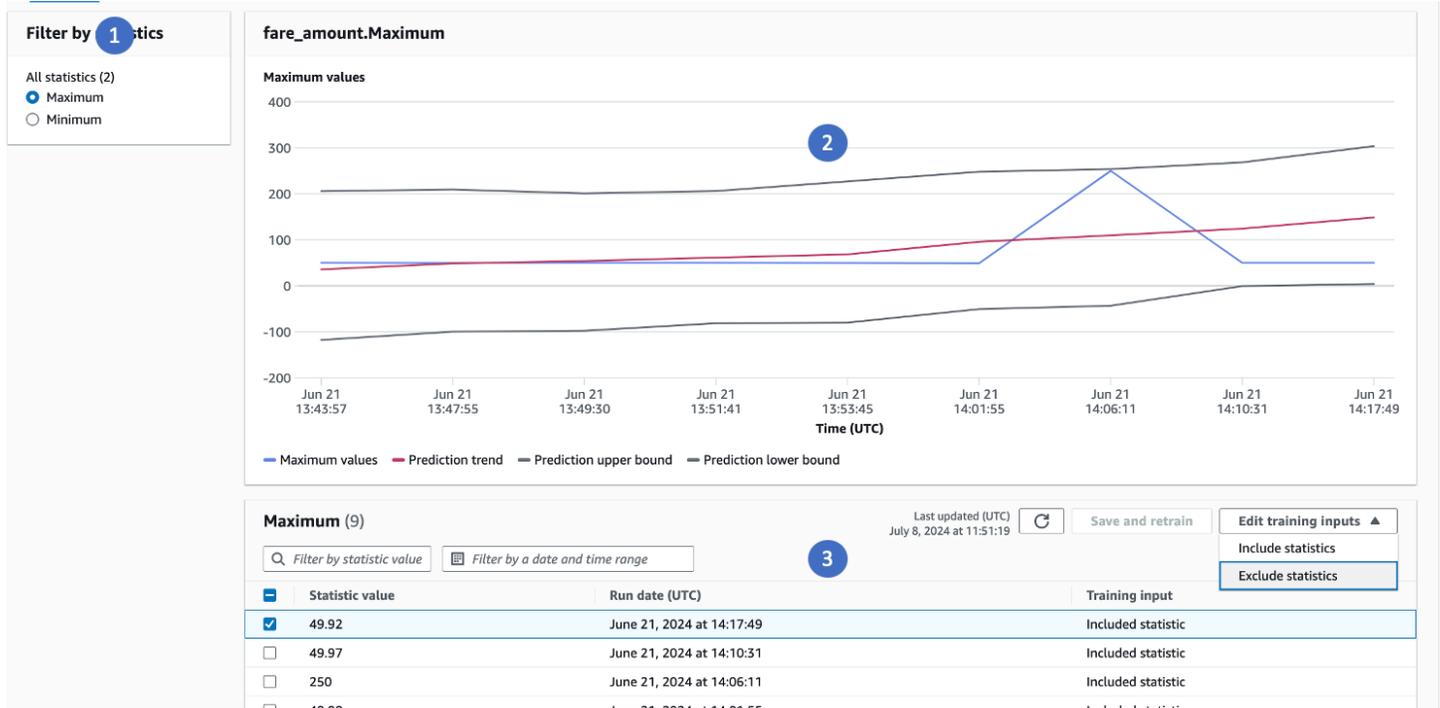

1. When anomalies are detected, click the anomaly or select the Anomalies tab
2. Amazon Glue Data Quality provides a detailed explanation of the anomaly, the actual value, predicted range
3. Amazon Glue Data Quality shows a trend line. It has the actual value, a derived trend based on the actual values (red line), the upper bound and the lower bound
4. Amazon Glue Data Quality recommends data quality rules that can be used to capture the patterns for future. You can copy all the rules that are recommended to you and apply them to your data quality node to capture these patterns effectively.
5. You can provide inputs to the machine learning (ML) model to exclude anomalous values, ensuring that future runs detect anomalies accurately. If you don't explicitly exclude anomalies, Amazon Glue Data Quality will automatically consider them as part of the model for future predictions. It's important to note that only the latest run will reflect the model inputs you provide. For example, if you went back and excluded anomalous points from a few previous runs, the model will not reflect those changes unless you view and update the model inputs in the latest run. The model will continue to use the previously provided inputs until you make necessary adjustments in the most recent run. By actively managing the exclusion of anomalous values, you can refine the ML model's understanding of what constitutes an anomaly for your specific data patterns and requirements, leading to more accurate anomaly detection over time.

Viewing Data Statistics over time and providing training inputs

Sometimes, you may want to view data statistics or data profiles and view how they are progressing over time. To do this, choose **Statistics** or open the **Statistics** tab. You can then view the latest data statistics gathered by Amazon Glue Data Quality.

Rules (1) Statistics (5) Anomalies (0)					
Dataset statistics - new info					
Name	RowCount	View trends			
AnomalyDetection1_node1718976627849	1386	View trends			
Column statistics - new info					
<input type="text" value="Filter statistics"/>					
Name	Maximum	Minimum	DistinctValuesCount	Completeness	View trends
fare_amount	49.92	1.3	-	-	View trends
pulocationid	-	-	20	-	View trends
passenger_count	-	-	-	1	View trends

Clicking **View Trends** shows you how each of the statistics are progressing over time.

1. You can select the statistic for a specified column
2. You can view how the trends are progressing
3. You can select anomalous values and choose to exclude or include them. By providing this feedback, the algorithm will either exclude or include the identified anomalous data points and retrain the model. This retraining process ensures accurate anomaly detection moving forward, as the model learns from the feedback you've provided about which values should be considered anomalous or not.

Through this feedback loop, you have the ability to refine the algorithm's understanding of what constitutes an anomaly for your specific data patterns and business requirements. By excluding values that should not be flagged as anomalies, or including values that were missed, the retrained model will become better at differentiating between expected and truly anomalous data points.

Data Quality for ETL jobs in Amazon Glue Studio notebooks

In this tutorial, you learn how to use Amazon Glue Data Quality for extract, transform, and load (ETL) jobs in Amazon Glue Studio notebooks.

You can use notebooks in Amazon Glue Studio to edit job scripts and view the output without having to run a full job. You can also add markdown and save notebooks as `.ipynb` files and job scripts. Note that you can start a notebook without installing software locally or managing servers. When you're satisfied with your code, you can use Amazon Glue Studio to easily convert your notebook to an Amazon Glue job.

The dataset that you use in this example consists of Medicare Provider payment data that was downloaded from two *Data.CMS.gov* datasets: "Inpatient Prospective Payment System Provider Summary for the Top 100 Diagnosis-Related Groups - FY2011" and "Inpatient Charge Data FY 2011".

After downloading the data, we modified the dataset to introduce a couple of erroneous records at the end of the file. This modified file is located in a public Amazon S3 bucket at `s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv`.

Prerequisites

- Amazon Glue role with Amazon S3 permission to write to your destination Amazon S3 bucket
- A new notebook (see [Getting started with notebooks in Amazon Glue Studio](#))

Creating an ETL job in Amazon Glue Studio

To create an ETL job

1. Change the session version to Amazon Glue 3.0.

To do this, remove all boilerplate code cells with the following magic and run the cell. Note that this boilerplate code is automatically provided in the first cell when a new notebook is created.

```
%glue_version 3.0
```

2. Copy the following code and run it in the cell.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
```

```
from awsglue.job import Job

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
```

3. In the next cell, import the `EvaluateDataQuality` class that evaluates Amazon Glue Data Quality.

```
from awsgluedq.transforms import EvaluateDataQuality
```

4. In the next cell, read in the source data by using the `.csv` file that's stored in the public Amazon S3 bucket.

```
medicare = spark.read.format(
    "csv").option(
    "header", "true").option(
    "inferSchema", "true").load(
    's3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv')
medicare.printSchema()
```

5. Convert the data to an Amazon Glue `DynamicFrame`.

```
from awsglue.dynamicframe import DynamicFrame
medicare_dyf = DynamicFrame.fromDF(medicare, glueContext, "medicare_dyf")
```

6. Create the ruleset using Data Quality Definition Language (DQDL).

```
EvaluateDataQuality_ruleset = """
    Rules = [
        ColumnExists "Provider Id",
        IsComplete "Provider Id",
        ColumnValues " Total Discharges " > 15
    ]
    """
```

7. Validate the dataset against the ruleset.

```
EvaluateDataQualityMultiframe = EvaluateDataQuality().process_rows(
    frame=medicare_dyf,
    ruleset=EvaluateDataQuality_ruleset,
    publishing_options={
        "dataQualityEvaluationContext": "EvaluateDataQualityMultiframe",
        "enableDataQualityCloudWatchMetrics": False,
        "enableDataQualityResultsPublishing": False,
    },
    additional_options={"performanceTuning.caching": "CACHE_NOHING"},
)
```

8. Review the results.

```
ruleOutcomes = SelectFromCollection.apply(
    dfc=EvaluateDataQualityMultiframe,
    key="ruleOutcomes",
    transformation_ctx="ruleOutcomes",
)

ruleOutcomes.toDF().show(truncate=False)
```

Output:

```
-----+-----
+-----+-----
+-----+-----+
|Rule                                     |Outcome|FailureReason
          |EvaluatedMetrics                               |
+-----+-----+-----
+-----+-----+-----
|ColumnExists "Provider Id"             |Passed |null
          |{}                                           |
|IsComplete "Provider Id"               |Passed |null
          |{Column.Provider Id.Completeness -> 1.0}   |
|ColumnValues " Total Discharges " > 15|Failed |Value: 11.0 does not meet the
constraint requirement!|{Column. Total Discharges .Minimum -> 11.0}|
```

```
+-----+-----
+-----
+-----+
```

9. Filter passed rows and review the failed rows from the Data Quality row-level results.

```
rowLevelOutcomes = SelectFromCollection.apply(
  dfc=EvaluateDataQualityMultiframe,
  key="rowLevelOutcomes",
  transformation_ctx="rowLevelOutcomes",
)

rowLevelOutcomes_df = rowLevelOutcomes.toDF() # Convert Glue DynamicFrame to
  SparkSQL DataFrame
rowLevelOutcomes_df_passed =
  rowLevelOutcomes_df.filter(rowLevelOutcomes_df.DataQualityEvaluationResult ==
  "Passed") # Filter only the Passed records.
rowLevelOutcomes_df.filter(rowLevelOutcomes_df.DataQualityEvaluationResult ==
  "Failed").show(5, truncate=False) # Review the Failed records
```

Output:

```
+-----+-----
+-----+-----+-----
+-----+-----+-----
+-----+-----+-----
+-----+-----
+-----+-----
+-----+
```

DRG Definition	Provider Id	Provider Name	Provider Street Address	Provider City	Provider State	Provider Zip Code	Hospital Referral Region Description	Total Discharges	Average Covered Charges	Average Total Payments	Average Medicare Payments	DataQualityRulesPass	DataQualityRulesFail	DataQualityRulesSkip	DataQualityEvaluationResult

only showing top 5 rows

```

Note that Amazon Glue Data Quality added four new columns (DataQualityRulesPass, DataQualityRulesFail, DataQualityRulesSkip, and DataQualityEvaluationResult). This indicates the records that passed, the records that failed, rules skipped for row-level evaluation, and the overall row-level results.

10. Write the output to an Amazon S3 bucket to analyze the data and visualize the results.

```
#Write the Passed records to the destination.

glueContext.write_dynamic_frame.from_options(
    frame = rowLevelOutcomes_df_passed,
    connection_type = "s3",
    connection_options = {"path": "s3://glue-sample-target/output-dir/
medicare_parquet"},
    format = "parquet")
```

Data Quality Definition Language (DQDL) reference

Data Quality Definition Language (DQDL) is a domain specific language that you use to define rules for Amazon Glue Data Quality.

This guide introduces key DQDL concepts to help you understand the language. It also provides a reference for DQDL rule types with syntax and examples. Before you use this guide, we recommend that you have familiarity with Amazon Glue Data Quality. For more information, see [Amazon Glue Data Quality](#).

Note

DynamicRules are only supported in Amazon Glue ETL.

DQDL syntax

A DQDL document is case sensitive and contains a *ruleset*, which groups individual data quality rules together. To construct a ruleset, you must create a list named `Rules` (capitalized), delimited by a pair of square brackets. The list should contain one or more comma-separated DQDL rules like the following example.

```
Rules = [  
    IsComplete "order-id",  
    IsUnique "order-id"  
]
```

Rule structure

The structure of a DQDL rule depends on the rule type. However, DQDL rules generally fit the following format.

```
<RuleType> <Parameter> <Parameter> <Expression>
```

`RuleType` is the case-sensitive name of the rule type that you want to configure. For example, `IsComplete`, `IsUnique`, or `CustomSql`. Rule parameters differ for each rule type. For a complete reference of DQDL rule types and their parameters, see [DQDL rule type reference](#).

Composite rules

DQDL supports the following logical operators that you can use to combine rules. These rules are called Composite Rules.

and

The logical `and` operator results in `true` if and only if the rules that it connects are `true`. Otherwise, the combined rule results in `false`. Each rule that you connect with the `and` operator must be surrounded by parentheses.

The following example uses the `and` operator to combine two DQDL rules.

```
(IsComplete "id") and (IsUnique "id")
```

or

The logical `or` operator results in `true` if and only if one or more of the rules that it connects are `true`. Each rule that you connect with the `or` operator must be surrounded by parentheses.

The following example uses the `or` operator to combine two DQDL rules.

```
(RowCount "id" > 100) or (IsPrimaryKey "id")
```

You can use the same operator to connect multiple rules, so the following rule combination is allowed.

```
(Mean "Star_Rating" > 3) and (Mean "Order_Total" > 500) and (IsComplete "Order_Id")
```

You can combine the logical operators into a single expression. For example:

```
(Mean "Star_Rating" > 3) and ((Mean "Order_Total" > 500) or (IsComplete "Order_Id"))
```

You can also author more complex, nested rules.

```
(RowCount > 0) or ((IsComplete "colA") and (IsUnique "colA"))
```

How Composite rules work

By default, Composite Rules are evaluated as individual rules across the entire dataset or table and then the results are combined. In other words, it evaluates the entire column first and then applies the operator. This default behaviour is explained below with an example:

```
# Dataset

+-----+-----+
|myCol1|myCol2|
+-----+-----+
|      2|      1|
|      0|      3|
+-----+-----+

# Overall outcome

+-----+-----+-----+-----+-----+-----+-----+-----+
|Rule                                                                 |Outcome|
+-----+-----+-----+-----+-----+-----+-----+-----+
|(ColumnValues "myCol1" > 1) OR (ColumnValues "myCol2" > 2)|Failed |
+-----+-----+-----+-----+-----+-----+-----+-----+
```

In the above example, Amazon Glue Data Quality first evaluates `(ColumnValues "myCol1" > 1)` which will result in a failure. Then it will evaluate `(ColumnValues "myCol2" > 2)` which will also fail. The combination of both results will be noted as FAILED.

However, if you prefer an SQL like behaviour, where you need the entire row to be evaluated, you have to explicitly set the `ruleEvaluation.scope` parameter as shown in `additionalOptions` in the code snippet below.

```
object GlueApp {
  val datasource = glueContext.getCatalogSource(
    database="<db>",
    tableName="<table>",
    transformationContext="datasource"
  ).getDynamicFrame()
```

```
val ruleset = """
  Rules = [
    (ColumnValues "age" >= 26) OR (ColumnLength "name" >= 4)
  ]
  """

val dq_results = EvaluateDataQuality.processRows(
  frame=datasource,
  ruleset=ruleset,
  additionalOptions=JsonOptions("""
    {
      "compositeRuleEvaluation.method":"ROW"
    }
  """)
)
}
```

In Amazon Glue Data Catalog, you can easily configure this option in the user interface as shown below.

▼ Composite rule settings - *new*

Rule evaluation configuration [Info](#)

Configure how composite rules should work. [Learn more](#) 

Row

The composite rules will behave as single rule evaluating entire row.

Column

The composite rules will evaluate individual rules across the entire dataset and combine the results.

Once set, the composite rules will behave as a single rule evaluating the entire row. The following example illustrates this behaviour.

```
# Row Level outcome

+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|myCol1|myCol2|DataQualityRulesPass                                     |
DataQualityEvaluationResult|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|2      |1      |[(ColumnValues "myCol1" > 1) OR (ColumnValues "myCol2" > 2)]|Passed
|      |      |      |
|0      |3      |[(ColumnValues "myCol1" > 1) OR (ColumnValues "myCol2" > 2)]|Passed
|      |      |      |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

Some rules cannot be supported in this feature because their overall outcome rely on thresholds or ratios. They are listed below.

Rules relying on ratios:

- Completeness
- DatasetMatch
- ReferentialIntegrity
- Uniqueness

Rules dependent on thresholds:

When the following rules include with threshold, they are not supported. However, rules that do not involve with threshold remain supported.

- ColumnDataType
- ColumnValues
- CustomSQL

Expressions

If a rule type doesn't produce a Boolean response, you must provide an expression as a parameter in order to create a Boolean response. For example, the following rule checks the mean (average) of all the values in a column against an expression to return a true or false result.

```
Mean "colA" between 80 and 100
```

Some rule types such as `IsUnique` and `IsComplete` already return a Boolean response.

The following table lists expressions that you can use in DQDL rules.

Supported DQDL expressions

Expression	Description	Example
<code>=x</code>	Resolves to true if the rule type response is equal to <code>x</code> .	<code>Completeness "colA" = "1.0", ColumnValues "colA" = "2022-06-30"</code>
<code>!=x</code>	<code>x</code> Resolves to true if the rule type response is not equal to <code>x</code> .	<code>ColumnValues "colA" != "a", ColumnValues "colA" != "2022-06-30"</code>
<code>> x</code>	Resolves to true if the rule type response is greater than <code>x</code> .	<code>ColumnValues "colA" > 10</code>
<code>< x</code>	Resolves to true if the rule type response is less than <code>x</code> .	<code>ColumnValues "colA" < 1000, ColumnValues "colA" < "2022-06-30"</code>
<code>>= x</code>	Resolves to true if the rule type response is greater than or equal to <code>x</code> .	<code>ColumnValues "colA" >= 10</code>

Expression	Description	Example
<code><= x</code>	Resolves to true if the rule type response is less than or equal to <i>x</i> .	ColumnValues "colA" <= 1000
between <i>x</i> and <i>y</i>	Resolves to true if the rule type response falls in a specified range (exclusive). Only use this expression type for numeric and date types.	Mean "colA" between 8 and 100, ColumnValues "colA" between "2022-05-31" and "2022-06-30"
not between <i>x</i> and <i>y</i>	Resolves to true if the rule type response does not fall in a specified range (inclusive). You should only use this expression type for numeric and date types.	ColumnValues "colA" not between "2022-05-31" and "2022-06-30"
in [<i>a</i> , <i>b</i> , <i>c</i> , ...]	Resolves to true if the rule type response is in the specified set.	ColumnValues "colA" in [1, 2, 3], ColumnValues "colA" in ["a", "b", "c"]
not in [<i>a</i> , <i>b</i> , <i>c</i> , ...]	Resolves to true if the rule type response is not in the specified set.	ColumnValues "colA" not in [1, 2, 3], ColumnValues "colA" not in ["a", "b", "c"]
matches <i>/ab+c/i</i>	Resolves to true if the rule type response matches a regular expression.	ColumnValues "colA" matches "[a-zA-Z]*"
not matches <i>/ab+c/i</i>	Resolves to true if the rule type response does not match a regular expression.	ColumnValues "colA" not matches "[a-zA-Z]*"

Expression	Description	Example
<code>now()</code>	Works only with the <code>ColumnValues</code> rule type to create a date expression.	<code>ColumnValues "load_date" > (now() - 3 days)</code>
<code>matches/in [...] /not matches/not in [...] with threshold</code>	Specifies the percentage of values that match the rule conditions. Works only with the <code>ColumnValues</code> , <code>ColumnDataType</code> , and <code>CustomSQL</code> rule types.	<code>ColumnValues "colA" in ["A", "B"] with threshold > 0.8,</code> <code>ColumnValues "colA" matches "[a-zA-Z]*" with threshold between 0.2 and 0.9</code> <code>ColumnDataType "colA" = "Timestamp" with threshold > 0.9</code>

Keywords for NULL, EMPTY and WHITESPACES_ONLY

If you want to validate if a string column has a null, empty or a string with only whitespaces you can use the following keywords:

- **NULL / null** – This keyword resolves to true for a null value in a string column.

`ColumnValues "colA" != NULL with threshold > 0.5` would return true if more than 50% of your data does not have null values.

`(ColumnValues "colA" = NULL) or (ColumnLength "colA" > 5)` would return true for all rows which either have a null value or have length >5. *Note that this will require the use of the "compositeRuleEvaluation.method" = "ROW" option.*

- **EMPTY / empty** – This keyword resolves to true for an empty string ("") value in a string column. Some data formats transform nulls in a string column to empty strings. This keyword helps filter out empty strings in your data.

`(ColumnValues "colA" = EMPTY) or (ColumnValues "colA" in ["a", "b"])` would return true if a row is either empty, "a" or "b". *Note that this requires the use of the "compositeRuleEvaluation.method" = "ROW" option.*

- **WHITESPACES_ONLY / whitespaces_only** – This keyword resolves to true for a string with only whitespaces (" ") value in a string column.

ColumnValues "colA" not in ["a", "b", WHITESPACES_ONLY] would return true if a row is neither "a" or "b" nor just whitespaces.

Supported rules:

- [ColumnValues](#)

For a numeric or date based expression, if you want to validate if a column has a null you can use the following keywords.

- NULL / null – This keyword resolves to true for a null value in a string column.

ColumnValues "colA" in [NULL, "2023-01-01"] would return true if a dates in your column are either 2023-01-01 or null.

(ColumnValues "colA" = NULL) or (ColumnValues "colA" between 1 and 9) would return true for all rows which either have a null value or have values between 1 and 9. *Note that this will require the use of the "compositeRuleEvaluation.method" = "ROW" option.*

Supported rules:

- [ColumnValues](#)

Filtering with Where Clause

Note

Where Clause is only supported in Amazon Glue 4.0.

You can filter your data when authoring rules. This is helpful when you want to apply conditional rules.

```
<DQDL Rule> where "<valid SparkSQL where clause> "
```

The filter must be specified with the where keyword, followed by a valid SparkSQL statement that is enclosed in quotes ("").

If the rule you wish to add the where clause to a rule with a threshold, the where clause should be specified before the threshold condition.

```
<DQDL Rule> where "valid SparkSQL statement" with threshold <threshold condition>
```

With this syntax you can write rules like the following.

```
Completeness "colA" > 0.5 where "colB = 10"
ColumnValues "colB" in ["A", "B"] where "colC is not null" with threshold > 0.9
ColumnLength "colC" > 10 where "colD != Concat(colE, colF)"
```

We will validate that the SparkSQL statement provided is valid. If invalid, the rule evaluation will fail and we will throw the an `IllegalArgumentException` with the following format:

```
Rule <DQDL Rule> where "<invalid SparkSQL>" has provided an invalid where clause :
<SparkSQL Error>
```

Where clause behaviour when Row level error record identification is turned on

With Amazon Glue Data Quality, you can identify specific records that failed. When applying a where clause to rules that support row level results, we will label the rows that are filtered out by the where clause as `Passed`.

If you prefer to separately label the filtered out rows as `SKIPPED`, you can set the following `additionalOptions` for the ETL job.

```
object GlueApp {
  val datasource = glueContext.getCatalogSource(
    database="<db>",
    tableName="<table>",
    transformationContext="datasource"
  ).getDynamicFrame()

  val ruleset = """"
    Rules = [
      IsComplete "att2" where "att1 = 'a'"
    ]
  """"

  val dq_results = EvaluateDataQuality.processRows(
    frame=datasource,
    ruleset=ruleset,
    additionalOptions=JsonOptions("""
```

```

    {
      "rowLevelConfiguration.filteredRowLabel":"SKIPPED"
    }
  ""
)
)
}

```

As an example, refer to the following rule and dataframe:

```
IsComplete att2 where "att1 = 'a'"
```

id	att1	att2	Row-level Results (Default)	Row Level Results (Skipped Option)	Comments
1	a	f	PASSED	PASSED	
2	b	d	PASSED	SKIPPED	Row is filtered out, since att1 is not "a"
3	a	null	FAILED	FAILED	
4	a	f	PASSED	PASSED	
5	b	null	PASSED	SKIPPED	Row is filtered out, since att1 is not "a"
6	a	f	PASSED	PASSED	

Constants

In DQDL, you can define constant values and reference them throughout your script. This helps prevent issues related to query size limits—for example, when working with large SQL statements

that might exceed allowable boundaries. By assigning these values to Constants, you can simplify your DQDL and avoid hitting those limits.

The following example shows how to define and use a constant:

```
mySql = "select count(*) from primary"

Rules = [
    CustomSql $mySql between 0 and 100
]
```

In this example, the SQL query is assigned to the constant `mySql`, which is then referenced in the rule using the `$` prefix.

Labels

Labels provide an effective way to organize and analyze data quality results. You can query results by specific labels to identify failing rules within particular categories, count rule outcomes by team or domain, and create focused reports for different stakeholders.

For example, you can apply all rules that pertain to the finance team with a label `"team=finance"` and generate a customized report to showcase quality metrics specific to the finance team. You can label high priority rules with `"criticality=high"` to prioritize remediation efforts. Labels can be authored as part of the DQDL. You can query the labels as part of rule outcomes, row-level results, and API responses, making it easy to integrate with your existing monitoring and reporting workflows.

Note

Labels are only available in Amazon Glue ETL and are not available in Amazon Glue Data Catalog based Data Quality.

Syntax for DQDL labels

DQDL supports both default and rule-specific labels. Default labels are defined at the ruleset level and automatically apply to all rules within that ruleset. Individual rules can also have their own labels, and since labels are implemented as key-value pairs, rule-specific labels can override the default labels when using the same key.

The following example shows how to use default and rule-specific labels:

```
DefaultLabels=["frequency"="monthly"]

Rules = [
  // Auto includes the default label ["frequency"="monthly"]
  ColumnValues "col" > 21,
  // Add ["foo"="bar"] to default label. Labels for this rule would be
  ["frequency"="monthly", "foo"="bar"]
  Rule 1 with threshold > 0.8 labels=["foo"="bar"],
  // Override default label. Labels for this rule would be ["frequency"="daily",
  "foo"="bar"]
  Rule 2 with threshold > 0.8 labels=["foo"="bar", "frequency"="daily"]
  // Labels must be applied to the entire composite rule (parentheses required)
  (Rule 1 AND Rule 2) labels=["foo"="bar"]
]
```

Label constraints

Labels have the following constraints:

- A maximum of 10 labels per DQDL rule.
- Labels are specified as a list of key-value pairs.
- The label key and label value are case sensitive.
- The maximum label key length is 128 characters. The label key must not be empty or null.
- The maximum label value length is 256 characters. The label value may be empty or null.

Retrieving DQDL labels

You can retrieve DQDL labels from rule outcomes, row-level results, and API responses.

Rule outcomes

DQDL labels are always visible in rule outcomes. No additional configuration is needed to enable them.

Row-level results

DQDL labels are disabled by default in row-level results but can be enabled using `AdditionalOptions` in `EvaluateDataQuality`.

The following example shows how to enable labels in row-level results:

```
val evaluateResult = EvaluateDataQuality.processRows(
  frame=AmazonS3_node1754591511068,
  ruleset=example_ruleset,
  publishingOptions=JsonOptions("""{
    "dataQualityEvaluationContext": "evaluateResult",
    "enableDataQualityCloudWatchMetrics": "true",
    "enableDataQualityResultsPublishing": "true"
  }"""),
  additionalOptions=JsonOptions("""{
    "performanceTuning.caching":"CACHE_NOTHING",
    "observations.scope":"ALL",
    "rowLevelConfiguration.ruleWithLabels":"ENABLED"
  }""")
)
```

When enabled, the row-level results dataframe includes labels for each rule in the `DataQualityRulesPass`, `DataQualityRulesFail`, and `DataQualityRulesSkip` columns.

API response

DQDL labels are always visible in API responses under a new field `Labels` in the `RuleResults` object.

The following example shows labels in an API response:

```
{
  "ResultId": "dqresult-example",
  "ProfileId": "dqprofile-example",
  "Score": 0.6666666666666666,
  "RulesetName": "EvaluateDataQuality_node1754591514205",
  "EvaluationContext": "EvaluateDataQuality_node1754591514205",
  "StartedOn": "2025-08-22T19:36:10.448000+00:00",
  "CompletedOn": "2025-08-22T19:36:16.368000+00:00",
  "JobName": "anniezc-test-labels",
  "JobRunId": "jr_068f6d7a45074d9105d14e4dee09db12c3b95664b45f6ee44fa29ed7e5619ba8",
  "RuleResults": [
    {
      "Name": "Rule_0",
      "Description": "IsComplete colA",
      "EvaluationMessage": "Input data does not include column colA!",
      "Result": "FAIL",
```

```

    "EvaluatedMetrics": {},
    "EvaluatedRule": "IsComplete colA",
    "Labels": {
      "frequency": "monthly"
    }
  },
  {
    "Name": "Rule_1",
    "Description": "Rule 1 with threshold > 0.8",
    "Result": "PASS",
    "EvaluatedMetrics": {},
    "EvaluatedRule": "Rule 1 with threshold > 0.8",
    "Labels": {
      "frequency": "monthly",
      "foo": "bar"
    }
  },
  {
    "Name": "Rule_3",
    "Description": "Rule 2 with threshold > 0.8",
    "Result": "PASS",
    "EvaluatedMetrics": {},
    "EvaluatedRule": "Rule 2 with threshold > 0.8",
    "Labels": {
      "frequency": "daily",
      "foo": "bar"
    }
  }
]
}

```

Dynamic rules

Note

Dynamic Rules are only supported in Amazon Glue ETL and is not supported in Amazon Glue Data Catalog.

You can now author dynamic rules to compare current metrics produced by your rules with their historical values. These historical comparisons are enabled by using the `last()` operator in expressions. For example, the rule `RowCount > last()` will succeed when the number of rows in

the current run is greater than the most recent prior row count for the same dataset. `last()` takes an optional natural number argument describing how many prior metrics to consider; `last(k)` where $k \geq 1$ will reference the last k metrics.

- If no data points are available, `last(k)` will return the default value 0.0.
- If fewer than k metrics are available, `last(k)` will return all prior metrics.

To form valid expressions use `last(k)`, where $k > 1$ requires an aggregation function to reduce multiple historical results to a single number. For example, `RowCount > avg(last(5))` will check whether the current dataset's row count is strictly greater than the average of the last five row counts for the same dataset. `RowCount > last(5)` will produce an error because the current dataset row count can't be meaningfully compared to a list.

Supported aggregation functions:

- `avg`
- `median`
- `max`
- `min`
- `sum`
- `std` (standard deviation)
- `abs` (absolute value)
- `index(last(k), i)` will allow for selecting the i th most recent value out of the last k . i is zero-indexed, so `index(last(3), 0)` will return the most recent datapoint and `index(last(3), 3)` will result in an error as there are only three datapoints and we attempt to index the 4th most recent one.

Sample expressions

ColumnCorrelation

- `ColumnCorrelation "colA" "colB" < avg(last(10))`

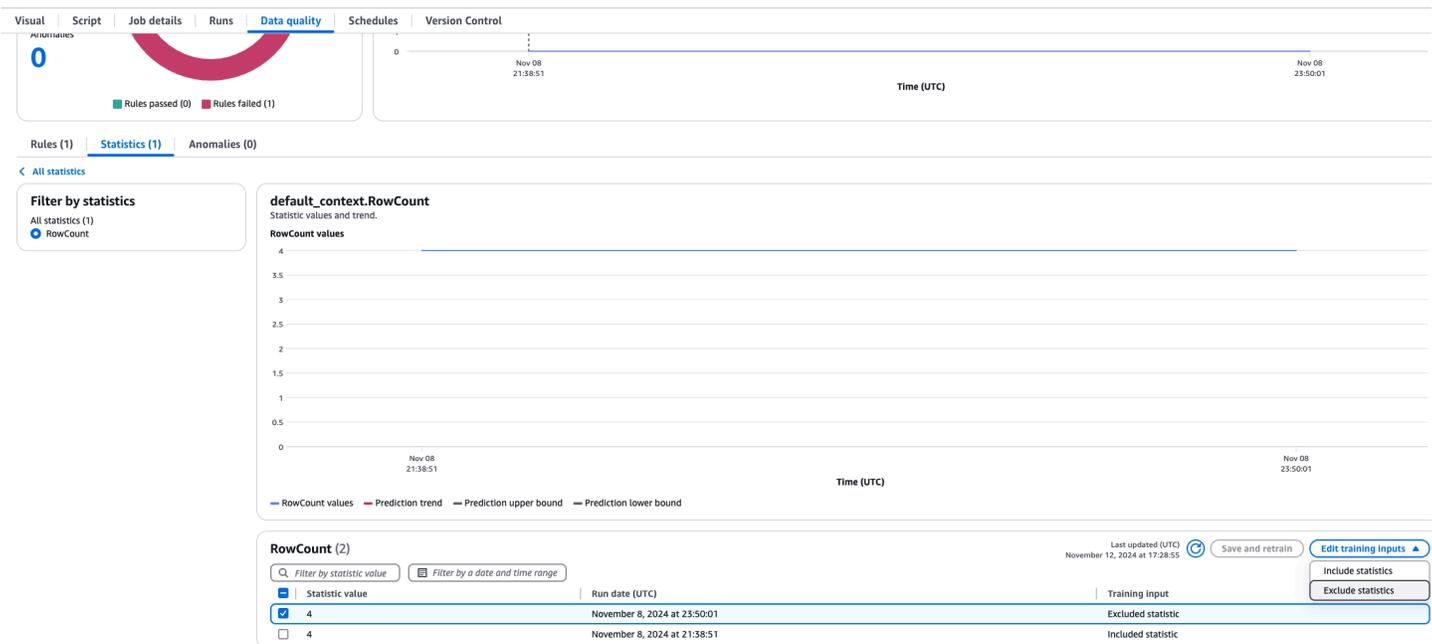

DistinctValuesCount

- `DistinctValuesCount "colA" between min(last(10))-1 and max(last(10))+1`

Most rule types with numeric conditions or thresholds support dynamic rules; see the provided table, [Analyzers and Rules](#), to determine whether dynamic rules are supported for your rule type.

Excluding statistics from dynamic rules

Sometimes, you will need to exclude data statistics from your dynamic rule calculations. Lets say you did a historical data load and you don't want that to impact your averages. To do this, open the job in Amazon Glue ETL and choose the **Data Quality** Tab, then choose **Statistics** and select the statistics that you want to exclude. You will be able to see a trend chart along with a table of statistics. Select the values you want to exclude and choose **Exclude Statistics**. Now the excluded statistics will not be included in the dynamic rule calculations.

Analyzers

Note

Analyzers are not supported in Amazon Glue Data Catalog.

DQDL rules use functions called *analyzers* to gather information about your data. This information is employed by a rule's Boolean expression to determine whether the rule should succeed or fail. For example, the RowCount rule `RowCount > 5` will use a row count analyzer to discover the number of rows in your dataset, and compare that count with the expression `> 5` to check whether more than five rows exist in the current dataset.

Sometimes, instead of authoring rules, we recommend creating analyzers and then have them generate statistics that can be used to detect anomalies. For such instances, you can create analyzers. Analyzers differ from rules in the following ways.

Characteristic	Analyzers	Rules
Part of ruleset	Yes	Yes
Generates statistics	Yes	Yes
Generates observations	Yes	Yes
Can evaluate and assert a condition	No	Yes
You can configure actions such as stop the jobs on failure, continue processing job	No	Yes

Analyzers can independently exist without rules, so you can quickly configure them and progressively build data quality rules.

Some rule types can be input in the `Analyzers` block of your ruleset to run the rules required for analyzers and gather information without applying checks for any condition. Some analyzers aren't associated with rules and can only be input in the `Analyzers` block. The following table indicates whether each item is supported as a rule or a standalone analyzer, along with additional details for each rule type.

Example Ruleset with Analyzer

The following ruleset uses:

- a dynamic rule to check whether a dataset is growing over its trailing average for the last three job runs
- a `DistinctValuesCount` analyzer to record the number of distinct values in the dataset's `Name` column
- a `ColumnLength` analyzer to track minimum and maximum `Name` size over time

Analyzer metric results can be viewed in the Data Quality tab for your job run.

```
Rules = [
  RowCount > avg(last(3))
]
Analyzers = [
  DistinctValuesCount "Name",
  ColumnLength "Name"
]
```

Amazon Glue Data Quality supports the following analyzers.

Analyzer name	Functionality
RowCount	Computes row counts for a dataset
Completeness	Computes the completeness percentage of a column
Uniqueness	Computes the uniqueness percentage of a column
Mean	Computes mean of a numeric column
Sum	Computes sum of a numeric column
StandardDeviation	Computes standard deviation of a numeric column
Entropy	Computes entropy of a numeric column
DistinctValuesCount	Computes the number of distinct values in a column
UniqueValueRatio	Computes the unique values ratio in a column
ColumnCount	Computes the number of columns in a dataset
ColumnLength	Computes the length of a column

Analyzer name	Functionality
ColumnValues	Computes the minimum, maximum for numerical columns. Computes Minimum ColumnLength and Maximum ColumnLength for non-numeric columns
ColumnCorrelation	Computes column correlations for given columns
CustomSql	Computes statistics returned by the CustomSQL
AllStatistics	<p>Computes the following statistics:</p> <ul style="list-style-type: none"> • RowCount, ColumnCount • Every column: Completeness, uniqueness • Numerical: Min, Max, Entropy, Mean, Standard Dev, Sum • String: MinLength, MaxLength

Comments

You can use the '#' character to add a comment to your DQDL document. Anything after the '#' character and until the end of the line is ignored by DQDL.

```
Rules = [
  # More items should generally mean a higher price, so correlation should be
  positive
  ColumnCorrelation "price" "num_items" > 0
]
```

DQDL rule type reference

This section provides a reference for each rule type that Amazon Glue Data Quality supports.

Note

- DQDL doesn't currently support nested or list-type column data.
- Bracketed values in the below table will be replaced with the information provided in rule arguments.
- Rules typically require an additional argument for expression.

Rule type	Description	Arguments	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
Aggregate Match	Checks if two datasets match by comparing summary metrics like total sales amount. Useful for financial institutions to compare if all data is ingested from	One or more aggregations	When first and second aggregation column names match: Column. [Column]. aggregation	Yes	No	No	No	No	No

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
	source systems.		names different : Column. [C olumn1, olumn2]. gregate tch						

Rule type	Description	Argument	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
AllStatistics	Standard analyzer to gather multiple metrics for the provided column in a dataset.	A single column name	For columns of all types: Dataset. .RowCount Column. [Column]. Completeness Column. [Column]. Uniqueness Additional metrics for string-valued columns: ColumnLength metrics	No	Yes	No	No	No	No

Rule type	Description	Arguments	Reported Metrics	Support as Rule?	Support as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
			Additional metrics for numeric-valued columns. Column-wise metrics						
ColumnCorrelation	Checks how well two columns are correlated.	Exactly two column names	Multiple. [Column1, Column2].Correlation	Yes	Yes	No	Yes	No	Yes
ColumnCount	Checks if any columns are dropped	None	Dataset.ColumnCount	Yes	Yes	No	Yes	Yes	No

Rule type	Description	Arguments	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
ColumnDataType	Checks if a column is compliant with a datatype	Exactly one column name	Column.[Column].ColumnType.Conformance	Yes	No	No	Yes, in row-level threshold expression	No	Yes
ColumnExists	Checks if columns exist in a dataset. This allows custom building self service data platform to ensure certain columns are made available.	Exactly one column name	N/A	Yes	No	No	No	No	No

Rule type	Description	Argument	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generate Observations	Supports Where Clause Syntax?
ColumnLength	Checks if length of data is consistent.	Exactly one column name	Column.[Column].maximumLength Column.[Column].minimumLength Additional metric when row-level threshold provided Column.[Column].columnValues.Compliance	Yes	Yes	Yes, when row-level threshold provided	No	Yes. Only generate observations by analyzing Minimum and Maximum length	Yes

Rule type	Description	Argument	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
ColumnNamesMatchPattern	Checks if column names match defined patterns. Useful for governance teams to enforce column name consistency.	A regex for column names	Dataset.ColumnNamesMatchFrequency	Yes	No	No	No	No	No

Rule type	Description	Argument	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generate Observations	Supports Where Clause Syntax?
Column values	Checks if data is consistent per defined values. This rule supports regular expressions.	Exactly one column name	Column.[Column].maximum Column.[Column].minimum Addition metric when row-level threshold provided Column.[Column].columnValues.Comparison	Yes	Yes	Yes, when row-level threshold provided	No	Yes. Only generate observations by analyzing Minimum and Maximum values	Yes

Rule type	Description	Argument	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generated Observations	Supports Where Clause Syntax?
Completeness	Checks for any blank or NULLs in data.	Exactly one column name	Column.[Column].Completeness	Yes	Yes	Yes	Yes	Yes	Yes
CustomSQL	Customers can implement almost any type of data quality checks in SQL.	A SQL statement (Optional) A row-level threshold	Dataset.CustomSQL.Compliance	Yes	No	Yes, when row-level threshold provided	Yes	No	No
DataFreshness	Checks if data is fresh.	Exactly one column name	Column.[Column].DataFreshness.Compliance	Yes	No	Yes	No	No	Yes

Rule type	Description	Argument	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
DatasetMatch	Compares two datasets and identifies if they are in synch.	Name of a reference dataset A column mapping (Optional) Columns to check for matches	Dataset [RefererDatasetAlias].DatasetMatch	Yes	No	Yes	Yes	No	No
DistinctValuesCount	Checks for duplicate values.	Exactly one column name	Column [Column].distinctValuesCount	Yes	Yes	Yes	Yes	Yes	Yes
DetectAnomalies	Checks for anomalies in another rule type's reported metrics.	A rule type	Metric(s) reported by the rule type argument	Yes	No	No	No	No	No

Rule type	Description	Argument	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
Entropy	Checks for entropy of the data.	Exactly one column name	Column. [Column]. entropy	Yes	Yes	No	Yes	No	Yes
IsComplete	Checks if 100% of the data is complete	Exactly one column name	Column. [Column]. completeness	Yes	No	Yes	No	No	Yes
IsPrimary Key	Checks if a column is a primary key (not NULL and unique).	Exactly one column name	For single column: Column. [Column]. uniqueness For multiple columns: Multicolumn. [Comma Delimited Columns]. uniqueness	Yes	No	Yes	No	No	Yes

Rule type	Description	Arguments	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
IsUnique	Checks if 100% of the data is unique.	Exactly one column name	Column [Column]. uniqueness	Yes	No	Yes	No	No	Yes
Mean	Checks if the mean matches the set threshold.	Exactly one column name	Column [Column]. mean	Yes	Yes	Yes	Yes	No	Yes
ReferentialIntegrity	Checks if two datasets have referential integrity.	One or more column names from dataset One or more column names from reference dataset	Column [ReferenceDataset/Tables]. ReferentialIntegrity	Yes	No	Yes	Yes	No	No

Rule type	Description	Arguments	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
RowCountMatch	Checks if record counts match a threshold.	None	Dataset.RowCountMatch	Yes	Yes	No	Yes	Yes	Yes
RowCountMatch	Checks if record counts between two datasets match.	ReferenceDatasetAlias	Dataset[ReferenceDatasetAlias].RowCountMatch	Yes	No	No	Yes	No	No
StandardDeviation	Checks if standard deviation matches the threshold.	Exactly one column name	Column[Column].StandardDeviation	Yes	Yes	Yes	Yes	No	Yes

Rule type	Description	Arguments	Reported Metrics	Support as Rule?	Support as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations	Supports Where Clause Syntax?
SchemaMatch	Checks if schema between two datasets match.	Referenced dataset alias	Dataset [Referenced Dataset alias].SchemaMatch	Yes	No	No	Yes	No	No
Sum	Checks if sum matches a set threshold.	Exactly one column name	Column [Column].sum	Yes	Yes	No	Yes	No	Yes
Uniqueness	Checks if uniqueness of dataset matches threshold.	Exactly one column name	Column [Column].uniqueness	Yes	Yes	Yes	Yes	No	Yes
UniqueValueRatio	Checks if the unique value ratio matches threshold.	Exactly one column name	Column [Column].uniqueValueRatio	Yes	Yes	Yes	Yes	No	Yes

Rule type	Description	Arguments	Reported Metrics	Support as Rule?	Support as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generated Observations	Supports Where Clause Syntax?
FileFreshness	Checks if files in Amazon S3 are fresh.	File or Folder path and a threshold.	Dataset .FileFreshness.Count Dataset .FileCount	Yes	No	No	No	No	No
FileMatch	Checks if contents of file match to a checksum or with other file. This rule uses checksum to validate if two files are same.	Source File or Folder path and Target file or folder path.	No statistics are generated.	Yes	No	No	No	No	No

Rule type	Description	Arguments	Reported Metrics	Support as Rule?	Support as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generated Observations	Supports Where Clause Syntax?
FileSize	Checks if the size of a file matches with a specified condition.	File or folder path and threshold.	Dataset .FileSize Dataset .Compliance Dataset .FileCount Dataset .MaximumFileSize Dataset .MinimumFileSize	Yes	No	No	No	No	No
FileUniqueness	Checks if files are unique using checksum.	File or folder path and threshold.	Dataset .FileUniqueness Dataset .FileCount	Yes	No	No	No	No	No

AggregateMatch

Checks the ratio of two column aggregations against a given expression. This rule type works on multiple datasets. The two column aggregations are evaluated and a ratio is produced by dividing the result of the first column aggregation with the result of the second column aggregation. The ratio is checked against the provided expression to produce a boolean response.

Syntax

Column aggregation

```
AggregateMatch <AGG_OPERATION> (<OPTIONAL_REFERENCE_ALIAS>.<COL_NAME>)
```

- **AGG_OPERATION** – The operation to use for the aggregation. Currently, sum and avg are supported.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **OPTIONAL_REFERENCE_ALIAS** – This parameter needs to be provided if the column is from a reference dataset and not the primary dataset. If you are using this rule in the Amazon Glue Data Catalog, your reference alias must follow the format "<database_name>.<table_name>.<column_name>"

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **COL_NAME** – The name of the column to aggregate.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

Example: Average

```
"avg(rating)"
```

Example: Sum

```
"sum(amount)"
```

Example: Average of column in reference dataset

```
"avg(reference.rating)"
```

Rule

```
AggregateMatch <AGG_EXP_1> <AGG_EXP_2> <EXPRESSION>
```

- **AGG_EXP_1** – The first column aggregation.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **AGG_EXP_2** – The second column aggregation.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Aggregate Match using sum

The following example rule checks whether the sum of the values in the `amount` column is exactly equal to the sum of the values in the `total_amount` column.

```
AggregateMatch "sum(amount)" "sum(total_amount)" = 1.0
```

Example: Aggregate Match using average

The following example rule checks whether the average of the values in the `ratings` column is equal to at least 90% of the average of the values in the `ratings` column in the reference dataset. The reference dataset is provided as an additional data source in the ETL or Data Catalog experience.

In Amazon Glue ETL, you can use:

```
AggregateMatch "avg(ratings)" "avg(reference.ratings)" >= 0.9
```

In the Amazon Glue Data Catalog, you can use:

```
AggregateMatch "avg(ratings)" "avg(database_name.tablename.ratings)" >= 0.9
```

Null behavior

The AggregateMatch rule will ignore rows with NULL values in the calculation of the aggregation methods (sum/mean). For example:

```
+---+-----+
|id |units   |
+---+-----+
|100|0      |
|101|null   |
|102|20     |
|103|null   |
|104|40     |
+---+-----+
```

The mean of column `units` will be $(0 + 20 + 40) / 3 = 20$. Rows 101 and 103 are not considered in this calculation.

ColumnCorrelation

Checks the *correlation* between two columns against a given expression. Amazon Glue Data Quality uses the Pearson correlation coefficient to measure the linear correlation between two columns. The result is a number between -1 and 1 that measures the strength and direction of the relationship.

Syntax

```
ColumnCorrelation <COL_1_NAME> <COL_2_NAME> <EXPRESSION>
```

- **COL_1_NAME** – The name of the first column that you want to evaluate the data quality rule against.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **COL_2_NAME** – The name of the second column that you want to evaluate the data quality rule against.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Column correlation

The following example rule checks whether the correlation coefficient between the columns `height` and `weight` has a strong positive correlation (a coefficient value greater than 0.8).

```
ColumnCorrelation "height" "weight" > 0.8
```

```
ColumnCorrelation "weightinkgs" "Salary" > 0.8 where "weightinkgs > 40"
```

Sample dynamic rules

- `ColumnCorrelation "colA" "colB" between min(last(10)) and max(last(10))`
- `ColumnCorrelation "colA" "colB" < avg(last(5)) + std(last(5))`

Null behavior

The `ColumnCorrelation` rule will ignore rows with NULL values in the calculation of the correlation. For example:

```
+---+-----+
|id |units  |
+---+-----+
|100|0      |
|101|null  |
|102|20     |
|103|null  |
|104|40     |
+---+-----+
```

Rows 101 and 103 will be ignored, and the `ColumnCorrelation` will be 1.0.

ColumnCount

Checks the column count of the primary dataset against a given expression. In the expression, you can specify the number of columns or a range of columns using operators like `>` and `<`.

Syntax

```
ColumnCount <EXPRESSION>
```

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Column count numeric check

The following example rule checks whether the column count is within a given range.

```
ColumnCount between 10 and 20
```

Sample dynamic rules

- `ColumnCount >= avg(last(10))`
- `ColumnCount between min(last(10))-1 and max(last(10))+1`

ColumnDataType

Checks if the values in a given column can be cast in Apache Spark to the provided type. Accepts a `with threshold` expression to check for a subset of the values in the column.

Syntax

```
ColumnDataType <COL_NAME> = <EXPECTED_TYPE>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: String type

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPECTED_TYPE** – The expected type of the values in the column.

Supported values: Boolean, Date, Timestamp, Integer, Double, Float, Long

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An optional expression to specify the percentage of values that should be of the expected type.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

Example: Column data type integers as strings

The following example rule checks whether the values in the given column, which is of type string, can be cast as integers.

```
ColumnDataType "colA" = "INTEGER"
```

Example: Column data type integers as strings check for a subset of the values

The following example rule checks whether more than 90% of the values in the given column, which is of type string, can be cast as integers.

```
ColumnDataType "colA" = "INTEGER" with threshold > 0.9
```

ColumnExists

Checks whether a column exists.

Syntax

```
ColumnExists <COL_NAME>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

Example: Column exists

The following example rule checks whether the column named `Middle_Name` exists.

```
ColumnExists "Middle_Name"
```

ColumnLength

Checks whether the length of each row in a column conforms to a given expression.

Syntax

```
ColumnLength <COL_NAME><EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: String

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Column row length

The following example rule checks whether the value in each row in the column named `Postal_Code` is 5 characters long.

```
ColumnLength "Postal_Code" = 5  
ColumnLength "weightinkgs" = 2 where "weightinkgs" > 10"
```

Null behavior

The `ColumnLength` rule treats NULLs as 0 length strings. For a NULL row:

```
ColumnLength "Postal_Code" > 4 # this will fail
```

```
ColumnLength "Postal_Code" < 6 # this will succeed
```

The following example compound rule provides a way to explicitly fail NULL values:

```
(ColumnLength "Postal_Code" > 4) AND (ColumnValues "Postal_Code" != NULL)
```

ColumnNamesMatchPattern

Checks whether the names of all columns in the primary dataset match the given regular expression.

Syntax

```
ColumnNamesMatchPattern <PATTERN>
```

- **PATTERN** – The pattern you want to evaluate the data quality rule against.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

Example: Column names match pattern

The following example rule checks whether all columns start with the prefix "aws_"

```
ColumnNamesMatchPattern "aws_.*"  
ColumnNamesMatchPattern "aws_.*" where "weightinkgs > 10"
```

ColumnValues

Runs an expression against the values in a column.

Syntax

```
ColumnValues <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Allowed values

The following example rule checks whether each value in the specified column is in a set of allowed values (including null, empty, and strings with only whitespaces).

```
ColumnValues "Country" in [ "US", "CA", "UK", NULL, EMPTY, WHITESPACES_ONLY ]  
ColumnValues "gender" in ["F", "M"] where "weightinkgs < 10"
```

Example: Regular expression

The following example rule checks the values in a column against a regular expression.

```
ColumnValues "First_Name" matches "[a-zA-Z]*"
```

Example: Date values

The following example rule checks the values in a date column against a date expression.

```
ColumnValues "Load_Date" > (now() - 3 days)
```

Example: Numeric values

The following example rule checks whether the column values match a certain numeric constraint.

```
ColumnValues "Customer_ID" between 1 and 2000
```

Null behavior

For all `ColumnValues` rules (other than `!=` and `NOT IN`), `NULL` rows will fail the rule. If the rule fails due to a null value, the failure reason will display the following:

```
Value: NULL does not meet the constraint requirement!
```

The following example compound rule provides a way to explicitly allow for `NULL` values:

```
(ColumnValues "Age" > 21) OR (ColumnValues "Age" = NULL)
```

Negated `ColumnValues` rules using the `!=` and `not in` syntax will pass for `NULL` rows. For example:

```
ColumnValues "Age" != 21
```

```
ColumnValues "Age" not in [21, 22, 23]
```

The following examples provide a way to explicitly fail `NULL` values

```
(ColumnValues "Age" != 21) AND (ColumnValues "Age" != NULL)
```

```
ColumnValues "Age" not in [21, 22, 23, NULL]
```

Completeness

Checks the percentage of complete (non-null) values in a column against a given expression.

Syntax

```
Completeness <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Null value percentage

The following example rules check if more than 95 percent of the values in a column are complete.

```
Completeness "First_Name" > 0.95  
Completeness "First_Name" > 0.95 where "weightinkgs > 10"
```

Sample dynamic rules

- Completeness "colA" between min(last(5)) - 1 and max(last(5)) + 1
- Completeness "colA" <= avg(last(10))

Null behavior

Note on CSV Data Formats: Blank rows on CSV columns can display multiple behaviors.

- If a column is of `String` type, the blank row will be recognized as an empty string and will not fail the Completeness rule.
- If a column is of another data type like `Int`, the blank row will be recognized as `NULL` and will fail the Completeness rule.

CustomSQL

This rule type has been extended to support two use cases:

- Run a custom SQL statement against a dataset and checks the return value against a given expression.

- Run a custom SQL statement where you specify a column name in your SELECT statement against which you compare with some condition to get row-level results.

Syntax

```
CustomSql <SQL_STATEMENT> <EXPRESSION>
```

- **SQL_STATEMENT** – A SQL statement that returns a single numeric value, surrounded by double quotes.
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Custom SQL to retrieve an overall rule outcome

This example rule uses a SQL statement to retrieve the record count for a data set. The rule then checks that the record count is between 10 and 20.

```
CustomSql "select count(*) from primary" between 10 and 20
```

Example: Custom SQL to retrieve row-level results

This example rule uses a SQL statement wherein you specify a column name in your SELECT statement against which you compare with some condition to get row level results. A threshold condition expression defines a threshold of how many records should fail for the entire rule to fail. Note that a rule may not contain both a condition and keyword together.

```
CustomSql "select Name from primary where Age > 18"
```

or

```
CustomSql "select Name from primary where Age > 18" with threshold > 3
```

Important

The `primary` alias stands in for the name of the data set that you want to evaluate. When you work with visual ETL jobs on the console, `primary` always represents the `DynamicFrame` being passed to the `EvaluateDataQuality.apply()` transform. When

you use the Amazon Glue Data Catalog to run data quality tasks against a table, primary represents the table.

If you are in Amazon Glue Data Catalog, you can also use the actual table names:

```
CustomSql "select count(*) from database.table" between 10 and 20
```

You can also join multiple tables to compare different data elements:

```
CustomSql "select count(*) from database.table inner join database.table2 on id1 = id2"
between 10 and 20
```

In Amazon Glue ETL, CustomSQL can identify records that failed the data quality checks. For this to work, you need to return records that are part of the primary table for which you are evaluating data quality. Records that are returned as part of the query are considered successful and records that are not returned are considered failed. This works by joining the result of your CustomSQL query with the original dataset. There may be performance implications based on the complexity of your SQL query.

To do this:

- You need to select at least 1 column from your primary table.
 - `select count(*) from primary` is a valid query for OVERALL CustomSQL DQ rule but not for Row Level Custom SQL.
 - This rule will throw an error during evaluation: The output from CustomSQL must contain at least one column that matches the input dataset for Amazon Glue Data Quality to provide row level results. The SQL query is a valid query but the columns from the SQL result are not present in the Input Dataset. Ensure that matching columns are returned from the SQL.
- In your SQL query, select a `Primary Key` from your table or select a set of columns that form a composite key. Not doing so may result in inconsistent results due to matching of duplicate rows and degraded performance.
- Select keys ONLY from your primary table and not from your reference tables.

The following rule will ensure that records with age < 100 are identified as successful and records that are above are marked as failed.

```
CustomSql "select id from primary where age < 100"
```

This CustomSQL rule will pass when 50% of the records have age > 10 and will also identify records that failed. The records returned by this CustomSQL will be considered passed while the ones not returned will be considered failed.

```
CustomSQL "select ID, CustomerID from primary where age > 10" with threshold > 0.5
```

Note: CustomSQL rule will fail if you return records that are not available in the dataset.

DataFreshness

Checks the freshness of data in a column by evaluating the difference between the current time and the values of a date column. You can specify a time-based expression for this rule type to make sure that column values are up to date.

Syntax

```
DataFreshness <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Date

- **EXPRESSION** – A numeric expression in hours or days. You must specify the time unit in your expression.

Example: Data freshness

The following example rules check for data freshness.

```
DataFreshness "Order_Date" <= 24 hours  
DataFreshness "Order_Date" between 2 days and 5 days
```

Null behavior

The DataFreshness rules will fail for rows with NULL values. If the rule fails due to a null value, the failure reason will display the following:

```
80.00 % of rows passed the threshold
```

where 20% of the rows that failed include the rows with NULL.

The following example compound rule provides a way to explicitly allow for NULL values:

```
(DataFreshness "Order_Date" <= 24 hours) OR (ColumnValues "Order_Date" = NULL)
```

Data Freshness for Amazon S3 objects

Sometimes you will need to validate the freshness of data based on the Amazon S3 file creating time. To do this, you can use the following code to get the timestamp and add it to your dataframe, and then apply Data Freshness checks.

```
df = glueContext.create_data_frame.from_catalog(database = "default", table_name =
  "mytable")
df = df.withColumn("file_ts", df["_metadata.file_modification_time"])

Rules = [
  DataFreshness "file_ts" < 24 hours
]
```

DatasetMatch

Checks if the data in the primary dataset matches the data in a reference dataset. The two datasets are joined using the provided key column mappings. Additional column mappings can be provided should you wish to check for the equality of the data in only those columns. Note that for **DataSetMatch** to work, your join keys should be unique and should not be NULL (must be a primary key). If you don't satisfy these conditions, you will get the error message, "Provided key map not suitable for given data frames". In cases where you can't have joined keys that are unique, consider using other rule types such as **AggregateMatch** to match on summary data.

Syntax

```
DatasetMatch <REFERENCE_DATASET_ALIAS> <JOIN_CONDITION_WITH
  MAPPING> <OPTIONAL_MATCH_COLUMN_MAPPINGS> <EXPRESSION>
```

- **REFERENCE_DATASET_ALIAS** – The alias of the reference dataset with which you compare data from the primary dataset.
- **KEY_COLUMN_MAPPINGS** – A comma-separated list of column names that form a key in the datasets. If the column names are not the same in both datasets, you must separate them with a ->

- **OPTIONAL_MATCH_COLUMN_MAPPINGS** – You can supply this parameter if you want to check for matching data only in certain columns. It uses the same syntax as the key column mappings. If this parameter is not provided, we will match the data in all remaining columns. The remaining, non-key columns must have the same names in both datasets.
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Match set datasets using ID column

The following example rule checks that more than 90% of the primary dataset matches the reference dataset, using the "ID" column to join the two datasets. It compares all columns in this case.

```
DatasetMatch "reference" "ID" >= 0.9
```

Example: Match set datasets using multiple key columns

In the following example, the primary dataset and the reference dataset have different names for the key columns. ID_1 and ID_2 together form a composite key in the primary dataset. ID_ref1 and ID_ref2 together forms a composite key in the reference dataset. In this scenario, you can use the special syntax to supply the column names.

```
DatasetMatch "reference" "ID_1->ID_ref1,ID_ref2->ID_ref2" >= 0.9
```

Example: Match set datasets using multiple key columns and check that specific column matches

This example builds on the previous example. We want to check that only the column containing the amounts match. This column is named Amount1 in the primary dataset and Amount2 in the reference dataset. You want an exact match.

```
DatasetMatch "reference" "ID_1->ID_ref1,ID_2->ID_ref2" "Amount1->Amount2" >= 0.9
```

DistinctValuesCount

Checks the number of distinct values in a column against a given expression.

Syntax

```
DistinctValuesCount <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Distinct column value count

The following example rule checks that the column named State contains more than 3 distinct values.

```
DistinctValuesCount "State" > 3  
DistinctValuesCount "Customer_ID" < 6 where "Customer_ID < 10"
```

Sample dynamic rules

- DistinctValuesCount "colA" between avg(last(10))-1 and avg(last(10))+1
- DistinctValuesCount "colA" <= index(last(10),2) + std(last(5))

Entropy

Checks whether the *entropy* value of a column matches a given expression. Entropy measures the level of information that's contained in a message. Given the probability distribution over values in a column, entropy describes how many bits are required to identify a value.

Syntax

```
Entropy <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Column entropy

The following example rule checks that the column named Feedback has an entropy value greater than one.

```
Entropy "Star_Rating" > 1
Entropy "First_Name" > 1 where "Customer_ID < 10"
```

Sample dynamic rules

- Entropy "colA" < max(last(10))
- Entropy "colA" between min(last(10)) and max(last(10))

IsComplete

Checks whether all of the values in a column are complete (non-null).

Syntax

```
IsComplete <COL_NAME>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

Example: Null values

The following example checks whether all of the values in a column named email are non-null.

```
IsComplete "email"
IsComplete "Email" where "Customer_ID between 1 and 50"
IsComplete "Customer_ID" where "Customer_ID < 16 and Customer_ID != 12"
IsComplete "passenger_count" where "payment_type<>0"
```

Null behavior

Note on CSV Data Formats: Blank rows on CSV columns can display multiple behaviors.

- If a column is of `String` type, the blank row will be recognized as an empty string and will not fail the Completeness rule.
- If a column is of another data type like `Int`, the blank row will be recognized as `NULL` and will fail the Completeness rule.

IsPrimaryKey

Checks whether a column contains a primary key. A column contains a primary key if all of the values in the column are unique and complete (non-null). You can also check for primary keys with multiple columns.

Syntax

```
IsPrimaryKey <COL_NAME>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

Example: Primary key

The following example rule checks whether the column named `Customer_ID` contains a primary key.

```
IsPrimaryKey "Customer_ID"  
IsPrimaryKey "Customer_ID" where "Customer_ID < 10"
```

Example: Primary key with multiple columns. Any of the following examples are valid.

```
IsPrimaryKey "colA" "colB"  
IsPrimaryKey "colA" "colB" "colC"  
IsPrimaryKey colA "colB" "colC"
```

IsUnique

Checks whether all of the values in a column are unique, and returns a Boolean value.

Syntax

```
IsUnique <COL_NAME>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

Examples

The following example rule checks whether all of the values in a column named `email` are unique.

```
IsUnique "email"  
IsUnique "Customer_ID" where "Customer_ID < 10"]
```

The following example rule checks multiple columns.

```
IsUnique "vendorid" "tpep_pickup_datetime"
```

Mean

Checks whether the mean (average) of all the values in a column matches a given expression.

Syntax

```
Mean <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Average value

The following example rule checks whether the average of all of the values in a column exceeds a threshold.

```
Mean "Star_Rating" > 3  
Mean "Salary" < 6200 where "Customer_ID < 10"
```

Sample dynamic rules

- Mean "colA" > avg(last(10)) + std(last(2))
- Mean "colA" between min(last(5)) - 1 and max(last(5)) + 1

Null behavior

The Mean rule will ignore rows with NULL values in the calculation of the mean. For example:

```
+---+-----+
|id |units   |
+---+-----+
|100|0       |
|101|null  |
|102|20    |
|103|null  |
|104|40    |
+---+-----+
```

The mean of column units will be $(0 + 20 + 40) / 3 = 20$. Rows 101 and 103 are not considered in this calculation.

ReferentialIntegrity

Checks to what extent the values of a set of columns in the primary dataset are a subset of the values of a set of columns in a reference dataset.

Syntax

```
ReferentialIntegrity <PRIMARY_COLS> <REFERENCE_DATASET_COLS> <EXPRESSION>
```

- **PRIMARY_COLS** – A comma-separated list of column names in the primary dataset.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **REFERENCE_DATASET_COLS** – This parameter contains two parts separated by a period. The first part is the alias of the reference dataset. The second part is the comma-separated list of column names in the reference dataset enclosed in braces.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Check the referential integrity of a zip code column

The following example rule checks that more than 90% of the values in the zipcode column in the primary dataset, are present in the zipcode column in the reference dataset.

```
ReferentialIntegrity "zipcode" "reference.zipcode" >= 0.9
```

Example: Check the referential integrity of the city and state columns

In the following example, columns containing city and state information exist in the primary dataset and the reference dataset. The names of the columns are different in both datasets. The rule checks if the set of values of the columns in the primary dataset is exactly equal to the set of values of the columns in the reference dataset.

```
ReferentialIntegrity "city,state" "reference.{ref_city,ref_state}" = 1.0
```

Sample dynamic rules

- `ReferentialIntegrity "city,state" "reference.{ref_city,ref_state}" > avg(last(10))`
- `ReferentialIntegrity "city,state" "reference.{ref_city,ref_state}" between min(last(10)) - 1 and max(last(10)) + 1`

RowCount

Checks the row count of a dataset against a given expression. In the expression, you can specify the number of rows or a range of rows using operators like > and <.

Syntax

```
RowCount <EXPRESSION>
```

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Row count numeric check

The following example rule checks whether the row count is within a given range.

```
RowCount between 10 and 100  
RowCount between 1 and 50 where "Customer_ID < 10"
```

Sample dynamic rules

```
RowCount > avg(last(10)) *0.8
```

RowCountMatch

Checks the ratio of the row count of the primary dataset and the row count of a reference dataset against the given expression.

Syntax

```
RowCountMatch <REFERENCE_DATASET_ALIAS> <EXPRESSION>
```

- **REFERENCE_DATASET_ALIAS** – The alias of the reference dataset against which to compare row counts.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Row count check against a reference dataset

The following example rule checks whether the row count of the primary dataset is at least 90% of the row count of the reference dataset.

```
RowCountMatch "reference" >= 0.9
```

StandardDeviation

Checks the standard deviation of all of the values in a column against a given expression.

Syntax

```
StandardDeviation <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Standard deviation

The following example rule checks whether the standard deviation of the values in a column named colA is less than a specified value.

```
StandardDeviation "Star_Rating" < 1.5
StandardDeviation "Salary" < 3500 where "Customer_ID" < 10"
```

Sample dynamic rules

- StandardDeviation "colA" > avg(last(10)) + 0.1
- StandardDeviation "colA" between min(last(10)) - 1 and max(last(10)) + 1

Null behavior

The StandardDeviation rule will ignore rows with NULL values in the calculation of standard deviation. For example:

```
+---+-----+-----+
|id |units1  |units2  |
+---+-----+-----+
|100|0       |0       |
|101|null   |0       |
|102|20      |20      |
|103|null   |0       |
|104|40      |40      |
+---+-----+-----+
```

The standard deviation of column units1 will not consider rows 101 and 103 and result to 16.33. The standard deviation for column units2 will result in 16.

Sum

Checks the sum of all the values in a column against a given expression.

Syntax

```
Sum <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Sum

The following example rule checks whether the sum of all of the values in a column exceeds a given threshold.

```
Sum "transaction_total" > 500000
Sum "Salary" < 55600 where "Customer_ID < 10"
```

Sample dynamic rules

- Sum "ColA" > avg(last(10))
- Sum "colA" between min(last(10)) - 1 and max(last(10)) + 1

Null behavior

The Sum rule will ignore rows with NULL values in the calculation of sum. For example:

```
+---+-----+
|id |units   |
+---+-----+
|100|0       |
|101|null  |
|102|20     |
|103|null  |
|104|40     |
```

```
+---+-----+
```

The sum of column units will not consider rows 101 and 103 and result to $(0 + 20 + 40) = 60$.

SchemaMatch

Checks if the schema of the primary dataset matches the schema of a reference dataset. The schema check is done column by column. The schema of two columns match if the names are identical and the types are identical. The order of the columns does not matter.

Syntax

```
SchemaMatch <REFERENCE_DATASET_ALIAS> <EXPRESSION>
```

- **REFERENCE_DATASET_ALIAS** – The alias of the reference dataset against which to compare schemas.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: SchemaMatch

The following example rule checks whether the schema of the primary dataset exactly matches the schema of a reference dataset.

```
SchemaMatch "reference" = 1.0
```

Uniqueness

Checks the percentage of unique values in a column against a given expression. Unique values occur exactly once.

Syntax

```
Uniqueness <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example

The following example rule checks whether the percentage of unique values in a column matches certain numeric criteria.

```
Uniqueness "email" = 1.0  
Uniqueness "Customer_ID" != 1.0 where "Customer_ID" < 10
```

The following example rule checks multiple columns.

```
Uniqueness "vendorid" "tpep_pickup_datetime" = 1
```

Sample dynamic rules

- Uniqueness "colA" between min(last(10)) and max(last(10))
- Uniqueness "colA" >= avg(last(10))

UniqueValueRatio

Checks the *unique value ratio* of a column against a given expression. A unique value ratio is the fraction of unique values divided by the number of all distinct values in a column. Unique values occur exactly one time, while distinct values occur *at least* once.

For example, the set [a, a, b] contains one unique value (b) and two distinct values (a and b). So the unique value ratio of the set is $\frac{1}{2} = 0.5$.

Syntax

```
UniqueValueRatio <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

Example: Unique value ratio

This example checks the unique value ratio of a column against a range of values.

```
UniqueValueRatio "test_score" between 0 and 0.5  
UniqueValueRatio "Customer_ID" between 0 and 0.9 where "Customer_ID < 10"
```

Sample dynamic rules

- UniqueValueRatio "colA" > avg(last(10))
- UniqueValueRatio "colA" <= index(last(10),2) + std(last(5))

DetectAnomalies

Detects anomalies for a given data quality rule. Every execution of DetectAnomalies rule result in saving evaluated value for the given rule. When there is enough data gathered, anomaly detection algorithm takes all historical data for that given rule and runs anomaly detection. DetectAnomalies rule fails when anomaly is detected. More info about what anomaly was detected can be obtained from Observations.

Syntax

```
DetectAnomalies <RULE_NAME> <RULE_PARAMETERS>
```

RULE_NAME – The name of the rule that you want to evaluate and detect anomalies for. Supported rules:

- "RowCount"
- "Completeness"
- "Uniqueness"

- "Mean"
- "Sum"
- "StandardDeviation"
- "Entropy"
- "DistinctValuesCount"
- "UniqueValueRatio"
- "ColumnLength"
- "ColumnValues"
- "ColumnCorrelation"
- "CustomSQL"
- "ColumnCount"

RULE_PARAMETERS – some rules require additional parameters to run. Refer to the given rule documentation to see required parameters.

Example: Anomalies for RowCount

For example, if we want to detect RowCount anomalies, we provide RowCount as a rule name.

```
DetectAnomalies "RowCount"
```

Example: Anomalies for ColumnLength

For example, if we want to detect ColumnLength anomalies, we provide ColumnLength as a rule name and the column name.

```
DetectAnomalies "ColumnLength" "id"
```

FileFreshness

FileFreshness ensures your data files are fresh based on the condition you provide. It uses your files' last modified time to ensure that data files or the entire folder is up-to-date.

This rule gathers two metrics:

- FileFreshness compliance based on the rule you set up

- The number of files that were scanned by the rule

```
{"Dataset.*.FileFreshness.Compliance":1,"Dataset.*.FileCount":1}
```

Anomaly detection does not consider these metrics.

Checking file freshness

The following rule ensures that tickets.parquet was created in the past 24 hours.

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/tickets.parquet" >
(now() - 24 hours)
```

Checking folder freshness

The following rule passes if all files in the folder were created or modified in past 24 hours.

```
FileFreshness "s3://bucket/" >= (now() -1 days)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" >= (now() - 24 hours)
```

Checking folder or file freshness with threshold

The following rule passes if 10% of the files in the folder "tickets" were created or modified in the past 10 days.

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" < (now() - 10 days)
with threshold > 0.1
```

Checking files or folders with specific dates

You can check for file freshness for specific days.

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > "2020-01-01"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "2023-01-01"
and "2024-01-01"
```

Checking files or folders with time

You can use FileFreshness to ensure that files have arrived based on certain times.

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between now() and
(now() - 45 minutes)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "9:30 AM" and
"9:30 PM"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > (now() - 10 minutes)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > now()
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between (now() - 2
hours) and (now() + 15 minutes)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between (now() - 3
days) and (now() + 15 minutes)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "2001-02-07"
and (now() + 15 minutes)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > "21:45"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > "2024-01-01"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "02:30" and
"04:30"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "9:30 AM" and
"22:15"
```

Key considerations:

- FileFreshness can evaluate files using days, hours, and minute units
- For times, it supports AM / PM and 24-hour
- Times are calculated in UTC unless an override is specified
- Dates are calculated in UTC at time 00:00

FileFreshness that are time-based works as follows:

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > "21:45"
```

- First, the time "21:45" is combined with today's date in UTC format to create a date-time field
- Next, the date-time is converted to a timezone that you have specified
- Finally, the rule is evaluated

Optional File-based Rule Tags:

Tags allow you to control the rule behavior.

recentFiles

This tag limits the number of files processed by keeping the most recent file first.

```
FileFreshness "s3://amzn-s3-demo-bucket/" between (now() - 100 minutes) and (now() + 10 minutes) with recentFiles = 1
```

timeZone

Accepted time zone overrides, see [Allowed Time Zones](#) for supported time zones.

```
FileFreshness "s3://path/" > "21:45" with timeZone = "America/New_York"
```

```
FileFreshness "s3://path/" > "21:45" with timeZone = "America/Chicago"
```

```
FileFreshness "s3://path/" > "21:45" with timeZone = "Europe/Paris"
```

```
FileFreshness "s3://path/" > "21:45" with timeZone = "Asia/Shanghai"
```

```
FileFreshness "s3://path/" > "21:45" with timeZone = "Australia/Darwin"
```

Inferring file names directly from data frames

You don't always have to provide a file path. For instance, when you are authoring the rule in the Amazon Glue Data Catalog, it may be hard to find which folders the catalog tables are using. Amazon Glue Data Quality can find the specific folders or files used to populate your dataframe and can detect if they are fresh.

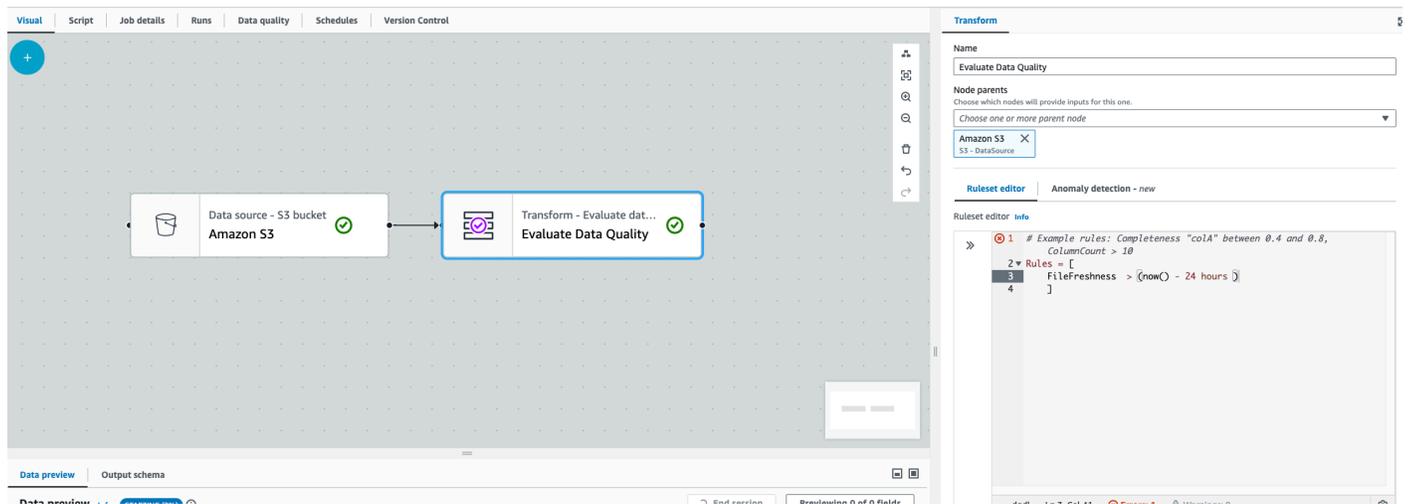

Note

This feature will only work when files are successfully read into the DynamicFrame or DataFrame.

```
FileFreshness > (now() - 24 hours)
```

This rule will find the folder path or files that are used to populate the dynamic frame or data frame. This works for Amazon S3 paths or Amazon S3-based Amazon Glue Data Catalog tables. There are a few considerations:

1. In Amazon Glue ETL, you must have the **EvaluateDataQuality** Transform immediately after an Amazon S3 or Amazon Glue Data Catalog transform.

2. This rule will not work in Amazon Glue Interactive Sessions.

If you attempt this in both of the cases, or when Amazon Glue can't find the files, Amazon Glue will throw the following error: "Unable to parse file path from DataFrame"

FileMatch

The FileMatch rule allows you to compare files against other files or checksums. This can be useful in a few scenarios:

1. Validating files received from external sources: You can use FileMatch to ensure that you have received the correct files from external sources by comparing against checksums. This helps validate the integrity of the data you're ingesting.
2. Comparing data in two different folders: FileMatch can be used to compare files between two folders.

This rule gathers one metric: the number of files that were scanned by the rule.

```
{"Dataset.*.FileCount":1}
```

Validate file with a checksum:

FileMatch accepts a file and a set checksums to ensure that at least one checksums match the file.

```
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac041793154713e5ef8f319"]
  with hashAlgorithm = "MD5"
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac041793154713e5ef8f319"]
  with hashAlgorithm = "SHA-1"
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac041793154713e5ef8f319"]
  with hashAlgorithm = "SHA-256"
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac041793154713e5ef8f319"]
```

The following standard algorithms are supported:

- MD5
- SHA-1
- SHA-256

If you do not supply an algorithm, the default is SHA-256.

Validate all files in a folder with set of checksum:

```
FileMatch "s3://amzn-s3-demo-bucket /" in ["3ee0d8617ac041793154713e5ef8f319",
  "7e8617ac041793154713e5ef8f319"] with hashAlgorithm = "MD5"
FileMatch "s3://amzn-s3-demo-bucket /internal-folder/" in
  ["3ee0d8617ac041793154713e5ef8f319", "7e8617ac041793154713e5ef8f319"]
```

Compare files in different folders

```
FileMatch "s3://original_bucket/" "s3://archive_bucket/"
FileMatch "s3://original_bucket/internal-folder/" "s3://original_bucket/other-folder/"
```

FileMatch will check the contents of the files in `original_bucket` and ensure they match what's in `archive_bucket`. The rule will fail if they don't exactly match. It also can check the contents of internal folders or individual files.

FileMatch can also check individual files against each other.

```
FileMatch "s3://amzn-s3-demo-bucket /file_old.json" "s3://amzn-s3-demo-bucket /
file_new.json"
```

Inferring file names directly from data frames

You don't always have to provide a file path. For instance, when you are authoring the rule in the Amazon Glue Data Catalog (backed by Amazon S3), it may be hard to find which folders the catalog tables are using. Amazon Glue Data Quality can find the specific folders or files used to populate your data frame.

Note

This feature will only work when files are successfully read into the `DynamicFrame` or `DataFrame`.

```
FileMatch in ["3ee0d8617ac041793154713e5ef8f319"] with hashAlgorithm = "MD5"
FileMatch in ["3ee0d8617ac041793154713e5ef8f319"] with hashAlgorithm = "SHA-1"
FileMatch in ["3ee0d8617ac041793154713e5ef8f319"] with hashAlgorithm = "SHA-256"
FileMatch in ["3ee0d8617ac041793154713e5ef8f319"]
```

If the supplied checksum is different than what's computed, `FileMatch` will alert you to the difference.

The screenshot shows the Amazon Glue Data Quality console interface. At the top, there are three tabs: 'Rules (1)', 'Statistics (0)', and 'Anomalies (0)'. The 'Rules (1)' tab is selected. Below the tabs, there is a section for 'Rules (1) Info' with a sub-header 'Data quality conditions and results.' and a search bar labeled 'Filter data quality rule results'. Below this is a table with two columns: 'Rules' and 'DQ status'. The table contains one row with the rule 'FileMatch in [\"3ee0d8617ac041793154713e5ef8f319\"]' and a status of 'Rule failed'. A tooltip is shown over the 'Rule failed' status, containing the following text: 'FileMatch - Checksum for file: s3://sompom-fake-bucket/debug_1.json using algorithm SHA-256 was not found in the checksum list. Computed checksum: 65a963c35fb2fb3318b034a0d3eefd71f6b0448b6446f1616cb31fc9b459c3d53e5ef8f319'.

Optional File-based Rule Tags:

Tags allow you to control the rule behaviour.

recentFiles

This tag limits the number of files processed by keeping the most recent file first.

```
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac04179sam4713e5ef8f319"]
with recentFiles = 1
```

matchFileName

This tag ensures that files don't have duplicate names. Default behavior is false.

```
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac04179sam4713e5ef8f319"]
with matchFileName = "true"
```

There are a few considerations:

1. In Amazon Glue ETL, you must have the **EvaluateDataQuality** Transform immediately after an Amazon S3 or Amazon Glue Data Catalog transform.

The screenshot displays the Amazon Glue console interface. On the left, a workflow diagram shows a 'Data source - S3 bucket Amazon S3' node connected to a 'Transform - Evaluate dat... Evaluate Data Quality' node. Below the diagram, the 'Output schema' section shows a 'READY' status and a 'Loading data previews. (0% complete)' message. On the right, the 'Transform' configuration panel is open, showing the 'Name' as 'Evaluate Data Quality' and 'Node parents' as 'Amazon S3 - DataSource'. The 'Ruleset editor' is active, displaying a rule configuration:

```
1 # Example rules: Completeness "colA" between 0.4 and 0.8, ColumnCount > 10
2 Rules = [
3   FileMatch in ["3ee0d8617ac041793154713e5ef8f319"]
4 ]
```

2. This rule will not work in Amazon Glue Interactive Sessions.

FileUniqueness

File Uniqueness allows you to ensure that there are no duplicate files in the data you have received from your data producers.

It gathers the following data statistics:

1. The number of files that were scanned by the rule
2. The Uniqueness Ratio of the files

```
Dataset.*.FileUniquenessRatio: 1.00, Dataset.*.FileCount: 8.00
```

Find duplicate files in a folder:

```
FileUniqueness "s3://bucket/" > 0.5  
FileUniqueness "s3://bucket/folder/" = 1
```

Inferring folder names directly from data frames to detect duplicates:

You don't always have to provide a file path. For instance, when you are authoring the rule in the Amazon Glue Data Catalog, it may be hard to find which folders the catalog tables are using. Amazon Glue Data Quality can find the specific folders or files used to populate your data frame.

Note

When using inference, file-based rules can only detect files successfully read into the `DynamicFrame` or `DataFrame`.

```
FileUniqueness > 0.5
```

Optional File-based Rule Tags:

Tags allow you to control the rule behaviour.

recentFiles

This tag limits the number of files processed by keeping the most recent file first.

```
FileUniqueness "s3://amzn-s3-demo-bucket/" > 0.5 with recentFiles = 1
```

matchFileName

This tag ensures that files don't have duplicate names. Default behavior is false.

```
FileUniqueness "s3://amzn-s3-demo-bucket/" > 0.5 with matchFileName = "true"
```

There are a few considerations:

1. In Amazon Glue ETL, you must have the **EvaluateDataQuality** Transform immediately after an Amazon S3 or Amazon Glue Data Catalog transform.
2. This rule will not work in Amazon Glue Interactive Sessions.

FileSize

The FileSize ruletype allows you to ensure that files meet a certain file size criteria. This is useful for following use cases:

1. Ensure that producers are not sending empty or substantially smaller files for processing.
2. Ensure that your target buckets don't have smaller files which may lead to performance issues.

FileSize gathers the following metrics:

1. Compliance: returns the % of files that meet the rule threshold you have established
2. File Count: the number of files that were scanned by the rule
3. Minimum file size in bytes
4. Maximum file size in bytes

```
Dataset.*.FileSize.Compliance: 1.00,  
Dataset.*.FileCount: 8.00,  
Dataset.*.MaximumFileSize: 327413121.00,  
Dataset.*.MinimumFileSize: 204558920.00
```

Anomaly detection is not supported for these metrics.

Validate size of files

This rule will pass when file.dat is greater than 2 MB.

```
FileSize "s3://amzn-s3-demo-bucket/file.dat" > 2 MB
```

The supported unites include B(bytes), MB(mega bytes), GB(giga bytes) and TB(terra bytes).

Validate size of files in folders

```
FileSize "s3://bucket/" > 5 B  
FileSize "s3://bucket/" < 2 GB
```

This rule will pass if 70% of the files in s3://amzn-s3-demo-bucket is between 2 GB and 1 TB.

```
FileSize "s3://amzn-s3-demo-bucket/" between 2 GB and 1 TB with threshold > 0.7
```

Inferring file names directly from data frames

You don't always have to provide a file path. For instance, when you are authoring the rule in the Data Catalog, it may be hard to find which folders the catalog tables are using. Amazon Glue Data Quality can find the specific folders or files used to populate your data frame.

Note

This feature will only work when files are successfully read into the `DynamicFrame` or `DataFrame`.

```
FileSize < 10 MB with threshold > 0.7
```

Optional File-based Rule Tags:

Tags allow you to control the rule behaviour.

recentFiles

This tag limits the number of files processed by keeping the most recent file first.

```
FileSize "s3://amzn-s3-demo-bucket/" > 5 B with recentFiles = 1
```

matchFileName

This tag ensures that files don't have duplicate names. Default behavior is false.

```
FileSize "s3://amzn-s3-demo-bucket/" > 5 B with matchFileName = "true"
```

There are a few considerations:

1. In Amazon Glue ETL, you must have Evaluate DataQuality Transform immediately after the Amazon S3 or Data Catalog transform.
2. This rule will not work in Amazon Glue Interactive Sessions.

Using APIs to measure and manage data quality

This topic describes how to use APIs to measure and manage data quality.

Contents

- [Prerequisites](#)
- [Working with Amazon Glue Data Quality recommendations](#)
- [Working with Amazon Glue Data Quality rulesets](#)
- [Working with Amazon Glue Data Quality runs](#)
- [Working with Amazon Glue Data Quality results](#)

Prerequisites

- Make sure your boto3 version is up to date so that it includes the latest Amazon Glue Data Quality API.
- Make sure your Amazon CLI version is up to date, so as to include the latest CLI.

If you're using an Amazon Glue job to run these APIs, you can use the following option to update the boto3 library to the latest version:

```
-additional-python-modules boto3==<version>
```

Working with Amazon Glue Data Quality recommendations

To start an Amazon Glue Data Quality recommendation run:

```
class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def start_data_quality_rule_recommendation_run(self, database_name, table_name,
role_arn):
        """
```

Starts a recommendation run that is used to generate rules when you don't know what rules to write. Amazon Glue Data Quality analyzes the data and comes up with recommendations for a potential ruleset. You can then triage the ruleset and modify the generated ruleset to your liking.

:param database_name: The name of the Amazon Glue database which contains the dataset.

:param table_name: The name of the Amazon Glue table against which we want a recommendation

:param role_arn: The Amazon Resource Name (ARN) of an Amazon Identity and Access Management (IAM) role that grants permission to let Amazon Glue access the resources it needs.

```

"""
try:
    response = self.client.start_data_quality_rule_recommendation_run(
        DataSource={
            'GlueTable': {
                'DatabaseName': database_name,
                'TableName': table_name
            }
        },
        Role=role_arn
    )
except ClientError as err:
    logger.error(
        "Couldn't start data quality recommendation run %s. Here's why: %s:
%s", name,
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response['RunId']

```

For a recommendation run, you are able to use your `pushDownPredicates` or `catalogPartitionPredicates` to improve performance and run recommendations only on specific partitions of your catalog sources.

```

client.start_data_quality_rule_recommendation_run(
    DataSource={
        'GlueTable': {
            'DatabaseName': database_name,
            'TableName': table_name,

```

```

        'AdditionalOptions': {
            'pushDownPredicate': "year=2022"
        }
    },
    Role=role_arn,
    NumberOfWorkers=2,
    CreatedRulesetName='<rule_set_name>'
)

```

To get results of an Amazon Glue Data Quality recommendation run:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def get_data_quality_rule_recommendation_run(self, run_id):
        """
        Gets the specified recommendation run that was used to generate rules.

        :param run_id: The id of the data quality recommendation run

        """
        try:
            response =
self.client.get_data_quality_rule_recommendation_run(RunId=run_id)
        except ClientError as err:
            logger.error(
                "Couldn't get data quality recommendation run %. Here's why: %s: %s",
run_id,
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response

```

From the above response object, you can extract the RuleSet that was recommended by the run, to use in further steps:

```
print(response['RecommendedRuleset'])
```

```
Rules = [
  RowCount between 2000 and 8000,
  IsComplete "col1",
  IsComplete "col2",
  StandardDeviation "col3" between 58138330.8 and 64258155.09,
  ColumnValues "col4" between 1000042965 and 1214474826,
  IsComplete "col5"
]
```

To get a list of all your recommendation runs that can be filtered and listed:

```
response = client.list_data_quality_rule_recommendation_runs(
  Filter={
    'DataSource': {
      'GlueTable': {
        'DatabaseName': '<database_name>',
        'TableName': '<table_name>'
      }
    }
  }
)
```

To cancel existing Amazon Glue Data Quality recommendation tasks:

```
response = client.cancel_data_quality_rule_recommendation_run(
  RunId='dqrun-d4b6b01957fdd79e59866365bf9cb0e40fxxxxxxx'
)
```

Working with Amazon Glue Data Quality rulesets

To create an Amazon Glue Data Quality ruleset:

```
response = client.create_data_quality_ruleset(
  Name='<ruleset_name>',
  Ruleset='Rules = [IsComplete "col1", IsPrimaryKey "col2", RowCount between 2000 and 8000]',
  TargetTable={
    'TableName': '<table_name>',
    'DatabaseName': '<database_name>'
  }
)
```

To get a data quality ruleset:

```
response = client.get_data_quality_ruleset(
    Name='<ruleset_name>'
)
print(response)
```

You can use this API to then extract the rule set:

```
print(response['Ruleset'])
```

To list all the data quality rulesets for a table:

```
response = client.list_data_quality_rulesets()
```

You can use the filter condition within the API to filter all rulesets attached to a specific database or table:

```
response = client.list_data_quality_rulesets(
    Filter={
        'TargetTable': {
            'TableName': '<table_name>',
            'DatabaseName': '<database_name>'
        }
    },
)
```

To update a data quality ruleset:

```
class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def update_data_quality_ruleset(self, ruleset_name, ruleset_string):
        """
        Update an Amazon Glue Data Quality Ruleset
        """
```

```

:param ruleset_name: The name of the Amazon Glue Data Quality ruleset to update
:param ruleset_string: The DQDL ruleset string to update the ruleset with

"""
try:
    response = self.client.update_data_quality_ruleset(
        Name=ruleset_name,
        Ruleset=ruleset_string
    )
except ClientError as err:
    logger.error(
        "Couldn't update the Amazon Glue Data Quality ruleset. Here's why: %s:
%s",
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response

```

To delete a data quality ruleset:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def delete_data_quality_ruleset(self, ruleset_name):
        """
        Delete a Amazon Glue Data Quality Ruleset

        :param ruleset_name: The name of the Amazon Glue Data Quality ruleset to delete

        """
        try:
            response = self.client.delete_data_quality_ruleset(
                Name=ruleset_name
            )
        except ClientError as err:
            logger.error(
                "Couldn't delete the Amazon Glue Data Quality ruleset. Here's why: %s:
%s",

```

```
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response
```

Working with Amazon Glue Data Quality runs

To start an Amazon Glue Data Quality run:

```
class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def start_data_quality_ruleset_evaluation_run(self, database_name, table_name,
        role_name, ruleset_list):
        """
        Start an Amazon Glue Data Quality evaluation run

        :param database_name: The name of the Amazon Glue database which contains the
        dataset.
        :param table_name: The name of the Amazon Glue table against which we want to
        evaluate.
        :param role_arn: The Amazon Resource Name (ARN) of an Amazon Identity and
        Access Management (IAM) role that grants permission to let Amazon Glue access the
        resources it needs.
        :param ruleset_list: The list of Amazon Glue Data Quality ruleset names to
        evaluate.

        """
        try:
            response = client.start_data_quality_ruleset_evaluation_run(
                DataSource={
                    'GlueTable': {
                        'DatabaseName': database_name,
                        'TableName': table_name
                    }
                },
                Role=role_name,
                RulesetNames=ruleset_list
```

```

    )
except ClientError as err:
    logger.error(
        "Couldn't start the Amazon Glue Data Quality Run. Here's why: %s: %s",
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response['RunId']

```

Remember that you can pass a `pushDownPredicate` or `catalogPartitionPredicate` parameter to ensure your data quality run only targets a specific set of partition within your catalog table. For example:

```

response = client.start_data_quality_ruleset_evaluation_run(
    DataSource={
        'GlueTable': {
            'DatabaseName': '<database_name>',
            'TableName': '<table_name>',
            'AdditionalOptions': {
                'pushDownPredicate': 'year=2023'
            }
        }
    },
    Role='<role_name>',
    NumberOfWorkers=5,
    Timeout=123,
    AdditionalRunOptions={
        'CloudWatchMetricsEnabled': False
    },
    RulesetNames=[
        '<ruleset_name>',
    ]
)

```

You can also configure how composite rules in your ruleset are evaluated, either at the ROW or COLUMN level. For more information on how composite rules work, please refer to [How composite rules work](#) in the documentation.

Example on how to set the composite rule evaluation method in your request:

```

response = client.start_data_quality_ruleset_evaluation_run(
    DataSource={

```

```

    'GlueTable': {
        'DatabaseName': '<database_name>',
        'TableName': '<table_name>',
        'AdditionalOptions': {
            'pushDownPredicate': 'year=2023'
        }
    },
    Role='<role_name>',
    NumberOfWorkers=5,
    Timeout=123,
    AdditionalRunOptions={
        'CompositeRuleEvaluationMethod':ROW
    },
    RulesetNames=[
        '<ruleset_name>',
    ]
)

```

To get information about an Amazon Glue Data Quality run:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def get_data_quality_ruleset_evaluation_run(self, run_id):
        """
        Get details about an Amazon Glue Data Quality Run

        :param run_id: The Amazon Glue Data Quality run ID to look up

        """
        try:
            response = self.client.get_data_quality_ruleset_evaluation_run(
                RunId=run_id
            )
        except ClientError as err:
            logger.error(

```

```

        "Couldn't look up the Amazon Glue Data Quality run ID. Here's why: %s:
%s",
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response

```

To get the results from an Amazon Glue Data Quality run:

For a given Amazon Glue Data Quality run, you can extract the results of the run's evaluation using the following method:

```

response = client.get_data_quality_ruleset_evaluation_run(
    RunId='d4b6b01957fdd79e59866365bf9cb0e40fxxxxxxx'
)

resultID = response['ResultIds'][0]

response = client.get_data_quality_result(
    ResultId=resultID
)

print(response['RuleResults'])

```

To list all your Amazon Glue Data Quality runs:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def list_data_quality_ruleset_evaluation_runs(self, database_name, table_name):
        """
        Lists all the Amazon Glue Data Quality runs against a given table

        :param database_name: The name of the database where the data quality runs
        :param table_name: The name of the table against which the data quality runs
        were created

```

```

"""
try:
    response = self.client.list_data_quality_ruleset_evaluation_runs(
        Filter={
            'DataSource': {
                'GlueTable': {
                    'DatabaseName': database_name,
                    'TableName': table_name
                }
            }
        }
    )
except ClientError as err:
    logger.error(
        "Couldn't list the Amazon Glue Quality runs. Here's why: %s: %s",
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response

```

You can modify the filter clause to only show results between specific times or running against specific tables.

To stop an ongoing Amazon Glue Data Quality run:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def cancel_data_quality_ruleset_evaluation_run(self, result_id):
        """
        Cancels a given Amazon Glue Data Quality run

        :param result_id: The result id of a Amazon Glue Data Quality run to cancel

        """
        try:
            response = self.client.cancel_data_quality_ruleset_evaluation_run(
                ResultId=result_id

```

```

    )
except ClientError as err:
    logger.error(
        "Couldn't cancel the Amazon Glue Data Quality run. Here's why: %s:
%s",
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response

```

Working with Amazon Glue Data Quality results

To get your Amazon Glue Data Quality run results:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def get_data_quality_result(self, result_id):
        """
        Outputs the result of an Amazon Glue Data Quality Result

        :param result_id: The result id of an Amazon Glue Data Quality run

        """
        try:
            response = self.client.get_data_quality_result(
                ResultId=result_id
            )
        except ClientError as err:
            logger.error(
                "Couldn't get the Amazon Glue Data Quality result. Here's why: %s:
%s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response

```

To view the statistics gathered for a given data quality result:

```

import boto3
from botocore.exceptions import ClientError
import logging

logger = logging.getLogger(__name__)
class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def get_profile_for_data_quality_result(self, result_id):
        """
        Outputs the statistic profile for a Amazon Glue Data Quality Result

        :param result_id: The result id of a Amazon Glue Data Quality run

        """
        try:
            response = self.glue_client.get_data_quality_result(
                ResultId=result_id
            )

            # the profile contains all statistics gathered for the result
            profile_id = response['ProfileId']
            profile = self.glue_client.list_data_quality_statistics(
                ProfileId = profile_id
            )
            return profile
        except ClientError as err:
            logger.error(
                "Couldn't retrieve Data Quality profile. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise

```

To view the timeseries for a statistic gathered across multiple data quality runs:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """

```

```

:param glue_client: A Boto3 Amazon Glue client.
"""
self.glue_client = glue_client

def get_statistics_for_data_quality_result(self, profile_id):
    """
    Outputs an array of datapoints for each statistic in the input result.

    :param result_id: The profile id of a Amazon Glue Data Quality run
    """
    try:
        profile = self.glue_client.list_data_quality_statistics(
            ProfileId = profile_id
        )
        statistics = [self.glue_client.list_data_quality_statistics(
            StatisticId = s['StatisticId']
        ) for s in profile['Statistics']]
        return statistics
    except ClientError as err:
        logger.error(
            "Couldn't retrieve Data Quality statistics. Here's why: %s: %s",
            err.response['Error']['Code'], err.response['Error']['Message'])
        raise

```

To view the anomaly detection model for a specific statistic:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def get_model_training_result_for_statistic(self, statistic_id, profile_id):
        """
        Outputs the details (bounds) of anomaly detection training for the given
        statistic at the given profile.

        :param statistic_id the model's statistic (the timeseries it is tracking)
        :param profile_id the profile associated with the model (a point in the
        timeseries)

```

```

"""
try:
    model = self.glue_client.get_data_quality_model_result(
        ProfileId = profile_id, StatisticId = statistic_id
    )
    return model
except ClientError as err:
    logger.error(
        "Couldn't retrieve Data Quality model results. Here's why: %s: %s",
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise

```

To exclude a datapoint from its statistic model's anomaly detection baseline:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def apply_exclusions_to_statistic(self, statistic_id, profile_ids):
        """
        Annotate some points along a given statistic timeseries.

        This example excludes the provided values; INCLUDE can also be used to undo
        this action.

        :param statistic_id the statistic timeseries to annotate
        :param profile_id the profiles we want to exclude (points in the timeseries)
        """

        try:
            response = self.glue_client.batch_put_data_quality_statistic_annotation(
                InclusionAnnotations = [
                    {'ProfileId': prof_id,
                     'StatisticId': statistic_id,
                     'InclusionAnnotation': 'EXCLUDE'} for prof_id in profile_ids
                ]
            )

```

```

        return response['FailedInclusionAnnotations']
    except ClientError as err:
        logger.error(
            "Couldn't store Data Quality annotations. Here's why: %s: %s",
            err.response['Error']['Code'], err.response['Error']['Message'])
        raise

```

To view the status of anomaly detection model training for a specific statistic:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Amazon Glue client.
        """
        self.glue_client = glue_client

    def get_model_training_status_for_statistic(self, statistic_id, profile_id):
        """
        Outputs the status of anomaly detection training for the given statistic at the
        given profile.

        :param statistic_id the model's statistic (the timeseries it is tracking)
        :param profile_id the profile associated with the model (a point in the
        timeseries)

        """
        try:
            model = self.glue_client.get_data_quality_model(
                ProfileId = profile_id, StatisticId = statistic_id
            )
            return model
        except ClientError as err:
            logger.error(
                "Couldn't retrieve Data Quality statistics. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise

```

To exclude all results from a specific data quality run from anomaly detection baselines:

```

class GlueWrapper:
    """Encapsulates Amazon Glue actions."""
    def __init__(self, glue_client):

```

```

"""
:param glue_client: A Boto3 Amazon Glue client.
"""
self.glue_client = glue_client

def apply_exclusions_to_profile(self, profile_id):
    """
    Exclude datapoints produced by a run across statistic timeseries.

    This example excludes the provided values; INCLUDE can also be used to undo
    this action.

    :param profile_id the profiles we want to exclude (points in the timeseries)
    """
    try:
        response = self.glue_client.put_data_quality_profile_annotation(
            ProfileId = profile_id,
            InclusionAnnotation = "EXCLUDE"
        )
        return response
    except ClientError as err:
        logger.error(
            "Couldn't store Data Quality annotations. Here's why: %s: %s",
            err.response['Error']['Code'], err.response['Error']['Message'])
        raise

```

To get the results from a given data quality run and display the results:

With a Amazon Glue Data Quality runID, you can extract the resultID to then get the actual results, as shown below:

```

response = client.get_data_quality_ruleset_evaluation_run(
    RunId='dqrn-abca77ee126abe1378c1da1ae0750d7dxxxx'
)

resultID = response['ResultIds'][0]

response = client.get_data_quality_result(
    ResultId=resultID
)

print(resp['RuleResults'])

```

Setting up alerts, deployments, and scheduling

This topic describes how to set up alerts, deployments, and scheduling for Amazon Glue Data Quality.

Contents

Setting up alerts and notifications in Amazon EventBridge integration

Amazon Glue Data Quality supports the publishing of EventBridge events, which are emitted upon completion of a Data Quality ruleset evaluation run. With this, you can easily setup alerts when data quality rules fail.

Here is a sample event when you evaluate data quality rulesets in the Data Catalog. With this information, you can review the data that is made available with Amazon EventBridge. You can issue additional API calls to get more details. For example, call the `get_data_quality_result` API with the result ID to get the details of a particular execution.

```
{
  "version": "0",
  "id": "abcdef00-1234-5678-9abc-def012345678",
  "detail-type": "Data Quality Evaluation Results Available",
  "source": "aws.glue-dataquality",
  "account": "123456789012",
  "time": "2017-09-07T18:57:21Z",
  "region": "us-west-2",
  "resources": [],
  "detail": {
    "context": {
      "contextType": "GLUE_DATA_CATALOG",
```

```

        "runId": "dqrun-12334567890",
        "databaseName": "db-123",
        "tableName": "table-123",
        "catalogId": "123456789012"
    },
    "resultID": "dqresult-12334567890",
    "rulesetNames": ["rulset1"],
    "state": "SUCCEEDED",
    "score": 1.00,
    "rulesSucceeded": 100,
    "rulesFailed": 0,
    "rulesSkipped": 0
}
}

```

Here is a sample event that gets published when you evaluate data quality rulesets in Amazon Glue ETL or Amazon Glue Studio notebooks.

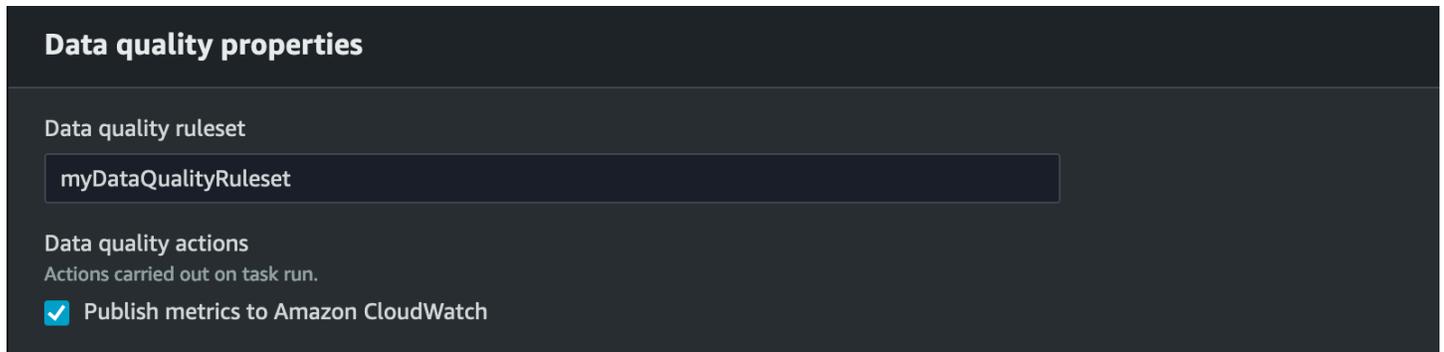

```

{
  "version": "0",
  "id": "abcdef00-1234-5678-9abc-def012345678",
  "detail-type": "Data Quality Evaluation Results Available",
  "source": "aws.glue-dataquality",
  "account": "123456789012",
  "time": "2017-09-07T18:57:21Z",
  "region": "us-west-2",
  "resources": [],
  "detail": {
    "context": {
      "contextType": "GLUE_JOB",
      "jobId": "jr-12334567890",
      "jobName": "dq-eval-job-1234",
      "evaluationContext": ""
    }
  }
  "resultID": "dqresult-12334567890",
  "rulesetNames": ["rulset1"],
  "state": "SUCCEEDED",
  "score": 1.00
  "rulesSucceeded": 100,
  "rulesFailed": 0,
  "rulesSkipped": 0
}
}

```

For Data Quality evaluation runs both in the Data Catalog and in ETL jobs, the **Publish metrics to Amazon CloudWatch** option, which is selected by default, must remain selected for EventBridge publishing to work.

Setting up EventBridge notifications

To receive the emitted events and define targets, you must configure Amazon EventBridge rules. To create rules:

1. Open the Amazon EventBridge console.
2. Choose **Rules** under the **Buses** section of the navigation bar.
3. Choose **Create Rule**.
4. On **Define Rule Detail**:
 - a. For Name, enter myDQRu1e.
 - b. Enter the description (optional).
 - c. For event bus, select your event bus. If you don't have one, leave it as default.
 - d. For Rule type select **Rule with an event pattern** then choose **Next**.
5. On **Build Event Pattern**:
 - a. For event source select **Amazon events or EventBridge partner events**.
 - b. Skip the sample event section.
 - c. For creation method select **Use pattern form**.
 - d. For event pattern:
 - i. Select **Amazon services** for Event source.
 - ii. Select **Glue Data Quality** for Amazon service.
 - iii. Select **Data Quality Evaluation Results Available** for Event type.
 - iv. Select **FAILED for Specific state(s)**. Then you see an event pattern similar to the following:

```
{
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "state": ["FAILED"]
  }
}
```

- v. For more configuration options see [Additional configuration options for the event pattern](#).

6. On **Select Target(s)**:

- a. For **Target Types** select **Amazon service**.
- b. Use the **Select a target** dropdown to choose your desired Amazon service to connect to (SNS, Lambda, SQS, etc.), then choose **Next**.

7. On **Configure tag(s)** click **Add new tags** to add optional tags then choose **Next**.

8. You see a summary page of all the selections. Choose **Create rule** at the bottom.

Additional configuration options for the event pattern

In addition to filtering your event on success or failure, you may want to further filter events on different parameters.

To do this, go to the Event Pattern section, and select **Edit pattern** to specify additional parameters. Note that fields in the event pattern are case sensitive. The following are examples of configuring the event pattern.

To capture events from a particular table evaluating specific rulesets use this type of pattern:

```
{
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "context": {
      "contextType": ["GLUE_DATA_CATALOG"],
      "databaseName": "db-123",
      "tableName": "table-123",
    },
    "rulesetNames": ["ruleset1", "ruleset2"]
  },
  "state": ["FAILED"]
}
```

```
}  
}
```

To capture events from specific jobs in the ETL experience use this type of pattern:

```
{  
  "source": ["aws.glue-dataquality"],  
  "detail-type": ["Data Quality Evaluation Results Available"],  
  "detail": {  
    "context": {  
      "contextType": ["GLUE_JOB"],  
      "jobName": ["dq_evaluation_job1", "dq_evaluation_job2"]  
    },  
    "state": ["FAILED"]  
  }  
}
```

To capture events with a score under a specific threshold (e.g. 70%):

```
{  
  "source": ["aws.glue-dataquality"],  
  "detail-type": ["Data Quality Evaluation Results Available"],  
  "detail": {  
    "score": [{  
      "numeric": ["<=", 0.7]  
    }]  
  }  
}
```

Formatting notifications as emails

Sometimes you need to send a well-formatted email notification to your business teams. You can use Amazon EventBridge and Amazon Lambda to achieve this.

Glue Data Quality rulesets **Glue_DQ_RULESET_CUSTOM_20de29c13537** run details

Notifications <no-reply@sns.amazonaws.com>

Thursday, 11. May 2023 at 15:01

    })
    message_text += "\n" + subresult

log_metadata['resultrun'] = subresult_info

sns_client.publish(
    TopicArn=sns_topic_arn,
    Message=message_text,
    Subject=subject_text
)

return {

```

```
'statusCode': 200,  
'body': json.dumps('Message published to SNS topic')  
}
```

Set up alerts and notifications in CloudWatch integration

Our recommended approach is to set up data quality alerts using Amazon EventBridge, because Amazon EventBridge requires a one-time setup to alert customers. However, some customers prefer Amazon CloudWatch due to familiarity. For such customers, we offer integration with Amazon CloudWatch.

Each Amazon Glue Data Quality evaluation emits a pair of metrics named `glue.data.quality.rules.passed` (indicating a number of rules that passed) and `glue.data.quality.rules.failed` (indicating the number of failed rules) per data quality run. You can use this emitted metric to create alarms to alert users if a given data quality run falls below a threshold. To get started with setting up an alarm that would send an email via an Amazon SNS notification, follow the steps below:

To get started with setting up an alarm that would send an email via an Amazon SNS notification, follow the steps below:

1. Open the Amazon CloudWatch console.
2. Choose **All metrics** under **Metrics**. You will see an additional namespace under Custom namespaces titled Glue Data Quality.

Note

When starting an Amazon Glue Data Quality run, make sure the **Publish metrics to Amazon CloudWatch** checkbox is enabled. Otherwise, metrics for that particular run will not be published to Amazon CloudWatch.

Under the Glue Data Quality namespace, you can see metrics being emitted per table, per ruleset. For the purpose of this topic, we will use the `glue.data.quality.rules.failed` rule and alarm if this value goes over 1 (indicating that, if we see a number of failed rule evaluations greater than 1, we want to be notified).

3. To create the alarm, choose **All alarms** under **Alarms**.

4. Choose **Create alarm**.
5. Choose **Select metric**.
6. Select the `glue.data.quality.rules.failed` metric corresponding to the table you've created, then choose **Select metric**.
7. Under the **Specify metric and conditions** tab, under the **Metrics** section:
 - a. For **Statistic**, choose **Sum**.
 - b. For **Period**, choose **1 minute**.
8. Under the **Conditions** section:
 - a. For **Threshold type**, choose **Static**.
 - b. For **Whenever glue.data.quality.rules.failed is...**, select **Greater/Equal**.
 - c. For **than...**, enter **1** as the threshold value.

These selections imply that if the `glue.data.quality.rules.failed` metric emits a value greater than or equal to 1, we will trigger an alarm. However, if there is no data, we will treat it as acceptable.

9. Choose **Next**.
10. On **Configure actions**:
 - a. For the **Alarm state trigger** section, choose **In alarm**.
 - b. For **Send a notification to the following SNS topic** section, choose **Create a new topic to send a notification via a new SNS topic**.
 - c. For **Email endpoints that will receive the notification** enter your email address. Then click **Create Topic**.
 - d. Choose **Next**.

11. For **Alarm name**, enter `myFirstDQAlarm`, then choose **Next**.

12. You see a summary page of all the selections. Choose **Create alarm** at the bottom.

You can now see the alarm being created from the Amazon CloudWatch alarms dashboard.

Querying data quality results to build dashboards

You may want to build a dashboard to display your data quality results. There are two ways to do this:

Set up Amazon EventBridge with the following code to write the data to Amazon S3:

```
import boto3
import json
from datetime import datetime

s3_client = boto3.client('s3')
glue_client = boto3.client('glue')

s3_bucket = 's3-bucket-name'

def write_logs(log_metadata):
    try:
        filename = datetime.now().strftime("%m%d%Y%H%M%S") + ".json"
        key_opts = {
            'year': datetime.now().year,
            'month': "{:02d}".format(datetime.now().month),
            'day': "{:02d}".format(datetime.now().day),
            'filename': filename
        }
        s3key = "gluedataqualitylogs/year={year}/month={month}/day={day}/
{filename}".format(**key_opts)
        s3_client.put_object(Bucket=s3_bucket, Key=s3key,
Body=json.dumps(log_metadata))
    except Exception as e:
        print(f'Error writing logs to S3: {e}')

def lambda_handler(event, context):
    log_metadata = {}
    message_text = ""
    subject_text = ""

    if event['detail']['context']['contextType'] == 'GLUE_DATA_CATALOG':
        log_metadata['ruleset_name'] = str(event['detail']['rulesetNames'][0])
        log_metadata['tableName'] = str(event['detail']['context']['tableName'])
        log_metadata['databaseName'] = str(event['detail']['context']['databaseName'])
        log_metadata['runId'] = str(event['detail']['context']['runId'])
        log_metadata['resultId'] = str(event['detail']['resultId'])
        log_metadata['state'] = str(event['detail']['state'])
        log_metadata['score'] = str(event['detail']['score'])
        log_metadata['numRulesSucceeded'] = str(event['detail']['numRulesSucceeded'])
        log_metadata['numRulesFailed'] = str(event['detail']['numRulesFailed'])
```

```

log_metadata['numRulesSkipped'] = str(event['detail']['numRulesSkipped'])

message_text += "Glue Data Quality run details:\n"
message_text += "ruleset_name: {}".format(log_metadata['ruleset_name'])
message_text += "glue_table_name: {}".format(log_metadata['tableName'])
message_text += "glue_database_name: {}".format(log_metadata['databaseName'])
message_text += "run_id: {}".format(log_metadata['runId'])
message_text += "result_id: {}".format(log_metadata['resultId'])
message_text += "state: {}".format(log_metadata['state'])
message_text += "score: {}".format(log_metadata['score'])
message_text += "numRulesSucceeded:
{}\n".format(log_metadata['numRulesSucceeded'])
message_text += "numRulesFailed: {}".format(log_metadata['numRulesFailed'])
message_text += "numRulesSkipped: {}".format(log_metadata['numRulesSkipped'])

subject_text = "Glue Data Quality ruleset {} run
details".format(log_metadata['ruleset_name'])

else:
log_metadata['ruleset_name'] = str(event['detail']['rulesetNames'][0])
log_metadata['jobName'] = str(event['detail']['context']['jobName'])
log_metadata['jobId'] = str(event['detail']['context']['jobId'])
log_metadata['resultId'] = str(event['detail']['resultId'])
log_metadata['state'] = str(event['detail']['state'])
log_metadata['score'] = str(event['detail']['score'])

log_metadata['numRulesSucceeded'] = str(event['detail']['numRulesSucceeded'])
log_metadata['numRulesFailed'] = str(event['detail']['numRulesFailed'])
log_metadata['numRulesSkipped'] = str(event['detail']['numRulesSkipped'])

message_text += "Glue Data Quality run details:\n"
message_text += "ruleset_name: {}".format(log_metadata['ruleset_name'])
message_text += "glue_job_name: {}".format(log_metadata['jobName'])
message_text += "job_id: {}".format(log_metadata['jobId'])
message_text += "result_id: {}".format(log_metadata['resultId'])
message_text += "state: {}".format(log_metadata['state'])
message_text += "score: {}".format(log_metadata['score'])
message_text += "numRulesSucceeded:
{}\n".format(log_metadata['numRulesSucceeded'])
message_text += "numRulesFailed: {}".format(log_metadata['numRulesFailed'])
message_text += "numRulesSkipped: {}".format(log_metadata['numRulesSkipped'])

subject_text = "Glue Data Quality ruleset {} run
details".format(log_metadata['ruleset_name'])

```

```

resultID = str(event['detail']['resultId'])
response = glue_client.get_data_quality_result(ResultId=resultID)
RuleResults = response['RuleResults']
message_text += "\n\nruleset details evaluation steps results:\n\n"
subresult_info = []

for dic in RuleResults:
    subresult = "Name: {} \t \t Result: {} \t \t Description: \t {}".format(dic['Name'],
dic['Result'], dic['Description'])
    if 'EvaluationMessage' in dic:
        subresult += "\t \t EvaluationMessage: {}".format(dic['EvaluationMessage'])
    subresult_info.append({
        'Name': dic['Name'],
        'Result': dic['Result'],
        'Description': dic['Description'],
        'EvaluationMessage': dic.get('EvaluationMessage', '')
    })
    message_text += "\n" + subresult

log_metadata['resultrun'] = subresult_info

write_logs(log_metadata)

return {
    'statusCode': 200,
    'body': json.dumps('Message published to SNS topic')
}

```

After writing to Amazon S3, you can use Amazon Glue crawlers to register to Athena and query the tables.

Configure an Amazon S3 location during a data quality evaluation::

When running data quality tasks in the Amazon Glue Data Catalog or Amazon Glue ETL, you can provide an Amazon S3 location to write the data quality results to Amazon S3. You can use the syntax below to create a table by referencing the target to read the data quality results.

Note that you must run the `CREATE EXTERNAL TABLE` and `MSCK REPAIR TABLE` queries separately.

```
CREATE EXTERNAL TABLE <my_table_name>(
  catalogid string,
  databasename string,
  tablename string,
  dqrunid string,
  evaluationstartedon timestamp,
  evaluationcompletedon timestamp,
  rule string,
  outcome string,
  failurereason string,
  evaluatedmetrics string)
PARTITIONED BY (
  `year` string,
  `month` string,
  `day` string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES (

  'paths'='catalogId,databaseName,dqRunId,evaluatedMetrics,evaluationCompletedOn,evaluationStartOn'
STORED AS INPUTFORMAT 'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT 'org.apache.hadoop.hive ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION 's3://glue-s3-dq-bucket-us-east-2-results/'
TBLPROPERTIES (
  'classification'='json',
  'compressionType'='none',
  'typeOfData'='file');
```

```
MSCK REPAIR TABLE <my_table_name>;
```

Once you create the above table, you can run analytical queries using Amazon Athena.

Deploying data quality rules using Amazon CloudFormation

You can use Amazon CloudFormation to create data quality rules. For more information, see [Amazon CloudFormation for Amazon Glue](#).

Scheduling data quality rules

You can schedule data quality rules using the following methods:

- Schedule data quality rules from the Data Catalog: no code users can use this option to easily schedule their data quality scans. Amazon Glue Data Quality will create the schedule in Amazon EventBridge. To schedule data quality rules:
 - Navigate to the ruleset and click **Run**.
 - In the **Run frequency**, select the desired schedule and provide a **Task Name**. This Task Name is the name of your schedule in EventBridge.
- Use Amazon EventBridge and Amazon Step Functions to orchestrate evaluations and recommendations for data quality rules.

Data encryption at rest for Amazon Glue Data Quality

Amazon Glue Data Quality provides encryption by default to protect sensitive customer data at rest using Amazon owned encryption keys.

Amazon owned keys

Amazon Glue Data Quality uses these keys to automatically encrypt customers' Data Quality assets. You cannot view, manage, or use Amazon owned keys, or audit their use. However, you don't need to take any action or change any programs to protect the keys that encrypt your data. For more information, see [Amazon owned keys](#) in the Amazon KMS Developer Guide.

Encryption of data at rest by default helps reduce the operational overhead and complexity involved in protecting sensitive data. At the same time, it enables you to build secure applications that meet strict encryption compliance and regulatory requirements.

While you can't disable this layer of encryption or select an alternate encryption type, you can add a second layer of encryption over the existing Amazon owned encryption keys by choosing a customer-managed key when you create your Data Quality resources.

Customer managed keys

Customer managed keys: Amazon Glue Data Quality supports the use of a symmetric customer-managed key that you create, own, and manage. This adds a second layer of encryption over the existing Amazon owned encryption. Because you have full control of this layer of encryption, you can perform tasks such as:

- Establishing and maintaining key policies

- Establishing and maintaining IAM policies
- Enabling and disabling key policies
- Rotating key cryptographic material
- Adding tags
- Creating key aliases
- Scheduling keys for deletion

For more information, see [Customer managed keys](#) in the Amazon KMS Developer Guide.

The following table summarizes how Amazon Glue Data Quality encrypts different Data Quality assets.

Data type	Amazon owned key encryption	Customer managed key encryption
<p>Data Quality Ruleset</p> <p>DQDL ruleset string that is referenced by the persisted DQ ruleset. These persisted rulesets are only used in the Amazon Glue Data Catalog experience for now.</p>	Enabled	Enabled
<p>Data Quality Rule/Analyzer Results</p> <p>Result artifacts that contains the pass/fail status of each rule in a ruleset as well as metrics collected by both rules and analyzers.</p>	Enabled	Enabled
<p>Observations</p> <p>Observations are generated when an anomaly is detected</p>	Enabled	Enabled

Data type	Amazon owned key encryption	Customer managed key encryption
<p>in the data. It contains information on the expected upper and lower bound and a suggested rule based on these bounds. If generated, they are displayed with the Data Quality Results.</p>		
<p>Statistics</p> <p>Contains information on metrics collected after evaluating the data given a ruleset, such as the value of the metric (e.g. RowCount, Completeness), column names, and other metadata.</p>	Enabled	Enabled
<p>Anomaly Detection Statistic Models</p> <p>The statistic models contain the time series of upper and lower bounds for a given metric generated based off of previous evaluations of the customer data.</p>	Enabled	Enabled

 **Note**

Amazon Data Quality automatically enables encryption at rest using Amazon owned keys to protect personally identifiable data at no charge. However, Amazon KMS charges apply for using a customer managed key. For more information about pricing, see [Amazon KMS Pricing](#).

For more information on Amazon KMS, see [Amazon KMS](#).

Create a Customer Managed Key

You can create a symmetric customer managed key by using the Amazon Web Services Management Console, or the Amazon KMS APIs.

To create a symmetric customer managed key:

- Follow the steps for [Creating symmetric encryption Amazon KMS keys](#) in the Amazon Key Management Service Developer Guide.

Key policy

Key policies control access to your customer managed key. Every customer managed key must have exactly one key policy, which contains statements that determine who can use the key and how they can use it. When you create your customer managed key, you can specify a key policy. For more information, see [Key policies in Amazon KMS keys](#) in the Amazon Key Management Service Developer Guide.

To use your customer managed key with your Data Quality resources, the following API operations must be permitted in the key policy:

- [kms:Decrypt](#) – Decrypts ciphertext that was encrypted by an Amazon KMS key using `GenerateDataKeyWithoutPlaintext`
- [kms:DescribeKey](#) – Provides the customer managed key details to allow Amazon Location to validate the key.
- [kms:GenerateDataKeyWithoutPlaintext](#) – Returns a unique symmetric data key for use outside of Amazon KMS. This operation returns a data key that is encrypted under a symmetric encryption KMS key that you specify. The bytes in the key are random; they are not related to the caller or to the KMS key. Used to reduce KMS calls the customer has to make.
- [kms:ReEncrypt*](#) – Decrypts ciphertext and then reencrypts it entirely within Amazon KMS. You can use this operation to change the KMS key under which data is encrypted, such as when you [manually rotate](#) a KMS key or change the KMS key that protects a ciphertext. You can also use it to reencrypt ciphertext under the same KMS key, such as to change the [encryption context](#) of a ciphertext.

The following are policy statement examples you can add for Amazon Location:

```

"Statement" : [
  {
    "Sid" : "Allow access to principals authorized to use AWS Glue Data Quality",
    "Effect" : "Allow",
    "Principal" : {
      "AWS" : "arn:aws:iam::<account_id>:role/ExampleRole"
    },
    "Action" : [
      "kms:Decrypt",
      "kms:DescribeKey",
      "kms:GenerateDataKeyWithoutPlaintext",
      "kms:ReEncrypt*"
    ],
    "Resource" : "*",
    "Condition" : {
      "StringEquals" : {
        "kms:ViaService" : "glue.amazonaws.com",
        "kms:CallerAccount" : "111122223333"
      }
    },
  },
  {
    "Sid": "Allow access for key administrators",
    "Effect": "Allow",
    "Principal": {
      "AWS": "arn:aws:iam::111122223333:root"
    },
    "Action" : [
      "kms:*"
    ],
    "Resource": "arn:aws:kms:region:111122223333:key/key_ID"
  },
  {
    "Sid" : "Allow read-only access to key metadata to the account",
    "Effect" : "Allow",
    "Principal" : {
      "AWS" : "arn:aws:iam::111122223333:root"
    },
    "Action" : [
      "kms:Describe*",
      "kms:Get*",
      "kms:List*",
    ],
  },

```

```
    "Resource" : "*"
  }
]
```

Notes about using KMS Keys in Amazon Glue Data Quality

Amazon Glue Data Quality does not support key transitions. This means that if you encrypt your Data Quality assets with Key A and decide to switch to Key B, we will not re-encrypt the data that was encrypted with Key A to use Key B. You can still switch to Key B, but will need to maintain access to Key A to access data previously encrypted with Key A.

For more information about specifying permissions in a policy, see [Permissions for Amazon services in key policies](#) in the Amazon Key Management Service Developer Guide.

For more information about troubleshooting key access, see [Troubleshooting key access](#) in the Amazon Key Management Service Developer Guide.

Create a security configuration

In Amazon Glue the [Security Configurations resource](#) contains properties that are needed when you write encrypted data.

To encrypt your data quality assets:

1. In **Encryption settings**, under **Advanced settings**, choose **Enable Data Quality Encryption**
2. Select your KMS key or choose **Create an Amazon KMS key**

[AWS Glue](#) > [Security configurations](#) > Add new security configuration

Add security configuration

Choose encryption and permission options for your accounts data catalog.

Security configuration properties

Name

Name can be up to 255 characters long. Some character set including control characters are prohibited.

Encryption settings [Info](#)

Enable and choose options for at-rest encryption.

- Enable S3 encryption**
Enable at-rest encryption for data stored on S3.
- Enable CloudWatch logs encryption**
Enable at-rest encryption when writing logs to Amazon CloudWatch.

▼ Advanced settings

- Enable job bookmark encryption**
Enable at-rest encryption of job bookmark.
- Enable DataQuality encryption**
Enable at-rest encryption of DataQuality.

AWS KMS key for DataQuality encryption

[Create an AWS KMS key](#) 

Cancel

Create

Amazon Glue Data Quality encryption context

An [encryption context](#) is an optional set of key-value pairs that contain additional contextual information about the data.

Amazon KMS uses the encryption context as [additional authenticated data](#) to support [authenticated encryption](#). When you include an encryption context in a request to encrypt data, Amazon KMS binds the encryption context to the encrypted data. To decrypt data, you include the same encryption context in the request.

Amazon Glue Data Quality encryption context example

```
"encryptionContext": {
  "kms-arn": "arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-123456SAMPLE",
  "branch-key-id": "111122223333+arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-123456SAMPLE",
  "hierarchy-version": "1",
  "aws-crypto-ec:aws:glue:securityConfiguration": "111122223333:customer-security-
configuration-name",
  "create-time": "2024-06-07T13:47:23:000861Z",
  "tablename": "AwsGlueMLEncryptionKeyStore",
  "type": "beacon:ACTIVE"
}
```

Using encryption context for monitoring

When you use a symmetric customer managed key to encrypt your tracker or geofence collection, you can also use the encryption context in audit records and logs to identify how the customer managed key is being used. The encryption context also appears in logs generated by Amazon CloudTrail or Amazon CloudWatch Logs.

Monitoring your encryption keys for Amazon Glue Data Quality

When you use an Amazon KMS customer managed key with your Amazon Glue Data Quality resources, you can use Amazon CloudTrail or Amazon CloudWatch Logs to track requests that Amazon Glue Data Quality sends to Amazon KMS.

The following examples are Amazon CloudTrail events for `GenerateDataKeyWithoutPlainText` and `Decrypt` to monitor KMS operations called by Amazon Glue Data Quality to access data encrypted by your customer managed key.

Decrypt

```
{
  "eventVersion": "1.09",
  "userIdentity": {
    "type": "AssumedRole",
    "arn": "arn:aws:sts::111122223333:role/CustomerRole",
    "accountId": "111122223333",
    "invokedBy": "glue.amazonaws.com"
  },

```

```

    "eventTime": "2024-07-02T20:03:10Z",

Troubleshooting Amazon Glue Data Quality errors

If you encounter errors in Amazon Glue Data Quality, use the following solutions to help you find the source of the problems and fix them.

Contents

- [Error: missing Amazon Glue Data Quality module](#)
- [Error: insufficient Amazon Lake Formation permissions](#)
- [Error: rulesets are not uniquely named](#)
- [Error: tables with special characters](#)
- [Error: overflow error with a large ruleset](#)
- [Error: overall rule status is failed](#)
- [AnalysisException: Unable to verify existence of default database](#)
- [Error Message: Provided key map not suitable for given data frames](#)
- [Exception in User Class: java.lang.RuntimeException : Failed to fetch data. Check the logs in CloudWatch to get more details](#)
- [LAUNCH ERROR: Error downloading from S3 for bucket](#)
- [InvalidInputException \(status: 400\): DataQuality rules cannot be parsed](#)
- [Error: Eventbridge is not triggering Glue DQ jobs based on the schedule I setup](#)
- [CustomSQL errors](#)
- [Dynamic Rules](#)
- [Exception in User Class: org.apache.spark.sql.AnalysisException: org.apache.hadoop.hive.ql.metadata.HiveException](#)
- [UNCLASSIFIED_ERROR; IllegalArgumentException: Parsing Error: No rules or analyzers provided., no viable alternative at input](#)

Error: missing Amazon Glue Data Quality module

Error message: No module named 'awsgluedq'.

Resolution: This error occurs when you run Amazon Glue Data Quality in an unsupported version. Amazon Glue Data Quality is supported only in Glue version 3.0 and later.

Error: insufficient Amazon Lake Formation permissions

Error message: Exception in User Class:

`com.amazonaws.services.glue.model.AccessDeniedException: Insufficient Lake Formation permission(s) on impact_sdg_involvement (Service: Amazon Glue; Status Code: 400; Error Code: AccessDeniedException; Request ID: 465ae693-b7ba-4df0-a4e4-6b17xxxxxxx; Proxy: null).`

Resolution: You must provide sufficient permissions in Amazon Lake Formation.

Error: rulesets are not uniquely named

Error message: Exception in User Class: `...services.glue.model.AlreadyExistsException: Another ruleset with the same name already exists.`

Resolution: Rulesets are global and must be unique.

Error: tables with special characters

Error message: Exception in User Class: `org.apache.spark.sql.AnalysisException: cannot resolve "C" given input columns: [primary.data_end_time, primary.data_start_time, primary.end_time, primary.last_updated, primary.message, primary.process_date, primary.rowhash, primary.run_by, primary.run_id, primary.start_time, primary.status]; line 1 pos 44;`

Resolution: There is a current limitation that Amazon Glue Data Quality cannot be executed on tables that have special characters such as ".".

Error: overflow error with a large ruleset

Error message: Exception in User Class: `java.lang.StackOverflowError.`

Resolution: If you have a large ruleset of greater than 2K rules, you may encounter this issue. Break your rules into multiple rulesets.

Error: overall rule status is failed

Error condition: My Ruleset is successful, but my overall rule status is failed.

Resolution: This error most likely occurred because you chose the option to publish metrics to Amazon CloudWatch while publishing. If your dataset is in a VPC, your VPC may not allow Amazon Glue to publish metrics to Amazon CloudWatch. In this case, you must set up an endpoint for your VPC to access Amazon CloudWatch.

AnalysisException: Unable to verify existence of default database

Error condition: AnalysisException: Unable to verify existence of default database: com.amazonaws.services.glue.model.AccessDeniedException: Insufficient Lake Formation permission(s) on default (Service: Amazon Glue; Status Code: 400; Error Code: AccessDeniedException; Request ID: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX; Proxy: null)

Resolution: In Amazon Glue job's catalog integration, Amazon Glue always tries to check whether default database exists or not using Amazon Glue GetDatabase API. When the DESCRIBE Lake Formation permission is not granted, or GetDatabase IAM permission is granted, then the job fails when verifying existence of the default database.

To resolve:

1. Add the DESCRIBE permission in Lake Formation for the default database.
2. Configure the IAM role attached to the Amazon Glue job as Database Creator in Lake Formation. This will automatically create a default database and grant required Lake Formation permissions for the role.
3. Disable `--enable-data-catalog` option. (It is shown as **Use Data Catalog as the Hive metastore** in Amazon Glue Studio).

If you do not need Spark SQL Data Catalog integration in the job, you can disable it.

Error Message: Provided key map not suitable for given data frames

Error condition: Provided key map not suitable for given data frames.

Resolution: You are using **DataSetMatch** ruletype and the join keys have duplicates. Your join keys must be unique and must not be NULL. In cases where you can't have join keys that are unique, consider using other ruletypes such as **AggregateMatch** to match on summary data.

Exception in User Class: java.lang.RuntimeException : Failed to fetch data. Check the logs in CloudWatch to get more details

Error condition: Exception in User Class: java.lang.RuntimeException : Failed to fetch data. Check the logs in CloudWatch to get more details.

Resolution: This happens when you are creating DQ rules on an Amazon S3-based table that compares against Amazon RDS or Amazon Redshift. In these cases, Amazon Glue cannot load the connection. Instead, try to set up DQ rule on the Amazon Redshift or Amazon RDS dataset. This is a known bug.

LAUNCH ERROR: Error downloading from S3 for bucket

Error condition: LAUNCH ERROR: Error downloading from S3 for bucket: aws-glue-ml-data-quality-assets-us-east-1, key: jars/aws-glue-ml-data-quality-etl.jar.Access Denied (Service: Amazon S3; Status Code: 403; Please refer logs for details) .

Resolution: The permissions in the role passed to Amazon Glue Data Quality must permit reading from the preceding Amazon S3 location. This IAM policy should be attached to the role:

```
{
  "Sid": "allowS3",
  "Effect": "Allow",
  "Action": "s3:GetObject",
  "Resource": "arn:aws:s3:::aws-glue-ml-data-quality-assets-<region>/*"
}
```

Refer to [Data Quality authorization](#) for detailed permissions. These libraries are required to evaluate data quality for your datasets.

InvalidInputException (status: 400): DataQuality rules cannot be parsed

Error condition: InvalidInputException (status: 400): DataQuality rules cannot be parsed.

Resolution: There are many possibilities for this error. One possibility is that your rules may have single quotes. Verify that they are in double quotes. For example:

```
Rules = [
```

```
ColumnValues "tipo_vinculo" in ["COD0", "DOC0", "COC0", "DOD0"] AND "categoria" = 'ES'  
AND "cod_bandera" = 'CEP'
```

Change this to:

```
Rules = [  
(ColumnValues "tipovinculo" in [ "COD0", "DOC0", "COC0", "DOD0"]) AND (ColumnValues  
"categoria" = "ES")  
AND (ColumnValues "codbandera" = "CEP")  
]
```

Error: Eventbridge is not triggering Glue DQ jobs based on the schedule I setup

Error condition: Eventbridge is not triggering Amazon Glue Data Quality jobs based on the schedule I setup.

Resolution: The role triggering the job may not have the right permissions. Make sure that the role that you are using to start the jobs has the permissions mentioned in [IAM setup required for scheduling evaluation runs](#).

CustomSQL errors

Error condition: The output from CustomSQL must contain at least one column that matches the input dataset for Amazon Glue Data Quality to provide row level results. The SQL query is a valid query but no columns from the SQL result are present in the Input Dataset. Ensure that matching columns are returned from the SQL.

Resolution: The SQL query is valid but verify that you're selecting only columns from the primary table. Selecting aggregate functions like sum, count on the columns from the primary can result in this error.

Error condition: There was a problem when executing your SQL statement: cannot resolve "Col".

Resolution: This column is not present in the primary table.

Error condition: The columns that are returned from the SQL statement should only belong to the primary table. "In this case, some columns (Col) belong to reference table".

Resolution: In SQL queries when you're joining the primary table with other reference tables, verify that your select statement has only column names from your primary table to generate row level results for the primary table.

Dynamic Rules

Error condition: Dynamic rules require job context, and cannot be evaluated in interactive session or data preview..

Cause: This error message might appear in your data preview results, or in other interactive sessions, when dynamic DQ rules are present in your ruleset. Dynamic rules reference historical metrics associated with a particular job name and evaluation context, so they can't be evaluated in interactive sessions.

Resolution: Running your Amazon Glue job will produce historical metrics, which can be referenced in later job runs for the same job.

Error condition:

- [RuleType] rule only supports simple atomic operands in thresholds..
- Function last not yet implemented for [RuleType] rule.

Resolution: Dynamic rules are generally supported for all DQDL ruletypes in numeric expressions (see [DQDL Reference](#)). However, some rules that produce multiple metrics, ColumnValues and ColumnLength, are not yet supported.

Error condition: Binary expression operands must resolve to a single number..

Cause: Dynamic rules support binary expressions, like `RowCount > avg(last(5)) * 0.9`. Here, the binary expression is `avg(last(5)) * 0.9`. This rule is valid because both operands `avg(last(5))` and `0.9` resolve to a single number. An incorrect example is `RowCount > last(5) * 0.9`, because `last(5)` will produce a list that can't be meaningfully compared to the current row count.

Resolution: Use aggregation functions to reduce a list-valued operand to a single number.

Error condition:

- Rule threshold results in list, and a single value is expected. Use aggregation functions to produce a single value. Valid example: `sum(last(10))`, `avg(last(10))`.
- Rule threshold results in empty list, and a single value is expected.

Cause: Dynamic rules can be used to compare some feature of your dataset with its historical values. The last function allows for the retrieval of multiple historical values, if a positive integer argument is provided. For example, `last(5)` will retrieve the last five most recent values observed in job runs for your rule.

Resolution: An aggregation function must be used to reduce these values to a single number to make a meaningful comparison with the value observed in the current job run.

Valid examples:

- `RowCount >= avg(last(5))`
- `RowCount > last(1)`
- `RowCount < last()`

Invalid example: `RowCount > last(5)`.

Error condition:

- Function index used in threshold requires positive integer argument.
- Index argument must be an integer. Valid syntax example: `RowCount > index(last(10, 2))`, which means RowCount must be greater than third most recent execution from last 10 job runs.

Resolution: When authoring dynamic rules, you can use the `index` aggregation function to select one historical value from a list. For example, `RowCount > index(last(5), 1)` will check whether the row count observed in the current job is strictly greater than the second most recent row count observed for your job. `index` is zero-indexed.

Error condition: `IllegalArgumentException: Parsing Error: Rule Type: DetectAnomalies is not valid.`

Resolution: Anomaly detection is only available in Amazon Glue 4.0.

Error condition: `IllegalArgumentException: Parsing Error: Unexpected condition for rule of type ... no viable alternative at input ...`

Note: ... is dynamic. Example: `IllegalArgumentException: Parsing Error: Unexpected condition for rule of type RowCount with number return type, line 4:19 no viable alternative at input '>last'.`

Resolution: Anomaly detection is only available in Amazon Glue 4.0.

Exception in User Class: org.apache.spark.sql.AnalysisException: org.apache.hadoop.hive.ql.metadata.HiveException

Error condition: Exception in User Class:

`org.apache.spark.sql.AnalysisException:`

`org.apache.hadoop.hive.ql.metadata.HiveException: Unable to fetch table mailpiece_submitted. StorageDescriptor#InputFormat cannot be null for table: mailpiece_submitted (Service: null; Status Code: 0; Error Code: null; Request ID: null; Proxy: null)`

Cause: You are using Apache Iceberg in Amazon Glue Data Catalog and the Input Format attribute in Amazon Glue Data Catalog is empty.

Resolution: This issue occurs when you are using CustomSQL ruletype in your DQ rule. One way to fix this is to use "primary" or add catalog name glue_catalog. to <database>.<table> in Custom ruletype.

UNCLASSIFIED_ERROR; IllegalArgumentException: Parsing Error: No rules or analyzers provided., no viable alternative at input

Error condition: `UNCLASSIFIED_ERROR; IllegalArgumentException: Parsing Error: No rules or analyzers provided., no viable alternative at input`

Resolution: DQDL is not parsable. There are a few instances where this can occur. If you are using composite rules, makes sure they have right parenthesis.

```
(RowCount >= avg(last(10)) * 0.6) and (RowCount <= avg(last(10)) * 1.4) instead of
    RowCount >= avg(last(10)) * 0.6 and RowCount <= avg(last(10)) * 1.4
```

Amazon Q data integration in Amazon Glue

Amazon Q data integration in Amazon Glue is a new generative AI capability of Amazon Glue that enables data engineers and ETL developers to build data integration jobs using natural language. Engineers and developers can ask Amazon Q to author jobs, troubleshoot issues, and answer questions about Amazon Glue and data integration.

What is Amazon Q?

Note

Powered by Amazon Bedrock: Amazon implements [automated abuse detection](#). Because Amazon Q data integration is built on Amazon Bedrock, users can take full advantage of the controls implemented in Amazon Bedrock to enforce safety, security, and the responsible use of artificial intelligence (AI).

Amazon Q is a generative artificial intelligence (AI) powered conversational assistant that can help you understand, build, extend, and operate Amazon applications. The model that powers Amazon Q has been augmented with high quality Amazon content to get you more complete, actionable, and referenced answers to accelerate your building on Amazon. For more information, see [What is Amazon Q?](#)

What is Amazon Q data integration in Amazon Glue?

Amazon Q data integration in Amazon Glue includes the following capabilities:

- **Chat** – Amazon Q data integration in Amazon Glue can answer natural language questions in English about Amazon Glue and data integration domains like Amazon Glue source and destination connectors, Amazon Glue ETL jobs, Data Catalog, crawlers and Amazon Lake Formation, and other feature documentation, and best practices. Amazon Q data integration in Amazon Glue responds with step-by-step instructions, and includes references to its information sources.
- **Data integration code generation** – Amazon Q data integration in Amazon Glue can answer questions about Amazon Glue ETL scripts, and generate new code given a natural language question in English.

- **Troubleshoot** – Amazon Q data integration in Amazon Glue is purpose built to help you understand errors in Amazon Glue jobs and provides step-by-step instructions, to root cause and resolve your issues.

Note

Amazon Q data integration in Amazon Glue does not use the context of your conversation to inform future responses for the duration of your conversation. Each conversation with Amazon Q data integration in Amazon Glue is independent of your prior or future conversations.

Working with Amazon Q data integration in Amazon Glue?

In the Amazon Q panel you can request Amazon Q generate code for an Amazon Glue ETL script, or answer a question on Amazon Glue features or troubleshooting an error. The response is an ETL script in PySpark with step-by-step instructions to customize the script, review and execute it. For questions, the response is generated based on the data integration knowledge base with a summary and source URL for references.

For example, you can ask Amazon Q to *"Please provide a Glue script that reads from Snowflake, renames the fields, and writes to Redshift"* and in response, Amazon Q data integration in Amazon Glue will return an Amazon Glue job script that can perform the requested action. You can review the generated code to ensure that it fulfills the requested intent. If satisfied, you can deploy it as an Amazon Glue job in production. You can troubleshoot jobs by asking the integration to explain errors and failures, and to propose solutions. Amazon Q can answer questions about Amazon Glue or data integration best practices.

The following are example questions that demonstrate how Amazon Q data integration in Amazon Glue can help you build on Amazon Glue:

Amazon Glue ETL code generation:

- Write an Amazon Glue script that reads JSON from S3, transforms fields using apply mapping and writes to Amazon Redshift
- How do I write an Amazon Glue script for reading from DynamoDB, applying the DropNullFields transform and writing to S3 as Parquet?

- Give me an Amazon Glue script that reads from MySQL, drops some fields based on my business logic, and writes to Snowflake
- Write an Amazon Glue job to read from DynamoDB and write to S3 as JSON
- Help me develop an Amazon Glue script for Amazon Glue Data Catalog to S3
- Write an Amazon Glue job to read JSON from S3, drop nulls and write to Redshift

Amazon Glue feature explanations:

- How do I use Amazon Glue Data Quality?
- How to use Amazon Glue job bookmarks?
- How do I enable Amazon Glue autoscaling?
- What is the difference between Amazon Glue dynamic frames and Spark data frames?
- What are the different types of connections supported by Amazon Glue?

Amazon Glue troubleshooting:

- How to troubleshoot Out Of Memory (OOM) errors on Amazon Glue jobs?
- What are some error messages you may see when setting up Amazon Glue Data Quality and how can you fix them?
- How do I fix an Amazon Glue job with the error Amazon S3 access denied?
- How do I resolve issues with data shuffle on Amazon Glue jobs?

Best practices for interacting with Amazon Q data integration

The following are best practices for interacting with Amazon Q data integration:

- When interacting with Amazon Q data integration, ask specific questions, iterate when you have complex requests, and verify the answers for accuracy.
- When providing data integration prompts in natural language, be as specific as possible to help the assistant understand exactly what you need. Instead of asking "extract data from S3," provide more details like "write an Amazon Glue script that extracts JSON files from S3."
- Review the generated script before running it to ensure accuracy. If the generated script has errors or does not match your intent, provide instructions to the assistant on how to correct it.

- Generative AI technology is new and there can be mistakes, sometimes called hallucinations, in the responses. Test and review all code for errors and vulnerabilities before using it in your environment or workload.

Amazon Q data integration in Amazon Glue service improvement

To help Amazon Q data integration in Amazon Glue provide the most relevant information about Amazon services, we may use certain content from Amazon Q, such as questions that you ask Amazon Q and its responses, for service improvement.

For information about what content we use and how to opt out, see [Amazon Q Developer service improvement](#) in the *Amazon Q Developer User Guide*.

Considerations

Consider the following items before you use Amazon Q data integration in Amazon Glue:

- Currently, the code generation only works with PySpark kernel. The generated code is for Amazon Glue jobs based on Python Spark.
- For information about the supported combinations of code generation abilities of Amazon Q data integration in Amazon Glue, see [Supported code generation abilities](#).

Setting up Amazon Q data integration in Amazon Glue

The following sections provide information setting up Amazon Q data integration in Amazon Glue.

Topics

- [Configuring IAM permissions](#)

Configuring IAM permissions

This topic describes the IAM permissions that you configure for the Amazon Q chat experience, and the Amazon Glue Studio notebook experience.

Topics

- [Configuring IAM permissions for Amazon Q chat](#)
- [Configuring IAM permissions for Amazon Glue Studio notebooks](#)

Configuring IAM permissions for Amazon Q chat

Granting permissions to the APIs used by Amazon Q data integration in Amazon Glue requires appropriate Amazon Identity and Access Management (IAM) permissions. You can obtain permissions by attaching the following custom Amazon policy to your IAM identity (such as a user, role, or group):

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartCompletion",
        "glue:GetCompletion"
      ],
      "Resource": [
        "arn:aws:glue:*:*:completion/*"
      ]
    }
  ]
}
```

Configuring IAM permissions for Amazon Glue Studio notebooks

To enable Amazon Q data integration in Amazon Glue Studio notebooks, ensure the following permission is attached to the notebook IAM role:

Note

The `codewhisperer` prefix is a legacy name from a service that merged with Amazon Q Developer. For more information, see [Amazon Q Developer rename - Summary of changes](#).

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartCompletion",
        "glue:GetCompletion"
      ],
      "Resource": [
        "arn:aws:glue:*:*:completion/*"
      ]
    },
    {
      "Sid": "AmazonQDeveloperPermissions",
      "Effect": "Allow",
      "Action": [
        "codewhisperer:GenerateRecommendations"
      ],
      "Resource": "*"
    }
  ]
}
```

Note

Amazon Q data integration in Amazon Glue does not have APIs available through the Amazon SDK that you can use programmatically. The following two APIs are used in the IAM policy for enabling this experience through the Amazon Q chat panel or Amazon Glue Studio notebooks: `StartCompletion` and `GetCompletion`.

Assigning permissions

To provide access, add permissions to your users, groups, or roles:

- Users and groups in Amazon IAM Identity Center: Create a permission set. Follow the instructions in [Create a permission set](#) in the *Amazon IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider: Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.
- IAM users:
 - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
 - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

Supported code generation abilities

The following are the combinations of the code generation abilities of Amazon Q data integration.

Sources and Targets	Transformation
S3 with the following format types: json, csv, parquet, hudi, delta	Drop
Amazon Glue Data Catalog	Aggregate
Redlake	DropDuplicates
Amazon DynamoDB	Join
MySQL	Filter
Oracle	RenameColumns
PostgreSQL	FillNull
Microsoft SQL Server	DropNull
Amazon DocumentDB / MongoDB	WithColumns
Snowflake	SQL Query
Google BigQuery	Union
Teradata	Select

Sources and Targets	Transformation
Amazon OpenSearch Service	
Vertica	
SAP HANA	
Amazon Redshift	

Example interactions

Amazon Q data integration in Amazon Glue allows you enter your question in the Amazon Q panel. You can enter a question regarding data integration functionality provided by Amazon Glue. A detailed answer, together with reference documents, will be returned.

Another use case is generating Amazon Glue ETL job scripts. You can ask a question regarding how to perform a data extract, transform, load job. A generated PySpark script will be returned.

Topics

- [Amazon Q chat interactions](#)
- [Amazon Glue Studio notebook interactions](#)

Amazon Q chat interactions

On the Amazon Glue console, start authoring a new job, and ask Amazon Q: *"Create a Glue ETL flow connect to two Glue catalog tables venue and event in my database glue_db, join the results on the venue's venueid and event's e_venueid, and then filter on venue state with condition as venuestate=='DC' and write to s3://amzn-s3-demo-bucket/codegen/BDB-9999/output/ in CSV format."*

You will notice that the code is generated. With this response, you can learn and understand how you can author Amazon Glue code for your purpose. You can copy/paste the generated code to the script editor and configure placeholders. After you configure an IAM role and Amazon Glue connections on the job, save and run the job. When the job is complete, you can verify the summary data is persisted to Amazon S3 as expected and can be used by your downstream workloads.

Amazon Glue Studio notebook interactions

Note

The Amazon Q Data integration experience in Amazon Glue Studio notebook still focuses on DynamicFrame-based data integration flow.

Add a new cell and enter your comment to describe what you want to achieve. After you press **Tab** and **Enter**, the recommended code is shown.

First intent is to extract the data: *"Give me code that reads a Glue Data Catalog table"*, followed by *"Give me code to apply a filter transform with star_rating>3"* and *"Give me code that writes the frame into S3 as Parquet"*.

Similar to the Amazon Q chat experience, the code is recommended. If you press **Tab**, then the recommended code is chosen.

You can run each cell by filling in the appropriate options for your sources in the generated code. At any point in the runs, you can also preview a sample of your dataset by using the `show()` method.

You can run the notebook as a job, either programmatically or by choosing **Run**.

Complex prompts

You can generate a full script with a single complex prompt. *"I have JSON data in S3 and data in Oracle that needs combining. Please provide a Glue script that reads from both sources, does a join, and then writes results to Redshift."*

You may notice that, on the notebook, Amazon Q data integration in Amazon Glue generated the same code snippet that was generated in the Amazon Q chat.

You can run the notebook as a job, either by choosing **Run** or programmatically.

Using context awareness with Amazon Q Data Integration in Amazon Glue

You can now create data processing jobs more efficiently with query based context-aware and PySpark DataFrame code generation in Amazon Q Data Integration. For example, you can use

this prompt to generate PySpark code: “create a job to load sales data from Redshift table ‘analytics.salesorder’ using connection ‘erp_conn’, filter order_amount below 50 dollars, and save to Amazon S3 in parquet format.”

Amazon Q will generate the script based on your prompt and setup data integration workflow setup with the details provided from your question, such as connection configurations, schema details, database/table names, and column specifications for transformations. Sensitive information, such as connection option passwords, continue to be redacted.

If required information is not provided from your prompt, Amazon Q will put placeholders, which you have to update the generated code with the appropriate values before running the code.

The following are examples on how to use context awareness.

Example: interactions

Reading an Amazon S3 file and writing to an Amazon S3 bucket

Prompt: Create an Amazon Glue spark job that reads a file `s3://amzn-s3-demo-bucket-input-bucket-name/input-filename.csv` and saves it into the parquet file under directory `s3://amzn-s3-demo-bucket-output-bucket-name/output-s3-prefix/`

```
import sys
from awsglue.transforms import *
from pyspark.context import SparkContext
from pyspark.sql import SparkSession

sc = SparkContext.getOrCreate()
spark = SparkSession.builder.getOrCreate()

# Script generated for node S3DataSource
S3DataSource_dsource1 = spark.read.format("csv").load(
    "s3://amzn-s3-demo-bucket-input-bucket-name/input-filename.csv"
)

# Script generated for node S3DataSink
S3DataSource_dsource1.write.format("parquet").mode("append").save(
    "s3://amzn-s3-demo-bucket-output-bucket-name/output-s3-prefix/"
)
```

Get data from Lakehouse and write to database

Prompt: write an ETL script to read from a Lakehouse table my-table in database my-database and write it to a RDS MySQL table my-target-table

For fields where you did not provide information (for example, the connectionName required is for MySQL data sink and default with a placeholder <connection-name> in the generated code), a placeholder is kept for you to fill in the required information before run the script.

Generated script:

```
import sys
from awsglue.transforms import *
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from connectivity.adapter import CatalogConnectionHelper

sc = SparkContext.getOrCreate()
spark = SparkSession.builder.getOrCreate()

# Script generated for node S3DataSource
S3DataSource_dsourcel = spark.read.format("parquet").load(
    "s3://amzn-lakehouse-demo-bucket/my-database/my-table"
)

# Script generated for node ConnectionV2DataSink
ConnectionV2DataSink_dsink1_additional_options = {"dbtable": "my-target-table"}
CatalogConnectionHelper(spark).write(
    S3DataSource_dsourcel,
    "mysql",
    "<connection-name>",
    ConnectionV2DataSink_dsink1_additional_options,
)
```

Example: Full ETL workflow

The following example demonstrates how you can ask Amazon Glue to create a Amazon Glue script to complete a full ETL workflow with the following prompt: Create a Amazon Glue ETL Script read from two Amazon Glue Data Catalog tables venue and event in my database glue_db_4fthqih3vvk1if, join the results on the field venueid, filter on venue state with condition as venuestate=='DC' after joining

the results and write output to an Amazon S3 location `s3://amz-s3-demo-bucket/output/` in CSV format.

The workflow contains reading from different data sources (two Amazon Glue Data Catalog tables), and a couple of transforms after the reading by join the result from two readings, filter based on some condition and write the transformed output to an Amazon S3 destination in CSV format.

The generated job will fill in the detailed information to the data source, transform and sink operation with corresponding information extracted from user question as below.

```
import sys
from awsglue.transforms import *
from pyspark.context import SparkContext
from pyspark.sql import SparkSession

sc = SparkContext.getOrCreate()
spark = SparkSession.builder.getOrCreate()

# Script generated for node CatalogDataSource
CatalogDataSource_dsource1 = spark.sql("select * from
`glue_db_4fthqih3vvk1if`.`venue`")

# Script generated for node CatalogDataSource
CatalogDataSource_dsource2 = spark.sql("select * from
`glue_db_4fthqih3vvk1if`.`event`")

# Script generated for node JoinTransform
JoinTransform_transform1 = CatalogDataSource_dsource1.join(
    CatalogDataSource_dsource2,
    (CatalogDataSource_dsource1["venueid"] == CatalogDataSource_dsource2["venueid"]),
    "inner",
)

# Script generated for node FilterTransform
FilterTransform_transform2 = JoinTransform_transform1.filter("venuestate=='DC'")

# Script generated for node S3DataSink
FilterTransform_transform2.write.format("csv").mode("append").save(
    "s3://amz-s3-demo-bucket/output//output/"
)
```

Limitations

- Context carryover:
 - The context-awareness feature only carries over context from the previous user query within the same conversation. It does not retain context beyond the immediate preceding query.
- Support for node configurations:
 - Currently, context-awareness supports only a subset of required configurations for various nodes.
 - Support for optional fields is planned in upcoming releases.
- Availability:
 - Context-awareness and DataFrame support are available in Q Chat and SageMaker Unified Studio notebooks. However, these features are not yet available in Amazon Glue Studio notebooks.

Orchestration in Amazon Glue

The following sections provide information on orchestration of jobs in Amazon Glue.

Topics

- [Starting jobs and crawlers using triggers](#)
- [Performing complex ETL activities using blueprints and workflows in Amazon Glue](#)
- [Developing blueprints in Amazon Glue](#)

Starting jobs and crawlers using triggers

In Amazon Glue, you can create Data Catalog objects called triggers, which you can use to either manually or automatically start one or more crawlers or extract, transform, and load (ETL) jobs. Using triggers, you can design a chain of dependent jobs and crawlers.

Note

You can accomplish the same thing by defining *workflows*. Workflows are preferred for creating complex multi-job ETL operations. For more information, see [the section called “Performing complex ETL activities using blueprints and workflows”](#).

Topics

- [Amazon Glue triggers](#)
- [Adding triggers](#)
- [Activating and deactivating triggers](#)

Amazon Glue triggers

When *fired*, a trigger can start specified jobs and crawlers. A trigger fires on demand, based on a schedule, or based on a combination of events.

Note

Only two crawlers can be activated by a single trigger. If you want to crawl multiple data stores, use multiple sources for each crawler instead of running multiple crawlers simultaneously.

A trigger can exist in one of several states. A trigger is either `CREATED`, `ACTIVATED`, or `DEACTIVATED`. There are also transitional states, such as `ACTIVATING`. To temporarily stop a trigger from firing, you can deactivate it. You can then reactivate it later.

There are three types of triggers:

Scheduled

A time-based trigger based on `cron`.

You can create a trigger for a set of jobs or crawlers based on a schedule. You can specify constraints, such as the frequency that the jobs or crawlers run, which days of the week they run, and at what time. These constraints are based on `cron`. When you're setting up a schedule for a trigger, consider the features and limitations of `cron`. For example, if you choose to run your crawler on day 31 each month, keep in mind that some months don't have 31 days. For more information about `cron`, see [Time-based schedules for jobs and crawlers](#).

Conditional

A trigger that fires when a previous job or crawler or multiple jobs or crawlers satisfy a list of conditions.

When you create a conditional trigger, you specify a list of jobs and a list of crawlers to watch. For each watched job or crawler, you specify a status to watch for, such as `succeeded`, `failed`, `timed out`, and so on. The trigger fires if the watched jobs or crawlers end with the specified statuses. You can configure the trigger to fire when any or all of the watched events occur.

For example, you could configure a trigger T1 to start job J3 when both job J1 and job J2 successfully complete, and another trigger T2 to start job J4 if either job J1 or job J2 fails.

The following table lists the job and crawler completion states (events) that triggers watch for.

Job completion states	Crawler completion states
<ul style="list-style-type: none"> • SUCCEEDED • STOPPED • FAILED • TIMEOUT 	<ul style="list-style-type: none"> • SUCCEEDED • FAILED • CANCELLED

On-demand

A trigger that fires when you activate it. On-demand triggers never enter the ACTIVATED or DEACTIVATED state. They always remain in the CREATED state.

So that they are ready to fire as soon as they exist, you can set a flag to activate scheduled and conditional triggers when you create them.

Important

Jobs or crawlers that run as a result of other jobs or crawlers completing are referred to as *dependent*. Dependent jobs or crawlers are only started if the job or crawler that completes was started by a trigger. All jobs or crawlers in a dependency chain must be descendants of a single **scheduled** or **on-demand** trigger.

Passing job parameters with triggers

A trigger can pass parameters to the jobs that it starts. Parameters include job arguments, timeout value, security configuration, and more. If the trigger starts multiple jobs, the parameters are passed to each job.

The following are the rules for job arguments passed by a trigger:

- If the key in the key-value pair matches a default job argument, the passed argument overrides the default argument. If the key doesn't match a default argument, then the argument is passed as an additional argument to the job.
- If the key in the key-value pair matches a non-overridable argument, the passed argument is ignored.

For more information, see [the section called "Triggers"](#) in the Amazon Glue API.

Adding triggers

You can add a trigger using the Amazon Glue console, the Amazon Command Line Interface (Amazon CLI), or the Amazon Glue API.

To add a trigger (console)

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **ETL**, choose **Triggers**. Then choose **Add trigger**.
3. Provide the following properties:

Name

Give your trigger a unique name.

Trigger type

Specify one of the following:

- **Schedule:** The trigger fires at a specific frequency and time.
 - **Job events:** A conditional trigger. The trigger fires when any or all jobs in the list match their designated statuses. For the trigger to fire, the watched jobs must have been started by triggers. For any job you choose, you can only watch one job event (completion status).
 - **On-demand:** The trigger fires when it is activated.
4. Complete the trigger wizard. On the **Review** page, you can activate **Schedule** and **Job events** (conditional) triggers immediately by selecting **Enable trigger on creation**.

To add a trigger (Amazon CLI)

- Enter a command similar to the following.

```
aws glue create-trigger --name MyTrigger --type SCHEDULED --schedule "cron(0 12 * * ? *)" --actions CrawlerName=MyCrawler --start-on-creation
```

This command creates a schedule trigger named `MyTrigger`, which runs every day at 12:00pm UTC and starts a crawler named `MyCrawler`. The trigger is created in the activated state.

For more information, see [the section called “Amazon Glue triggers”](#).

Time-based schedules for jobs and crawlers

You can define a time-based schedule for your crawlers and jobs in Amazon Glue. The definition of these schedules uses the Unix-like [cron](#) syntax. You specify time in [Coordinated Universal Time \(UTC\)](#), and the minimum precision for a schedule is 5 minutes.

To learn more about configuring jobs and crawlers to run using a schedule, see [Starting jobs and crawlers using triggers](#).

Cron expressions

Cron expressions have six required fields, which are separated by white space.

Syntax

```
cron(Minutes Hours Day-of-month Month Day-of-week Year)
```

Fields	Values	Wildcards
Minutes	0–59	, - * /
Hours	0–23	, - * /
Day-of-month	1–31	, - * ? / L W
Month	1–12 or JAN-DEC	, - * /
Day-of-week	1–7 or SUN-SAT	, - * ? / L
Year	1970–2199	, - * /

Wildcards

- The , (comma) wildcard includes additional values. In the Month field, JAN, FEB, MAR would include January, February, and March.
- The - (dash) wildcard specifies ranges. In the Day field, 1–15 would include days 1 through 15 of the specified month.
- The * (asterisk) wildcard includes all values in the field. In the Hours field, * would include every hour.
- The / (forward slash) wildcard specifies increments. In the Minutes field, you could enter **1/10** to specify every 10th minute, starting from the first minute of the hour (for example, the 11th, 21st, and 31st minute).
- The ? (question mark) wildcard specifies one or another. In the Day-of-month field you could enter **7**, and if you didn't care what day of the week the seventh was, you could enter **?** in the Day-of-week field.
- The **L** wildcard in the Day-of-month or Day-of-week fields specifies the last day of the month or week.
- The **W** wildcard in the Day-of-month field specifies a weekday. In the Day-of-month field, **3W** specifies the day closest to the third weekday of the month.

Limits

- You can't specify the Day-of-month and Day-of-week fields in the same cron expression. If you specify a value in one of the fields, you must use a ? (question mark) in the other.
- Cron expressions that lead to rates faster than 5 minutes are not supported.

Examples

When creating a schedule, you can use the following sample cron strings.

Minutes	Hours	Day of month	Month	Day of week	Year	Meaning
0	10	*	*	?	*	Run at 10:00

Minutes	Hours	Day of month	Month	Day of week	Year	Meaning
						am (UTC) every day
15	12	*	*	?	*	Run at 12:15 pm (UTC) every day
0	18	?	*	MON-FRI	*	Run at 6:00 pm (UTC) every Monday through Friday
0	8	1	*	?	*	Run at 8:00 am (UTC) every first day of the month
0/15	*	*	*	?	*	Run every 15 minutes
0/10	*	?	*	MON-FRI	*	Run every 10 minutes Monday through Friday

Minutes	Hours	Day of month	Month	Day of week	Year	Meaning
0/5	8-17	?	*	MON-FRI	*	Run every 5 minutes Monday through Friday between 8:00 am and 5:55 pm (UTC)

For example to run on a schedule of every day at 12:15 UTC, specify:

```
cron(15 12 * * ? *)
```

Activating and deactivating triggers

You can activate or deactivate a trigger using the Amazon Glue console, the Amazon Command Line Interface (Amazon CLI), or the Amazon Glue API.

To activate or deactivate a trigger (console)

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **ETL**, choose **Triggers**.
3. Select the check box next to the desired trigger, and on the **Action** menu choose **Enable trigger** to activate the trigger or **Disable trigger** to deactivate the trigger.

To activate or deactivate a trigger (Amazon CLI)

- Enter one of the following commands.

```
aws glue start-trigger --name MyTrigger
```

```
aws glue stop-trigger --name MyTrigger
```

Starting a trigger activates it, and stopping a trigger deactivates it. When you activate an on-demand trigger, it fires immediately.

For more information, see [the section called “Amazon Glue triggers”](#).

Performing complex ETL activities using blueprints and workflows in Amazon Glue

Some of your organization's complex extract, transform, and load (ETL) processes might best be implemented by using multiple, dependent Amazon Glue jobs and crawlers. Using Amazon Glue *workflows*, you can design a complex multi-job, multi-crawler ETL process that Amazon Glue can run and track as single entity. After you create a workflow and specify the jobs, crawlers, and triggers in the workflow, you can run the workflow on demand or on a schedule.

Topics

- [Overview of workflows in Amazon Glue](#)
- [Creating and building out a workflow manually in Amazon Glue](#)
- [Starting an Amazon Glue workflow with an Amazon EventBridge event](#)
- [Viewing the EventBridge events that started a workflow](#)
- [Running and monitoring a workflow in Amazon Glue](#)
- [Stopping a workflow run](#)
- [Repairing and resuming a workflow run](#)
- [Getting and setting workflow run properties in Amazon Glue](#)

- [Troubleshooting blueprint errors in Amazon Glue](#)
- [Permissions for personas and roles for Amazon Glue blueprints](#)

Overview of workflows in Amazon Glue

In Amazon Glue, you can use workflows to create and visualize complex extract, transform, and load (ETL) activities involving multiple crawlers, jobs, and triggers. Each workflow manages the

execution and monitoring of all its jobs and crawlers. As a workflow runs each component, it records execution progress and status. This provides you with an overview of the larger task and the details of each step. The Amazon Glue console provides a visual representation of a workflow as a graph.

You can create a workflow from an Amazon Glue blueprint, or you can manually build a workflow a component at a time using the Amazon Web Services Management Console or the Amazon Glue API. For more information about blueprints, see [the section called “Overview of blueprints”](#).

Triggers within workflows can start both jobs and crawlers and can be fired when jobs or crawlers complete. By using triggers, you can create large chains of interdependent jobs and crawlers. In addition to triggers within a workflow that define job and crawler dependencies, each workflow has a *start trigger*. There are three types of start triggers:

- **Schedule** – The workflow is started according to a schedule that you define. The schedule can be daily, weekly, monthly, and so on, or can be a custom schedule based on a cron expression.
- **On demand** – The workflow is started manually from the Amazon Glue console, API, or Amazon CLI.
- **EventBridge event** – The workflow is started upon the occurrence of a single Amazon EventBridge event or a batch of Amazon EventBridge events. With this trigger type, Amazon Glue can be an event consumer in an event-driven architecture. Any EventBridge event type can start a workflow. A common use case is the arrival of a new object in an Amazon S3 bucket (the S3 PutObject operation).

Starting a workflow with a batch of events means waiting until a specified number of events have been received or until a specified amount of time has passed. When you create the EventBridge event trigger, you can optionally specify batch conditions. If you specify batch conditions, you must specify the batch size (number of events), and can optionally specify a batch window (number of seconds). The default and maximum batch window is 900 seconds (15 minutes). The batch condition that is met first starts the workflow. The batch window starts when the first event arrives. If you don't specify batch conditions when creating a trigger, the batch size defaults to 1.

When the workflow starts, the batch conditions are reset and the event trigger begins watching for the next batch condition to be met to start the workflow again.

The following table shows how batch size and batch window operate together to trigger a workflow.

Batch size	Batch window	Resulting triggering condition
10		The workflow is triggered upon the arrival of 10 EventBridge events, or 15 minutes after the arrival of the first event, whichever occurs first. (If windows size isn't specified, it defaults to 15 minutes.)
10	2 mins	The workflow is triggered upon the arrival of 10 EventBridge events, or 2 minutes after the arrival of the first event, whichever occurs first.
1		The workflow is triggered upon the arrival of the first event. Window size is irrelevant. The batch size defaults to 1 if you don't specify batch conditions when you create the EventBridge event trigger.

The `GetWorkflowRun` API operation returns the batch condition that triggered the workflow.

Regardless of how a workflow is started, you can specify the maximum number of concurrent workflow runs when you create the workflow.

If an event or batch of events starts a workflow run that eventually fails, that event or batch of events is no longer considered for starting a workflow run. A new workflow run is started only when the next event or batch of events arrives.

Important

Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

A workflow run will not be started if it would exceed the concurrency limit set for the workflow, even though the event condition is met. It's advisable to adjust workflow concurrency limits based on the expected event volume. Amazon Glue does not retry workflow runs that fail due

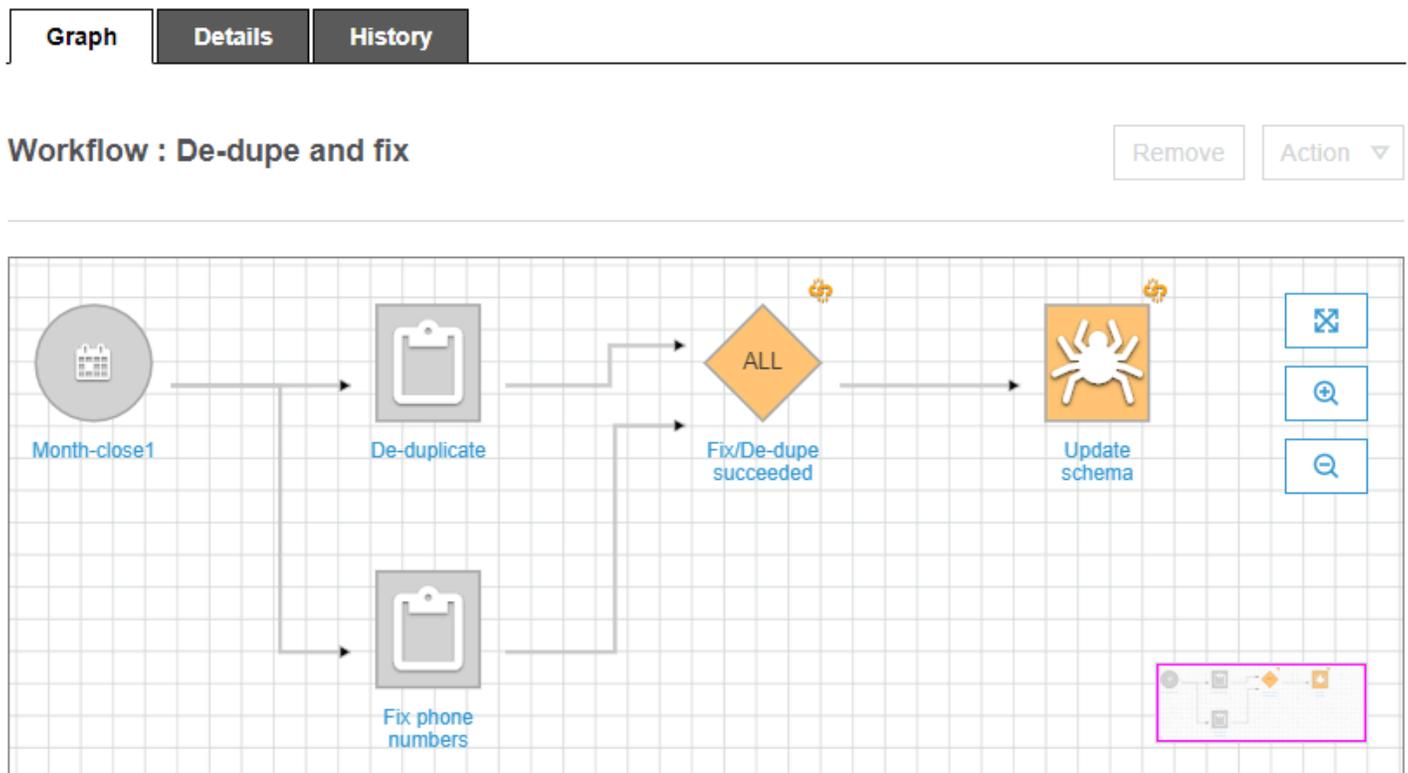

to exceeded concurrency limits. Likewise, it's advisable to adjust concurrency limits for jobs and crawlers within workflows based on expected event volume.

Workflow run properties

To share and manage state throughout a workflow run, you can define default workflow run properties. These properties, which are name/value pairs, are available to all the jobs in the workflow. Using the Amazon Glue API, jobs can retrieve the workflow run properties and modify them for jobs that come later in the workflow.

Workflow graph

The following image shows the graph of a very basic workflow on the Amazon Glue console. Your workflow could have dozens of components.

This workflow is started by a schedule trigger, `Month-close1`, which starts two jobs, `De-duplicate` and `Fix phone numbers`. Upon successful completion of both jobs, an event trigger, `Fix/De-dupe succeeded`, starts a crawler, `Update schema`.

Static and dynamic workflow views

For each workflow, there is the notion of *static view* and *dynamic view*. The static view indicates the design of the workflow. The dynamic view is a runtime view that includes the latest run information for each of the jobs and crawlers. Run information includes success status and error details.

When a workflow is running, the console displays the dynamic view, graphically indicating the jobs that have completed and that are yet to be run. You can also retrieve a dynamic view of a running workflow using the Amazon Glue API. For more information, see [Querying workflows using the Amazon Glue API](#).

See also

- [the section called “Creating a workflow from a blueprint”](#)
- [the section called “Creating and building out a workflow manually”](#)
- [Workflows](#) (for the workflows API)

Creating and building out a workflow manually in Amazon Glue

You can use the Amazon Glue console to manually create and build out a workflow one node at a time.

A workflow contains jobs, crawlers, and triggers. Before manually creating a workflow, create the jobs and crawlers that the workflow is to include. It's best to specify run-on-demand crawlers for workflows. You can create new triggers while you are building out your workflow, or you can *clone* existing triggers into the workflow. When you clone a trigger, all the catalog objects associated with the trigger—the jobs or crawlers that fire it and the jobs or crawlers that it starts—are added to the workflow.

Important

Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

You build out your workflow by adding triggers to the workflow graph, and defining the watched events and actions for each trigger. You begin with a *start trigger*, which can be either an on-demand or schedule trigger, and complete the graph by adding event (conditional) triggers.

Step 1: Create the workflow

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **ETL**, choose **Workflows**.
3. Choose **Add workflow** and complete the **Add a new ETL workflow** form.

Any optional default run properties that you add are made available as arguments to all jobs in the workflow. For more information, see [Getting and setting workflow run properties in Amazon Glue](#).

4. Choose **Add workflow**.

The new workflow appears in the list on the **Workflows** page.

Step 2: Add a start trigger

1. On the **Workflows** page, select your new workflow. Then, at the bottom of the page, ensure that the **Graph** tab is selected.
2. Choose **Add trigger**, and in the **Add trigger** dialog box, do one of the following:
 - Choose **Clone existing**, and choose a trigger to clone. Then choose **Add**.

The trigger appears on the graph, along with the jobs and crawlers that it watches and the jobs and crawlers that it starts.

If you mistakenly selected the wrong trigger, select the trigger on the graph, and then choose **Remove**.

- Choose **Add new**, and complete the **Add trigger** form.
 1. For **Trigger type**, select **Schedule**, **On demand**, or **EventBridge event**.

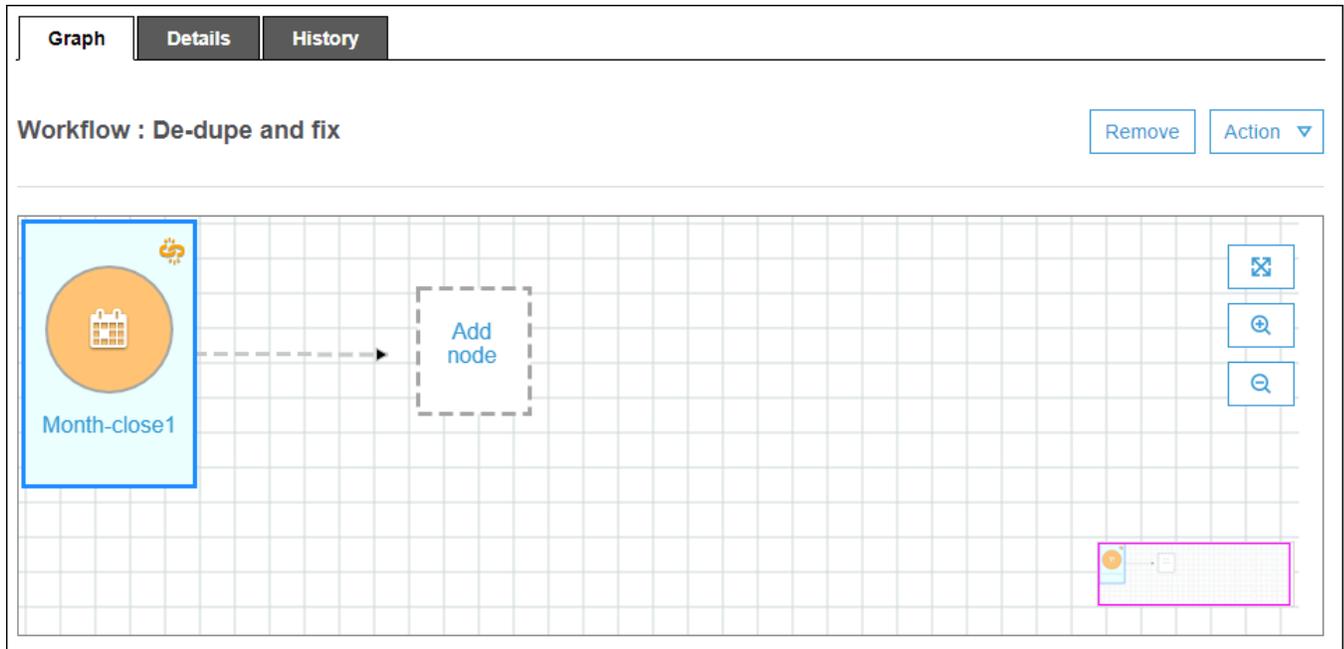

For trigger type **Schedule**, choose one of the **Frequency** options. Choose **Custom** to enter a cron expression.

For trigger type **EventBridge event**, enter **Number of events** (batch size), and optionally enter **Time delay** (batch window). If you omit **Time delay**, the batch window defaults to 15 minutes. For more information, see [Overview of workflows in Amazon Glue](#).

2. Choose **Add**.

The trigger appears on the graph, along with a placeholder node (labeled **Add node**). In the example below, the start trigger is a schedule trigger named `Month-close1`.

At this point, the trigger isn't saved yet.

3. If you added a new trigger, complete these steps:

- a. Do one of the following:
 - Choose the placeholder node (**Add node**).
 - Ensure that the start trigger is selected, and on the **Action** menu above the graph, choose **Add jobs/crawlers to trigger**.
- b. In the **Add job(s) and crawler(s) to trigger** dialog box, select one or more jobs or crawlers, and then choose **Add**.

The trigger is saved, and the selected jobs or crawlers appear on the graph with connectors from the trigger.

If you mistakenly added the wrong jobs or crawlers, you can select either the trigger or a connector and choose **Remove**.

Step 3: Add more triggers

Continue to build out your workflow by adding more triggers of type **Event**. To zoom in or out or to enlarge the graph canvas, use the icons to the right of the graph. For each trigger to add, complete the following steps:

Note

There is no action to save the workflow. After you add your last trigger and assign actions to the trigger, the workflow is complete and saved. You can always come back later and add more nodes.

1. Do one of the following:

- To clone an existing trigger, ensure that no node on the graph is selected, and on the **Action** menu, choose **Add trigger**.
- To add a new trigger that watches a particular job or crawler on the graph, select the job or crawler node, and then choose the **Add trigger** placeholder node.

You can add more jobs or crawlers to watch for this trigger in a later step.

2. In the **Add trigger** dialog box, do one of the following:

- Choose **Add new**, and complete the **Add trigger** form. Then choose **Add**.

The trigger appears on the graph. You will complete the trigger in a later step.

- Choose **Clone existing**, and choose a trigger to clone. Then choose **Add**.

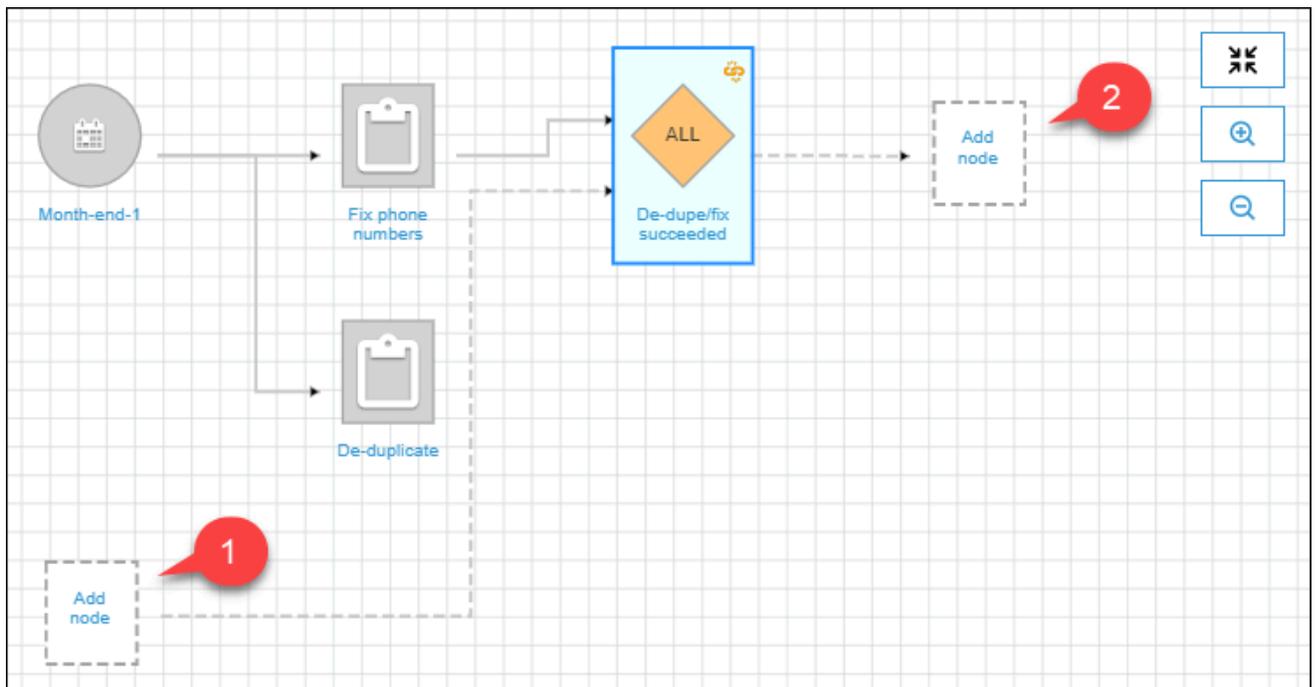

The trigger appears on the graph, along with the jobs and crawlers that it watches and the jobs and crawlers that it starts.

If you mistakenly chose the wrong trigger, select the trigger on the graph, and then choose **Remove**.

3. If you added a new trigger, complete these steps:

- a. Select the new trigger.

As the following graph shows, the trigger `De-dupe/fix succeeded` is selected, and placeholder nodes appear for (1) events to watch and (2) actions.

- b. (Optional if the trigger already watches an event and you want to add more jobs or crawlers to watch.) Choose the events-to-watch placeholder node, and in the **Add job(s) and crawler(s) to watch** dialog box, select one or more jobs or crawlers. Choose an event to watch (SUCCEEDED, FAILED, etc.), and choose **Add**.
- c. Ensure that the trigger is selected, and choose the actions placeholder node.
- d. In the **Add job(s) and crawler(s) to watch dialog** box, select one or more jobs or crawlers, and choose **Add**.

The selected jobs and crawlers appear on the graph, with connectors from the trigger.

For more information on workflows and blueprints, see the following topics.

- [Overview of workflows in Amazon Glue](#)
- [Running and monitoring a workflow in Amazon Glue](#)
- [Creating a workflow from a blueprint in Amazon Glue](#)

Starting an Amazon Glue workflow with an Amazon EventBridge event

Amazon EventBridge, also known as CloudWatch Events, enables you to automate your Amazon services and respond automatically to system events such as application availability issues or resource changes. Events from Amazon services are delivered to EventBridge in near real time. You can write simple rules to indicate which events are of interest to you, and what automated actions to take when an event matches a rule.

With EventBridge support, Amazon Glue can serve as an event producer and consumer in an event-driven architecture. For workflows, Amazon Glue supports any type of EventBridge event as a consumer. The likely most common use case is the arrival of a new object in an Amazon S3 bucket. If you have data arriving in irregular or undefined intervals, you can process this data as close to its arrival as possible.

Note

Amazon Glue does not provide guaranteed delivery of EventBridge messages. Amazon Glue performs no deduplication if EventBridge delivers duplicate messages. You must manage idempotency based on your use case.

Be sure to configure EventBridge rules correctly to avoid sending unwanted events.

Before you begin

If you want to start a workflow with Amazon S3 data events, you must ensure that events for the S3 bucket of interest are logged to Amazon CloudTrail and EventBridge. To do so, you must create a CloudTrail trail. For more information, see [Creating a trail for your Amazon account](#).

To start a workflow with an EventBridge event

Note

In the following commands, replace:

- *<workflow-name>* with the name to assign to the workflow.
- *<trigger-name>* with the name to assign to the trigger.
- *<bucket-name>* with the name of the Amazon S3 bucket.
- *<account-id>* with a valid Amazon account ID.

- `<region>` with the name of the Region (for example, `us-east-1`).
- `<rule-name>` with the name to assign to the EventBridge rule.

1. Ensure that you have Amazon Identity and Access Management (IAM) permissions to create and view EventBridge rules and targets. The following is a sample policy that you can attach. You might want to scope it down to put limits on the operations and resources.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "events:PutRule",
        "events:DisableRule",
        "events>DeleteRule",
        "events:PutTargets",
        "events:RemoveTargets",
        "events:EnableRule",
        "events:List*",
        "events:Describe*"
      ],
      "Resource": "*"
    }
  ]
}
```

2. Create an IAM role that the EventBridge service can assume when passing an event to Amazon Glue.
 - a. On the **Create role** page of the IAM console, choose **Amazon Service**. Then choose the service **CloudWatch Events**.
 - b. Complete the **Create role** wizard. The wizard automatically attaches the `CloudWatchEventsBuiltInTargetExecutionAccess` and `CloudWatchEventsInvocationAccess` policies.

- c. Attach the following inline policy to the role. This policy allows the EventBridge service to direct events to Amazon Glue.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:notifyEvent"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:workflow/workflow-name"
      ]
    }
  ]
}
```

3. Enter the following command to create the workflow.

See [create-workflow](#) in the *Amazon CLI Command Reference* for information about additional optional command-line parameters.

```
aws glue create-workflow --name <workflow-name>
```

4. Enter the following command to create an EventBridge event trigger for the workflow. This will be the start trigger for the workflow. Replace *<actions>* with the actions to perform (the jobs and crawlers to start).

See [create-trigger](#) in the *Amazon CLI Command Reference* for information about how to code the actions argument.

```
aws glue create-trigger --workflow-name <workflow-name> --type EVENT --
name <trigger-name> --actions <actions>
```

If you want the workflow to be triggered by a batch of events instead of a single EventBridge event, enter the following command instead.

```
aws glue create-trigger --workflow-name <workflow-name> --type EVENT
--name <trigger-name> --event-batching-condition BatchSize=<number-of-
events>,BatchWindow=<seconds> --actions <actions>
```

For the event-batching-condition argument, BatchSize is required and BatchWindow is optional. If BatchWindow is omitted, the window defaults to 900 seconds, which is the maximum window size.

Example

The following example creates a trigger that starts the eventtest workflow after three EventBridge events have arrived, or five minutes after the first event arrives, whichever comes first.

```
aws glue create-trigger --workflow-name eventtest --type EVENT --name objectArrival
--event-batching-condition BatchSize=3,BatchWindow=300 --actions JobName=test1
```

5. Create a rule in Amazon EventBridge.
 - a. Create the JSON object for the rule details in your preferred text editor.

The following example specifies Amazon S3 as the event source, PutObject as the event name, and the bucket name as a request parameter. This rule starts a workflow when a new object arrives in the bucket.

```
{
  "source": [
    "aws.s3"
  ],
  "detail-type": [
    "Amazon API Call via CloudTrail"
  ],
  "detail": {
    "eventSource": [
      "s3.amazonaws.com"
    ],
    "eventName": [
      "PutObject"
    ],
    "requestParameters": {
```

```

    "bucketName": [
      "<bucket-name>"
    ]
  }
}

```

To start the workflow when a new object arrives in a folder within the bucket, you can substitute the following code for `requestParameters`.

```

"requestParameters": {
  "bucketName": [
    "<bucket-name>"
  ]
  "key" : [{ "prefix" : "<folder1>/<folder2>/*"}]}
}

```

- b. Use your preferred tool to convert the rule JSON object to an escaped string.

```

{\n  \"source\": [\n    \"aws.s3\"\n  ],\n  \"detail-type\": [\n    \"Amazon API Call via CloudTrail\"\n  ],\n  \"detail\": {\n    \"eventSource\": [\n      \"s3.amazonaws.com\"\n    ],\n    \"eventName\": [\n      \"PutObject\"\n    ],\n    \"requestParameters\": {\n      \"bucketName\": [\n        \"<bucket-name>\"\n      ]\n    }\n  }\n}

```

- c. Run the following command to create a JSON parameter template that you can edit to specify input parameters to a subsequent `put-rule` command. Save the output in a file. In this example, the file is called `ruleCommand`.

```
aws events put-rule --name <rule-name> --generate-cli-skeleton >ruleCommand
```

For more information about the `--generate-cli-skeleton` parameter, see [Generating Amazon CLI skeleton and input parameters from a JSON or YAML input file](#) in the *Amazon Command Line Interface User Guide*.

The output file should look like the following.

```

{
  "Name": "",
  "ScheduleExpression": "",
  "EventPattern": "",

```

```

    "State": "ENABLED",
    "Description": "",
    "RoleArn": "",
    "Tags": [
      {
        "Key": "",
        "Value": ""
      }
    ],
    "EventBusName": ""
  }

```

- d. Edit the file to optionally remove parameters and to specify at a minimum the Name, EventPattern, and State parameters. For the EventPattern parameter, provide the escaped string for the rule details that you created in a previous step.

```

{
  "Name": "<rule-name>",
  "EventPattern": "{\n  \"source\": [\n    \"aws.s3\"\n  ],\n  \"detail-type\": [\n    \"Amazon API Call via CloudTrail\"\n  ],\n  \"detail\": {\n    \"eventSource\": [\n      \"s3.amazonaws.com\"\n    ],\n    \"eventName\": [\n      \"PutObject\"\n    ],\n    \"requestParameters\": {\n      \"bucketName\": [\n        \"<bucket-name>\"\n      ]\n    }\n  }",
  "State": "DISABLED",
  "Description": "Start an Amazon Glue workflow upon new file arrival in an Amazon S3 bucket"
}

```

 **Note**

It is best to leave the rule disabled until you finish building out the workflow.

- e. Enter the following put-rule command, which reads input parameters from the file ruleCommand.

```
aws events put-rule --name <rule-name> --cli-input-json file://ruleCommand
```

The following output indicates success.

```

{
  "RuleArn": "<rule-arn>"
}

```

```
}
```

6. Enter the following command to attach the rule to a target. The target is the workflow in Amazon Glue. Replace *<role-name>* with the role that you created at the beginning of this procedure.

```
aws events put-targets --rule <rule-name> --targets  
  "Id"="1", "Arn"="arn:aws:glue:<region>:<account-id>:workflow/<workflow-  
<name>", "RoleArn"="arn:aws:iam::<account-id>:role/<role-name>" --region <region>
```

The following output indicates success.

```
{  
  "FailedEntryCount": 0,  
  "FailedEntries": []  
}
```

7. Confirm successful connection of the rule and target by entering the following command.

```
aws events list-rule-names-by-target --target-arn arn:aws:glue:<region>:<account-  
<id>:workflow/<workflow-name>
```

The following output indicates success, where *<rule-name>* is the name of the rule that you created.

```
{  
  "RuleNames": [  
    "<rule-name>"  
  ]  
}
```

8. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
9. Select the workflow, and verify that the start trigger and its actions—the jobs or crawlers that it starts— appear on the workflow graph. Then continue with the procedure in [Step 3: Add more triggers](#). Or add more components to the workflow by using the Amazon Glue API or Amazon Command Line Interface.
10. When the workflow is completely specified, enable the rule.

```
aws events enable-rule --name <rule-name>
```

The workflow is now ready to be started by an EventBridge event or event batch.

Viewing the EventBridge events that started a workflow

You can view the event ID of the Amazon EventBridge event that started your workflow. If your workflow was started by a batch of events, you can view the event IDs of all events in the batch.

For workflows with a batch size greater than one, you can also see which batch condition started the workflow: the arrival of the number of events in the batch size, or the expiration of the batch window.

To view the EventBridge events that started a workflow (console)

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, choose **Workflows**.
3. Select the workflow. Then at the bottom, choose the **History** tab.
4. Select a workflow run, and then choose **View run details**.
5. On the run details page, locate the **Run properties** field, and look for the **aws:eventIds** key.

The value for that key is a list of EventBridge event IDs.

To view the EventBridge events that started a workflow (Amazon API)

- Include the following code in your Python script.

```
workflow_params =  
    glue_client.get_workflow_run_properties(Name=workflow_name, RunId=workflow_run_id)  
batched_events = workflow_params['aws:eventIds']
```

`batched_events` will be a list of strings, where each string is an event ID.

Running and monitoring a workflow in Amazon Glue

If the start trigger for a workflow is an on-demand trigger, you can start the workflow from the Amazon Glue console. Complete the following steps to run and monitor a workflow. If the workflow fails, you can view the run graph to determine the node that failed. To help troubleshoot, if the workflow was created from a blueprint, you can view the blueprint run to see the blueprint parameter values that were used to create the workflow. For more information, see [the section called “Viewing blueprint runs”](#).

You can run and monitor a workflow by using the Amazon Glue console, API, or Amazon Command Line Interface (Amazon CLI).

To run and monitor a workflow (console)

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **ETL**, choose **Workflows**.
3. Select a workflow. On the **Actions** menu, choose **Run**.
4. Check the **Last run status** column in the workflows list. Choose the refresh button to view ongoing workflow status.
5. While the workflow is running or after it has completed (or failed), view the run details by completing the following steps.
 - a. Ensure that the workflow is selected, and choose the **History** tab.
 - b. Choose the current or most recent workflow run, and then choose **View run details**.

The workflow runtime graph shows the current run status.

- c. Choose any node in the graph to view details and status of the node.

To run and monitor a workflow (Amazon CLI)

1. Enter the following command. Replace *<workflow-name>* with the workflow to run.

```
aws glue start-workflow-run --name <workflow-name>
```

If the workflow is successfully started, the command returns the run ID.

2. View workflow run status by using the `get-workflow-run` command. Supply the workflow name and run ID.

```
aws glue get-workflow-run --name myWorkflow --run-id
wr_d2af14217e8eae775ba7b1fc6fc7a42c795aed3cbcd8763f9415452e2dbc8705
```

The following is sample command output.

```
{
  "Run": {
    "Name": "myWorkflow",
    "WorkflowRunId":
    "wr_d2af14217e8eae775ba7b1fc6fc7a42c795aed3cbcd8763f9415452e2dbc8705",
    "WorkflowRunProperties": {
      "run_state": "COMPLETED",
      "unique_id": "fee63f30-c512-4742-a9b1-7c8183bdaae2"
    }
  },
}
```

```
"StartedOn": 1578556843.049,
"CompletedOn": 1578558649.928,
"Status": "COMPLETED",
"Statistics": {
  "TotalActions": 11,
  "TimeoutActions": 0,
  "FailedActions": 0,
  "StoppedActions": 0,
  "SucceededActions": 9,
  "RunningActions": 0,
  "ErroredActions": 0
}
}
```

- [the section called “Overview of blueprints”](#)

Stopping a workflow run

You can use the Amazon Glue console, Amazon Command Line Interface (Amazon CLI) or Amazon Glue API to stop a workflow run. When you stop a workflow run, all running jobs and crawlers are immediately terminated, and jobs and crawlers that are not yet started never start. It might take up to a minute for all running jobs and crawlers to stop. The workflow run status goes from **Running** to **Stopping**, and when the workflow run is completely stopped, the status goes to **Stopped**.

After the workflow run is stopped, you can view the run graph to see which jobs and crawlers completed and which never started. You can then determine if you must perform any steps to ensure data integrity. Stopping a workflow run causes no automatic rollback operations to be performed.

To stop a workflow run (console)

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **ETL**, choose **Workflows**.

3. Choose a running workflow, and then choose the **History** tab.
4. Choose the workflow run, and then choose **Stop run**.

The run status changes to **Stopping**.

5. (Optional) Choose the workflow run, choose **View run details**, and review the run graph.

To stop a workflow run (Amazon CLI)

- Enter the following command. Replace *<workflow-name>* with the name of the workflow and *<run-id>* with the run ID of the workflow run to stop.

```
aws glue stop-workflow-run --name <workflow-name> --run-id <run-id>
```

The following is an example of the **stop-workflow-run** command.

```
aws glue stop-workflow-run --name my-workflow --run-id  
wr_137b88917411d128081069901e4a80595d97f719282094b7f271d09576770354
```

Repairing and resuming a workflow run

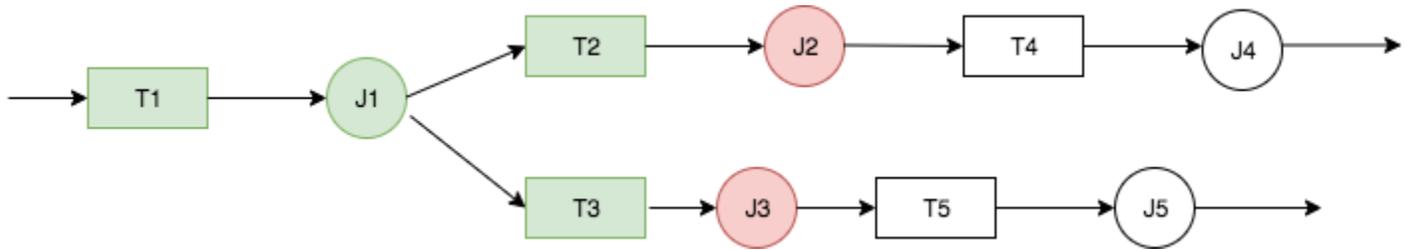

If one or more nodes (jobs or crawlers) in a workflow do not successfully complete, this means that the workflow only partially ran. After you find the root causes and make corrections, you can select one or more nodes to resume the workflow run from, and then resume the workflow run. The selected nodes and all nodes that are downstream from those nodes are then run.

Topics

- [Resuming a workflow run: How it works](#)
- [Resuming a workflow run](#)
- [Notes and limitations for resuming workflow runs](#)

Resuming a workflow run: How it works

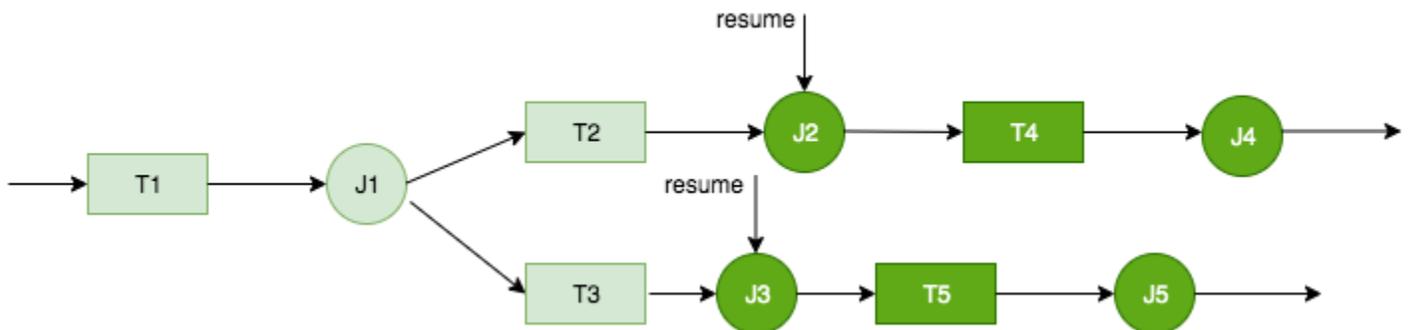

Consider the workflow W1 in the following diagram.

The workflow run proceeds as follows:

1. Trigger T1 starts job J1.
2. Successful completion of J1 fires triggers T2 and T3, which run jobs J2 and J3, respectively.
3. Jobs J2 and J3 fail.
4. Triggers T4 and T5 depend on the successful completion of J2 and J3, so they don't fire, and jobs J4 and J5 don't run. Workflow W1 is only partially run.

Now assume that the issues that caused J2 and J3 to fail are corrected. J2 and J3 are selected as the starting points to resume the workflow run from.

The workflow run resumes as follows:

1. Jobs J2 and J3 run successfully.
2. Triggers T4 and T5 fire.
3. Jobs J4 and J5 run successfully.

The resumed workflow run is tracked as a separate workflow run with a new run ID. When you view the workflow history, you can view the previous run ID for any workflow run. In the example in the following screenshot, the workflow run with run ID `wr_c7a22...` (the second row) had a node that did not complete. The user fixed the problem and resumed the workflow run, which resulted in run ID `wr_a07e55...` (the first row).

Graph Details History				
View run details Stop run 				
Run ID	Previous run ID	Run status	Execution time	
 wr_a07e55f2087afdd415a404403f644a4265278...	wr_c7a2219a8dc412f1366a5b30df3c58be30b9...	Completed	17 Minutes	
 wr_c7a2219a8dc412f1366a5b30df3c58be30b9...	-	Completed	8 Minutes	

Note

For the rest of this discussion, the term "resumed workflow run" refers to the workflow run that was created when the previous workflow run was resumed. The "original workflow run" refers to the workflow run that only partially ran and that needed to be resumed.

Resumed workflow run graph

In a resumed workflow run, although only a subset of nodes are run, the run graph is a complete graph. That is, the nodes that didn't run in the resumed workflow are copied from the run graph of the original workflow run. Copied job and crawler nodes that ran in the original workflow run include run details.

Consider again the workflow W1 in the previous diagram. When the workflow run is resumed starting with J2 and J3, the run graph for the resumed workflow run shows all jobs, J1 through J5, and all triggers, T1 through T5. The run details for J1 are copied from the original workflow run.

Workflow run snapshots

When a workflow run is started, Amazon Glue takes a snapshot of the workflow design graph at that point in time. That snapshot is used for the duration of the workflow run. If you make changes to any triggers after the run starts, those changes don't affect the current workflow run. Snapshots ensure that workflow runs proceed in a consistent manner.

Snapshots make only triggers immutable. Changes that you make to downstream jobs and crawlers during the workflow run take effect for the current run.

Resuming a workflow run

Follow these steps to resume a workflow run. You can resume a workflow run by using the Amazon Glue console, API, or Amazon Command Line Interface (Amazon CLI).

To resume a workflow run (console)

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.

Sign in as a user who has permissions to view workflows and resume workflow runs.

Note

To resume workflow runs, you need the `glue:ResumeWorkflowRun` Amazon Identity and Access Management (IAM) permission.

2. In the navigation pane, choose **Workflows**.
3. Select a workflow, and then choose the **History** tab.
4. Select the workflow run that only partially ran, and then choose **View run details**.
5. In the run graph, select the first (or only) node that you want to restart and that you want to resume the workflow run from.
6. In the details pane to the right of the graph, select the **Resume** check box.

The screenshot displays the Amazon Glue console interface. On the left, a workflow graph is shown with three nodes: a green circle (Completed), a red square (Failed), and a grey diamond (ALL). The red square node is highlighted with a blue border and has a small resume icon at its top right. A 'Resume run' button is located above the graph. Below the graph is a legend with icons for Completed (green check), Running (blue refresh), Failed (red X), Warning (yellow triangle), and Error (red circle with X). On the right, the 'Job details' pane shows the selected run as 'Tue, 21 Jul 2020 19:55:10 GMT - FAILED'. The job status is 'Failed' and the 'Resume' checkbox is unchecked. The job run error is 'Error: Invalid argument type'.

The node changes color and shows a small resume icon at the upper right.

The screenshot displays the Amazon Glue console interface. On the left, a workflow graph is shown with three nodes: a green circle labeled 'myDemoBPWorkflow1_start...', a purple square labeled 'myDemoBPWorkflow1_etl_j...', and a grey diamond labeled 'myDemoBPWorkflow1_myD...'. The purple square node is highlighted with a blue border and a 'C' icon, indicating it is selected. A 'Resume run' button is visible in the top right of the graph area. On the right, the 'Job details' panel shows the 'Selected run' as 'Tue, 21 Jul 2020 19:55:10 GMT - RESUME'. Below this, the job details include: Name: myDemoBPWorkflow1_etl_jo, Description: -, Job run id: jr_8e74182b093deea6bf63d, Status: Resume, Resume: , Retry attempt: -, Job run error: Error: Invalid argument type, Execution time: 28, Start time: Tue, 21 Jul 2020 19:55:10 G, and End time: Tue, 21 Jul 2020 20:21:17 G.

7. Complete the previous two steps for any additional nodes to restart.
8. Choose **Resume run**.

To resume a workflow run (Amazon CLI)

1. Ensure that you have the `glue:ResumeWorkflowRun` IAM permission.
2. Retrieve the node IDs for the nodes that you want to restart.
 - a. Run the `get-workflow-run` command for the original workflow run. Supply the workflow name and run ID, and add the `--include-graph` option, as shown in the following example. Get the run ID from the **History** tab on the console, or by running the `get-workflow` command.

```
aws glue get-workflow-run --name cloudtrailtest1 --run-id
wr_a07e55f2087afdd415a404403f644a4265278f68b13ba3da08c71924ebe3c3a8 --include-
graph
```

The command returns the nodes and edges of the graph as a large JSON object.

- b. Locate the nodes of interest by the `Type` and `Name` properties of the node objects.

The following is an example node object from the output.

```
{
  "Type": "JOB",
  "Name": "test1_post_failure_4592978",
  "UniqueId":
  "wnode_d1b2563c503078b153142ee76ce545fe5ceef66e053628a786ddd74a05da86fd",
```

```

    "JobDetails": {
      "JobRuns": [
        {
          "Id":
"jr_690b9f7fc5cb399204bc542c6c956f39934496a5d665a42de891e5b01f59e613",
          "Attempt": 0,
          "TriggerName": "test1_aggregate_failure_649b2432",
          "JobName": "test1_post_failure_4592978",
          "StartedOn": 1595358275.375,
          "LastModifiedOn": 1595358298.785,
          "CompletedOn": 1595358298.785,
          "JobRunState": "FAILED",
          "PredecessorRuns": [],
          "AllocatedCapacity": 0,
          "ExecutionTime": 16,
          "Timeout": 2880,
          "MaxCapacity": 0.0625,
          "LogGroupName": "/aws-glue/python-jobs"
        }
      ]
    }
  }
}

```

- c. Get the node ID from the UniqueId property of the node object.
3. Run the `resume-workflow-run` command. Provide the workflow name, run ID, and list of node IDs separated by spaces, as shown in the following example.

```

aws glue resume-workflow-run --name cloudtrailtest1 --run-id
wr_a07e55f2087afdd415a404403f644a4265278f68b13ba3da08c71924ebe3c3a8 --node-
ids wnode_ca1f63e918fb855e063aed2f42ec5762ccf71b80082ae2eb5daeb8052442f2f3
wnode_d1b2563c503078b153142ee76ce545fe5ceef66e053628a786ddd74a05da86fd

```

The command outputs the run ID of the resumed (new) workflow run and a list of nodes that will be started.

```

{
  "RunId": "wr_2ada0d3209a262fc1156e4291134b3bd643491bcfb0ceead30bd3e4efac24de9",
  "NodeIds": [
    "wnode_ca1f63e918fb855e063aed2f42ec5762ccf71b80082ae2eb5daeb8052442f2f3"
  ]
}

```

Note that although the example `resume-workflow-run` command listed two nodes to restart, the example output indicated that only one node would be restarted. This is because one node was downstream of the other node, and the downstream node would be restarted anyway by the normal flow of the workflow.

Notes and limitations for resuming workflow runs

Keep the following notes and limitations in mind when resuming workflow runs.

- You can resume a workflow run only if it's in the COMPLETED state.

Note

Even if one or more nodes in a workflow run don't complete, the workflow run state is shown as COMPLETED. Be sure to check the run graph to discover any nodes that didn't successfully complete.

- You can resume a workflow run from any job or crawler node that the original workflow run attempted to run. You can't resume a workflow run from a trigger node.
- Restarting a node does not reset its state. Any data that was partially processed is not rolled back.
- You can resume a failed workflow run multiple times. However, a resumed run can only be resumed once more. For additional retries, resume the original failed run instead.
- If you select two nodes to restart and they're dependent upon each other, the upstream node is run before the downstream node. In fact, selecting the downstream node is redundant, because it will be run according to the normal flow of the workflow.

Getting and setting workflow run properties in Amazon Glue

Use workflow run properties to share and manage state among the jobs in your Amazon Glue workflow. You can set default run properties when you create the workflow. Then, as your jobs run, they can retrieve the run property values and optionally modify them for input to jobs that are later in the workflow. When a job modifies a run property, the new value exists only for the workflow run. The default run properties aren't affected.

If your Amazon Glue job is not part of a workflow, these properties will not be set.

The following sample Python code from an extract, transform, and load (ETL) job demonstrates how to get the workflow run properties.

```
import sys
import boto3
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from awsglue.context import GlueContext
from pyspark.context import SparkContext

glue_client = boto3.client("glue")
args = getResolvedOptions(sys.argv, ['JOB_NAME', 'WORKFLOW_NAME', 'WORKFLOW_RUN_ID'])
workflow_name = args['WORKFLOW_NAME']
workflow_run_id = args['WORKFLOW_RUN_ID']
workflow_params = glue_client.get_workflow_run_properties(Name=workflow_name,
                                                         RunId=workflow_run_id)["RunProperties"]

target_database = workflow_params['target_database']
target_s3_location = workflow_params['target_s3_location']
```

The following code continues by setting the `target_format` run property to `'csv'`.

```
workflow_params['target_format'] = 'csv'
glue_client.put_workflow_run_properties(Name=workflow_name, RunId=workflow_run_id,
                                       RunProperties=workflow_params)
```

For more information, see the following:

- [GetWorkflowRunProperties action \(Python: `get_workflow_run_properties`\)](#)
- [PutWorkflowRunProperties action \(Python: `put_workflow_run_properties`\)](#)

Querying workflows using the Amazon Glue API

Amazon Glue provides a rich API for managing workflows. You can retrieve a static view of a workflow or a dynamic view of a running workflow using the Amazon Glue API. For more information, see [Workflows](#).

Topics

- [Querying static views](#)
- [Querying dynamic views](#)

Querying static views

Use the `GetWorkflow` API operation to get a static view that indicates the design of a workflow. This operation returns a directed graph consisting of nodes and edges, where a node represents a trigger, a job, or a crawler. Edges define the relationships between nodes. They are represented by connectors (arrows) on the graph in the Amazon Glue console.

You can also use this operation with popular graph-processing libraries such as NetworkX, igraph, JGraphT, and the Java Universal Network/Graph (JUNG) Framework. Because all these libraries represent graphs similarly, minimal transformations are needed.

The static view returned by this API is the most up-to-date view according to the latest definition of triggers associated with the workflow.

Graph definition

A workflow graph G is an ordered pair (N, E) , where N is a set of nodes and E a set of edges. *Node* is a vertex in the graph identified by a unique number. A node can be of type trigger, job, or crawler. For example: `{name:T1, type:Trigger, uniqueId:1}`, `{name:J1, type:Job, uniqueId:2}`.

Edge is a 2-tuple of the form $(src, dest)$, where src and $dest$ are nodes and there is a directed edge from src to $dest$.

Example of querying a static view

Consider a conditional trigger T , which triggers job $J2$ upon completion of job $J1$.

```
J1 ----> T ----> J2
```

Nodes: $J1, T, J2$

Edges: $(J1, T), (T, J2)$

Querying dynamic views

Use the `GetWorkflowRun` API operation to get a dynamic view of a running workflow. This operation returns the same static view of the graph along with metadata related to the workflow run.

For run, nodes representing jobs in the `GetWorkflowRun` call have a list of job runs initiated as part of the latest run of the workflow. You can use this list to display the run status of each job in the graph itself. For downstream dependencies that are not yet run, this field is set to `null`. The graphed information makes you aware of the current state of any workflow at any point of time.

The dynamic view returned by this API is based on the static view that was present when the workflow run was started.

Runtime nodes example: `{name:T1, type: Trigger, uniqueId:1},{name:J1, type:Job, uniqueId:2, jobDetails:{jobRuns}},{name:C1, type:Crawler, uniqueId:3, crawlerDetails:{crawls}}`

Example 1: Dynamic view

The following example illustrates a simple two-trigger workflow.

- Nodes: t1, j1, t2, j2
- Edges: (t1, j1), (j1, t2), (t2, j2)

The `GetWorkflow` response contains the following.

```
{
  Nodes : [
    {
      "type" : Trigger,
      "name" : "t1",
      "uniqueId" : 1
    },
    {
      "type" : Job,
      "name" : "j1",
      "uniqueId" : 2
    },
    {
      "type" : Trigger,
      "name" : "t2",
      "uniqueId" : 3
    },
    {
      "type" : Job,
      "name" : "j2",
```

```
        "uniqueId" : 4
      }
    ],
    Edges : [
      {
        "sourceId" : 1,
        "destinationId" : 2
      },
      {
        "sourceId" : 2,
        "destinationId" : 3
      },
      {
        "sourceId" : 3,
        "destinationId" : 4
      }
    ]
  }
}
```

The `GetWorkflowRun` response contains the following.

```
{
  Nodes : [
    {
      "type" : Trigger,
      "name" : "t1",
      "uniqueId" : 1,
      "jobDetails" : null,
      "crawlerDetails" : null
    },
    {
      "type" : Job,
      "name" : "j1",
      "uniqueId" : 2,
      "jobDetails" : [
        {
          "id" : "jr_12334",
          "jobRunState" : "SUCCEEDED",
          "errorMessage" : "error string"
        }
      ],
      "crawlerDetails" : null
    },
    {

```

```

        "type" : Trigger,
        "name" : "t2",
        "uniqueId" : 3,
        "jobDetails" : null,
        "crawlerDetails" : null
    },
    {
        "type" : Job,
        "name" : "j2",
        "uniqueId" : 4,
        "jobDetails" : [
            {
                "id" : "jr_1233sdf4",
                "jobRunState" : "SUCCEEDED",
                "errorMessage" : "error string"
            }
        ],
        "crawlerDetails" : null
    }
],
Edges : [
    {
        "sourceId" : 1,
        "destinationId" : 2
    },
    {
        "sourceId" : 2,
        "destinationId" : 3
    },
    {
        "sourceId" : 3,
        "destinationId" : 4
    }
]
}

```

Example 2: Multiple jobs with a conditional trigger

The following example shows a workflow with multiple jobs and a conditional trigger (t3).

Consider Flow:

```

T(t1) ----> J(j1) ----> T(t2) ----> J(j2)
      |                |
      |                |
      >+-----> T(t3) <-----+

```

```
  |
  |
J(j3)
```

Graph generated:

Nodes: t1, t2, t3, j1, j2, j3

Edges: (t1, j1), (j1, t2), (t2, j2), (j1, t3), (j2, t3), (t3, j3)

Blueprint and workflow restrictions in Amazon Glue

The following are restrictions for blueprints and workflows.

Blueprint restrictions

Keep the following blueprint restrictions in mind:

- The blueprint must be registered in the same Amazon Region where the Amazon S3 bucket resides in.
- To share blueprints across Amazon accounts you must give the read permissions on the blueprint ZIP archive in Amazon S3. Customers who have read permission on a blueprint ZIP archive can register the blueprint in their Amazon account and use it.
- The set of blueprint parameters is stored as a single JSON object. The maximum length of this object is 128 KB.
- The maximum uncompressed size of the blueprint ZIP archive is 5 MB. The maximum compressed size is 1 MB.
- Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

Workflow restrictions

Keep the following workflow restrictions in mind. Some of these comments are directed more at a user creating workflows manually.

- The maximum batch size for an Amazon EventBridge event trigger is 100. The maximum window size is 900 seconds (15 minutes).
- A trigger can be associated with only one workflow.
- Only one starting trigger (on-demand or schedule) is permitted.

- If a job or crawler in a workflow is started by a trigger that is outside the workflow, any triggers inside the workflow that depend on job or crawler completion (succeeded or otherwise) do not fire.
- Similarly, if a job or crawler in a workflow has triggers that depend on job or crawler completion (succeeded or otherwise) both within the workflow and outside the workflow, and if the job or crawler is started from within a workflow, only the triggers inside the workflow fire upon job or crawler completion.

Troubleshooting blueprint errors in Amazon Glue

If you encounter errors when using Amazon Glue blueprints, use the following solutions to help you find the source of the problems and fix them.

Topics

- [Error: missing PySpark module](#)
- [Error: missing blueprint config file](#)
- [Error: missing imported file](#)
- [Error: not authorized to perform iamPassRole on resource](#)
- [Error: invalid cron schedule](#)
- [Error: a trigger with the same name already exists](#)
- [Error: workflow with name: foo already exists.](#)
- [Error: module not found in specified layoutGenerator path](#)
- [Error: validation error in Connections field](#)

Error: missing PySpark module

Amazon Glue returns the error "Unknown error executing layout generator function ModuleNotFoundError: No module named 'pyspark'".

When you unzip the blueprint archive it could be like either of the following:

```
$ unzip compaction.zip
Archive:  compaction.zip
  creating:  compaction/
  inflating:  compaction/blueprint.cfg
  inflating:  compaction/layout.py
```

```
inflating: compaction/README.md
inflating: compaction/compaction.py

$ unzip compaction.zip
Archive:  compaction.zip
  inflating: blueprint.cfg
  inflating: compaction.py
  inflating: layout.py
  inflating: README.md
```

In the first case, all the files related to the blueprint were placed under a folder named `compaction` and it was then converted into a zip file named `compaction.zip`.

In the second case, all the files required for the blueprint were not included into a folder and were added as root files under the zip file `compaction.zip`.

Creating a file in either of the above formats is allowed. However make sure that `blueprint.cfg` has the correct path to the name of the function in the script that generates the layout.

Examples

In case 1: `blueprint.cfg` should have `layoutGenerator` as the following:

```
layoutGenerator": "compaction.layout.generate_layout"
```

In case 2: `blueprint.cfg` should have `layoutGenerator` as the following

```
layoutGenerator": "layout.generate_layout"
```

If this path is not included correctly, you could see an error as indicated. For example, if you have the folder structure as mentioned in case 2 and you have the `layoutGenerator` indicated as in case 1, you can see the above error.

Error: missing blueprint config file

Amazon Glue returns the error "Unknown error executing layout generator function `FileNotFoundException: [Errno 2] No such file or directory: '/tmp/compaction/blueprint.cfg'`".

The `blueprint.cfg` should be placed at the root level of the ZIP archive or within a folder which has the same name as the ZIP archive.

When we extract the blueprint ZIP archive, `blueprint.cfg` is expected to be found in one of the following paths. If it is not found in one of the following paths, you can see the above error.

```
$ unzip compaction.zip
Archive:  compaction.zip
  creating: compaction/
  inflating: compaction/blueprint.cfg

$ unzip compaction.zip
Archive:  compaction.zip
  inflating: blueprint.cfg
```

Error: missing imported file

Amazon Glue returns the error "Unknown error executing layout generator function FileNotFoundError: [Errno 2] No such file or directory: * *demo-project/foo.py".

If your layout generation script has functionality to read other files, make sure you give a full path for the file to be imported. For example, the `Conversion.py` script may be referenced in `Layout.py`. For more information, see [Sample blueprint Project](#).

Error: not authorized to perform iamPassRole on resource

Amazon Glue returns the error "User: arn:aws:sts::123456789012:assumed-role/AWSGlueServiceRole/GlueSession is not authorized to perform: iam:PassRole on resource: arn:aws:iam::123456789012:role/AWSGlueServiceRole"

If the jobs and crawlers in the workflow assume the same role as the role passed to create workflow from the blueprint, then the blueprint role needs to include the `iam:PassRole` permission on itself.

If the jobs and crawlers in the workflow assume a role other than the role passed to create the entities of the workflow from the blueprint, then the blueprint role needs to include the `iam:PassRole` permission on that other role instead of on the blueprint role.

For more information, see [Permissions for blueprint Roles](#).

Error: invalid cron schedule

Amazon Glue returns the error "The schedule cron(0 0 * * * *) is invalid."

Provide a valid [cron](#) expression. For more information, see [Time-Based Schedules for Jobs and Crawlers](#).

Error: a trigger with the same name already exists

Amazon Glue returns the error "Trigger with name 'foo_starting_trigger' already submitted with different configuration".

A blueprint does not require you to define triggers in the layout script for workflow creation. Trigger creation is managed by the blueprint library based on the dependencies defined between two actions.

The naming for the triggers is as follows:

- For the starting trigger in the workflow the naming is <workflow_name>_starting_trigger.
- For a node(job/crawler) in the workflow that depends on the completion of either one or multiple upstream nodes; Amazon Glue defines a trigger with the name <workflow_name>_<node_name>_trigger

This error means a trigger with same name already exists. You can delete the existing trigger and re-run the workflow creation.

Note

Deleting a workflow doesn't delete the nodes within the workflow. It is possible that though the workflow is deleted, triggers are left behind. Due to this, you may not receive a 'workflow already exists' error, but you may receive a 'trigger already exists' error in a case where you create a workflow, delete it and then try to re-create it with the same name from same blueprint.

Error: workflow with name: foo already exists.

The workflow name should be unique. Please try with a different name.

Error: module not found in specified layoutGenerator path

Amazon Glue returns the error "Unknown error executing layout generator function ModuleNotFoundError: No module named 'crawl_s3_locations'".

```
layoutGenerator": "crawl_s3_locations.layout.generate_layout"
```

For example, if you have the above `layoutGenerator` path, then when you unzip the blueprint archive, it needs to look like the following:

```
$ unzip crawl_s3_locations.zip
Archive:  crawl_s3_locations.zip
  creating: crawl_s3_locations/
  inflating: crawl_s3_locations/blueprint.cfg
  inflating: crawl_s3_locations/layout.py
  inflating: crawl_s3_locations/README.md
```

When you unzip the archive, if the blueprint archive looks like the following, then you can get the above error.

```
$ unzip crawl_s3_locations.zip
Archive:  crawl_s3_locations.zip
  inflating: blueprint.cfg
  inflating: layout.py
  inflating: README.md
```

You can see that there is no folder named `crawl_s3_locations` and when the `layoutGenerator` path refers to the layout file via the module `crawl_s3_locations`, you can get the above error.

Error: validation error in Connections field

Amazon Glue returns the error "Unknown error executing layout generator function TypeError: Value ['foo'] for key Connections should be of type <class 'dict'>!".

This is a validation error. The `Connections` field in the `Job` class is expecting a dictionary and instead a list of values are provided causing the error.

```
User input was list of values
Connections= ['string']

Should be a dict like the following
Connections*={'Connections': ['string']}
```

To avoid these run time errors while creating a workflow from a blueprint, you can validate the workflow, job and crawler definitions as outlined in [Testing a blueprint](#).

Refer to the syntax in [Amazon Glue blueprint Classes Reference](#) for defining the Amazon Glue job, crawler and workflow in the layout script.

Permissions for personas and roles for Amazon Glue blueprints

The following are the typical personas and suggested Amazon Identity and Access Management (IAM) permissions policies for personas and roles for Amazon Glue blueprints.

Topics

- [Blueprint personas](#)
- [Permissions for blueprint personas](#)
- [Permissions for blueprint roles](#)

Blueprint personas

The following are the personas typically involved in the lifecycle of Amazon Glue blueprints.

Persona	Description
Amazon Glue developer	Develops, tests, and publishes blueprints.
Amazon Glue administrator	Registers, maintains, and grants permissions on blueprints.
Data analyst	Runs blueprints to create workflows.

For more information, see [the section called “Overview of blueprints”](#).

Permissions for blueprint personas

The following are the suggested permissions for each blueprint persona.

Amazon Glue developer permissions for blueprints

The Amazon Glue developer must have write permissions on the Amazon S3 bucket that is used to publish the blueprint. Often, the developer registers the blueprint after uploading it. In that

case, the developer needs the permissions listed in [the section called “Amazon Glue administrator permissions for blueprints”](#). Additionally, if the developer wishes to test the blueprint after its registered, he or she also needs the permissions listed in [the section called “Data analyst permissions for blueprints”](#).

Amazon Glue administrator permissions for blueprints

The following policy grants permissions to register, view, and maintain Amazon Glue blueprints.

Important

In the following policy, replace *<s3-bucket-name>* and *<prefix>* with the Amazon S3 path to uploaded blueprint ZIP archives to register.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:CreateBlueprint",
        "glue:UpdateBlueprint",
        "glue>DeleteBlueprint",
        "glue:GetBlueprint",
        "glue:ListBlueprints",
        "glue:BatchGetBlueprints"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": "arn:aws-cn:s3:::amzn-s3-demo-bucket/prefix/*"
    }
  ]
}
```

Data analyst permissions for blueprints

The following policy grants permissions to run blueprints and to view the resulting workflow and workflow components. It also grants PassRole on the role that Amazon Glue assumes to create the workflow and workflow components.

The policy grants permissions on any resource. If you want to configure fine-grained access to individual blueprints, use the following format for blueprint ARNs:

```
arn:aws-cn:glue:<region>:<account-id>:blueprint/<blueprint-name>
```

Important

In the following policy, replace *<account-id>* with a valid Amazon account and replace *<role-name>* with the name of the role used to run a blueprint. See [the section called "Permissions for blueprint roles"](#) for the permissions that this role requires.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:ListBlueprints",
        "glue:GetBlueprint",
        "glue:StartBlueprintRun",
        "glue:GetBlueprintRun",
        "glue:GetBlueprintRuns",
        "glue:GetCrawler",
        "glue:ListTriggers",
        "glue:ListJobs",
        "glue:BatchGetCrawlers",
        "glue:GetTrigger",
        "glue:BatchGetWorkflows",
        "glue:BatchGetTriggers",
        "glue:BatchGetJobs",
        "glue:BatchGetBlueprints",
        "glue:GetWorkflowRun",

```

```

        "glue:GetWorkflowRuns",
        "glue:ListCrawlers",
        "glue:ListWorkflows",
        "glue:GetJob",
        "glue:GetWorkflow",
        "glue:StartWorkflowRun"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "arn:aws-cn:iam::111122223333:role/role-name"
  }
]
}

```

Permissions for blueprint roles

The following are the suggested permissions for the IAM role used to create a workflow from a blueprint. The role has to have a trust relationship with `glue.amazonaws.com`.

Important

In the following policy, replace `<account-id>` with a valid Amazon account, and replace `<role-name>` with the name of the role.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:CreateJob",
        "glue:GetCrawler",
        "glue:GetTrigger",
        "glue>DeleteCrawler",

```

```
    "glue:CreateTrigger",
    "glue>DeleteTrigger",
    "glue>DeleteJob",
    "glue:CreateWorkflow",
    "glue>DeleteWorkflow",
    "glue:GetJob",
    "glue:GetWorkflow",
    "glue:CreateCrawler"
  ],
  "Resource": "*"
},
{
  "Effect": "Allow",
  "Action": "iam:PassRole",
  "Resource": "arn:aws-cn:iam::111122223333:role/role-name"
}
]
```

Note

If the jobs and crawlers in the workflow assume a role other than this role, this policy must include the `iam:PassRole` permission on that other role instead of on the blueprint role.

Developing blueprints in Amazon Glue

Your organization might have a set of similar ETL use cases that could benefit from being able to parametrize a single workflow to handle them all. To address this need, Amazon Glue enables you to define *blueprints*, which you can use to generate workflows. A blueprint accepts parameters, so that from a single blueprint, a data analyst can create different workflows to handle similar ETL use cases. After you create a blueprint, you can reuse it for different departments, teams, and projects.

Topics

- [Overview of blueprints in Amazon Glue](#)
- [Developing blueprints in Amazon Glue](#)
- [Registering a blueprint in Amazon Glue](#)
- [Viewing blueprints in Amazon Glue](#)

- [Updating a blueprint in Amazon Glue](#)
- [Creating a workflow from a blueprint in Amazon Glue](#)
- [Viewing blueprint runs in Amazon Glue](#)

Overview of blueprints in Amazon Glue

Note

The blueprints feature is currently unavailable in the following Regions in the Amazon Glue console: Asia Pacific (Jakarta) and Middle East (UAE).

Amazon Glue blueprints provide a way to create and share Amazon Glue workflows. When there is a complex ETL process that could be used for similar use cases, rather than creating an Amazon Glue workflow for each use case, you can create a single blueprint.

The blueprint specifies the jobs and crawlers to include in a workflow, and specifies parameters that the workflow user supplies when they run the blueprint to create a workflow. The use of parameters enables a single blueprint to generate workflows for the various similar use cases. For more information about workflows, see [Overview of workflows in Amazon Glue](#).

The following are example use cases for blueprints:

- You want to partition an existing dataset. The input parameters to the blueprint are Amazon Simple Storage Service (Amazon S3) source and target paths and a list of partition columns.
- You want to snapshot an Amazon DynamoDB table into a SQL data store like Amazon Redshift. The input parameters to the blueprint are the DynamoDB table name and an Amazon Glue connection, which designates an Amazon Redshift cluster and destination database.
- You want to convert CSV data in multiple Amazon S3 paths to Parquet. You want the Amazon Glue workflow to include a separate crawler and job for each path. The input parameters are the destination database in the Amazon Glue Data Catalog and a comma-delimited list of Amazon S3 paths. Note that in this case, the number of crawlers and jobs that the workflow creates is variable.

Blueprint components

A blueprint is a ZIP archive that contains the following components:

- A Python layout generator script

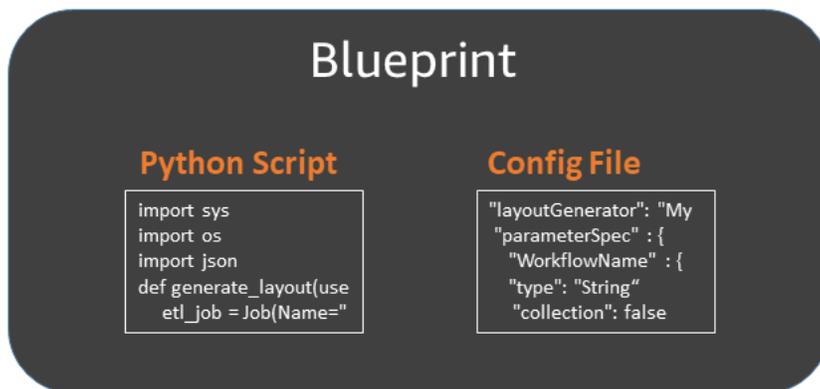

Contains a function that specifies the workflow *layout*—the crawlers and jobs to create for the workflow, the job and crawler properties, and the dependencies between the jobs and crawlers. The function accepts blueprint parameters and returns a workflow structure (JSON object) that Amazon Glue uses to generate the workflow. Because you use a Python script to generate the workflow, you can add your own logic that is suitable for your use cases.

- A configuration file

Specifies the fully qualified name of the Python function that generates the workflow layout. Also specifies the names, data types, and other properties of all blueprint parameters used by the script.

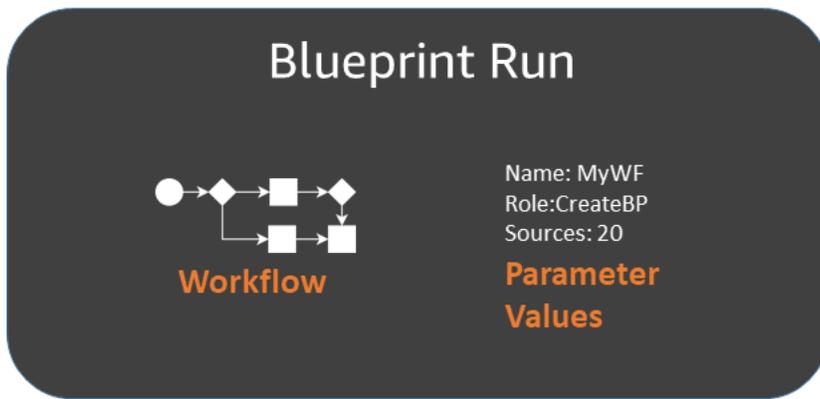

- (Optional) ETL scripts and supporting files

As an advanced use case, you can parameterize the location of the ETL scripts that your jobs use. You can include job script files in the ZIP archive and specify a blueprint parameter for an Amazon S3 location where the scripts are to be copied to. The layout generator script can copy the ETL scripts to the designated location and specify that location as the job script location property. You can also include any libraries or other supporting files, provided that your script handles them.

Blueprint runs

When you create a workflow from a blueprint, Amazon Glue runs the blueprint, which starts an asynchronous process to create the workflow and the jobs, crawlers, and triggers that the workflow encapsulates. Amazon Glue uses the blueprint run to orchestrate the creation of the workflow and its components. You view the status of the creation process by viewing the blueprint run status. The blueprint run also stores the values that you supplied for the blueprint parameters.

You can view blueprint runs using the Amazon Glue console or Amazon Command Line Interface (Amazon CLI). When viewing or troubleshooting a workflow, you can always return to the blueprint run to view the blueprint parameter values that were used to create the workflow.

Lifecycle of a blueprint

blueprints are developed, tested, registered with Amazon Glue, and run to create workflows. There are typically three personas involved in the blueprint lifecycle.

Persona	Tasks
Amazon Glue developer	<ul style="list-style-type: none"> Writes the workflow layout script and creates the configuration file. Tests the blueprint locally using libraries provided by the Amazon Glue service. Creates a ZIP archive of the script, configuration file, and supporting files and publishes the archive to a location in Amazon S3. Adds a bucket policy to the Amazon S3 bucket that grants read permissions on bucket objects to the Amazon Glue administrator's Amazon account. Grants IAM read permissions on the ZIP archive in Amazon S3 to the Amazon Glue administrator.
Amazon Glue administrator	<ul style="list-style-type: none"> <i>Registers</i> the blueprint with Amazon Glue. Amazon Glue makes a copy of the ZIP archive into a reserved Amazon S3 location.

Persona	Tasks
	<ul style="list-style-type: none">• Grants IAM permissions on the blueprint to data analysts.
Data analyst	<ul style="list-style-type: none">• Runs the blueprint to create a workflow, and provides blueprint parameter values. Checks the blueprint run status to ensure that the workflow and workflow components were successfully generated.• Runs and troubleshoots the workflow. Before running the workflow, can verify the workflow by viewing the workflow design graph on the Amazon Glue console.

Developing blueprints in Amazon Glue

As an Amazon Glue developer, you can create and publish blueprints that data analysts can use to generate workflows.

Overview of developing blueprints

The first step in your development process is to identify a common use case that would benefit from a blueprint. A typical use case involves a recurring ETL problem that you believe should be solved in a general manner. Next, design a blueprint that implements the generalized use case, and define the blueprint input parameters that together can define a specific use case from the generalized use case.

A blueprint consists of a project that contains a blueprint parameter configuration file and a script that defines the *layout* of the workflow to generate. The layout defines the jobs and crawlers (or *entities* in blueprint script terminology) to create.

You do not directly specify any triggers in the layout script. Instead you write code to specify the dependencies between the jobs and crawlers that the script creates. Amazon Glue generates the triggers based on your dependency specifications. The output of the layout script is a workflow object, which contains specifications for all workflow entities.

You build your workflow object using the following Amazon Glue blueprint libraries:

- `awsglue.blueprint.base_resource` – A library of base resources used by the libraries.
- `awsglue.blueprint.workflow` – A library for defining a `Workflow` class.
- `awsglue.blueprint.job` – A library for defining a `Job` class.
- `awsglue.blueprint.crawler` – A library for defining a `Crawler` class.

The only other libraries that are supported for layout generation are those libraries that are available for the Python shell.

Before publishing your blueprint, you can use methods defined in the blueprint libraries to test the blueprint locally.

When you're ready to make the blueprint available to data analysts, you package the script, the parameter configuration file, and any supporting files, such as additional scripts and libraries, into

a single deployable asset. You then upload the asset to Amazon S3 and ask an administrator to register it with Amazon Glue.

For information about more sample blueprint projects, see [Sample blueprint project](#) and [Blueprint samples](#).

Prerequisites for developing blueprints

To develop blueprints, you should be familiar with using Amazon Glue and writing scripts for Apache Spark ETL jobs or Python shell jobs. In addition, you must complete the following setup tasks.

- Download four Amazon Python libraries to use in your blueprint layout scripts.
- Set up the Amazon SDKs.
- Set up the Amazon CLI.

Download the Python libraries

Download the following libraries from GitHub, and install them into your project:

- https://github.com/aws-labs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/base_resource.py
- <https://github.com/aws-labs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/workflow.py>
- <https://github.com/aws-labs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/crawler.py>
- <https://github.com/aws-labs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/job.py>

Set up the Amazon Java SDK

For the Amazon Java SDK, you must add a `jar` file that includes the API for blueprints.

1. If you haven't already done so, set up the Amazon SDK for Java.
 - For Java 1.x, follow the instructions in [Set up the Amazon SDK for Java](#) in the *Amazon SDK for Java Developer Guide*.
 - For Java 2.x, follow the instructions in [Setting up the Amazon SDK for Java 2.x](#) in the *Amazon SDK for Java 2.x Developer Guide*.

2. Download the client jar file that has access to the APIs for blueprints.
 - For Java 1.x: `s3://awsglue-custom-blueprints-preview-artifacts/awsglue-java-sdk-preview/AWSGlueJavaClient-1.11.x.jar`
 - For Java 2.x: `s3://awsglue-custom-blueprints-preview-artifacts/awsglue-java-sdk-v2-preview/AwsJavaSdk-Glue-2.0.jar`
3. Add the client jar to the front of the Java classpath to override the Amazon Glue client provided by the Amazon Java SDK.

```
export CLASSPATH=<path-to-preview-client-jar>:$CLASSPATH
```

4. (Optional) Test the SDK with the following Java application. The application should output an empty list.

Replace `accessKey` and `secretKey` with your credentials, and replace `us-east-1` with your Region.

```
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.services.glue.AWSGlue;
import com.amazonaws.services.glue.AWSGlueClientBuilder;
import com.amazonaws.services.glue.model.ListBlueprintsRequest;

public class App{
    public static void main(String[] args) {
        AWSCredentials credentials = new BasicAWSCredentials("accessKey",
"secretKey");
        AWSCredentialsProvider provider = new
AWSStaticCredentialsProvider(credentials);
        AWSGlue glue = AWSGlueClientBuilder.standard().withCredentials(provider)
                .withRegion("us-east-1").build();
        ListBlueprintsRequest request = new
ListBlueprintsRequest().withMaxResults(2);
        System.out.println(glue.listBlueprints(request));
    }
}
```

Set up the Amazon Python SDK

The following steps assume that you have Python version 2.7 or later, or version 3.9 or later installed on your computer.

1. Download the following boto3 wheel file. If prompted to open or save, save the file. `s3://awsglue-custom-blueprints-preview-artifacts/aws-python-sdk-preview/boto3-1.17.31-py2.py3-none-any.whl`
2. Download the following botocore wheel file: `s3://awsglue-custom-blueprints-preview-artifacts/aws-python-sdk-preview/botocore-1.20.31-py2.py3-none-any.whl`
3. Check your Python version.

```
python --version
```

4. Depending on your Python version, enter the following commands (for Linux):

- For Python 2.7 or later.

```
python3 -m pip install --user virtualenv  
source env/bin/activate
```

- For Python 3.9 or later.

```
python3 -m venv python-sdk-test  
source python-sdk-test/bin/activate
```

5. Install the botocore wheel file.

```
python3 -m pip install <download-directory>/botocore-1.20.31-py2.py3-none-any.whl
```

6. Install the boto3 wheel file.

```
python3 -m pip install <download-directory>/boto3-1.17.31-py2.py3-none-any.whl
```

7. Configure your credentials and default region in the `~/.aws/credentials` and `~/.aws/config` files. For more information, see [Configuring the Amazon CLI](#) in the *Amazon Command Line Interface User Guide*.
8. (Optional) Test your setup. The following commands should return an empty list.

Replace `us-east-1` with your Region.

```
$ python
>>> import boto3
>>> glue = boto3.client('glue', 'us-east-1')
>>> glue.list_blueprints()
```

Set up the preview Amazon CLI

1. If you haven't already done so, install and/or update the Amazon Command Line Interface (Amazon CLI) on your computer. The easiest way to do this is with `pip`, the Python installer utility:

```
pip install awscli --upgrade --user
```

You can find complete installation instructions for the Amazon CLI here: [Installing the Amazon Command Line Interface](#).

2. Download the Amazon CLI wheel file from: `s3://awsglue-custom-blueprints-preview-artifacts/awscli-preview-build/awscli-1.19.31-py2.py3-none-any.whl`
3. Install the Amazon CLI wheel file.

```
python3 -m pip install awscli-1.19.31-py2.py3-none-any.whl
```

4. Run the `aws configure` command. Configure your Amazon credentials (including access key, and secret key) and Amazon Region. You can find information on configuring the Amazon CLI here: [Configuring the Amazon CLI](#).
5. Test the Amazon CLI. The following command should return an empty list.

Replace `us-east-1` with your Region.

```
aws glue list-blueprints --region us-east-1
```

Writing the blueprint code

Each blueprint project that you create must contain at a minimum the following files:

- A Python layout script that defines the workflow. The script contains a function that defines the entities (jobs and crawlers) in a workflow, and the dependencies between them.

- A configuration file, `blueprint.cfg`, which defines:
 - The full path of the workflow layout definition function.
 - The parameters that the blueprint accepts.

Topics

- [Creating the blueprint layout script](#)
- [Creating the configuration file](#)
- [Specifying blueprint parameters](#)

Creating the blueprint layout script

The blueprint layout script must include a function that generates the entities in your workflow. You can name this function whatever you like. Amazon Glue uses the configuration file to determine the fully qualified name of the function.

Your layout function does the following:

- (Optional) Instantiates the `Job` class to create `Job` objects, and passes arguments such as `Command` and `Role`. These are job properties that you would specify if you were creating the job using the Amazon Glue console or API.
- (Optional) Instantiates the `Crawler` class to create `Crawler` objects, and passes `name`, `role`, and `target` arguments.
- To indicate dependencies between the objects (workflow entities), passes the `DependsOn` and `WaitForDependencies` additional arguments to `Job()` and `Crawler()`. These arguments are explained later in this section.
- Instantiates the `Workflow` class to create the workflow object that is returned to Amazon Glue, passing a `Name` argument, an `Entities` argument, and an optional `OnSchedule` argument. The `Entities` argument specifies all of the jobs and crawlers to include in the workflow. To see how to construct an `Entities` object, see the sample project later in this section.
- Returns the `Workflow` object.

For definitions of the `Job`, `Crawler`, and `Workflow` classes, see [Amazon Glue blueprint classes reference](#).

The layout function must accept the following input arguments.

Argument	Description
user_params	Python dictionary of blueprint parameter names and values. For more information, see Specifying blueprint parameters .
system_params	Python dictionary containing two properties: region and accountId .

Here is a sample layout generator script in a file named Layout . py:

```
import argparse
import sys
import os
import json
from awsglue.blueprint.workflow import *
from awsglue.blueprint.job import *
from awsglue.blueprint.crawler import *

def generate_layout(user_params, system_params):

    etl_job = Job(Name="{}_etl_job".format(user_params['WorkflowName']),
                  Command={
                      "Name": "glueetl",
                      "ScriptLocation": user_params['ScriptLocation'],
                      "PythonVersion": "2"
                  },
                  Role=user_params['PassRole'])
    post_process_job = Job(Name="{}_post_process".format(user_params['WorkflowName']),
                           Command={
                               "Name": "pythonshell",
                               "ScriptLocation": user_params['ScriptLocation'],
                               "PythonVersion": "2"
                           },
                           Role=user_params['PassRole'],
                           DependsOn={
                               etl_job: "SUCCEEDED"
                           },
                           WaitForDependencies="AND")
    sample_workflow = Workflow(Name=user_params['WorkflowName'],
                               Entities=Entities(Jobs=[etl_job, post_process_job]))
```

```
return sample_workflow
```

The sample script imports the required blueprint libraries and includes a `generate_layout` function that generates a workflow with two jobs. This is a very simple script. A more complex script could employ additional logic and parameters to generate a workflow with many jobs and crawlers, or even a variable number of jobs and crawlers.

Using the `DependsOn` argument

The `DependsOn` argument is a dictionary representation of a dependency that this entity has on other entities within the workflow. It has the following form.

```
DependsOn = {dependency1 : state, dependency2 : state, ...}
```

The keys in this dictionary represent the object reference, not the name, of the entity, while the values are strings that correspond to the state to watch for. Amazon Glue infers the proper triggers. For the valid states, see [Condition Structure](#).

For example, a job might depend on the successful completion of a crawler. If you define a crawler object named `crawler2` as follows:

```
crawler2 = Crawler(Name="my_crawler", ...)
```

Then an object depending on `crawler2` would include a constructor argument such as:

```
DependsOn = {crawler2 : "SUCCEEDED"}
```

For example:

```
job1 = Job(Name="Job1", ..., DependsOn = {crawler2 : "SUCCEEDED", ...})
```

If `DependsOn` is omitted for an entity, that entity depends on the workflow start trigger.

Using the `WaitForDependencies` argument

The `WaitForDependencies` argument defines whether a job or crawler entity should wait until *all* entities on which it depends complete or until *any* completes.

The allowable values are "AND" or "ANY".

Using the OnSchedule argument

The OnSchedule argument for the Workflow class constructor is a cron expression that defines the starting trigger definition for a workflow.

If this argument is specified, Amazon Glue creates a schedule trigger with the corresponding schedule. If it isn't specified, the starting trigger for the workflow is an on-demand trigger.

Creating the configuration file

The blueprint configuration file is a required file that defines the script entry point for generating the workflow, and the parameters that the blueprint accepts. The file must be named `blueprint.cfg`.

Here is a sample configuration file.

```
{
  "layoutGenerator": "DemoBlueprintProject.Layout.generate_layout",
  "parameterSpec" : {
    "WorkflowName" : {
      "type": "String",
      "collection": false
    },
    "WorkerType" : {
      "type": "String",
      "collection": false,
      "allowedValues": ["G1.X", "G2.X"],
      "defaultValue": "G1.X"
    },
    "Dpu" : {
      "type" : "Integer",
      "allowedValues" : [2, 4, 6],
      "defaultValue" : 2
    },
    "DynamoDBTableName": {
      "type": "String",
      "collection" : false
    },
    "ScriptLocation" : {
      "type": "String",
      "collection": false
    }
  }
}
```

```

    }
  }
}

```

The `layoutGenerator` property specifies the fully qualified name of the function in the script that generates the layout.

The `parameterSpec` property specifies the parameters that this blueprint accepts. For more information, see [Specifying blueprint parameters](#).

Important

Your configuration file must include the workflow name as a blueprint parameter, or you must generate a unique workflow name in your layout script.

Specifying blueprint parameters

The configuration file contains blueprint parameter specifications in a `parameterSpec` JSON object. `parameterSpec` contains one or more parameter objects.

```

"parameterSpec": {
  "<parameter_name>": {
    "type": "<parameter-type>",
    "collection": true|false,
    "description": "<parameter-description>",
    "defaultValue": "<default value for the parameter if value not specified>"
    "allowedValues": "<list of allowed values>"
  },
  "<parameter_name>": {
    ...
  }
}

```

The following are the rules for coding each parameter object:

- The parameter name and type are mandatory. All other properties are optional.
- If you specify the `defaultValue` property, the parameter is optional. Otherwise the parameter is mandatory and the data analyst who is creating a workflow from the blueprint must provide a value for it.

- If you set the collection property to `true`, the parameter can take a collection of values. Collections can be of any data type.
- If you specify `allowedValues`, the Amazon Glue console displays a dropdown list of values for the data analyst to choose from when creating a workflow from the blueprint.

The following are the permitted values for type:

Parameter data type	Notes
String	-
Integer	-
Double	-
Boolean	Possible values are <code>true</code> and <code>false</code> . Generates a check box on the Create a workflow from <blueprint> page on the Amazon Glue console.
S3Uri	Complete Amazon S3 path, beginning with <code>s3://</code> . Generates a text field and Browse button on the Create a workflow from <blueprint> page.
S3Bucket	Amazon S3 bucket name only. Generates a bucket picker on the Create a workflow from <blueprint> page.
IAMRoleArn	Amazon Resource Name (ARN) of an Amazon Identity and Access Management (IAM) role. Generates a role picker on the Create a workflow from <blueprint> page.
IAMRoleName	Name of an IAM role. Generates a role picker on the Create a workflow from <blueprint> page.

Sample blueprint project

Data format conversion is a frequent extract, transform, and load (ETL) use case. In typical analytic workloads, column-based file formats like Parquet or ORC are preferred over text formats like CSV

or JSON. This sample blueprint enables you to convert data from CSV/JSON/etc. into Parquet for files on Amazon S3.

This blueprint takes a list of S3 paths defined by a blueprint parameter, converts the data to Parquet format, and writes it to the S3 location specified by another blueprint parameter. The layout script creates a crawler and job for each path. The layout script also uploads the ETL script in `Conversion.py` to an S3 bucket specified by another blueprint parameter. The layout script then specifies the uploaded script as the ETL script for each job. The ZIP archive for the project contains the layout script, the ETL script, and the blueprint configuration file.

For information about more sample blueprint projects, see [Blueprint samples](#).

The following is the layout script, in the file `Layout.py`.

```
from awsglue.blueprint.workflow import *
from awsglue.blueprint.job import *
from awsglue.blueprint.crawler import *
import boto3

s3_client = boto3.client('s3')

# Ingesting all the S3 paths as Glue table in parquet format
def generate_layout(user_params, system_params):
    #Always give the full path for the file
    with open("ConversionBlueprint/Conversion.py", "rb") as f:
        s3_client.upload_fileobj(f, user_params['ScriptsBucket'], "Conversion.py")
        etlScriptLocation = "s3://{}/Conversion.py".format(user_params['ScriptsBucket'])

    crawlers = []
    jobs = []
    workflowName = user_params['WorkflowName']
    for path in user_params['S3Paths']:
        tablePrefix = "source_"
        crawler = Crawler(Name="{}_crawler".format(workflowName),
                          Role=user_params['PassRole'],
                          DatabaseName=user_params['TargetDatabase'],
                          TablePrefix=tablePrefix,
                          Targets= {"S3Targets": [{"Path": path}]})
        crawlers.append(crawler)
    transform_job = Job(Name="{}_transform_job".format(workflowName),
                        Command={"Name": "glueetl",
                                "ScriptLocation": etlScriptLocation,
                                "PythonVersion": "3"},
```

```

        Role=user_params['PassRole'],
        DefaultArguments={"--database_name":
user_params['TargetDatabase'],
                        "--table_prefix": tablePrefix,
                        "--region_name": system_params['region'],
                        "--output_path":
user_params['TargetS3Location']},
        DependsOn={crawler: "SUCCEEDED"},
        WaitForDependencies="AND")
    jobs.append(transform_job)
    conversion_workflow = Workflow(Name=workflowName, Entities=Entities(Jobs=jobs,
Crawlers=crawlers))
    return conversion_workflow

```

The following is the corresponding blueprint configuration file `blueprint.cfg`.

```

{
  "layoutGenerator": "ConversionBlueprint.Layout.generate_layout",
  "parameterSpec" : {
    "WorkflowName" : {
      "type": "String",
      "collection": false,
      "description": "Name for the workflow."
    },
    "S3Paths" : {
      "type": "S3Uri",
      "collection": true,
      "description": "List of Amazon S3 paths for data ingestion."
    },
    "PassRole" : {
      "type": "IAMRoleName",
      "collection": false,
      "description": "Choose an IAM role to be used in running the job/crawler"
    },
    "TargetDatabase": {
      "type": "String",
      "collection" : false,
      "description": "Choose a database in the Data Catalog."
    },
    "TargetS3Location": {
      "type": "S3Uri",
      "collection" : false,
      "description": "Choose an Amazon S3 output path: ex:s3://<target_path>/."
    }
  }
}

```

```
    },
    "ScriptsBucket": {
        "type": "S3Bucket",
        "collection": false,
        "description": "Provide an S3 bucket name(in the same Amazon Region) to
store the scripts."
    }
}
}
```

The following script in the file `Conversion.py` is the uploaded ETL script. Note that it preserves the partitioning scheme during conversion.

```
import sys
from pyspark.sql.functions import *
from pyspark.context import SparkContext
from awsglue.transforms import *
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions
import boto3

args = getResolvedOptions(sys.argv, [
    'JOB_NAME',
    'region_name',
    'database_name',
    'table_prefix',
    'output_path'])
databaseName = args['database_name']
tablePrefix = args['table_prefix']
outputPath = args['output_path']

glue = boto3.client('glue', region_name=args['region_name'])

glue_context = GlueContext(SparkContext.getOrCreate())
spark = glue_context.spark_session
job = Job(glue_context)
job.init(args['JOB_NAME'], args)

def get_tables(database_name, table_prefix):
    tables = []
    paginator = glue.get_paginator('get_tables')
```

```
for page in paginator.paginate(DatabaseName=database_name, Expression=table_prefix
+ "*""):
    tables.extend(page['TableList'])
return tables

for table in get_tables(databaseName, tablePrefix):
    tableName = table['Name']
    partitionList = table['PartitionKeys']
    partitionKeys = []
    for partition in partitionList:
        partitionKeys.append(partition['Name'])

# Create DynamicFrame from Catalog
dyf = glue_context.create_dynamic_frame.from_catalog(
    name_space=databaseName,
    table_name=tableName,
    additional_options={
        'useS3ListImplementation': True
    },
    transformation_ctx='dyf'
)

# Resolve choice type with make_struct
dyf = ResolveChoice.apply(
    frame=dyf,
    choice='make_struct',
    transformation_ctx='resolvechoice_' + tableName
)

# Drop null fields
dyf = DropNullFields.apply(
    frame=dyf,
    transformation_ctx="dropnullfields_" + tableName
)

# Write DynamicFrame to S3 in glueparquet
sink = glue_context.getSink(
    connection_type="s3",
    path=outputPath,
    enableUpdateCatalog=True,
    partitionKeys=partitionKeys
)
sink.setFormat("glueparquet")
```

```
    sink.setCatalogInfo(
        catalogDatabase=databaseName,
        catalogTableName=tableName[len(tablePrefix):]
    )
    sink.writeFrame(dyf)

job.commit()
```

Note

Only two Amazon S3 paths can be supplied as an input to the sample blueprint. This is because Amazon Glue triggers are limited to invoking only two crawler actions.

Testing a blueprint

While you develop your code, you should perform local testing to verify that the workflow layout is correct.

Local testing doesn't generate Amazon Glue jobs, crawlers, or triggers. Instead, you run the layout script locally and use the `to_json()` and `validate()` methods to print objects and find errors. These methods are available in all three classes defined in the libraries.

There are two ways to handle the `user_params` and `system_params` arguments that Amazon Glue passes to your layout function. Your test-bench code can create a dictionary of sample blueprint parameter values and pass that to the layout function as the `user_params` argument. Or, you can remove the references to `user_params` and replace them with hardcoded strings.

If your code makes use of the `region` and `accountId` properties in the `system_params` argument, you can pass in your own dictionary for `system_params`.

To test a blueprint

1. Start a Python interpreter in a directory with the libraries, or load the blueprint files and the supplied libraries into your preferred integrated development environment (IDE).
2. Ensure that your code imports the supplied libraries.
3. Add code to your layout function to call `validate()` or `to_json()` on any entity or on the `Workflow` object. For example, if your code creates a `Crawler` object named `mycrawler`, you can call `validate()` as follows.

```
mycrawler.validate()
```

You can print `mycrawler` as follows:

```
print(mycrawler.to_json())
```

If you call `to_json` on an object, there is no need to also call `validate()`, because `to_json()` calls `validate()`.

It is most useful to call these methods on the workflow object. Assuming that your script names the workflow object `my_workflow`, validate and print the workflow object as follows.

```
print(my_workflow.to_json())
```

For more information about `to_json()` and `validate()`, see [Class methods](#).

You can also import `pprint` and pretty-print the workflow object, as shown in the example later in this section.

4. Run the code, fix errors, and finally remove any calls to `validate()` or `to_json()`.

Example

The following example shows how to construct a dictionary of sample blueprint parameters and pass it in as the `user_params` argument to layout function `generate_compaction_workflow`. It also shows how to pretty-print the generated workflow object.

```
from pprint import pprint
from awsglue.blueprint.workflow import *
from awsglue.blueprint.job import *
from awsglue.blueprint.crawler import *

USER_PARAMS = {"WorkflowName": "compaction_workflow",
               "ScriptLocation": "s3://amzn-s3-demo-bucket/scripts/threaded-
compaction.py",
               "PassRole": "arn:aws:iam::111122223333:role/GlueRole-ETL",
               "DatabaseName": "cloudtrial",
               "TableName": "ct_cloudtrail",
               "CoalesceFactor": 4,
```

```

        "MaxThreadWorkers": 200}

def generate_compaction_workflow(user_params: dict, system_params: dict) -> Workflow:
    compaction_job = Job(Name=f"{user_params['WorkflowName']}_etl_job",
        Command={"Name": "glueetl",
            "ScriptLocation": user_params['ScriptLocation'],
            "PythonVersion": "3"},
        Role="arn:aws:iam::111122223333:role/
AWSGlueServiceRoleDefault",
        DefaultArguments={"DatabaseName": user_params['DatabaseName'],
            "TableName": user_params['TableName'],
            "CoalesceFactor":
user_params['CoalesceFactor'],
            "max_thread_workers":
user_params['MaxThreadWorkers']})

    catalog_target = {"CatalogTargets": [{"DatabaseName": user_params['DatabaseName'],
"Tables": [user_params['TableName']]}]}

    compacted_files_crawler = Crawler(Name=f"{user_params['WorkflowName']}_post_crawl",
        Targets = catalog_target,
        Role=user_params['PassRole'],
        DependsOn={compaction_job: "SUCCEEDED"},
        WaitForDependencies="AND",
        SchemaChangePolicy={"DeleteBehavior": "LOG"})

    compaction_workflow = Workflow(Name=user_params['WorkflowName'],
        Entities=Entities(Jobs=[compaction_job],
Crawlers=[compacted_files_crawler]))
    return compaction_workflow

generated = generate_compaction_workflow(user_params=USER_PARAMS, system_params={})
gen_dict = generated.to_json()

pprint(gen_dict)

```

Publishing a blueprint

After you develop a blueprint, you must upload it to Amazon S3. You must have write permissions on the Amazon S3 bucket that you use to publish the blueprint. You must also make sure that the Amazon Glue administrator, who will register the blueprint, has read access to the Amazon S3

bucket. For the suggested Amazon Identity and Access Management (IAM) permissions policies for personas and roles for Amazon Glue blueprints, see [Permissions for personas and roles for Amazon Glue blueprints](#).

To publish a blueprint

1. Create the necessary scripts, resources, and blueprint configuration file.
2. Add all files to a ZIP archive and upload the ZIP file to Amazon S3. Use an S3 bucket that is in the same Region as the Region in which users will register and run the blueprint.

You can create a ZIP file from the command line using the following command.

```
zip -r folder.zip folder
```

3. Add a bucket policy that grants read permissions to the Amazon desired account. The following is a sample policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      },
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::my-blueprints/*"
    }
  ]
}
```

4. Grant the IAM `s3:GetObject` permission on the Amazon S3 bucket to the Amazon Glue administrator or to whoever will be registering blueprints. For a sample policy to grant to administrators, see [Amazon Glue administrator permissions for blueprints](#).

After you have completed local testing of your blueprint, you may also want to test a blueprint on Amazon Glue. To test a blueprint on Amazon Glue, it must be registered. You can limit who sees the registered blueprint using IAM authorization, or by using separate testing accounts.

- [Registering a blueprint in Amazon Glue](#)

Amazon Glue blueprint classes reference

The libraries for Amazon Glue blueprints define three classes that you use in your workflow layout script: `Job`, `Crawler`, and `Workflow`.

Topics

- [Job class](#)
- [Crawler class](#)
- [Workflow class](#)
- [Class methods](#)

Job class

The `Job` class represents an Amazon Glue ETL job.

Mandatory constructor arguments

The following are mandatory constructor arguments for the `Job` class.

Argument name	Type	Description
Name	str	Name to assign to the job. Amazon Glue adds a randomly generated suffix to the name to distinguish the job from those created by other blueprint runs.
Role	str	Amazon Resource Name (ARN) of the role that the job should assume while executing.
Command	dict	Job command, as specified in the JobCommand structure in the API documentation.

Optional constructor arguments

The following are optional constructor arguments for the `Job` class.

Argument name	Type	Description
<code>DependsOn</code>	<code>dict</code>	List of workflow entities that the job depends on. For more information, see Using the DependsOn argument .
<code>WaitForDependencies</code>	<code>str</code>	Indicates whether the job should wait until <i>all</i> entities on which it depends complete before executing or until <i>any</i> completes. For more information, see Using the WaitForDependencies argument . Omit if the job depends on only one entity.
(Job properties)	-	Any of the job properties listed in Job structure in the Amazon Glue API documentation (except <code>CreatedOn</code> and <code>LastModifiedOn</code>).

Crawler class

The `Crawler` class represents an Amazon Glue crawler.

Mandatory constructor arguments

The following are mandatory constructor arguments for the `Crawler` class.

Argument name	Type	Description
<code>Name</code>	<code>str</code>	Name to assign to the crawler. Amazon Glue adds a randomly generated suffix to the name to distinguish the crawler from those created by other blueprint runs.
<code>Role</code>	<code>str</code>	ARN of the role that the crawler should assume while running.

Argument name	Type	Description
Targets	dict	Collection of targets to crawl. Targets class constructor arguments are defined in the CrawlerTargets structure in the API documentation. All Targets constructor arguments are optional, but you must pass at least one.

Optional constructor arguments

The following are optional constructor arguments for the `Crawler` class.

Argument name	Type	Description
DependsOn	dict	List of workflow entities that the crawler depends on. For more information, see Using the DependsOn argument .
WaitForDependencies	str	Indicates whether the crawler should wait until <i>all</i> entities on which it depends complete before running or until <i>any</i> completes. For more information, see Using the WaitForDependencies argument . Omit if the crawler depends on only one entity.
(Crawler properties)	-	Any of the crawler properties listed in Crawler structure in the Amazon Glue API documentation, with the following exceptions: <ul style="list-style-type: none"> • State • CrawlElapsedTime • CreationTime • LastUpdated • LastCrawl • Version

Workflow class

The `Workflow` class represents an Amazon Glue workflow. The workflow layout script returns a `Workflow` object. Amazon Glue creates a workflow based on this object.

Mandatory constructor arguments

The following are mandatory constructor arguments for the `Workflow` class.

Argument name	Type	Description
Name	str	Name to assign to the workflow.
Entities	Entities	A collection of entities (jobs and crawlers) to include in the workflow. The <code>Entities</code> class constructor accepts a <code>Jobs</code> argument, which is a list of <code>Job</code> objects, and a <code>Crawlers</code> argument, which is a list of <code>Crawler</code> objects.

Optional constructor arguments

The following are optional constructor arguments for the `Workflow` class.

Argument name	Type	Description
Description	str	See Workflow structure .
DefaultRunProperties	dict	See Workflow structure .
OnSchedule	str	A cron expression.

Class methods

All three classes include the following methods.

validate()

Validates the properties of the object and if errors are found, outputs a message and exits. Generates no output if there are no errors. For the `Workflow` class, calls itself on every entity in the workflow.

to_json()

Serializes the object to JSON. Also calls `validate()`. For the `Workflow` class, the JSON object includes job and crawler lists, and a list of triggers generated by the job and crawler dependency specifications.

Blueprint samples

There are a number of sample blueprint projects available on the [Amazon Glue blueprint Github repository](#). These samples are for reference only and are not intended for production use.

The titles of the sample projects are:

- **Compaction:** this blueprint creates a job that compacts input files into larger chunks based on desired file size.
- **Conversion:** this blueprint converts input files in various standard file formats into Apache Parquet format, which is optimized for analytic workloads.
- **Crawling Amazon S3 locations:** this blueprint crawls multiple Amazon S3 locations to add metadata tables to the Data Catalog.
- **Custom connection to Data Catalog:** this blueprint accesses data stores using Amazon Glue custom connectors, reads the records, and populates the table definitions in the Amazon Glue Data Catalog based on the record schema.
- **Encoding:** this blueprint converts your non-UTF files into UTF encoded files.
- **Partitioning:** this blueprint creates a partitioning job that places output files into partitions based on specific partition keys.
- **Importing Amazon S3 data into a DynamoDB table:** this blueprint imports data from Amazon S3 into a DynamoDB table.
- **Standard table to governed:** this blueprint imports an Amazon Glue Data Catalog table into a Lake Formation table.

Registering a blueprint in Amazon Glue

After the Amazon Glue developer has coded the blueprint and uploaded a ZIP archive to Amazon Simple Storage Service (Amazon S3), an Amazon Glue administrator must register the blueprint. Registering the blueprint makes it available for use.

When you register a blueprint, Amazon Glue copies the blueprint archive to a reserved Amazon S3 location. You can then delete the archive from the upload location.

To register a blueprint, you need read permissions on the Amazon S3 location that contains the uploaded archive. You also need the Amazon Identity and Access Management (IAM) permission `glue:CreateBlueprint`. For the suggested permissions for an Amazon Glue administrator who must register, view, and maintain blueprints, see [Amazon Glue administrator permissions for blueprints](#).

You can register a blueprint by using the Amazon Glue console, Amazon Glue API, or Amazon Command Line Interface (Amazon CLI).

To register a blueprint (console)

1. Ensure that you have read permissions (`s3:GetObject`) on the blueprint ZIP archive in Amazon S3.
2. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.

Sign in as a user that has permissions to register a blueprint. Switch to the same Amazon Region as the Amazon S3 bucket that contains the blueprint ZIP archive.

3. In the navigation pane, choose **blueprints**. Then on the **blueprints** page, choose **Add blueprint**.
4. Enter a blueprint name and optional description.
5. For **ZIP archive location (S3)**, enter the Amazon S3 path of the uploaded blueprint ZIP archive. Include the archive file name in the path and begin the path with `s3://`.
6. (Optional) Add tag one or more tags.
7. Choose **Add blueprint**.

The **blueprints** page returns and shows that the blueprint status is **CREATING**. Choose the refresh button until the status changes to **ACTIVE** or **FAILED**.

8. If the status is **FAILED**, select the blueprint, and on the **Actions** menu, choose **View**.

The detail page shows the reason for the failure. If the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.
 - The Amazon S3 bucket that contains the ZIP archive must have a bucket policy that grants read permission on the object to your Amazon account ID. For more information, see [Developing blueprints in Amazon Glue](#).
 - The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.
9. Ensure that data analysts have permissions on the blueprint.

The suggested IAM policy for data analysts is shown in [Data analyst permissions for blueprints](#). This policy grants `glue:GetBlueprint` on any resource. If your policy is more fine-grained at the resource level, then grant data analysts permissions on this newly created resource.

To register a blueprint (Amazon CLI)

1. Enter the following command.

```
aws glue create-blueprint --name <blueprint-name> [--description <description>] --  
blueprint-location s3://<s3-path>/<archive-filename>
```

2. Enter the following command to check the blueprint status. Repeat the command until the status goes to ACTIVE or FAILED.

```
aws glue get-blueprint --name <blueprint-name>
```

If the status is FAILED and the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.
- The Amazon S3 bucket containing the ZIP archive must have a bucket policy that grants read permission on the object to your Amazon account ID. For more information, see [Publishing a blueprint](#).

- The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

- [Overview of blueprints in Amazon Glue](#)

Viewing blueprints in Amazon Glue

View a blueprint to review the blueprint description, status, and parameter specifications, and to download the blueprint ZIP archive.

You can view a blueprint by using the Amazon Glue console, Amazon Glue API, or Amazon Command Line Interface (Amazon CLI).

To view a blueprint (console)

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, choose **blueprints**.
3. On the **blueprints** page, select a blueprint. Then on the **Actions** menu, choose **View**.

To view a blueprint (Amazon CLI)

- Enter the following command to view just the blueprint name, description, and status. Replace *<blueprint-name>* with the name of the blueprint to view.

```
aws glue get-blueprint --name <blueprint-name>
```

The command output looks something like the following.

```
{
  "Blueprint": {
    "Name": "myDemoBP",
    "CreatedOn": 1587414516.92,
    "LastModifiedOn": 1587428838.671,
    "BlueprintLocation": "s3://amzn-s3-demo-bucket1/demo/
DemoBlueprintProject.zip",
```

```

    "Status": "ACTIVE"
  }
}

```

Enter the following command to also view the parameter specifications.

```
aws glue get-blueprint --name <blueprint-name> --include-parameter-spec
```

The command output looks something like the following.

```

{
  "Blueprint": {
    "Name": "myDemoBP",
    "CreatedOn": 1587414516.92,
    "LastModifiedOn": 1587428838.671,
    "ParameterSpec": "{\"WorkflowName\":{\"type\":\"String\",\"collection\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null},\"PassRole\":{\"type\":\"String\",\"collection\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null},\"DynamoDBTableName\":{\"type\":\"String\",\"collection\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null},\"ScriptLocation\":{\"type\":\"String\",\"collection\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null}}",
    "BlueprintLocation": "s3://awsexamplebucket1/demo/DemoBlueprintProject.zip",
    "Status": "ACTIVE"
  }
}

```

Add the `--include-blueprint` argument to include a URL in the output that you can paste into your browser to download the blueprint ZIP archive that Amazon Glue stored.

See also:

- [Overview of blueprints in Amazon Glue](#)

Updating a blueprint in Amazon Glue

You can update a blueprint if you have a revised layout script, a revised set of blueprint parameters, or revised supporting files. Updating a blueprint creates a new version.

Updating a blueprint doesn't affect existing workflows created from the blueprint.

You can update a blueprint by using the Amazon Glue console, Amazon Glue API, or Amazon Command Line Interface (Amazon CLI).

The following procedure assumes that the Amazon Glue developer has created and uploaded an updated blueprint ZIP archive to Amazon S3.

To update a blueprint (console)

1. Ensure that you have read permissions (`s3:GetObject`) on the blueprint ZIP archive in Amazon S3.
2. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.

Sign in as a user that has permissions to update a blueprint. Switch to the same Amazon Region as the Amazon S3 bucket that contains the blueprint ZIP archive.

3. In the navigation pane, choose **blueprints**.
4. On the **blueprints** page, select a blueprint, and on the **Actions** menu, choose **Edit**.
5. On the **Edit a blueprint** page, update the blueprint **Description** or **ZIP archive location (S3)**. Be sure to include the archive file name in the path.
6. Choose **Save**.

The **blueprints** page returns and shows that the blueprint status is UPDATING. Choose the refresh button until the status changes to ACTIVE or FAILED.

7. If the status is FAILED, select the blueprint, and on the **Actions** menu, choose **View**.

The detail page shows the reason for the failure. If the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.

- The Amazon S3 bucket that contains the ZIP archive must have a bucket policy that grants read permission on the object to your Amazon account ID. For more information, see [Publishing a blueprint](#).
- The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

Note

If the update fails, the next blueprint run uses the latest version of the blueprint that was successfully registered or updated.

To update a blueprint (Amazon CLI)

1. Enter the following command.

```
aws glue update-blueprint --name <blueprint-name> [--description <description>] --  
blueprint-location s3://<s3-path>/<archive-filename>
```

2. Enter the following command to check the blueprint status. Repeat the command until the status goes to ACTIVE or FAILED.

```
aws glue get-blueprint --name <blueprint-name>
```

If the status is FAILED and the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.
- The Amazon S3 bucket containing the ZIP archive must have a bucket policy that grants read permission on the object to your Amazon account ID. For more information, see [Publishing a blueprint](#).
- The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

Creating a workflow from a blueprint in Amazon Glue

You can create an Amazon Glue workflow manually, adding one component at a time, or you can create a workflow from an Amazon Glue [blueprint](#). Amazon Glue includes blueprints for common use cases. Your Amazon Glue developers can create additional blueprints.

Important

Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

When you use a blueprint, you can quickly generate a workflow for a specific use case based on the generalized use case defined by the blueprint. You define the specific use case by providing values for the blueprint parameters. For example, a blueprint that partitions a dataset could have the Amazon S3 source and target paths as parameters.

Amazon Glue creates a workflow from a blueprint by *running* the blueprint. The blueprint run saves the parameter values that you supplied, and is used to track the progress and outcome of the creation of the workflow and its components. When troubleshooting a workflow, you can view the blueprint run to determine the blueprint parameter values that were used to create a workflow.

To create and view workflows, you require certain IAM permissions. For a suggested IAM policy, see [Data analyst permissions for blueprints](#).

You can create a workflow from a blueprint by using the Amazon Glue console, Amazon Glue API, or Amazon Command Line Interface (Amazon CLI).

To create a workflow from a blueprint (console)

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.

Sign in as a user that has permissions to create a workflow.

2. In the navigation pane, choose **blueprints**.
3. Select a blueprint, and on the **Actions** menu, choose **Create workflow**.
4. On the **Create a workflow from <blueprint-name>** page, enter the following information:

Blueprint parameters

These vary depending on the blueprint design. For questions about the parameters, see the developer. blueprints typically include a parameter for the workflow name.

IAM role

The role that Amazon Glue assumes to create the workflow and its components. The role must have permissions to create and delete workflows, jobs, crawlers, and triggers. For a suggested policy for the role, see [Permissions for blueprint roles](#).

5. Choose **Submit**.

The **Blueprint Details** page appears, showing a list of blueprint runs at the bottom.

6. In the blueprint runs list, check the topmost blueprint run for workflow creation status.

The initial status is RUNNING. Choose the refresh button until the status goes to SUCCEEDED or FAILED.

7. Do one of the following:
 - If the completion status is SUCCEEDED, you can go to the **Workflows** page, select the newly created workflow, and run it. Before running the workflow, you can review the design graph.
 - If the completion status is FAILED, select the blueprint run, and on the **Actions** menu, choose **View** to see the error message.

For more information on workflows and blueprints, see the following topics.

- [Overview of workflows in Amazon Glue](#)
- [Updating a blueprint in Amazon Glue](#)
- [Creating and building out a workflow manually in Amazon Glue](#)

Viewing blueprint runs in Amazon Glue

View a blueprint run to see the following information:

- Name of the workflow that was created.
- blueprint parameter values that were used to create the workflow.
- Status of the workflow creation operation.

You can view a blueprint run by using the Amazon Glue console, Amazon Glue API, or Amazon Command Line Interface (Amazon CLI).

To view a blueprint run (console)

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, choose **blueprints**.
3. On the **blueprints** page, select a blueprint. Then on the **Actions** menu, choose **View**.
4. At the bottom of the **Blueprint Details** page, select a blueprint run, and on the **Actions** menu, choose **View**.

To view a blueprint run (Amazon CLI)

- Enter the following command. Replace *<blueprint-name>* with the name of the blueprint. Replace *<blueprint-run-id>* with the blueprint run ID.

```
aws glue get-blueprint-run --blueprint-name <blueprint-name> --run-id <blueprint-run-id>
```

See also:

- [Overview of blueprints in Amazon Glue](#)

Amazon CloudFormation for Amazon Glue

Amazon CloudFormation is a service that can create many Amazon resources. Amazon Glue provides API operations to create objects in the Amazon Glue Data Catalog. However, it might be more convenient to define and create Amazon Glue objects and other related Amazon resource objects in an Amazon CloudFormation template file. Then you can automate the process of creating the objects.

Amazon CloudFormation provides a simplified syntax—either JSON (JavaScript Object Notation) or YAML (YAML Ain't Markup Language)—to express the creation of Amazon resources. You can use Amazon CloudFormation templates to define Data Catalog objects such as databases, tables, partitions, crawlers, classifiers, and connections. You can also define ETL objects such as jobs, triggers, and development endpoints. You create a template that describes all the Amazon resources you want, and Amazon CloudFormation takes care of provisioning and configuring those resources for you.

For more information, see [What Is Amazon CloudFormation?](#) and [Working with Amazon CloudFormation Templates](#) in the *Amazon CloudFormation User Guide*.

If you plan to use Amazon CloudFormation templates that are compatible with Amazon Glue, as an administrator, you must grant access to Amazon CloudFormation and to the Amazon services and actions on which it depends. To grant permissions to create Amazon CloudFormation resources, attach the following policy to users that work with Amazon CloudFormation:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudformation:*"
      ],
      "Resource": "*"
    }
  ]
}
```

The following table contains the actions that an Amazon CloudFormation template can perform on your behalf. It includes links to information about the Amazon resource types and their property types that you can add to an Amazon CloudFormation template.

Amazon Glue resource	Amazon CloudFormation template	Amazon Glue samples
Classifier	AWS::Glue::Classifier	Grok classifier , JSON classifier , XML classifier
Connection	AWS::Glue::Connection	MySQL connection
Crawler	AWS::Glue::Crawler	Amazon S3 crawler , MySQL crawler
Database	AWS::Glue::Database	Empty database , Database with tables
Development endpoint	AWS::Glue::DevEndpoint	Development endpoint
Integration	AWS::Glue::Integration	Zero-ETL integration
Integration Resource Property	AWS::Glue::IntegrationResourceProperty	Zero-ETL integration with integration resource property
Job	AWS::Glue::Job	Amazon S3 job , JDBC job
Machine learning transform	AWS::Glue::MLTransform	Machine learning transform
Data quality ruleset	AWS::Glue::DataQualityRuleset	Data quality ruleset , Data quality ruleset with EventBridge scheduler
Partition	AWS::Glue::Partition	Partitions of a table
Table	AWS::Glue::Table	Table in a database
Trigger	AWS::Glue::Trigger	On-demand trigger , Scheduled trigger , Conditional trigger

To get started, use the following sample templates and customize them with your own metadata. Then use the Amazon CloudFormation console to create an Amazon CloudFormation stack to add objects to Amazon Glue and any associated services. Many fields in an Amazon Glue object are optional. These templates illustrate the fields that are required or are necessary for a working and functional Amazon Glue object.

An Amazon CloudFormation template can be in either JSON or YAML format. In these examples, YAML is used for easier readability. The examples contain comments (#) to describe the values that are defined in the templates.

Amazon CloudFormation templates can include a `Parameters` section. This section can be changed in the sample text or when the YAML file is submitted to the Amazon CloudFormation console to create a stack. The `Resources` section of the template contains the definition of Amazon Glue and related objects. Amazon CloudFormation template syntax definitions might contain properties that include more detailed property syntax. Not all properties might be required to create an Amazon Glue object. These samples show example values for common properties to create an Amazon Glue object.

Sample Amazon CloudFormation template for an Amazon Glue database

An Amazon Glue database in the Data Catalog contains metadata tables. The database consists of very few properties and can be created in the Data Catalog with an Amazon CloudFormation template. The following sample template is provided to get you started and to illustrate the use of Amazon CloudFormation stacks with Amazon Glue. The only resource created by the sample template is a database named `cfn-mysampledatabase`. You can change it by editing the text of the sample or changing the value on the Amazon CloudFormation console when you submit the YAML.

The following shows example values for common properties to create an Amazon Glue database. For more information about the Amazon CloudFormation database template for Amazon Glue, see [AWS::Glue::Database](#).

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CloudFormation template in YAML to demonstrate creating a database named
  mysampledatabase
# The metadata created in the Data Catalog points to the flights public S3 bucket
```

```
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:
  CFNDatabaseName:
    Type: String
    Default: cfn-mysampledatabse

# Resources section defines metadata for the Data Catalog
Resources:
# Create an Amazon Glue database
  CFNDatabaseFlights:
    Type: AWS::Glue::Database
    Properties:
      # The database is created in the Data Catalog for your account
      CatalogId: !Ref AWS::AccountId
      DatabaseInput:
        # The name of the database is defined in the Parameters section above
        Name: !Ref CFNDatabaseName
        Description: Database to hold tables for flights data
        LocationUri: s3://crawler-public-us-east-1/flight/2016/csv/
        #Parameters: Leave Amazon database parameters blank
```

Sample Amazon CloudFormation template for an Amazon Glue database, table, and partition

An Amazon Glue table contains the metadata that defines the structure and location of data that you want to process with your ETL scripts. Within a table, you can define partitions to parallelize the processing of your data. A partition is a chunk of data that you defined with a key. For example, using month as a key, all the data for January is contained in the same partition. In Amazon Glue, databases can contain tables, and tables can contain partitions.

The following sample shows how to populate a database, a table, and partitions using an Amazon CloudFormation template. The base data format is csv and delimited by a comma (,). Because a database must exist before it can contain a table, and a table must exist before partitions can be created, the template uses the `DependsOn` statement to define the dependency of these objects when they are created.

The values in this sample define a table that contains flight data from a publicly available Amazon S3 bucket. For illustration, only a few columns of the data and one partitioning key are defined.

Four partitions are also defined in the Data Catalog. Some fields to describe the storage of the base data are also shown in the `StorageDescriptor` fields.

```

```

Sample Amazon CloudFormation template for an Amazon Glue grok classifier

An Amazon Glue classifier determines the schema of your data. One type of custom classifier uses a grok pattern to match your data. If the pattern matches, then the custom classifier is used to create your table's schema and set the classification to the value set in the classifier definition.

This sample creates a classifier that creates a schema with one column named message and sets the classification to greedy.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a classifier
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the classifier to be created
CFNClassifierName:
  Type: String
  Default: cfn-classifier-grok-one-column-1

#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create classifier that uses grok pattern to put all data in one column and classifies
it as "greedy".
CFNClassifierFlights:
  Type: AWS::Glue::Classifier
  Properties:
    GrokClassifier:
      #Grok classifier that puts all data in one column
      Name: !Ref CFNClassifierName
      Classification: greedy

      GrokPattern: "%{GREEDYDATA:message}"
      #CustomPatterns: none
```

Sample Amazon CloudFormation template for an Amazon Glue JSON classifier

An Amazon Glue classifier determines the schema of your data. One type of custom classifier uses a `JsonPath` string defining the JSON data for the classifier to classify. Amazon Glue supports a subset of the operators for `JsonPath`, as described in [Writing JsonPath Custom Classifiers](#).

If the pattern matches, then the custom classifier is used to create your table's schema.

This sample creates a classifier that creates a schema with each record in the `Records3` array in an object.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a JSON classifier
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the classifier to be created
  CFNClassifierName:
    Type: String
    Default: cfn-classifier-json-one-column-1

#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create classifier that uses a JSON pattern.
  CFNClassifierFlights:
    Type: AWS::Glue::Classifier
    Properties:
      JSONClassifier:
        #JSON classifier
        Name: !Ref CFNClassifierName
        JsonPath: $.Records3[*]
```

Sample Amazon CloudFormation template for an Amazon Glue XML classifier

An Amazon Glue classifier determines the schema of your data. One type of custom classifier specifies an XML tag to designate the element that contains each record in an XML document that is being parsed. If the pattern matches, then the custom classifier is used to create your table's schema and set the classification to the value set in the classifier definition.

This sample creates a classifier that creates a schema with each record in the `Record` tag and sets the classification to XML.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating an XML classifier
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the classifier to be created
  CFNClassifierName:
    Type: String
    Default: cfn-classifier-xml-one-column-1

#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create classifier that uses the XML pattern and classifies it as "XML".
  CFNClassifierFlights:
    Type: AWS::Glue::Classifier
    Properties:
      XMLClassifier:
        #XML classifier
        Name: !Ref CFNClassifierName
        Classification: XML
        RowTag: <Records>
```

Sample Amazon CloudFormation template for an Amazon Glue crawler for Amazon S3

An Amazon Glue crawler creates metadata tables in your Data Catalog that correspond to your data. You can then use these table definitions as sources and targets in your ETL jobs.

This sample creates a crawler, the required IAM role, and an Amazon Glue database in the Data Catalog. When this crawler is run, it assumes the IAM role and creates a table in the database for the public flights data. The table is created with the prefix "cfn_sample_1_". The IAM role created by this template allows global permissions; you might want to create a custom role. No custom classifiers are defined by this classifier. Amazon Glue built-in classifiers are used by default.

When you submit this sample to the Amazon CloudFormation console, you must confirm that you want to create the IAM role.

```
---

Sample Amazon CloudFormation template for an Amazon Glue connection

An Amazon Glue connection in the Data Catalog contains the JDBC and network information that is required to connect to a JDBC database. This information is used when you connect to a JDBC database to crawl or run ETL jobs.

This sample creates a connection to an Amazon RDS MySQL database named devdb. When this connection is used, an IAM role, database credentials, and network connection values must also be supplied. See the details of necessary fields in the template.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a connection
#

Sample Amazon CloudFormation template for an Amazon Glue zero-ETL integration

Amazon zero-ETL is a set of fully managed integrations that minimize the need to build ETL data pipelines for common ingestion and replication use cases.

This sample creates a zero-ETL integration from the given source to the target.

```

---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a zero-ETL integration in Amazon Glue
#
# Parameters section contains names that are substituted in the Resources section
#
Parameters:

  # The name of the zero-ETL integration to be created
  IntegrationName:
    Type: String
  # The ARN for the source of the zero-ETL integration
  SourceArn:
    Type: String
  # The ARN for the target of the zero-ETL integration
  TargetArn:

```

```

    Type: String
#
#

    SourceArn: !Ref SourceArn
    TargetArn: !Ref TargetArn
    DataFilter: "include:table1"
  Tags:
    - Key: Purpose
      Value: GlueZeroETLIntegration

```

Sample Amazon CloudFormation template for an Amazon Glue zero-ETL integration with integration resource properties

An Amazon Glue zero-ETL integration requires resource properties to be defined for the source and the target. For the source, the only property that needs to be defined is the IAM role that the integration will use to access the Amazon Glue connection or DynamoDB database. For the target, the properties that can be configured include the IAM role that will be used to access the target, the VPC network that the integration should be created in, the event bus that will be used to setup event notifications for the integration and the KMS key that will be used for data encryption.

The below sample defines the source and target resource properties and then creates a zero-ETL integration from the source to the target.

```

---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate defining the integration resource properties and then
  creating a zero-ETL integration in Amazon Glue

Sample Amazon CloudFormation template for an Amazon Glue job for Amazon S3 to Amazon S3

An Amazon Glue job in the Data Catalog contains the parameter values that are required to run a script in Amazon Glue.

This sample creates a job that reads flight data from an Amazon S3 bucket in csv format and writes it to an Amazon S3 Parquet file. The script that is run by this job must already exist. You can generate an ETL script for your environment with the Amazon Glue console. When this job is run, an IAM role with the correct permissions must also be supplied.

Common parameter values are shown in the template. For example, `AllocatedCapacity` (DPUs) defaults to 5.

```
---
AWSTemplateFormatVersion: '2010-09-09'

Sample Amazon CloudFormation template for an Amazon Glue on-demand trigger

An Amazon Glue trigger in the Data Catalog contains the parameter values that are required to start a job run when the trigger fires. An on-demand trigger fires when you enable it.

This sample creates an on-demand trigger that starts one job named `cfn-job-S3-to-S3-1`.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating an on-demand trigger
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:
  # The existing job to be started by this trigger
  CFNJobName:
    Type: String
    Default: cfn-job-S3-to-S3-1
  # The name of the trigger to be created
  CFNTriggerName:
    Type: String
    Default: cfn-trigger-ondemand-flights-1
#
# Resources section defines metadata for the Data Catalog
# Sample CFN YAML to demonstrate creating an on-demand trigger for a job
Resources:
  # Create trigger to run an existing job (CFNJobName) on an on-demand schedule.
  CFNTriggerSample:
    Type: AWS::Glue::Trigger

# Arguments: JSON object
#Schedule:
#Predicate:
```

Sample Amazon CloudFormation template for an Amazon Glue scheduled trigger

An Amazon Glue trigger in the Data Catalog contains the parameter values that are required to start a job run when the trigger fires. A scheduled trigger fires when it is enabled and the cron timer pops.

This sample creates a scheduled trigger that starts one job named `cfn-job-S3-to-S3-1`. The timer is a cron expression to run the job every 10 minutes on weekdays.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a scheduled trigger
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:
  # The existing job to be started by this trigger
  CFNJobName:
    Type: String
    Default: cfn-job-S3-to-S3-1
  # The name of the trigger to be created
  CFNTriggerName:

          State: SUCCEEDED
```

Sample Amazon CloudFormation template for an Amazon Glue development endpoint

An Amazon Glue machine learning transform is a custom transform to cleanse your data. There is currently one available transform named FindMatches. The FindMatches transform enables you to identify duplicate or matching records in your dataset, even when the records do not have a common unique identifier and no fields match exactly.

This sample creates a machine learning transform. For more information about the parameters that you need to create a machine learning transform, see [Record matching with Amazon Lake Formation FindMatches](#).

```

Sample Amazon CloudFormation template for an Amazon Glue Data Quality ruleset

An Amazon Glue Data Quality ruleset contains rules that can be evaluated on a table within the Data Catalog. Once the ruleset is placed on your targeted table you can go into the Data Catalog and run an evaluation which runs your data against those rules within the ruleset. These rules can vary from evaluating the row count to evaluating referential integrity on your data.

The following sample is a CloudFormation template which creates a ruleset with a variety of rules on the specified target table.

```
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a DataQualityRuleset
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the ruleset to be created
RulesetName:
  Type: String
  Default: "CFNRulesetName"
RulesetDescription:
  Type: String
  Default: "CFN DataQualityRuleset"
# Rules that will be associated with this ruleset
Rules:
  Type: String
  Default: 'Rules = [
    RowCount > 100,
    IsUnique "id",
    IsComplete "nametype"
  ]'
# Name of database and table within Data Catalog which the ruleset will
# be applied too
DatabaseName:
  Type: String
  Default: "ExampleDatabaseName"
TableName:
  Type: String
  Default: "ExampleTableName"

# Resources section defines metadata for the Data Catalog
Resources:
# Creates a Data Quality ruleset under specified rules
DQRuleset:
  Type: AWS::Glue::DataQualityRuleset
  Properties:
    Name: !Ref RulesetName
    Description: !Ref RulesetDescription
    # The String within rules must be formatted in DQDL, a language
```

```
# used specifically to make rules
Ruleset: !Ref Rules
# The targeted table must exist within Data Catalog alongside
# the correct database
TargetTable:
  DatabaseName: !Ref DatabaseName
  TableName: !Ref TableName
```

Sample Amazon CloudFormation template for an Amazon Glue Data Quality ruleset with EventBridge scheduler

An Amazon Glue Data Quality ruleset contains rules that can be evaluated on a table within the Data Catalog. Once the ruleset is placed on your targeted table you can go into the Data Catalog and run an evaluation which runs your data against those rules within the ruleset. Instead of having to manually go into the Data Catalog to evaluate the ruleset, you can also add an EventBridge Scheduler within our CloudFormation template to schedule these ruleset evaluations for you on a timed interval.

The following sample is a CloudFormation template which creates a Data Quality ruleset and a EventBridge Scheduler to evaluate the aforementioned ruleset every five minutes.

```
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a DataQualityRuleset
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

  # The name of the ruleset to be created
  RulesetName:
    Type: String
    Default: "CFNRulesetName"
  # Rules that will be associated with this Ruleset
  Rules:
    Type: String
    Default: 'Rules = [
      RowCount > 100,
      IsUnique "id",
      IsComplete "nametype"
    ]'
  # The name of the Schedule to be created
```

```

ScheduleName:
  Type: String
  Default: "ScheduleDQRulsetEvaluation"
# This expression determines the rate at which the Schedule will evaluate
# your data using the above ruleset
ScheduleRate:
  Type: String
  Default: "rate(5 minutes)"
# The Request that being sent must match the details of the Data Quality Ruleset
ScheduleRequest:
  Type: String
  Default: '
    { "DataSource": { "GlueTable": { "DatabaseName": "ExampleDatabaseName",
      "TableName": "ExampleTableName" } },
      "Role": "role/AWSGlueServiceRoleDefault",
      "RulesetNames": [ "CFNRulesetName" ] }
    ,

# Resources section defines metadata for the Data Catalog

Sample Amazon CloudFormation template for an Amazon Glue development endpoint

An Amazon Glue development endpoint is an environment that you can use to develop and test your Amazon Glue scripts.

This sample creates a development endpoint with the minimal network parameter values required to successfully create it. For more information about the parameters that you need to set up a development endpoint, see [Setting up networking for development for Amazon Glue](#).

You provide an existing IAM role ARN (Amazon Resource Name) to create the development endpoint. Supply a valid RSA public key and keep the corresponding private key available if you plan to create a notebook server on the development endpoint.

Note

For any notebook server that you create that is associated with a development endpoint, you manage it. Therefore, if you delete the development endpoint, to delete the notebook server, you must delete the Amazon CloudFormation stack on the Amazon CloudFormation console.

```
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a development endpoint
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the crawler to be created
CFNEndpointName:
  Type: String
  Default: cfn-devendpoint-1
CFNIAMRoleArn:

```

Amazon Glue programming guide

A script contains the code that extracts data from sources, transforms it, and loads it into targets. Amazon Glue runs a script when it starts a job.

Amazon Glue ETL scripts are coded in Python or Scala. While all job types can be written in Python, Amazon Glue for Spark jobs can be written in Scala as well. When you automatically generate the source code logic for your job in Amazon Glue Studio, a script is created. You can edit this script, or you can provide your own script to process your ETL work.

Providing your own custom scripts

Scripts perform the extract, transform, and load (ETL) work in Amazon Glue. A script is created when you automatically generate the source code logic for a job. You can either edit this generated script, or you can provide your own custom script.

To provide your own custom script in Amazon Glue, follow these general steps:

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose the **ETL Jobs** tab, and then view the **Create job** section. Choose a **script editor** option.
3. Under **This job runs**, choose one of the following:
 - **Create a new script with boilerplate code**
 - **Upload and edit an existing script**
4. On the **Job details** page, choose the **IAM role** that is required for your custom script to run. For more information, see [Identity and access management for Amazon Glue](#).
5. Choose any connections that your script references. These objects are needed to connect to the necessary JDBC data stores.

An elastic network interface is a virtual network interface that you can attach to an instance in a virtual private cloud (VPC). Choose the elastic network interface that is required to connect to the data store that's used in the script.

6. Provide additional configuration, including parameters, specific to your job type. For more information about configuration for your job type, see the [Building visual ETL jobs](#) section.
7. On the **Script** tab, paste or write your custom script.

Use the content in this section to guide the process of writing your custom script.

For more information about adding jobs in Amazon Glue, see [Building visual ETL jobs](#).

For step-by-step guidance, see the **Add job** tutorial in the Amazon Glue console.

Programming Spark scripts

Amazon Glue makes it easy to write or autogenerate extract, transform, and load (ETL) scripts, in addition to testing and running them. This section describes the extensions to Apache Spark that Amazon Glue has introduced, and provides examples of how to code and run ETL scripts in Python and Scala.

Important

Different versions of Amazon Glue support different versions of Apache Spark. Your custom script must be compatible with the supported Apache Spark version. For information about Amazon Glue versions, see the [Glue version job property](#).

Topics

- [Tutorial: Writing an Amazon Glue for Spark script](#)
- [Program Amazon Glue ETL scripts in PySpark](#)
- [Programming Amazon Glue ETL scripts in Scala](#)
- [Features and optimizations for programming Amazon Glue for Spark ETL scripts](#)

Tutorial: Writing an Amazon Glue for Spark script

This tutorial introduces you to the process of writing Amazon Glue scripts. You can run scripts on a schedule with jobs, or interactively with interactive sessions. For more information about jobs, see [Building visual ETL jobs](#). For more information about interactive sessions, see [the section called "Overview of Amazon Glue interactive sessions"](#).

The Amazon Glue Studio visual editor offers a graphical, no-code interface for building Amazon Glue jobs. Amazon Glue scripts back visual jobs. They give you access to the expanded set of tools available to work with Apache Spark programs. You can access native Spark APIs, as well as Amazon Glue libraries that facilitate extract, transform, and load (ETL) workflows from within an Amazon Glue script.

In this tutorial, you extract, transform, and load a dataset of parking tickets. The script that does this work is identical in form and function to the one generated in [Making ETL easier with Amazon Glue Studio](#) on the Amazon Big Data Blog, which introduces the Amazon Glue Studio visual editor. By running this script in a job, you can compare it to visual jobs and see how Amazon Glue ETL scripts work. This prepares you to use additional functionalities that aren't yet available in visual jobs.

You use the Python language and libraries in this tutorial. Similar functionality is available in Scala. After going through this tutorial, you should be able to generate and inspect a sample Scala script to understand how to perform the Scala Amazon Glue ETL script writing process.

Prerequisites

This tutorial has the following prerequisites:

- The same prerequisites as the Amazon Glue Studio blog post, which instructs you to run a Amazon CloudFormation template.

This template uses the Amazon Glue Data Catalog to manage the parking ticket dataset available in `s3://aws-bigdata-blog/artifacts/gluestudio/`. It creates the following resources which will be referenced:

- **Amazon Glue StudioRole** – IAM role to run Amazon Gluejobs
- **Amazon Glue StudioAmazon S3Bucket** – Name of the Amazon S3 bucket to store blog-related files
- **Amazon Glue StudioTicketsYYZDB** – Amazon Glue Data Catalog database
- **Amazon Glue StudioTableTickets** – Data Catalog table to use as a source
- **Amazon Glue StudioTableTrials** – Data Catalog table to use as a source
- **Amazon Glue StudioParkingTicketCount** – Data Catalog table to use as the destination
- The script generated in the Amazon Glue Studio blog post. If the blog post changes, the script is also available in the following text.

Generate a sample script

You can use the Amazon Glue Studio visual editor as a powerful code generation tool to create a scaffold for the script you want to write. You will use this tool to create a sample script.

If you want to skip these steps, the script is provided.

Tutorial sample script

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args["JOB_NAME"], args)

# Script generated for node S3 bucket
S3bucket_node1 = glueContext.create_dynamic_frame.from_catalog(
    database="yyz-tickets", table_name="tickets", transformation_ctx="S3bucket_node1"
)

# Script generated for node ApplyMapping
ApplyMapping_node2 = ApplyMapping.apply(
    frame=S3bucket_node1,
    mappings=[
        ("tag_number_masked", "string", "tag_number_masked", "string"),
        ("date_of_infraction", "string", "date_of_infraction", "string"),
        ("ticket_date", "string", "ticket_date", "string"),
        ("ticket_number", "decimal", "ticket_number", "float"),
        ("officer", "decimal", "officer_name", "decimal"),
        ("infraction_code", "decimal", "infraction_code", "decimal"),
        ("infraction_description", "string", "infraction_description", "string"),
        ("set_fine_amount", "decimal", "set_fine_amount", "float"),
        ("time_of_infraction", "decimal", "time_of_infraction", "decimal"),
    ],
    transformation_ctx="ApplyMapping_node2",
)

# Script generated for node S3 bucket
S3bucket_node3 = glueContext.write_dynamic_frame.from_options(
    frame=ApplyMapping_node2,
    connection_type="s3",
    format="glueparquet",
    connection_options={"path": "s3://DOC-EXAMPLE-BUCKET", "partitionKeys": []},
```

```

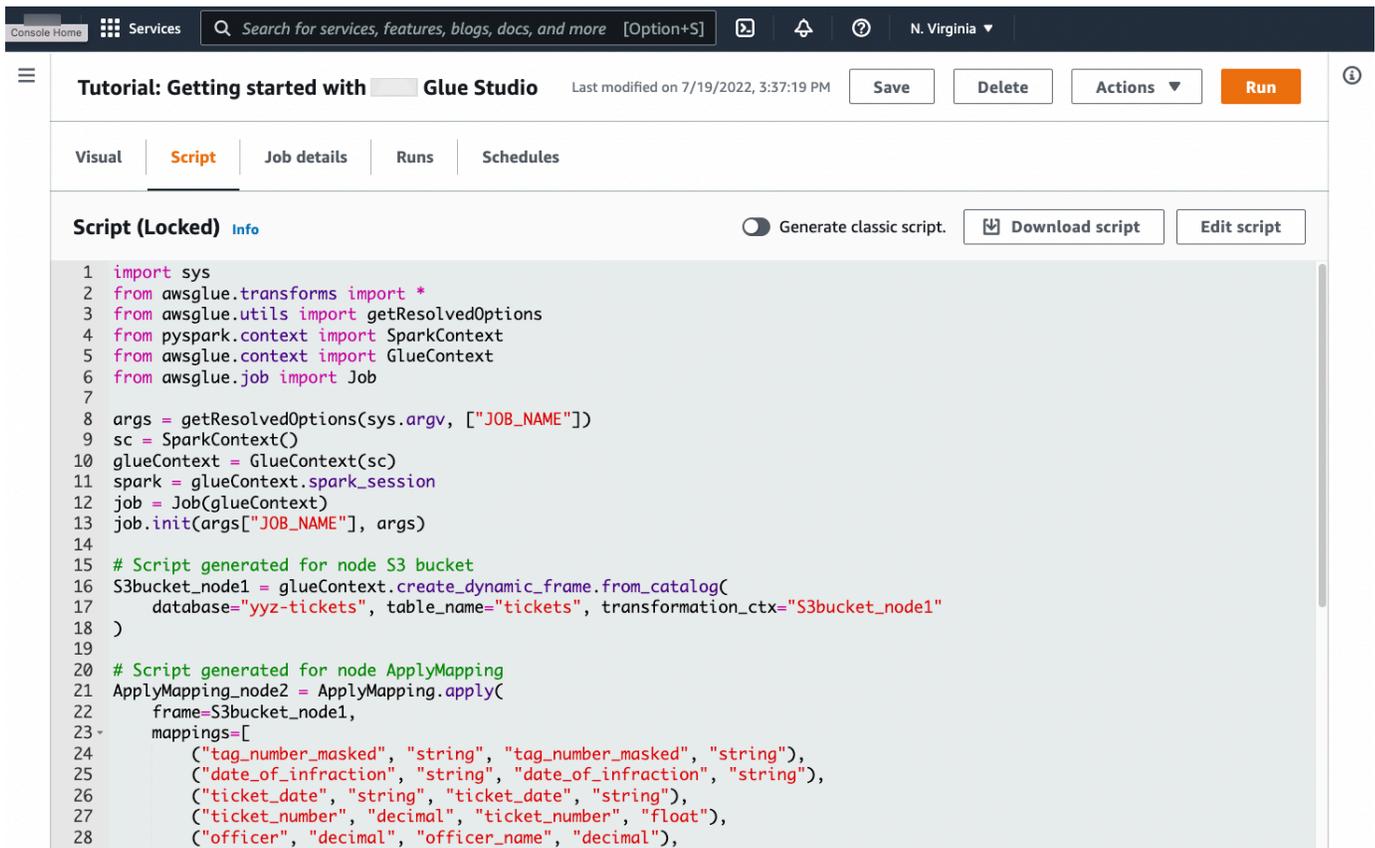

format_options={"compression": "gzip"},
transformation_ctx="S3bucket_node3",
)

job.commit()

```

To generate a sample script

1. Complete the Amazon Glue Studio tutorial. To complete this tutorial, see [Creating a job in Amazon Glue Studio from an example job](#).
2. Navigate to the **Script** tab on the job page, as shown in the following screenshot:

3. Copy the complete contents of the **Script** tab. By setting the script language in **Job details**, you can switch back and forth between generating Python or Scala code.

Step 1. Create a job and paste your script

In this step, you create an Amazon Glue job in the Amazon Web Services Management Console. This sets up a configuration that allows Amazon Glue to run your script. It also creates a place for you to store and edit your script.

To create a job

1. In the Amazon Web Services Management Console, navigate to the Amazon Glue landing page.
2. In the side navigation pane, choose **Jobs**.
3. Choose **Spark script editor** in **Create job**, and then choose **Create**.
4. **Optional** - Paste the full text of your script into the **Script** pane. Alternatively, you can follow along with the tutorial.

Step 2. Import Amazon Glue libraries

You need to set your script up to interact with code and configuration that are defined outside of the script. This work is done behind the scenes in Amazon Glue Studio.

In this step, you perform the following actions.

- Import and initialize a `GlueContext` object. This is the most important import, from the script writing perspective. This exposes standard methods for defining source and target datasets, which is the starting point for any ETL script. To learn more about the `GlueContext` class, see [GlueContext class](#).
- Initialize a `SparkContext` and `SparkSession`. These allow you to configure the Spark engine available inside the Amazon Glue job. You won't need to use them directly within introductory Amazon Glue scripts.
- Call `getResolvedOptions` to prepare your job arguments for use within the script. For more information about resolving job parameters, see [the section called "getResolvedOptions"](#).
- Initialize a `Job`. The `Job` object sets configuration and tracks the state of various optional Amazon Glue features. Your script can run without a `Job` object, but the best practice is to initialize it so that you don't encounter confusion if those features are later integrated.

One of these features is job bookmarks, which you can optionally configure in this tutorial. You can learn about job bookmarks in the following section, [the section called "Optional - Enable job bookmarks"](#).

In this procedure, you write the following code. This code is a portion of the generated sample script.

```
from awsglue.transforms import *
```

```
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args["JOB_NAME"], args)
```

To import Amazon Glue libraries

- Copy this section of code and paste it into the **Script** editor.

Note

You might consider copying code to be a bad engineering practice. In this tutorial, we suggest this to encourage you to consistently name your core variables across all Amazon Glue ETL scripts.

Step 3. Extract data from a source

In any ETL process, you first need to define a source dataset that you want to change. In the Amazon Glue Studio visual editor, you provide this information by creating a **Source** node.

In this step, you provide the `create_dynamic_frame.from_catalog` method a database and `table_name` to extract data from a source configured in the Amazon Glue Data Catalog.

In the previous step, you initialized a `GlueContext` object. You use this object to find methods that are used to configure sources, such as `create_dynamic_frame.from_catalog`.

In this procedure, you write the following code using `create_dynamic_frame.from_catalog`. This code is a portion of the generated sample script.

```
S3bucket_node1 = glueContext.create_dynamic_frame.from_catalog(
    database="yyz-tickets", table_name="tickets", transformation_ctx="S3bucket_node1"
)
```

To extract data from a source

1. Examine the documentation to find a method on `GlueContext` to extract data from a source defined in the Amazon Glue Data Catalog. These methods are documented in [the section called "GlueContext"](#). Choose the [create_dynamic_frame_from_catalog](#) method. Call this method on `glueContext`.
2. Examine the documentation for `create_dynamic_frame_from_catalog`. This method requires `database` and `table_name` parameters. Provide the necessary parameters to `create_dynamic_frame_from_catalog`.

The Amazon Glue Data Catalog stores information about the location and format of your source data, and was set up in the prerequisite section. You don't have to directly provide your script with that information.

3. **Optional** – Provide the `transformation_ctx` parameter to the method in order to support job bookmarks. You can learn about job bookmarks in the following section, [the section called "Optional - Enable job bookmarks"](#).

Note

Common methods for extracting data

[the section called "create_dynamic_frame_from_catalog"](#) is used to connect to tables in the Amazon Glue Data Catalog.

If you need to directly provide your job with configuration that describes the structure and location of your source, see the [the section called "create_dynamic_frame_from_options"](#) method. You will need to provide more detailed parameters describing your data than when using `create_dynamic_frame_from_catalog`.

Refer to the supplemental documentation about `format_options` and `connection_parameters` to identify your required parameters. For an explanation of how to provide your script information about your source data format, see [the section called "Data format options"](#). For an explanation of how to provide your script information about your source data location, see [the section called "Connection parameters"](#).

If you're reading information from a streaming source, you provide your job with source information through the [the section called "create_data_frame_from_catalog"](#) or [the section called "create_data_frame_from_options"](#) methods. Note that these methods return Apache Spark `DataFrames`.

Our generated code calls `create_dynamic_frame.from_catalog` while the reference documentation refers to `create_dynamic_frame_from_catalog`. These methods ultimately call the same code, and are included so you can write cleaner code. You can verify this by viewing the source for our Python wrapper, available at [aws-glue-libs](https://github.com/aws-glue-libs).

Step 4. Transform data with Amazon Glue

After extracting source data in an ETL process, you need to describe how you want to change your data. You provide this information by creating a **Transform** node in the Amazon Glue Studio visual editor.

In this step, you provide the `ApplyMapping` method with a map of current and desired field names and types to transform your `DynamicFrame`.

You perform the following transformations.

- Drop the four `location` and `province` keys.
- Change the name of `officer` to `officer_name`.
- Change the type of `ticket_number` and `set_fine_amount` to `float`.

`create_dynamic_frame.from_catalog` provides you with a `DynamicFrame` object. A `DynamicFrame` represents a dataset in Amazon Glue. Amazon Glue transforms are operations that change `DynamicFrames`.

Note

What is a `DynamicFrame`?

A `DynamicFrame` is an abstraction that allows you to connect a dataset with a description of the names and types of entries in the data. In Apache Spark, a similar abstraction exists called a `DataFrame`. For an explanation of `DataFrames`, see [Spark SQL Guide](#).

With `DynamicFrames`, you can describe dataset schemas dynamically. Consider a dataset with a `price` column, where some entries store price as a string, and others store price as a double. Amazon Glue computes a schema on-the-fly—it creates a self-describing record for each row.

Inconsistent fields (like `price`) are explicitly represented with a type (`ChoiceType`) in the schema for the frame. You can address your inconsistent fields by dropping them with `DropFields` or resolving them with `ResolveChoice`. These are transforms that are

available on the `DynamicFrame`. You can then write your data back to your data lake with `writeDynamicFrame`.

You can call many of the same transforms from methods on the `DynamicFrame` class, which can lead to more readable scripts. For more information about `DynamicFrame`, see [the section called “DynamicFrame”](#).

In this procedure, you write the following code using `ApplyMapping`. This code is a portion of the generated sample script.

```
ApplyMapping_node2 = ApplyMapping.apply(  
    frame=S3bucket_node1,  
    mappings=[  
        ("tag_number_masked", "string", "tag_number_masked", "string"),  
        ("date_of_infraction", "string", "date_of_infraction", "string"),  
        ("ticket_date", "string", "ticket_date", "string"),  
        ("ticket_number", "decimal", "ticket_number", "float"),  
        ("officer", "decimal", "officer_name", "decimal"),  
        ("infraction_code", "decimal", "infraction_code", "decimal"),  
        ("infraction_description", "string", "infraction_description", "string"),  
        ("set_fine_amount", "decimal", "set_fine_amount", "float"),  
        ("time_of_infraction", "decimal", "time_of_infraction", "decimal"),  
    ],  
    transformation_ctx="ApplyMapping_node2",  
)
```

To transform data with Amazon Glue

1. Examine the documentation to identify a transform to change and drop fields. For details, see [the section called “GlueTransform”](#). Choose the `ApplyMapping` transform. For more information about `ApplyMapping`, see [the section called “ApplyMapping”](#). Call `apply` on the `ApplyMapping` transform object.

Note

What is `ApplyMapping`?

`ApplyMapping` takes a `DynamicFrame` and transforms it. It takes a list of tuples that represent transformations on fields—a “mapping”. The first two tuple elements, a field name and type, are used to identify a field in the frame. The second two parameters are also a field name and type.

ApplyMapping converts the source field to the target name and type in a new DynamicFrame, which it returns. Fields that aren't provided are dropped in the return value.

Rather than calling `apply`, you can call the same transform with the `apply_mapping` method on the DynamicFrame to create more fluent, readable code. For more information, see [the section called "apply_mapping"](#).

2. Examine the documentation for ApplyMapping to identify required parameters. See [the section called "ApplyMapping"](#). You will find that this method requires `frame` and `mappings` parameters. Provide the necessary parameters to ApplyMapping.
3. **Optional** – Provide `transformation_ctx` to the method to support job bookmarks. You can learn about job bookmarks in the following section, [the section called "Optional - Enable job bookmarks"](#).

Note

Apache Spark functionality

We provide transforms to streamline ETL workflows within your job. You also have access to the libraries that are available in a Spark program in your job, built for more general purposes. In order to use them, you convert between DynamicFrame and DataFrame. You can create a DataFrame with [the section called "toDF"](#). Then, you can use methods available on the DataFrame to transform your dataset. For more information on these methods, see [DataFrame](#). You can then convert backwards with [the section called "fromDF"](#) to use Amazon Glue operations for loading your frame to a target.

Step 5. Load data into a target

After you transform your data, you typically store the transformed data in a different place from the source. You perform this operation by creating a **target** node in the Amazon Glue Studio visual editor.

In this step, you provide the `write_dynamic_frame.from_options` method a `connection_type`, `connection_options`, `format`, and `format_options` to load data into a target bucket in Amazon S3.

In Step 1, you initialized a `GlueContext` object. In Amazon Glue, this is where you will find methods that are used to configure targets, much like sources.

In this procedure, you write the following code using `write_dynamic_frame.from_options`. This code is a portion of the generated sample script.

```
S3bucket_node3 = glueContext.write_dynamic_frame.from_options(  
    frame=ApplyMapping_node2,  
    connection_type="s3",  
    format="glueparquet",  
    connection_options={"path": "s3://amzn-s3-demo-bucket", "partitionKeys": []},  
    format_options={"compression": "gzip"},  
    transformation_ctx="S3bucket_node3",  
)
```

To load data into a target

1. Examine the documentation to find a method to load data into a target Amazon S3 bucket. These methods are documented in [the section called “GlueContext”](#). Choose the [the section called “write_dynamic_frame_from_options”](#) method. Call this method on `glueContext`.

Note

Common methods for loading data

`write_dynamic_frame.from_options` is the most common method used to load data. It supports all targets that are available in Amazon Glue.

If you're writing to a JDBC target defined in an Amazon Glue connection, use the [the section called “write_dynamic_frame_from_jdbc_conf”](#) method. Amazon Glue connections store information about how to connect to a data source. This removes the need to provide that information in `connection_options`. However, you still need to use `connection_options` to provide `dbtable`.

`write_dynamic_frame.from_catalog` is not a common method for loading data. This method updates the Amazon Glue Data Catalog without updating the underlying dataset, and is used in combination with other processes that change the underlying dataset. For more information, see [the section called “Updating the schema and adding new partitions”](#).

2. Examine the documentation for [the section called “write_dynamic_frame_from_options”](#). This method requires `frame`, `connection_type`, `format`, `connection_options`, and `format_options`. Call this method on `glueContext`.
 - a. Refer to the supplemental documentation about `format_options` and `format` to identify the parameters you need. For an explanation of data formats, see [the section called “Data format options”](#).
 - b. Refer to the supplemental documentation about `connection_type` and `connection_options` to identify the parameters you need. For an explanation of connections, see [the section called “Connection parameters”](#).
 - c. Provide the necessary parameters to `write_dynamic_frame.from_options`. This method has a similar configuration to `create_dynamic_frame.from_options`.
3. **Optional** – Provide `transformation_ctx` to `write_dynamic_frame.from_options` to support job bookmarks. You can learn about job bookmarks in the following section, [the section called “Optional - Enable job bookmarks”](#).

Step 6. Commit the Job object

You initialized a Job object in Step 1. You may need to manually conclude its lifecycle at the end of your script if certain optional features need this to function properly, such as when using Job Bookmarks. This work is done behind the scenes in Amazon Glue Studio.

In this step, call the `commit` method on the Job object.

In this procedure, you write the following code. This code is a portion of the generated sample script.

```
job.commit()
```

To commit the Job object

1. If you have not yet done this, perform the optional steps outlined in previous sections to include `transformation_ctx`.
2. Call `commit`.

Optional - Enable job bookmarks

In every prior step, you have been instructed to set `transformation_ctx` parameters. This is related to a feature called job bookmarks.

With job bookmarks, you can save time and money with jobs that run on a recurring basis, against datasets where previous work can easily be tracked. Job bookmarks track the progress of an Amazon Glue transform across a dataset from previous runs. By tracking where previous runs ended, Amazon Glue can limit its work to rows it hasn't processed before. For more information about job bookmarks, see [the section called "Tracking processed data using job bookmarks"](#).

To enable job bookmarks, first add the `transformation_ctx` statements into our provided functions, as described in the previous examples. Job bookmark state is persisted across runs. `transformation_ctx` parameters are keys used to access that state. On their own, these statements will do nothing. You also need to activate the feature in the configuration for your job.

In this procedure, you enable job bookmarks using the Amazon Web Services Management Console.

To enable job bookmarks

1. Navigate to the **Job details** section of your corresponding job.
2. Set **Job bookmark** to **Enable**.

Step 7. Run your code as a job

In this step, you run your job to verify that you successfully completed this tutorial. This is done with the click of a button, as in the Amazon Glue Studio visual editor.

To run your code as a job

1. Choose **Untitled job** on the title bar to edit and set your job name.
2. Navigate to the **Job details** tab. Assign your job an **IAM Role**. You can use the one created by the Amazon CloudFormation template in the prerequisites for the Amazon Glue Studio tutorial. If you have completed that tutorial, it should be available as `AWS Glue StudioRole`.
3. Choose **Save** to save your script.
4. Choose **Run** to run your job.
5. Navigate to the **Runs** tab to verify that your job completes.

6. Navigate to *amzn-s3-demo-bucket*, the target for `write_dynamic_frame.from_options`. Confirm that the output matches your expectations.

For more information about configuring and managing jobs, see [the section called “Providing your own custom scripts”](#).

More information

Apache Spark libraries and methods are available in Amazon Glue scripts. You can look at the Spark documentation to understand what you can do with those included libraries. For more information, see the [examples section of the Spark source repository](#).

Amazon Glue 2.0+ includes several common Python libraries by default. There are also mechanisms for loading your own dependencies into an Amazon Glue job in a Scala or Python environment. For information about Python dependencies, see [the section called “Python libraries”](#).

For more examples of how to use Amazon Glue features in Python, see [the section called “Python samples”](#). Scala and Python jobs have feature parity, so our Python examples should give you some thoughts about how to perform similar work in Scala.

Program Amazon Glue ETL scripts in PySpark

You can find Python code examples and utilities for Amazon Glue in the [Amazon Glue samples repository](#) on the GitHub website.

Using Python with Amazon Glue

Amazon Glue supports an extension of the PySpark Python dialect for scripting extract, transform, and load (ETL) jobs. This section describes how to use Python in ETL scripts and with the Amazon Glue API.

- [Setting up to use Python with Amazon Glue](#)
- [Calling Amazon Glue APIs in Python](#)
- [Using Python libraries with Amazon Glue](#)
- [Amazon Glue Python code samples](#)

Amazon Glue PySpark extensions

Amazon Glue has created the following extensions to the PySpark Python dialect.

- [Accessing parameters using getResolvedOptions](#)
- [PySpark extension types](#)
- [DynamicFrame class](#)
- [DynamicFrameCollection class](#)
- [DynamicFrameWriter class](#)
- [DynamicFrameReader class](#)
- [GlueContext class](#)

Amazon Glue PySpark transforms

Amazon Glue has created the following transform Classes to use in PySpark ETL operations.

- [GlueTransform base class](#)
- [ApplyMapping class](#)
- [DropFields class](#)
- [DropNullFields class](#)
- [ErrorsAsDynamicFrame class](#)
- [FillMissingValues class](#)
- [Filter class](#)
- [FindIncrementalMatches class](#)
- [FindMatches class](#)
- [FlatMap class](#)
- [Join class](#)
- [Map class](#)
- [MapToCollection class](#)
- [mergeDynamicFrame](#)
- [Relationalize class](#)
- [RenameField class](#)

- [ResolveChoice class](#)
- [SelectFields class](#)
- [SelectFromCollection class](#)
- [Spigot class](#)
- [SplitFields class](#)
- [SplitRows class](#)
- [Unbox class](#)
- [UnnestFrame class](#)

Setting up to use Python with Amazon Glue

Use Python to develop your ETL scripts for Spark jobs. The supported Python versions for ETL jobs depend on the Amazon Glue version of the job. For more information on Amazon Glue versions, see the [Glue version job property](#).

To set up your system for using Python with Amazon Glue

Follow these steps to install Python and to be able to invoke the Amazon Glue APIs.

1. If you don't already have Python installed, download and install it from the [Python.org download page](#).
2. Install the Amazon Command Line Interface (Amazon CLI) as documented in the [Amazon CLI documentation](#).

The Amazon CLI is not directly necessary for using Python. However, installing and configuring it is a convenient way to set up Amazon with your account credentials and verify that they work.

3. Install the Amazon SDK for Python (Boto 3), as documented in the [Boto3 Quickstart](#).

Boto 3 resource APIs are not yet available for Amazon Glue. Currently, only the Boto 3 client APIs can be used.

For more information about Boto 3, see [Amazon SDK for Python \(Boto3\) Getting Started](#).

You can find Python code examples and utilities for Amazon Glue in the [Amazon Glue samples repository](#) on the GitHub website.

Calling Amazon Glue APIs in Python

Note that Boto 3 resource APIs are not yet available for Amazon Glue. Currently, only the Boto 3 client APIs can be used.

Amazon Glue API names in Python

Amazon Glue API names in Java and other programming languages are generally CamelCased. However, when called from Python, these generic names are changed to lowercase, with the parts of the name separated by underscore characters to make them more "Pythonic". In the [Amazon Glue API](#) reference documentation, these Pythonic names are listed in parentheses after the generic CamelCased names.

However, although the Amazon Glue API names themselves are transformed to lowercase, their parameter names remain capitalized. It is important to remember this, because parameters should be passed by name when calling Amazon Glue APIs, as described in the following section.

Passing and accessing Python parameters in Amazon Glue

In Python calls to Amazon Glue APIs, it's best to pass parameters explicitly by name. For example:

```
job = glue.create_job(Name='sample', Role='Glue_DefaultRole',
                    Command={'Name': 'glueetl',
                              'ScriptLocation': 's3://my_script_bucket/scripts/
my_etl_script.py'})
```

It is helpful to understand that Python creates a dictionary of the name/value tuples that you specify as arguments to an ETL script in a [Job structure](#) or [JobRun structure](#). Boto 3 then passes them to Amazon Glue in JSON format by way of a REST API call. This means that you cannot rely on the order of the arguments when you access them in your script.

For example, suppose that you're starting a JobRun in a Python Lambda handler function, and you want to specify several parameters. Your code might look something like the following:

```
from datetime import datetime, timedelta

client = boto3.client('glue')

def lambda_handler(event, context):
    last_hour_date_time = datetime.now() - timedelta(hours = 1)
    day_partition_value = last_hour_date_time.strftime("%Y-%m-%d")
    hour_partition_value = last_hour_date_time.strftime("%-H")
```

```

response = client.start_job_run(
    JobName = 'my_test_job',
    Arguments = {
        '--day_partition_key': 'partition_0',
        '--hour_partition_key': 'partition_1',
        '--day_partition_value': day_partition_value,
        '--hour_partition_value': hour_partition_value } )

```

To access these parameters reliably in your ETL script, specify them by name using Amazon Glue's `getResolvedOptions` function and then access them from the resulting dictionary:

```

import sys
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv,
                          ['JOB_NAME',
                           'day_partition_key',
                           'hour_partition_key',
                           'day_partition_value',
                           'hour_partition_value'])
print "The day partition key is: ", args['day_partition_key']
print "and the day partition value is: ", args['day_partition_value']

```

If you want to pass an argument that is a nested JSON string, to preserve the parameter value as it gets passed to your Amazon Glue ETL job, you must encode the parameter string before starting the job run, and then decode the parameter string before referencing it your job script. For example, consider the following argument string:

```

glue_client.start_job_run(JobName = "gluejobname", Arguments={
"--my_curly_braces_string": '{"a": {"b": {"c": [{"d": {"e": 42}}]}}'})
})

```

To pass this parameter correctly, you should encode the argument as a Base64 encoded string.

```

import base64
...
sample_string='{"a": {"b": {"c": [{"d": {"e": 42}}]}}'
sample_string_bytes = sample_string.encode("ascii")

base64_bytes = base64.b64encode(sample_string_bytes)

```

```
base64_string = base64_bytes.decode("ascii")
...
glue_client.start_job_run(JobName = "gluejobname", Arguments={
"--my_curly_braces_string": base64_bytes})
...
sample_string_bytes = base64.b64decode(base64_bytes)
sample_string = sample_string_bytes.decode("ascii")
print(f"Decoded string: {sample_string}")
...
```

Example: Create and run a job

The following example shows how call the Amazon Glue APIs using Python, to create and run an ETL job.

To create and run a job

1. Create an instance of the Amazon Glue client:

```
import boto3
glue = boto3.client(service_name='glue', region_name='us-east-1',
                    endpoint_url='https://glue.us-east-1.amazonaws.com')
```

2. Create a job. You must use `glueetl` as the name for the ETL command, as shown in the following code:

```
myJob = glue.create_job(Name='sample', Role='Glue_DefaultRole',
                        Command={'Name': 'glueetl',
                                'ScriptLocation': 's3://my_script_bucket/
scripts/my_etl_script.py'})
```

3. Start a new run of the job that you created in the previous step:

```
myNewJobRun = glue.start_job_run(JobName=myJob['Name'])
```

4. Get the job status:

```
status = glue.get_job_run(JobName=myJob['Name'], RunId=myNewJobRun['JobRunId'])
```

5. Print the current state of the job run:

```
print(status['JobRun']['JobRunState'])
```

Using Python libraries with Amazon Glue

You can install additional Python modules and libraries for use with Amazon Glue ETL. For Amazon Glue 2.0 and above, Amazon Glue uses the Python Package Installer (pip3) to install additional modules used by Amazon Glue ETL. Amazon Glue provides multiple options to bring the additional Python modules to your Amazon Glue job environment. You can use the `--additional-python-modules` parameter to bring in new modules using zip files containing bundled Python wheels (also known as "zip of wheels", available for Amazon Glue 5.0 and above), individual Python wheel files, requirements files (requirements.txt, available for Amazon Glue 5.0 and above), or a list of comma-separated Python modules. It could also be used to change the version of the python modules provided in the Amazon Glue environment (see [Python modules already provided in Amazon Glue](#) for more details).

Topics

- [Proactively analyze Python dependencies](#)
- [Python modules already provided in Amazon Glue](#)
- [Appendix A: Creating a Zip of Wheels Artifact](#)
- [Appendix B: Amazon Glue environment details](#)

Installing additional Python modules with pip in Amazon Glue 2.0 or later

Amazon Glue uses the Python Package Installer (pip3) to install additional modules to be used by Amazon Glue ETL. You can use the `--additional-python-modules` parameter with a list of comma-separated Python modules to add a new module or change the version of an existing module. You can install built wheel artifacts either through a zip of wheels or a standalone wheel artifact by uploading the file to Amazon S3, then including the path to the Amazon S3 object in your list of modules. For more information about setting job parameters, see [Using job parameters in Amazon Glue jobs](#).

You can pass additional options to pip3 with the `--python-modules-installer-option` parameter. For example, you could pass `--only-binary` to force pip to install only pre-built artifacts for the packages specified by `--additional-python-modules`. For more examples, see [Building Python modules from a wheel for Spark ETL workloads using Amazon Glue 2.0](#).

Best Practices for Python Dependency Management

For production workloads, Amazon Glue recommend packaging all your Python dependencies as wheel files in a single zip artifact. This approach provides:

- **Deterministic execution:** Exact control over which package versions are installed
- **Reliability:** No dependency on external package repositories during job execution
- **Performance:** Single download operation instead of multiple network calls
- **Offline installation:** Works in private VPC environments without internet access

Important Considerations

Under the [Amazon shared responsibility model](#), you are responsible for managing additional Python modules, libraries, and their dependencies. This includes:

- **Security updates:** Regularly updating packages to address security vulnerabilities
- **Version compatibility:** Ensuring packages are compatible with your Amazon Glue version
- **Testing:** Validating that your packaged dependencies work correctly in the Glue environment

If you have minimal dependencies, you may consider using individual wheel files instead.

(Recommended) Installing additional Python libraries in Amazon Glue 5.0 or above using Zip of Wheels

Amazon Glue 5.0 and above supports packaging multiple wheel files into a single zip artifact containing bundled Python wheels for more reliable and deterministic dependency management. To use this approach, create a zip file containing all your wheel dependencies and their transitive dependencies with the `.gluewheels.zip` suffix, upload it to Amazon S3, and reference it using the `--additional-python-modules` parameter. Be sure to add `--no-index` to the `--python-modules-installer-option` job parameter. With this configuration, the zip of wheels file essentially acts as a local index for pip to resolve dependencies from at runtime. This eliminates dependencies on external package repositories like PyPI during job execution, providing greater stability and consistency for production workloads. For example:

```
--additional-python-modules s3://amzn-s3-demo-bucket/path/to/zip-of-  
wheels-1.0.0.gluewheels.zip  
--python-modules-installer-option --no-index
```

For Instructions on how to create a zip of wheels file, see [Appendix A: Creating a Zip of Wheels Artifact](#).

Installing additional Python libraries using Wheel

Amazon Glue supports installing custom Python packages using wheel (.whl) files stored in Amazon S3. To include wheel files in your Amazon Glue jobs, provide a comma-separated list of your wheel files stored in s3 to the `--additional-python-modules` job parameter. For example:

```
--additional-python-modules s3://amzn-s3-demo-bucket/path/to/package-1.0.0-py3-none-  
any.whl,s3://your-bucket/path/to/another-package-2.1.0-cp311-cp311-linux_x86_64.whl
```

This approach also supports when you need custom distributions, or packages with native dependencies that are pre-compiled for the correct operating system. For more examples, see [Building Python modules from a wheel for Spark ETL workloads using Amazon Glue 2.0](#).

Installing additional Python libraries in Amazon Glue 5.0 or above using requirements.txt

In Amazon Glue 5.0+, you can provide the defacto-standard `requirements.txt` to manage Python library dependencies. To do that, provide following two job parameters:

- Key: `--python-modules-installer-option`

Value: `-r`

- Key: `--additional-python-modules`

Value: `s3://path_to_requirements.txt`

Amazon Glue 5.0 nodes initially load python libraries specified in `requirements.txt`.

Here's a sample `requirements.txt`:

```
awsrangler==3.9.1  
elasticsearch==8.15.1
```

```
PyAthena==3.9.0
PyMySQL==1.1.1
PyYAML==6.0.2
pyodbc==5.2.0
pyorc==0.9.0
redshift-connector==2.1.3
scipy==1.14.1
scikit-learn==1.5.2
SQLAlchemy==2.0.36
```

Important

Use this option with caution, especially in production workloads. Pulling dependencies from PyPI at runtime is highly risky because you cannot be sure what artifact pip resolves to. Using unpinned library versions is especially risky since it pulls latest version of the python modules, which can introduce breaking changes or bring in incompatible python module. This could result in job failure due to python installation failure in Amazon Glue job environment. While pinning library version increases stability, pip resolution is still not fully deterministic, so similar issues can arise. As a best practice, Amazon Glue recommends using frozen artifacts such as zip of wheels or individual wheel files (see [the section called “\(Recommended\) Installing additional Python libraries in Amazon Glue 5.0 or above using Zip of Wheels”](#) for more details).

Important

If you do not pin the versions of your transitive dependencies, a primary dependency may pull incompatible transitive dependency versions. As a best practice, all library versions should be pinned for increased consistency in Amazon Glue jobs. Even better, Amazon Glue recommends packaging your dependencies into a zip of wheels file to ensure maximum consistency and reliability for your production workloads.

Installing additional Python libraries directly configuring as comma separated list

To update or to add a new Python module Amazon Glue allows passing `--additional-python-modules` parameter with a list of comma-separated Python modules as values. For example to update/ add scikit-learn module use the following key/value: `--additional-python-`

modules", "scikit-learn==0.21.3". You have two options to directly configure the python modules.

- **Pinned Python Module**

```
--additional-python-modules", "scikit-learn==0.21.3,ephem==4.1.6"
```

- **Unpinned Python Module: (Not recommended for Production Workloads)**

```
--additional-python-modules", "scikit-learn>=0.20.0,ephem>=4.0.0"
```

OR

```
--additional-python-modules", "scikit-learn,ephem"
```

Important

Use this option with caution, especially in production workloads. Pulling dependencies from PyPI at runtime is highly risky because you cannot be sure what artifact pip resolves to. Using unpinned library versions is especially risky since it pulls latest version of the python modules, which can introduce breaking changes or bring in incompatible python module. This could result in job failure due to python installation failure in Amazon Glue job environment. While pinning library version increases stability, pip resolution is still not fully deterministic, so similar issues can arise. As a best practice, Amazon Glue recommends using frozen artifacts such as zip of wheels or individual wheel files (see [the section called “\(Recommended\) Installing additional Python libraries in Amazon Glue 5.0 or above using Zip of Wheels”](#) for more details).

Important

If you do not pin the versions of your transitive dependencies, a primary dependency may pull incompatible transitive dependency versions. As a best practice, all library versions should be pinned for increased consistency in Amazon Glue jobs. Even better, Amazon Glue recommends packaging your dependencies into a zip of wheels file to ensure maximum consistency and reliability for your production workloads.

Including Python files with PySpark native features

Amazon Glue uses PySpark to include Python files in Amazon Glue ETL jobs. You will want to use `--additional-python-modules` to manage your dependencies when available. You can use the `--extra-py-files` job parameter to include Python files. Dependencies must be hosted in Amazon S3 and the argument value should be a comma delimited list of Amazon S3 paths with no spaces. This functionality behaves like the Python dependency management you would use with Spark. For more information on Python dependency management in Spark, see [Using PySpark Native Features](#) page in Apache Spark documentation. `--extra-py-files` is useful in cases where your additional code is not packaged, or when you are migrating a Spark program with an existing toolchain for managing dependencies. For your dependency tooling to be maintainable, you will have to bundle your dependencies before submitting.

Programming scripts that use visual transforms

When you create a Amazon Glue job using the Amazon Glue Studio visual interface, you can transform your data with managed data transform nodes and custom visual transforms. For more information about managed data transform nodes, see [the section called "Transform data with Amazon Glue managed transforms"](#). For more information about custom visual transforms, see [the section called " Transform data with custom visual transforms "](#). Scripts using visual transforms can only be generated when your job **Language** is set to use Python.

When generating a Amazon Glue job using visual transforms, Amazon Glue Studio will include these transforms in the runtime environment using the `--extra-py-files` parameter in the job configuration. For more information about job parameters, see [the section called "Job parameters"](#). When making changes to a generated script or runtime environment, you will need to preserve this job configuration for your script to run successfully.

Ziping libraries for inclusion

Unless a library is contained in a single `.py` file, it should be packaged in a `.zip` archive. The package directory should be at the root of the archive, and must contain an `__init__.py` file for the package. Python will then be able to import the package in the normal way.

If your library only consists of a single Python module in one `.py` file, you do not need to place it in a `.zip` file.

Loading Python libraries in Amazon Glue Studio notebooks

To specify Python libraries in Amazon Glue Studio notebooks, see [Installing additional Python modules](#).

Loading Python libraries in a development endpoint in Amazon Glue 0.9/1.0

If you are using different library sets for different ETL scripts, you can either set up a separate development endpoint for each set, or you can overwrite the library .zip file(s) that your development endpoint loads every time you switch scripts.

You can use the console to specify one or more library .zip files for a development endpoint when you create it. After assigning a name and an IAM role, choose **Script Libraries and job parameters (optional)** and enter the full Amazon S3 path to your library .zip file in the **Python library path** box. For example:

```
s3://bucket/prefix/site-packages.zip
```

If you want, you can specify multiple full paths to files, separating them with commas but no spaces, like this:

```
s3://bucket/prefix/lib_A.zip,s3://bucket_B/prefix/lib_X.zip
```

If you update these .zip files later, you can use the console to re-import them into your development endpoint. Navigate to the developer endpoint in question, check the box beside it, and choose **Update ETL libraries** from the **Action** menu.

In a similar way, you can specify library files using the Amazon Glue APIs. When you create a development endpoint by calling [CreateDevEndpoint action \(Python: create_dev_endpoint\)](#), you can specify one or more full paths to libraries in the `ExtraPythonLibsS3Path` parameter, in a call that looks this:

```
dep = glue.create_dev_endpoint(  
    EndpointName="testDevEndpoint",  
    RoleArn="arn:aws:iam::123456789012",  
    SecurityGroupIds="sg-7f5ad1ff",  
    SubnetId="subnet-c12fdb4",  
    PublicKey="ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAQCTp04H/y...",  
    NumberOfNodes=3,  
    ExtraPythonLibsS3Path="s3://bucket/prefix/lib_A.zip,s3://bucket_B/prefix/  
lib_X.zip")
```

When you update a development endpoint, you can also update the libraries it loads using a [DevEndpointCustomLibraries](#) object and setting the `UpdateEtlLibraries` parameter to `True` when calling [UpdateDevEndpoint \(update_dev_endpoint\)](#).

Using Python libraries in a job or JobRun

When you are creating a new Job on the console, you can specify one or more library .zip files by choosing **Script Libraries and job parameters (optional)** and entering the full Amazon S3 library path(s) in the same way you would when creating a development endpoint:

```
s3://bucket/prefix/lib_A.zip,s3://bucket_B/prefix/lib_X.zip
```

If you are calling [CreateJob \(create_job\)](#), you can specify one or more full paths to default libraries using the `--extra-py-files` default parameter, like this:

```
job = glue.create_job(Name='sampleJob',
                      Role='Glue_DefaultRole',
                      Command={'Name': 'glueetl',
                              'ScriptLocation': 's3://my_script_bucket/scripts/
my_etl_script.py'},
                      DefaultArguments={'--extra-py-files': 's3://bucket/prefix/
lib_A.zip,s3://bucket_B/prefix/lib_X.zip'})
```

Then when you are starting a JobRun, you can override the default library setting with a different one:

```
runId = glue.start_job_run(JobName='sampleJob',
                           Arguments={'--extra-py-files': 's3://bucket/prefix/
lib_B.zip'})
```

Proactively analyze Python dependencies

To proactively identify potential dependency issues before deploying to Amazon Glue, you can use the dependency analysis tool to validate your Python packages against your target Amazon Glue environment.

Amazon provides an open-source Python dependency analyzer tool specifically designed for Amazon Glue environments. This tool is available in the Amazon Glue samples repository and can be used locally to validate your dependencies before deployment.

This analysis helps ensure your dependencies follow the recommended practice of pinning all library versions for consistent production deployments. For more details, please see the tool's [README](#).

Using the Amazon Glue Dependency Analyzer

The Amazon Glue Python Dependency Analyzer helps identify unpinned dependencies and version conflicts by simulating pip installation with platform-specific constraints that match your target Amazon Glue environment.

```
# Analyze a single Glue job
python glue_dependency_analyzer.py -j my-glue-job

# Analyze multiple jobs with specific AWS configuration
python glue_dependency_analyzer.py -j job1 -j job2 --aws-profile production --aws-region us-west-2
```

The tool will flag:

- Unpinned dependencies that could install different versions across job runs
- Version conflicts between packages
- Dependencies not available for your target Amazon Glue environment

Analyze and fix job failures due to Python dependencies with Amazon Q Developer

Amazon Q Developer is a generative artificial intelligence (AI) powered conversational assistant that can help you understand, build, extend, and operate Amazon applications. You can download it by following the instructions in the Getting started guide for Amazon Q.

Amazon Q Developer can be used to analyze and fix job failures due to python dependency. We suggest using the following prompt by replacing the job <Job-Name> placeholder with the name of your glue job.

```
I have an AWS Glue job named <Job-Name> that has failed due to Python module installation conflicts. Please assist in diagnosing and resolving this issue using the following systematic approach. Proceed once sufficient information is available.
```

```
Objective: Implement a fix that addresses the root cause module while minimizing disruption to the existing working environment.
```

Step 1: Root Cause Analysis

- Retrieve the most recent failed job run ID for the specified Glue job
- Extract error logs from CloudWatch Logs using the job run ID as a log stream prefix
- Analyze the logs to identify:
 - The recently added or modified Python module that triggered the dependency conflict
 - The specific dependency chain causing the installation failure
 - Version compatibility conflicts between required and existing modules

Step 2: Baseline Configuration Identification

- Locate the last successful job run ID prior to the dependency failure
- Document the Python module versions that were functioning correctly in that baseline run
- Establish the compatible version constraints for conflicting dependencies

Step 3: Targeted Resolution Implementation

- Apply pinning by updating the job's `additional_python_modules` parameter
- Pin only the root cause module and its directly conflicting dependencies to compatible versions, and do not remove python modules unless necessary
- Preserve flexibility for non-conflicting modules by avoiding unnecessary version constraints
- Deploy the configuration changes with minimal changes to the existing configuration and execute a validation test run. Do not change the Glue versions.

Implementation Example:

Scenario: Recently added `pandas==2.0.0` to `additional_python_modules`

Error: `numpy` version conflict (`pandas 2.0.0` requires `numpy>=1.21`, but existing job code requires `numpy<1.20`)

Resolution: Update `additional_python_modules` to `"pandas==1.5.3,numpy==1.19.5"`

Rationale: Use `pandas 1.5.3` (compatible with `numpy 1.19.5`) and pin `numpy` to last known working version

Expected Outcome: Restore job functionality with minimal configuration changes while maintaining system stability.

The prompt instructs Q to:

1. Fetch the latest failed job run ID
2. Find associated logs and details
3. Find successful job runs to detect any changed Python packages
4. Make any configuration fixes and trigger another test run

Python modules already provided in Amazon Glue

To change the version of these provided modules, provide new versions with the `--additional-python-modules` job parameter.

Amazon Glue version 5.1

Amazon Glue version 5.1 includes the following Python modules out of the box:

- aiobotocore==2.25.1
- aiohappyeyeballs==2.6.1
- aiohttp==3.13.2
- aioitertools==0.12.0
- aiosignal==1.4.0
- appdirs==1.4.4
- attrs==25.4.0
- boto3==1.40.61
- botocore==1.40.61
- certifi==2025.10.5
- charset-normalizer==3.4.4
- choreographer==1.2.0
- contourpy==1.3.3
- cycler==0.12.1
- distlib==0.4.0
- filelock==3.20.0
- fonttools==4.60.1
- frozenlist==1.8.0
- fsspec==2025.10.0
- idna==3.11
- iniconfig==2.3.0
- jmespath==1.0.1
- kaleido==1.2.0

- kiwisolver==1.4.9
- logistro==2.0.1
- matplotlib==3.10.7
- multidict==6.7.0
- narwhals==2.10.2
- numpy==2.3.4
- orjson==3.11.4
- packaging==25.0
- pandas==2.3.3
- pillow==12.0.0
- pip==24.0
- platformdirs==4.5.0
- plotly==6.4.0
- pluggy==1.6.0
- propcache==0.4.1
- pyarrow==22.0.0
- Pygments==2.19.2
- pyparsing==3.2.5
- pytest-timeout==2.4.0
- pytest==8.4.2
- python-dateutil==2.9.0.post0
- pytz==2025.2
- requests==2.32.5
- s3fs==2025.10.0
- s3transfer==0.14.0
- seaborn==0.13.2
- setuptools==79.0.1
- simplejson==3.20.2
- six==1.17.0

- tenacity==9.1.2
- typing_extensions==4.15.0
- tzdata==2025.2
- urllib3==2.5.0
- uv==0.9.7
- virtualenv==20.35.4
- wrapt==1.17.3
- yarl==1.22.0

Amazon Glue version 5.0

Amazon Glue version 5.0 includes the following Python modules out of the box:

- aiobotocore==2.13.1
- aiohappyeyeballs==2.3.5
- aiohttp==3.10.1
- aioitertools==0.11.0
- aiosignal==1.3.1
- appdirs==1.4.4
- attrs==24.2.0
- boto3==1.34.131
- botocore==1.34.131
- certifi==2024.7.4
- charset-normalizer==3.3.2
- contourpy==1.2.1
- cycler==0.12.1
- fonttools==4.53.1
- frozenlist==1.4.1
- fsspec==2024.6.1
- idna==2.10
- jmespath==0.10.0

- kaleido==0.2.1
- kiwisolver==1.4.5
- matplotlib==3.9.0
- multidict==6.0.5
- numpy==1.26.4
- packaging==24.1
- pandas==2.2.2
- pillow==10.4.0
- pip==23.0.1
- plotly==5.23.0
- pyarrow==17.0.0
- pyparsing==3.1.2
- python-dateutil==2.9.0.post0
- pytz==2024.1
- requests==2.32.2
- s3fs==2024.6.1
- s3transfer==0.10.2
- seaborn==0.13.2
- setuptools==59.6.0
- six==1.16.0
- tenacity==9.0.0
- tzdata==2024.1
- urllib3==1.25.10
- virtualenv==20.4.0
- wrapt==1.16.0
- yarl==1.9.4

Amazon Glue version 4.0

Amazon Glue version 4.0 includes the following Python modules out of the box:

- aiobotocore==2.4.1
- aiohttp==3.8.3
- aioitertools==0.11.0
- aiosignal==1.3.1
- async-timeout==4.0.2
- asynctest==0.13.0
- attrs==22.2.0
- avro-python3==1.10.2
- boto3==1.24.70
- botocore==1.27.59
- certifi==2021.5.30
- chardet==3.0.4
- charset-normalizer==2.1.1
- click==8.1.3
- cycler==0.10.0
- Cython==0.29.32
- fsspec==2021.8.1
- idna==2.10
- importlib-metadata==5.0.0
- jmespath==0.10.0
- joblib==1.0.1
- kaleido==0.2.1
- kiwisolver==1.4.4
- matplotlib==3.4.3
- mpmath==1.2.1
- multidict==6.0.4
- nltk==3.7
- numpy==1.23.5
- packaging==23.0

- pandas==1.5.1
- patsy==0.5.1
- Pillow==9.4.0
- pip==23.0.1
- plotly==5.16.0
- pmdarima==2.0.1
- ptvsd==4.3.2
- pyarrow==10.0.0
- pydevd==2.5.0
- pyhocon==0.3.58
- PyMySQL==1.0.2
- pyparsing==2.4.7
- python-dateutil==2.8.2
- pytz==2021.1
- PyYAML==6.0.1
- regex==2022.10.31
- requests==2.23.0
- s3fs==2022.11.0
- s3transfer==0.6.0
- scikit-learn==1.1.3
- scipy==1.9.3
- setuptools==49.1.3
- six==1.16.0
- statsmodels==0.13.5
- subprocess32==3.5.4
- sympy==1.8
- tbats==1.1.0
- threadpoolctl==3.1.0
- tqdm==4.64.1

- typing_extensions==4.4.0
- urllib3==1.25.11
- wheel==0.37.0
- wrapt==1.14.1
- yarl==1.8.2
- zipp==3.10.0

Amazon Glue version 3.0

Amazon Glue version 3.0 includes the following Python modules out of the box;

- aiobotocore==1.4.2
- aiohttp==3.8.3
- aioitertools==0.11.0
- aiosignal==1.3.1
- async-timeout==4.0.2
- asyncctest==0.13.0
- attrs==22.2.0
- avro-python3==1.10.2
- boto3==1.18.50
- botocore==1.21.50
- certifi==2021.5.30
- chardet==3.0.4
- charset-normalizer==2.1.1
- click==8.1.3
- cycler==0.10.0
- Cython==0.29.4
- docutils==0.17.1
- enum34==1.1.10
- frozenlist==1.3.3
- fsspec==2021.8.1

- idna==2.10
- importlib-metadata==6.0.0
- jmespath==0.10.0
- joblib==1.0.1
- kiwisolver==1.3.2
- matplotlib==3.4.3
- mpmath==1.2.1
- multidict==6.0.4
- nltk==3.6.3
- numpy==1.19.5
- packaging==23.0
- pandas==1.3.2
- patsy==0.5.1
- Pillow==9.4.0
- pip==23.0
- pmdarima==1.8.2
- ptvsd==4.3.2
- pyarrow==5.0.0
- pydevd==2.5.0
- pyhocon==0.3.58
- PyMySQL==1.0.2
- pyparsing==2.4.7
- python-dateutil==2.8.2
- pytz==2021.1
- PyYAML==5.4.1
- regex==2022.10.31
- requests==2.23.0
- s3fs==2021.8.1
- s3transfer==0.5.0

- scikit-learn==0.24.2
- scipy==1.7.1
- six==1.16.0
- Spark==1.0
- statsmodels==0.12.2
- subprocess32==3.5.4
- sympy==1.8
- tbats==1.1.0
- threadpoolctl==3.1.0
- tqdm==4.64.1
- typing_extensions==4.4.0
- urllib3==1.25.11
- wheel==0.37.0
- wrapt==1.14.1
- yarl==1.8.2
- zipp==3.12.0

Amazon Glue version 2.0

Amazon Glue version 2.0 includes the following Python modules out of the box:

- avro-python3==1.10.0
- awscli==1.27.60
- boto3==1.12.4
- botocore==1.15.4
- certifi==2019.11.28
- chardet==3.0.4
- click==8.1.3
- colorama==0.4.4
- cycler==0.10.0
- Cython==0.29.15

- docutils==0.15.2
- enum34==1.1.9
- fsspec==0.6.2
- idna==2.9
- importlib-metadata==6.0.0
- jmespath==0.9.4
- joblib==0.14.1
- kiwisolver==1.1.0
- matplotlib==3.1.3
- mpmath==1.1.0
- nltk==3.5
- numpy==1.18.1
- pandas==1.0.1
- patsy==0.5.1
- pmdarima==1.5.3
- ptvsd==4.3.2
- pyarrow==0.16.0
- pyasn1==0.4.8
- pydevd==1.9.0
- pyhocon==0.3.54
- PyMySQL==0.9.3
- pyparsing==2.4.6
- python-dateutil==2.8.1
- pytz==2019.3

- tbats==1.0.9
- tqdm==4.64.1
- typing-extensions==4.4.0
- urllib3==1.25.8
- wheel==0.35.1
- zipp==3.12.0

Appendix A: Creating a Zip of Wheels Artifact

We demonstrate by example how to create a zip of wheels artifact. The example shown downloads the packages `cryptography` and `scipy` into a zip of wheels artifact and copies the zip of wheels to an Amazon S3 location.

1. You must run the commands to create the zip of wheels in an Amazon Linux environment similar to Glue's environment. See [Appendix B: Amazon Glue environment details](#). Glue 5.1 uses AL2023 with python version 3.11. Create Dockerfile that will build this environment:

```
FROM --platform=linux/amd64 public.ecr.aws/amazonlinux/amazonlinux:2023-minimal

# Install Python 3.11, pip, and zip utility
RUN dnf install -y python3.11 pip zip && \
    dnf clean all

WORKDIR /build
```

2. Create a `requirements.txt` file

```
cryptography
scipy
```

3. Build and spin up docker container

```
# Build docker image
docker build --platform linux/amd64 -t glue-wheel-builder .

# Spin up container
docker run --platform linux/amd64 -v $(pwd)/requirements.txt:/input/
requirements.txt:ro -v $(pwd):/output -it glue-wheel-builder bash
```

4. Run the following commands in the docker image

```
# Create a directory for the wheels
mkdir wheels

# Copy requirements.txt into wheels directory
cp /input/requirements.txt wheels/

# Download the wheels with the correct platform and Python version
pip3 download \
  -r wheels/requirements.txt \
  --dest wheels/ \
  --platform manylinux2014_x86_64 \
  --python-version 311 \
  --only-binary=:all:

# Package the wheels into a zip archive with the .gluewheels.zip suffix
zip -r mylibraries-1.0.0.gluewheels.zip wheels/

# Copy zip to output
cp mylibraries-1.0.0.gluewheels.zip /output/

# Exit the container
exit
```

5. Upload zip of wheels to Amazon S3 location

```
aws s3 cp mylibraries-1.0.0.gluewheels.zip s3://amzn-s3-demo-bucket/example-prefix/
```

6. Optional cleanup

```
rm mylibraries-1.0.0.gluewheels.zip
rm Dockerfile
rm requirements.txt
```

7. Run the Glue job with the following job args:

```
--additional-python-modules s3://amzn-s3-demo-bucket/example-prefix/
mylibraries-1.0.0.gluewheels.zip
--python-modules-installer-option --no-index
```

Appendix B: Amazon Glue environment details

Glue Version Compatibility and Installation Methods

Amazon Glue version	Python version	Base image	glibc version	Compatible platform tags
5.1	3.11	Amazon Linux 2023 (AL2023)	2.34	manylinux_2_34_x86_64 manylinux_2_28_x86_64 manylinux2014_x86_64
5.0	3.11	Amazon Linux 2023 (AL2023)	2.34	manylinux_2_34_x86_64 manylinux_2_28_x86_64 manylinux2014_x86_64
4.0	3.10	Amazon Linux 2 (AL2)	2.26	manylinux2014_x86_64
3.0	3.7	Amazon Linux 2 (AL2)	2.26	manylinux2014_x86_64
2.0	3.7	Amazon Linux AMI (AL1)	2.17	manylinux2014_x86_64

Under the [Amazon shared responsibility model](#), you are responsible for the management of additional Python modules, libraries, and their dependencies that you use with your Amazon Glue ETL jobs. This includes applying updates and security patches.

Amazon Glue does not support compiling native code in the job environment. However, Amazon Glue jobs run within an Amazon-managed Linux environment. You may be able to provide your native dependencies in a compiled form through a Python wheel file. Please refer to above table for Amazon Glue version compatibility details.

Important

Using incompatible dependencies can result in runtime issues, particularly for libraries with native extensions that must match the target environment's architecture and system libraries. Each Amazon Glue version runs on a specific Python version with pre-installed libraries and system configurations.

Amazon Glue Python code samples

- [Code example: Joining and relationalizing data](#)
- [Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping](#)

Code example: Joining and relationalizing data

This example uses a dataset that was downloaded from <http://everypolitician.org/> to the sample-dataset bucket in Amazon Simple Storage Service (Amazon S3): `s3://awsglue-datasets/examples/us-legislators/all`. The dataset contains data in JSON format about United States legislators and the seats that they have held in the US House of Representatives and Senate, and has been modified slightly and made available in a public Amazon S3 bucket for purposes of this tutorial.

You can find the source code for this example in the `join_and_relationalize.py` file in the [Amazon Glue samples repository](#) on the GitHub website.

Using this data, this tutorial shows you how to do the following:

- Use an Amazon Glue crawler to classify objects that are stored in a public Amazon S3 bucket and save their schemas into the Amazon Glue Data Catalog.
- Examine the table metadata and schemas that result from the crawl.
- Write a Python extract, transfer, and load (ETL) script that uses the metadata in the Data Catalog to do the following:

- Join the data in the different source files together into a single data table (that is, denormalize the data).
- Filter the joined table into separate tables by type of legislator.
- Write out the resulting data to separate Apache Parquet files for later analysis.

The preferred way to debug Python or PySpark scripts while running on Amazon is to use [Notebooks on Amazon Glue Studio](#).

Step 1: Crawl the data in the Amazon S3 bucket

1. Sign in to the Amazon Web Services Management Console, and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Following the steps in [Configuring a crawler](#), create a new crawler that can crawl the `s3://awsglue-datasets/examples/us-legislators/all` dataset into a database named `legislators` in the Amazon Glue Data Catalog. The example data is already in this public Amazon S3 bucket.
3. Run the new crawler, and then check the `legislators` database.

The crawler creates the following metadata tables:

- `persons_json`
- `memberships_json`
- `organizations_json`
- `events_json`
- `areas_json`
- `countries_r_json`

This is a semi-normalized collection of tables containing legislators and their histories.

Step 2: Add boilerplate script to the development endpoint notebook

Paste the following boilerplate script into the development endpoint notebook to import the Amazon Glue libraries that you need, and set up a single `GlueContext`:

```
import sys
```

```
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

glueContext = GlueContext(SparkContext.getOrCreate())
```

Step 3: Examine the schemas from the data in the Data Catalog

Next, you can easily create examine a DynamicFrame from the Amazon Glue Data Catalog, and examine the schemas of the data. For example, to see the schema of the persons_json table, add the following in your notebook:

```
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators",
    table_name="persons_json")
print "Count: ", persons.count()
persons.printSchema()
```

Here's the output from the print calls:

```
Count: 1961
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- name: string
|   |   |-- lang: string
```

```
|-- sort_name: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- death_date: string
```

Each person in the table is a member of some US congressional body.

To view the schema of the `memberships_json` table, type the following:

```
memberships = glueContext.create_dynamic_frame.from_catalog(
    database="legislators",
    table_name="memberships_json")
print "Count: ", memberships.count()
memberships.printSchema()
```

The output is as follows:

```
Count: 10439
root
|-- area_id: string
|-- on_behalf_of_id: string
|-- organization_id: string
|-- role: string
|-- person_id: string
|-- legislative_period_id: string
|-- start_date: string
|-- end_date: string
```

The organizations are parties and the two chambers of Congress, the Senate and House of Representatives. To view the schema of the `organizations_json` table, type the following:

```
orgs = glueContext.create_dynamic_frame.from_catalog(  
    database="legislators",  
    table_name="organizations_json")  
print "Count: ", orgs.count()  
orgs.printSchema()
```

The output is as follows:

```
Count: 13  
root  
|-- classification: string  
|-- links: array  
|   |-- element: struct  
|   |   |-- note: string  
|   |   |-- url: string  
|-- image: string  
|-- identifiers: array  
|   |-- element: struct  
|   |   |-- scheme: string  
|   |   |-- identifier: string  
|-- other_names: array  
|   |-- element: struct  
|   |   |-- lang: string  
|   |   |-- note: string  
|   |   |-- name: string  
|-- id: string  
|-- name: string  
|-- seats: int  
|-- type: string
```

Step 4: Filter the data

Next, keep only the fields that you want, and rename `id` to `org_id`. The dataset is small enough that you can view the whole thing.

The `toDF()` converts a `DynamicFrame` to an Apache Spark `DataFrame`, so you can apply the transforms that already exist in Apache Spark SQL:

```
orgs = orgs.drop_fields(['other_names',  
                        'identifiers']).rename_field(  
    'id', 'org_id')
```

```

        'id', 'org_id').rename_field(
            'name', 'org_name')
orgs.toDF().show()

```

The following shows the output:

```

+-----+-----+-----+-----+-----+
+-----+-----+
|classification|          org_id|          org_name|          links|seats|
|      type|          image|                  |              |
+-----+-----+-----+-----+-----+
+-----+-----+
|      party|      party/al|          AL|          null| null|
|      null|          null|            |              |

|      party|party/republican-...|Republican-Conser...|[[website,http://...| null|
|      null|          null|            |              |
|      party|      party/democrat|      Democrat|[[website,http://...| null|
|      null|https://upload.wi...|            |              |
|      party|      party/independent|      Independent|          null| null|
|      null|          null|            |              |
|      party|      party/republican|      Republican|[[website,http://...| null|
|      null|https://upload.wi...|            |              |
| legislature|8fa6c3d2-71dc-478...|          Senate|          null| 100|
upper house|          null|            |              |
+-----+-----+-----+-----+-----+
+-----+-----+

```

Type the following to view the organizations that appear in memberships:

```
memberships.select_fields(['organization_id']).toDF().distinct().show()
```

The following shows the output:

```
+-----+
| organization_id|
+-----+
|d56acebe-8fdc-47b...|
|8fa6c3d2-71dc-478...|
+-----+
```

Step 5: Put it all together

Now, use Amazon Glue to join these relational tables and create one full history table of legislator memberships and their corresponding organizations.

1. First, join persons and memberships on id and person_id.
2. Next, join the result with orgs on org_id and organization_id.
3. Then, drop the redundant fields, person_id and org_id.

You can do all these operations in one (extended) line of code:

```
l_history = Join.apply(orgs,
                      Join.apply(persons, memberships, 'id', 'person_id'),
                      'org_id', 'organization_id').drop_fields(['person_id',
                        'org_id'])
print "Count: ", l_history.count()
l_history.printSchema()
```

The output is as follows:

```
Count:  10439
root
 |-- role: string
 |-- seats: int
```

```
|-- org_name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- type: string
|-- sort_name: string
|-- area_id: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- on_behalf_of_id: string
|-- other_names: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- name: string
|   |   |-- lang: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- name: string
|-- birth_date: string
|-- organization_id: string
|-- gender: string
|-- classification: string
|-- death_date: string
|-- legislative_period_id: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- image: string
|-- given_name: string
|-- family_name: string
|-- id: string
|-- start_date: string
|-- end_date: string
```

You now have the final table that you can use for analysis. You can write it out in a compact, efficient format for analytics—namely Parquet—that you can run SQL over in Amazon Glue, Amazon Athena, or Amazon Redshift Spectrum.

The following call writes the table across multiple files to support fast parallel reads when doing analysis later:

```
glueContext.write_dynamic_frame.from_options(frame = l_history,
      connection_type = "s3",
      connection_options = {"path": "s3://glue-sample-target/output-dir/legislator_history"},
      format = "parquet")
```

To put all the history data into a single file, you must convert it to a data frame, repartition it, and write it out:

```
s_history = l_history.toDF().repartition(1)
s_history.write.parquet('s3://glue-sample-target/output-dir/legislator_single')
```

Or, if you want to separate it by the Senate and the House:

```
l_history.toDF().write.parquet('s3://glue-sample-target/output-dir/legislator_part',
      partitionBy=['org_name'])
```

Step 6: Transform the data for relational databases

Amazon Glue makes it easy to write the data to relational databases like Amazon Redshift, even with semi-structured data. It offers a transform `relationalize`, which flattens `DynamicFrames` no matter how complex the objects in the frame might be.

Using the `l_history` `DynamicFrame` in this example, pass in the name of a root table (`hist_root`) and a temporary working path to `relationalize`. This returns a `DynamicFrameCollection`. You can then list the names of the `DynamicFrames` in that collection:

```
dfc = l_history.relationalize("hist_root", "s3://glue-sample-target/temp-dir/")
dfc.keys()
```

The following is the output of the keys call:

```
[u'hist_root', u'hist_root_contact_details', u'hist_root_links',
 u'hist_root_other_names', u'hist_root_images', u'hist_root_identifiers']
```

Relationalize broke the history table out into six new tables: a root table that contains a record for each object in the DynamicFrame, and auxiliary tables for the arrays. Array handling in relational databases is often suboptimal, especially as those arrays become large. Separating the arrays into different tables makes the queries go much faster.

Next, look at the separation by examining `contact_details`:

```
l_history.select_fields('contact_details').printSchema()
dfc.select('hist_root_contact_details').toDF().where("id = 10 or id =
 75").orderBy(['id', 'index']).show()
```

The following is the output of the show call:

```
root
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
+---+-----+-----+-----+-----+-----+
| id|index|contact_details.val.type|contact_details.val.value|
+---+-----+-----+-----+-----+-----+
| 10|  0|                fax|                |
| 10|  1|                |                202-225-1314|
| 10|  2|                phone|                |
| 10|  3|                |                202-225-3772|
| 10|  4|                twitter|                |
| 10|  5|                |                MikeRossUpdates|
| 75|  0|                fax|                |
| 75|  1|                |                202-225-7856|
| 75|  2|                phone|                |
| 75|  3|                |                202-225-2711|
| 75|  4|                twitter|                |
| 75|  5|                |                SenCapito|
+---+-----+-----+-----+-----+-----+

```

The `contact_details` field was an array of structs in the original `DynamicFrame`. Each element of those arrays is a separate row in the auxiliary table, indexed by `index`. The `id` here is a foreign key into the `hist_root` table with the key `contact_details`:

```
dfc.select('hist_root').toDF().where(
    "contact_details = 10 or contact_details = 75").select(
    ['id', 'given_name', 'family_name', 'contact_details']).show()
```

The following is the output:

```
+-----+-----+-----+-----+
|          id|given_name|family_name|contact_details|
+-----+-----+-----+-----+
|f4fc30ee-7b42-432...|    Mike|    Ross|    10|
|e3c60f34-7d1b-4c0...|  Shelley|    Capito|    75|
+-----+-----+-----+-----+
```

Notice in these commands that `toDF()` and then a `where` expression are used to filter for the rows that you want to see.

So, joining the `hist_root` table with the auxiliary tables lets you do the following:

- Load data into databases without array support.
- Query each individual item in an array using SQL.

Safely store and access your Amazon Redshift credentials with a Amazon Glue connection. For information about how to create your own connection, see [Connecting to data](#).

You are now ready to write your data to a connection by cycling through the `DynamicFrames` one at a time:

```
for df_name in dfc.keys():
    m_df = dfc.select(df_name)
    print "Writing to table: ", df_name
    glueContext.write_dynamic_frame.from_jdbc_conf(frame = m_df, connection settings here)
```

Your connection settings will differ based on your type of relational database:

- For instructions on writing to Amazon Redshift consult [the section called “Redshift connections”](#).
- For other databases, consult [Connection types and options for ETL in Amazon Glue for Spark](#).

Conclusion

Overall, Amazon Glue is very flexible. It lets you accomplish, in a few lines of code, what normally would take days to write. You can find the entire source-to-target ETL scripts in the Python file `join_and_relationalize.py` in the [Amazon Glue samples](#) on GitHub.

Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping

The dataset that is used in this example consists of Medicare Provider payment data that was downloaded from two [Data.CMS.gov](#) data sets: "Inpatient Prospective Payment System Provider Summary for the Top 100 Diagnosis-Related Groups - FY2011" and "Inpatient Charge Data FY 2011". After downloading the data, we modified the dataset to introduce a couple of erroneous records at the end of the file. This modified file is located in a public Amazon S3 bucket at `s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv`.

You can find the source code for this example in the `data_cleaning_and_lambda.py` file in the [Amazon Glue examples](#) GitHub repository.

The preferred way to debug Python or PySpark scripts while running on Amazon is to use [Notebooks on Amazon Glue Studio](#).

Step 1: Crawl the data in the Amazon S3 bucket

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Following the process described in [Configuring a crawler](#), create a new crawler that can crawl the `s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv` file, and can place the resulting metadata into a database named `payments` in the Amazon Glue Data Catalog.
3. Run the new crawler, and then check the `payments` database. You should find that the crawler has created a metadata table named `medicare` in the database after reading the beginning of the file to determine its format and delimiter.

The schema of the new `medicare` table is as follows:

Column name	Data type
=====	
drg definition	string
provider id	bigint
provider name	string
provider street address	string
provider city	string
provider state	string
provider zip code	bigint
hospital referral region description	string
total discharges	bigint
average covered charges	string
average total payments	string
average medicare payments	string

Step 2: Add boilerplate script to the development endpoint notebook

Paste the following boilerplate script into the development endpoint notebook to import the Amazon Glue libraries that you need, and set up a single GlueContext:

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

glueContext = GlueContext(SparkContext.getOrCreate())
```

Step 3: Compare different schema parsings

Next, you can see if the schema that was recognized by an Apache Spark DataFrame is the same as the one that your Amazon Glue crawler recorded. Run this code:

```
medicare = spark.read.format(
    "com.databricks.spark.csv").option(
    "header", "true").option(
    "inferSchema", "true").load(
    's3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv')
```

```
medicare.printSchema()
```

Here's the output from the `printSchema` call:

```
root
 |-- DRG Definition: string (nullable = true)
 |-- Provider Id: string (nullable = true)
 |-- Provider Name: string (nullable = true)
 |-- Provider Street Address: string (nullable = true)
 |-- Provider City: string (nullable = true)
 |-- Provider State: string (nullable = true)
 |-- Provider Zip Code: integer (nullable = true)
 |-- Hospital Referral Region Description: string (nullable = true)
 |-- Total Discharges : integer (nullable = true)
 |-- Average Covered Charges : string (nullable = true)
 |-- Average Total Payments : string (nullable = true)
 |-- Average Medicare Payments: string (nullable = true)
```

Next, look at the schema that an Amazon Glue `DynamicFrame` generates:

```
medicare_dynamicframe = glueContext.create_dynamic_frame.from_catalog(
    database = "payments",
    table_name = "medicare")
medicare_dynamicframe.printSchema()
```

The output from `printSchema` is as follows:

```
root
 |-- drg definition: string
 |-- provider id: choice
 |   |-- long
 |   |-- string
 |-- provider name: string
 |-- provider street address: string
 |-- provider city: string
 |-- provider state: string
 |-- provider zip code: long
 |-- hospital referral region description: string
 |-- total discharges: long
```

```
|-- average covered charges: string
|-- average total payments: string
|-- average medicare payments: string
```

The `DynamicFrame` generates a schema in which `provider id` could be either a `long` or a `string` type. The `DataFrame` schema lists `Provider Id` as being a `string` type, and the `Data Catalog` lists `provider id` as being a `bigint` type.

Which one is correct? There are two records at the end of the file (out of 160,000 records) with `string` values in that column. These are the erroneous records that were introduced to illustrate a problem.

To address this kind of problem, the Amazon Glue `DynamicFrame` introduces the concept of a *choice* type. In this case, the `DynamicFrame` shows that both `long` and `string` values can appear in that column. The Amazon Glue crawler missed the `string` values because it considered only a 2 MB prefix of the data. The Apache Spark `DataFrame` considered the whole dataset, but it was forced to assign the most general type to the column, namely `string`. In fact, Spark often resorts to the most general case when there are complex types or variations with which it is unfamiliar.

To query the `provider id` column, resolve the choice type first. You can use the `resolveChoice` transform method in your `DynamicFrame` to convert those `string` values to `long` values with a `cast:long` option:

```
medicare_res = medicare_dynamicframe.resolveChoice(specs = [('provider
id', 'cast:long')])
medicare_res.printSchema()
```

The `printSchema` output is now:

```
root
 |-- drg definition: string
 |-- provider id: long
 |-- provider name: string
 |-- provider street address: string
 |-- provider city: string
 |-- provider state: string
 |-- provider zip code: long
 |-- hospital referral region description: string
 |-- total discharges: long
```

```
|-- average covered charges: string
|-- average total payments: string
|-- average medicare payments: string
```

Where the value was a string that could not be cast, Amazon Glue inserted a null.

Another option is to convert the choice type to a struct, which keeps values of both types.

Next, look at the rows that were anomalous:

```
medicare_res.toDF().where("'provider id' is NULL").show()
```

You see the following:

```
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
|      drg definition|provider id|  provider name|provider street address|provider
city|provider state|provider zip code|hospital referral region description|total
discharges|average covered charges|average total payments|average medicare payments|
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
|948 - SIGNS & SYM...|      null|          INC|      1050 DIVISION ST|
MAUSTON|          WI|      53948|          WI - Madison|
      12|      $11961.41|      $4619.00|      $3775.33|
|948 - SIGNS & SYM...|      null| INC- ST JOSEPH|      5000 W CHAMBERS ST|
MILWAUKEE|          WI|      53210|          WI - Milwaukee|
      14|      $10514.28|      $5562.50|      $4522.78|
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
```

Now remove the two malformed records, as follows:

```
medicare_dataframe = medicare_res.toDF()
medicare_dataframe = medicare_dataframe.where("'provider id' is NOT NULL")
```

Step 4: Map the data and use Apache Spark Lambda functions

Amazon Glue does not yet directly support Lambda functions, also known as user-defined functions. But you can always convert a `DynamicFrame` to and from an Apache Spark `DataFrame` to take advantage of Spark functionality in addition to the special features of `DynamicFrames`.

Next, turn the payment information into numbers, so analytic engines like Amazon Redshift or Amazon Athena can do their number crunching faster:

```
from pyspark.sql.functions import udf
from pyspark.sql.types import StringType

chop_f = udf(lambda x: x[1:], StringType())
medicare_dataframe = medicare_dataframe.withColumn(
    "ACC", chop_f(
        medicare_dataframe["average covered charges"])).withColumn(
    "ATP", chop_f(
        medicare_dataframe["average total payments"])).withColumn(
    "AMP", chop_f(
        medicare_dataframe["average medicare payments"]))
medicare_dataframe.select(['ACC', 'ATP', 'AMP']).show()
```

The output from the show call is as follows:

```
+-----+-----+-----+
|   ACC|   ATP|   AMP|
+-----+-----+-----+
|32963.07|5777.24|4763.73|
|15131.85|5787.57|4976.71|
|37560.37|5434.95|4453.79|
|13998.28|5417.56|4129.16|
|31633.27|5658.33|4851.44|
|16920.79|6653.80|5374.14|
|11977.13|5834.74|4761.41|
|35841.09|8031.12|5858.50|
|28523.39|6113.38|5228.40|
|75233.38|5541.05|4386.94|
|67327.92|5461.57|4493.57|
|39607.28|5356.28|4408.20|
|22862.23|5374.65|4186.02|
|31110.85|5366.23|4376.23|
|25411.33|5282.93|4383.73|
```

```
| 9234.51|5676.55|4509.11|
|15895.85|5930.11|3972.85|
|19721.16|6192.54|5179.38|
|10710.88|4968.00|3898.88|
|51343.75|5996.00|4962.45|
+-----+-----+-----+
only showing top 20 rows
```

These are all still strings in the data. We can use the powerful `apply_mapping` transform method to drop, rename, cast, and nest the data so that other data programming languages and systems can easily access it:

```
from awsglue.dynamicframe import DynamicFrame
medicare_tmp_dyf = DynamicFrame.fromDF(medicare_dataframe, glueContext, "nested")
medicare_nest_dyf = medicare_tmp_dyf.apply_mapping([('drg definition', 'string', 'drg',
'string'),
          ('provider id', 'long', 'provider.id', 'long'),
          ('provider name', 'string', 'provider.name', 'string'),
          ('provider city', 'string', 'provider.city', 'string'),
          ('provider state', 'string', 'provider.state', 'string'),
          ('provider zip code', 'long', 'provider.zip', 'long'),
          ('hospital referral region description', 'string', 'rr', 'string'),
          ('ACC', 'string', 'charges.covered', 'double'),
          ('ATP', 'string', 'charges.total_pay', 'double'),
          ('AMP', 'string', 'charges.medicare_pay', 'double')])
medicare_nest_dyf.printSchema()
```

The `printSchema` output is as follows:

```
root
 |-- drg: string
 |-- provider: struct
 |   |-- id: long
 |   |-- name: string
 |   |-- city: string
 |   |-- state: string
 |   |-- zip: long
 |-- rr: string
 |-- charges: struct
 |   |-- covered: double
 |   |-- total_pay: double
 |   |-- medicare_pay: double
```

Turning the data back into a Spark DataFrame, you can show what it looks like now:

```
medicare_nest_dyf.toDF().show()
```

The output is as follows:

```
+-----+-----+-----+-----+
|          drg|          provider|          rr|          charges|
+-----+-----+-----+-----+

Step 5: Write the data to Apache Parquet

Amazon Glue makes it easy to write the data in a format such as Apache Parquet that relational databases can effectively consume:

```
glueContext.write_dynamic_frame.from_options(
    frame = medicare_nest_dyf,
    connection_type = "s3",
    connection_options = {"path": "s3://glue-sample-target/output-dir/
medicare_parquet"},
```

```
format = "parquet")
```

Amazon Glue PySpark extensions reference

Amazon Glue has created the following extensions to the PySpark Python dialect.

- [Accessing parameters using getResolvedOptions](#)
- [PySpark extension types](#)
- [DynamicFrame class](#)
- [DynamicFrameCollection class](#)
- [DynamicFrameWriter class](#)
- [DynamicFrameReader class](#)
- [GlueContext class](#)

Accessing parameters using getResolvedOptions

The Amazon Glue `getResolvedOptions(args, options)` utility function gives you access to the arguments that are passed to your script when you run a job. To use this function, start by importing it from the Amazon Glue `utils` module, along with the `sys` module:

```
import sys
from awsglue.utils import getResolvedOptions
```

getResolvedOptions(args, options)

- `args` – The list of arguments contained in `sys.argv`.
- `options` – A Python array of the argument names that you want to retrieve.

Example Retrieving arguments passed to a JobRun

Suppose that you created a `JobRun` in a script, perhaps within a Lambda function:

```
response = client.start_job_run(
    JobName = 'my_test_job',
    Arguments = {
        '--day_partition_key': 'partition_0',
        '--hour_partition_key': 'partition_1',
```

```
'--day_partition_value': day_partition_value,  
'--hour_partition_value': hour_partition_value } )
```

To retrieve the arguments that are passed, you can use the `getResolvedOptions` function as follows:

```
import sys  
from awsglue.utils import getResolvedOptions  
  
args = getResolvedOptions(sys.argv,  
                          ['JOB_NAME',  
                          'day_partition_key',  
                          'hour_partition_key',  
                          'day_partition_value',  
                          'hour_partition_value'])  
print "The day-partition key is: ", args['day_partition_key']  
print "and the day-partition value is: ", args['day_partition_value']
```

Note that each of the arguments are defined as beginning with two hyphens, then referenced in the script without the hyphens. The arguments use only underscores, not hyphens. Your arguments need to follow this convention to be resolved.

PySpark extension types

The types that are used by the Amazon Glue PySpark extensions.

DataType

The base class for the other Amazon Glue types.

`__init__(properties={})`

- `properties` – Properties of the data type (optional).

`typeName(cls)`

Returns the type of the Amazon Glue type class (that is, the class name with "Type" removed from the end).

- `cls` – An Amazon Glue class instance derived from `DataType`.

`jsonValue()`

Returns a JSON object that contains the data type and properties of the class:

```
{
  "dataType": typeName,
  "properties": properties
}
```

AtomicType and simple derivatives

Inherits from and extends the [DataType](#) class, and serves as the base class for all the Amazon Glue atomic data types.

fromJsonValue(cls, json_value)

Initializes a class instance with values from a JSON object.

- `cls` – An Amazon Glue type class instance to initialize.
- `json_value` – The JSON object to load key-value pairs from.

The following types are simple derivatives of the [AtomicType](#) class:

- `BinaryType` – Binary data.
- `BooleanType` – Boolean values.
- `ByteType` – A byte value.
- `DateType` – A datetime value.
- `DoubleType` – A floating-point double value.
- `IntegerType` – An integer value.
- `LongType` – A long integer value.
- `NullType` – A null value.
- `ShortType` – A short integer value.
- `StringType` – A text string.
- `TimestampType` – A timestamp value (typically in seconds from 1/1/1970).

- `UnknownType` – A value of unidentified type.

DecimalType(AtomicType)

Inherits from and extends the [AtomicType](#) class to represent a decimal number (a number expressed in decimal digits, as opposed to binary base-2 numbers).

`__init__(precision=10, scale=2, properties={})`

- `precision` – The number of digits in the decimal number (optional; the default is 10).
- `scale` – The number of digits to the right of the decimal point (optional; the default is 2).
- `properties` – The properties of the decimal number (optional).

EnumType(AtomicType)

Inherits from and extends the [AtomicType](#) class to represent an enumeration of valid options.

`__init__(options)`

- `options` – A list of the options being enumerated.

collection types

- [ArrayType\(DataType\)](#)
- [ChoiceType\(DataType\)](#)
- [MapType\(DataType\)](#)
- [Field\(Object\)](#)
- [StructType\(DataType\)](#)
- [EntityType\(DataType\)](#)

ArrayType(DataType)

`__init__(elementType=UnknownType(), properties={})`

- `elementType` – The type of elements in the array (optional; the default is `UnknownType`).
- `properties` – Properties of the array (optional).

ChoiceType(DataType)

`__init__(choices=[], properties={})`

- `choices` – A list of possible choices (optional).
- `properties` – Properties of these choices (optional).

`add(new_choice)`

Adds a new choice to the list of possible choices.

- `new_choice` – The choice to add to the list of possible choices.

`merge(new_choices)`

Merges a list of new choices with the existing list of choices.

- `new_choices` – A list of new choices to merge with existing choices.

MapType(DataType)

`__init__(valueType=UnknownType, properties={})`

- `valueType` – The type of values in the map (optional; the default is `UnknownType`).
- `properties` – Properties of the map (optional).

Field(Object)

Creates a field object out of an object that derives from [DataType](#).

`__init__(name, dataType, properties={})`

- `name` – The name to be assigned to the field.
- `dataType` – The object to create a field from.
- `properties` – Properties of the field (optional).

StructType(DataType)

Defines a data structure (struct).

`__init__(fields=[], properties={})`

- `fields` – A list of the fields (of type `Field`) to include in the structure (optional).
- `properties` – Properties of the structure (optional).

`add(field)`

- `field` – An object of type `Field` to add to the structure.

`hasField(field)`

Returns `True` if this structure has a field of the same name, or `False` if not.

- `field` – A field name, or an object of type `Field` whose name is used.

`getField(field)`

- `field` – A field name or an object of type `Field` whose name is used. If the structure has a field of the same name, it is returned.

EntityType(DataType)

`__init__(entity, base_type, properties)`

This class is not yet implemented.

other types

- [DataSource\(object\)](#)
- [DataSink\(object\)](#)

DataSource(object)

`__init__(j_source, sql_ctx, name)`

- `j_source` – The data source.
- `sql_ctx` – The SQL context.
- `name` – The data-source name.

`setFormat(format, **options)`

- `format` – The format to set for the data source.
- `options` – A collection of options to set for the data source. For more information about format options, see [the section called “Data format options”](#).

`getFrame()`

Returns a `DynamicFrame` for the data source.

DataSink(object)

`__init__(j_sink, sql_ctx)`

- `j_sink` – The sink to create.
- `sql_ctx` – The SQL context for the data sink.

`setFormat(format, **options)`

- `format` – The format to set for the data sink.
- `options` – A collection of options to set for the data sink. For more information about format options, see [the section called “Data format options”](#).

`setAccumulableSize(size)`

- `size` – The accumulable size to set, in bytes.

`writeFrame(dynamic_frame, info="")`

- `dynamic_frame` – The `DynamicFrame` to write.
- `info` – Information about the `DynamicFrame` (optional).

`write(dynamic_frame_or_dfc, info="")`

Writes a `DynamicFrame` or a `DynamicFrameCollection`.

- `dynamic_frame_or_dfc` – Either a `DynamicFrame` object or a `DynamicFrameCollection` object to be written.
- `info` – Information about the `DynamicFrame` or `DynamicFrames` to be written (optional).

DynamicFrame class

One of the major abstractions in Apache Spark is the SparkSQL `DataFrame`, which is similar to the `DataFrame` construct found in R and Pandas. A `DataFrame` is similar to a table and supports functional-style (map/reduce/filter/etc.) operations and SQL operations (select, project, aggregate).

`DataFrames` are powerful and widely used, but they have limitations with respect to extract, transform, and load (ETL) operations. Most significantly, they require a schema to be specified before any data is loaded. SparkSQL addresses this by making two passes over the data—the first to infer the schema, and the second to load the data. However, this inference is limited and doesn't address the realities of messy data. For example, the same field might be of a different type in different records. Apache Spark often gives up and reports the type as `string` using the original field text. This might not be correct, and you might want finer control over how schema discrepancies are resolved. And for large datasets, an additional pass over the source data might be prohibitively expensive.

To address these limitations, Amazon Glue introduces the `DynamicFrame`. A `DynamicFrame` is similar to a `DataFrame`, except that each record is self-describing, so no schema is required initially. Instead, Amazon Glue computes a schema on-the-fly when required, and explicitly encodes schema inconsistencies using a choice (or union) type. You can resolve these inconsistencies to make your datasets compatible with data stores that require a fixed schema.

Similarly, a `DynamicRecord` represents a logical record within a `DynamicFrame`. It is like a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that does

not conform to a fixed schema. When using Amazon Glue with PySpark, you do not typically manipulate independent `DynamicRecords`. Rather, you will transform the dataset together through its `DynamicFrame`.

You can convert `DynamicFrames` to and from `DataFrames` after you resolve any schema inconsistencies.

— construction —

- [__init__](#)
- [fromDF](#)
- [toDF](#)

`__init__`

`__init__(jdf, glue_ctx, name)`

- `jdf` – A reference to the data frame in the Java Virtual Machine (JVM).
- `glue_ctx` – A [GlueContext class](#) object.
- `name` – An optional name string, empty by default.

`fromDF`

`fromDF(dataframe, glue_ctx, name)`

Converts a `DataFrame` to a `DynamicFrame` by converting `DataFrame` fields to `DynamicRecord` fields. Returns the new `DynamicFrame`.

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It is similar to a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that does not conform to a fixed schema.

This function expects columns with duplicated names in your `DataFrame` to have already been resolved.

- `dataframe` – The Apache Spark SQL `DataFrame` to convert (required).
- `glue_ctx` – The [GlueContext class](#) object that specifies the context for this transform (required).

- `name` – The name of the resulting `DynamicFrame` (optional since Amazon Glue 3.0).

toDF

toDF(options)

Converts a `DynamicFrame` to an Apache Spark `DataFrame` by converting `DynamicRecords` into `DataFrame` fields. Returns the new `DataFrame`.

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It is similar to a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that does not conform to a fixed schema.

- `options` – A list of `ResolveOption` objects that specify how to resolve choice types during the conversion. This parameter is used to handle schema inconsistencies, not for format options like CSV parsing.

For CSV parsing and other format options, specify these in the `from_options` method when creating the `DynamicFrame`, not in the `toDF` method.

Here's an example of the correct way to handle CSV format options:

```
from awsglue.context import GlueContext
from awsglue.dynamicframe import DynamicFrame
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

# Correct: Specify format options in from_options
csv_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://my-bucket/path/to/csv/"]},
    format="csv",
    format_options={
        "withHeader": True,
        "separator": ",",
        "inferSchema": True
    }
)

# Convert to DataFrame (no format options needed here)
```

```
csv_df = csv_dyf.toDF()
```

The `options` parameter in `toDF` is specifically for resolving choice types. Specify the target type if you choose the `Project` and `Cast` action type. Examples include the following.

```
>>>toDF([ResolveOption("a.b.c", "KeepAsStruct")])  
>>>toDF([ResolveOption("a.b.c", "Project", DoubleType())])
```

— information —

- [count](#)
- [schema](#)
- [printSchema](#)
- [show](#)
- [repartition](#)
- [coalesce](#)

count

`count()` – Returns the number of rows in the underlying `DataFrame`.

schema

`schema()` – Returns the schema of this `DynamicFrame`, or if that is not available, the schema of the underlying `DataFrame`.

For more information about the `DynamicFrame` types that make up this schema, see [the section called “Types”](#).

printSchema

`printSchema()` – Prints the schema of the underlying `DataFrame`.

show

`show(num_rows)` – Prints a specified number of rows from the underlying `DataFrame`.

repartition

`repartition(numPartitions)` – Returns a new `DynamicFrame` with `numPartitions` partitions.

coalesce

`coalesce(numPartitions)` – Returns a new `DynamicFrame` with `numPartitions` partitions.

— transforms —

- [apply_mapping](#)
- [drop_fields](#)
- [filter](#)
- [join](#)
- [map](#)
- [mergeDynamicFrame](#)
- [relationalize](#)
- [rename_field](#)
- [resolveChoice](#)
- [select_fields](#)
- [spigot](#)
- [split_fields](#)
- [split_rows](#)
- [unbox](#)
- [the section called “union”](#)
- [unnest](#)
- [unnest_ddb_json](#)
- [write](#)

apply_mapping

apply_mapping(mappings, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)

Applies a declarative mapping to a `DynamicFrame` and returns a new `DynamicFrame` with those mappings applied to the fields that you specify. Unspecified fields are omitted from the new `DynamicFrame`.

- `mappings` – A list of mapping tuples (required). Each consists of: (source column, source type, target column, target type).

If the source column has a dot "." in the name, you must place backticks "`" around it. For example, to map `this.old.name` (string) to `thisNewName`, you would use the following tuple:

```
("`this.old.name`", "string", "thisNewName", "string")
```

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use apply_mapping to rename fields and change field types

The following code example shows how to use the `apply_mapping` method to rename selected fields and change field types.

Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use apply_mapping to reshape source data into
# the desired column names and types as a new DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create a DynamicFrame and view its schema
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()

# Select and rename fields, change field type
print("Schema for the persons_mapped DynamicFrame, created with apply_mapping:")
persons_mapped = persons.apply_mapping(
    [
        ("family_name", "String", "last_name", "String"),
        ("name", "String", "first_name", "String"),
        ("birth_date", "String", "date_of_birth", "Date"),
    ]
)
persons_mapped.printSchema()
```

Output

```
Schema for the persons DynamicFrame:
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
```

```

|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- sort_name: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- death_date: string

```

Schema for the `persons_mapped` `DynamicFrame`, created with `apply_mapping`:

```

root
|-- last_name: string
|-- first_name: string
|-- date_of_birth: date

```

drop_fields

drop_fields(paths, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)

Calls the [FlatMap class](#) transform to remove fields from a `DynamicFrame`. Returns a new `DynamicFrame` with the specified fields dropped.

- `paths` – A list of strings. Each contains the full path to a field node that you want to drop. You can use dot notation to specify nested fields. For example, if field `first` is a child of field `name` in the tree, you specify `"name.first"` for the path.

If a field node has a literal `.` in the name, you must enclose the name in backticks (```).

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).

- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use `drop_fields` to remove fields from a `DynamicFrame`

This code example uses the `drop_fields` method to remove selected top-level and nested fields from a `DynamicFrame`.

Example dataset

The example uses the following dataset that is represented by the `EXAMPLE-FRIENDS-DATA` table in the code:

```
{"name": "Sally", "age": 23, "location": {"state": "WY", "county": "Fremont"},  
  "friends": []}  
{"name": "Varun", "age": 34, "location": {"state": "NE", "county": "Douglas"},  
  "friends": [{"name": "Arjun", "age": 3}]  
{"name": "George", "age": 52, "location": {"state": "NY"}, "friends": [{"name":  
  "Fred"}, {"name": "Amy", "age": 15}]}  
{"name": "Haruki", "age": 21, "location": {"state": "AK", "county": "Denali"}}  
{"name": "Sheila", "age": 63, "friends": [{"name": "Nancy", "age": 22}]}
```

Example code

```
# Example: Use drop_fields to remove top-level and nested fields from a DynamicFrame.  
# Replace MY-EXAMPLE-DATABASE with your Glue Data Catalog database name.  
# Replace EXAMPLE-FRIENDS-DATA with your table name.  
  
from pyspark.context import SparkContext  
from awsglue.context import GlueContext  
  
# Create GlueContext  
sc = SparkContext.getOrCreate()  
glueContext = GlueContext(sc)  
  
# Create a DynamicFrame from Glue Data Catalog
```

```
glue_source_database = "MY-EXAMPLE-DATABASE"
glue_source_table = "EXAMPLE-FRIENDS-DATA"

friends = glueContext.create_dynamic_frame.from_catalog(
    database=glue_source_database, table_name=glue_source_table
)
print("Schema for friends DynamicFrame before calling drop_fields:")
friends.printSchema()

# Remove location.county, remove friends.age, remove age
friends = friends.drop_fields(paths=["age", "location.county", "friends.age"])
print("Schema for friends DynamicFrame after removing age, county, and friend age:")
friends.printSchema()
```

Output

```
Schema for friends DynamicFrame before calling drop_fields:
```

```
root
|-- name: string
|-- age: int
|-- location: struct
|   |-- state: string
|   |-- county: string
|-- friends: array
|   |-- element: struct
|   |   |-- name: string
|   |   |-- age: int
```

```
Schema for friends DynamicFrame after removing age, county, and friend age:
```

```
root
|-- name: string
|-- location: struct
|   |-- state: string
|-- friends: array
|   |-- element: struct
|   |   |-- name: string
```

filter

```
filter(f, transformation_ctx="", info="", stageThreshold=0,  
totalThreshold=0)
```

Returns a new `DynamicFrame` that contains all `DynamicRecords` within the input `DynamicFrame` that satisfy the specified predicate function `f`.

- `f` – The predicate function to apply to the `DynamicFrame`. The function must take a `DynamicRecord` as an argument and return `True` if the `DynamicRecord` meets the filter requirements, or `False` if not (required).

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use filter to get a filtered selection of fields

This example uses the `filter` method to create a new `DynamicFrame` that includes a filtered selection of another `DynamicFrame`'s fields.

Like the `map` method, `filter` takes a function as an argument that gets applied to each record in the original `DynamicFrame`. The function takes a record as an input and returns a Boolean value. If the return value is `true`, the record gets included in the resulting `DynamicFrame`. If it's `false`, the record is left out.

Note

To access the dataset that is used in this example, see [Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use filter to create a new DynamicFrame
# with a filtered selection of records

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create DynamicFrame from Glue Data Catalog
medicare = glueContext.create_dynamic_frame.from_options(
    "s3",
    {
        "paths": [
            "s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv"
        ]
    },
    "csv",
    {"withHeader": True},
)

# Create filtered DynamicFrame with custom lambda
# to filter records by Provider State and Provider City
sac_or_mon = medicare.filter(
    f=lambda x: x["Provider State"] in ["CA", "AL"]
    and x["Provider City"] in ["SACRAMENTO", "MONTGOMERY"]
)

# Compare record counts
print("Unfiltered record count: ", medicare.count())
print("Filtered record count: ", sac_or_mon.count())
```

Output

```
Unfiltered record count: 163065
Filtered record count: 564
```

join

```
join(paths1, paths2, frame2, transformation_ctx="", info="",
stageThreshold=0, totalThreshold=0)
```

Performs an equality join with another `DynamicFrame` and returns the resulting `DynamicFrame`.

- `paths1` – A list of the keys in this frame to join.
- `paths2` – A list of the keys in the other frame to join.
- `frame2` – The other `DynamicFrame` to join.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use `join` to combine `DynamicFrames`

This example uses the `join` method to perform a join on three `DynamicFrames`. Amazon Glue performs the join based on the field keys that you provide. The resulting `DynamicFrame` contains rows from the two original frames where the specified keys match.

Note that the `join` transform keeps all fields intact. This means that the fields that you specify to match appear in the resulting `DynamicFrame`, even if they're redundant and contain the same keys. In this example, we use `drop_fields` to remove these redundant keys after the join.

Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use join to combine data from three DynamicFrames

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load DynamicFrames from Glue Data Catalog
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
memberships = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="memberships_json"
)
orgs = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="organizations_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()
print("Schema for the memberships DynamicFrame:")
memberships.printSchema()
print("Schema for the orgs DynamicFrame:")
orgs.printSchema()

# Join persons and memberships by ID
persons_memberships = persons.join(
    paths1=["id"], paths2=["person_id"], frame2=memberships
)

# Rename and drop fields from orgs
# to prevent field name collisions with persons_memberships
orgs = (
    orgs.drop_fields(["other_names", "identifiers"])
```

```
.rename_field("id", "org_id")
.rename_field("name", "org_name")
)

# Create final join of all three DynamicFrames
legislators_combined = orgs.join(
    paths1=["org_id"], paths2=["organization_id"], frame2=persons_memberships
).drop_fields(["person_id", "org_id"])

# Inspect the schema for the joined data
print("Schema for the new legislators_combined DynamicFrame:")
legislators_combined.printSchema()
```

Output

```
Schema for the persons DynamicFrame:

```

map

map(f, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)

Returns a new `DynamicFrame` that results from applying the specified mapping function to all records in the original `DynamicFrame`.

- `f` – The mapping function to apply to all records in the `DynamicFrame`. The function must take a `DynamicRecord` as an argument and return a new `DynamicRecord` (required).

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in an Apache Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Example: Use `map` to apply a function to every record in a `DynamicFrame`

This example shows how to use the `map` method to apply a function to every record of a `DynamicFrame`. Specifically, this example applies a function called `MergeAddress` to each record in order to merge several address fields into a single `struct` type.

Note

To access the dataset that is used in this example, see [Code example: Data preparation using `ResolveChoice`, `Lambda`, and `ApplyMapping`](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use map to combine fields in all records
# of a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create a DynamicFrame and view its schema
medicare = glueContext.create_dynamic_frame.from_options(
```

```

    "s3",
    {"paths": ["s3://awsglue-datasets/examples/medicare/
Medicare_Hospital_Provider.csv"]},
    "csv",
    {"withHeader": True})
print("Schema for medicare DynamicFrame:")
medicare.printSchema()

# Define a function to supply to the map transform
# that merges address fields into a single field
def MergeAddress(rec):
    rec["Address"] = {}
    rec["Address"]["Street"] = rec["Provider Street Address"]
    rec["Address"]["City"] = rec["Provider City"]
    rec["Address"]["State"] = rec["Provider State"]
    rec["Address"]["Zip.Code"] = rec["Provider Zip Code"]
    rec["Address"]["Array"] = [rec["Provider Street Address"], rec["Provider City"],
rec["Provider State"], rec["Provider Zip Code"]]
    del rec["Provider Street Address"]
    del rec["Provider City"]
    del rec["Provider State"]
    del rec["Provider Zip Code"]
    return rec

# Use map to apply MergeAddress to every record
mapped_medicare = medicare.map(f = MergeAddress)
print("Schema for mapped_medicare DynamicFrame:")
mapped_medicare.printSchema()

```

Output

```

Schema for medicare DynamicFrame:
root
|-- DRG Definition: string
|-- Provider Id: string
|-- Provider Name: string
|-- Provider Street Address: string
|-- Provider City: string
|-- Provider State: string
|-- Provider Zip Code: string
|-- Hospital Referral Region Description: string
|-- Total Discharges: string

```

```

|-- Average Covered Charges: string
|-- Average Total Payments: string
|-- Average Medicare Payments: string

Schema for mapped_medicare DynamicFrame:
root
|-- Average Total Payments: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string
|-- Hospital Referral Region Description: string
|-- Address: struct
|   |-- Zip.Code: string
|   |-- City: string
|   |-- Array: array
|   |   |-- element: string

|-- Provider Name: string

```

mergeDynamicFrame

```

mergeDynamicFrame(stage_dynamic_frame, primary_keys, transformation_ctx =
"", options = {}, info = "", stageThreshold = 0, totalThreshold = 0)

```

Merges this DynamicFrame with a staging DynamicFrame based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not deduplicated. If there is no matching record in the staging frame, all records (including duplicates) are retained from the source. If the staging frame has matching records, the records from the staging frame overwrite the records in the source in Amazon Glue.

- `stage_dynamic_frame` – The staging DynamicFrame to merge.
- `primary_keys` – The list of primary key fields to match records from the source and staging dynamic frames.
- `transformation_ctx` – A unique string that is used to retrieve metadata about the current transformation (optional).
- `options` – A string of JSON name-value pairs that provide additional information for this transformation. This argument is not currently used.

- `info` – A `String`. Any string to be associated with errors in this transformation.
- `stageThreshold` – A `Long`. The number of errors in the given transformation for which the processing needs to error out.
- `totalThreshold` – A `Long`. The total number of errors up to and including this transformation for which the processing needs to error out.

This method returns a new `DynamicFrame` that is obtained by merging this `DynamicFrame` with the staging `DynamicFrame`.

The returned `DynamicFrame` contains record A in these cases:

- If A exists in both the source frame and the staging frame, then A in the staging frame is returned.
- If A is in the source table and A.`primaryKeys` is not in the `stagingDynamicFrame`, A is not updated in the staging table.

The source frame and staging frame don't need to have the same schema.

Example: Use `mergeDynamicFrame` to merge two `DynamicFrames` based on a primary key

The following code example shows how to use the `mergeDynamicFrame` method to merge a `DynamicFrame` with a "staging" `DynamicFrame`, based on the primary key `id`.

Example dataset

The example uses two `DynamicFrames` from a `DynamicFrameCollection` called `split_rows_collection`. The following is the list of keys in `split_rows_collection`.

```
dict_keys(['high', 'low'])
```

Example code

```
# Example: Use mergeDynamicFrame to merge DynamicFrames
# based on a set of specified primary keys

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import SelectFromCollection
```

```

# Inspect the original DynamicFrames
frame_low = SelectFromCollection.apply(dfc=split_rows_collection, key="low")
print("Inspect the DynamicFrame that contains rows where ID < 10")
frame_low.toDF().show()

frame_high = SelectFromCollection.apply(dfc=split_rows_collection, key="high")
print("Inspect the DynamicFrame that contains rows where ID > 10")
frame_high.toDF().show()

# Merge the DynamicFrames based on the "id" primary key
merged_high_low = frame_high.mergeDynamicFrame(
    stage_dynamic_frame=frame_low, primary_keys=["id"]
)

# View the results where the ID is 1 or 20
print("Inspect the merged DynamicFrame that contains the combined rows")
merged_high_low.toDF().where("id = 1 or id= 20").orderBy("id").show()

```

Output

```

Inspect the DynamicFrame that contains rows where ID < 10
+---+-----+-----+-----+

```

relationalize

```
relationalize(root_table_name, staging_path, options,  
transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)
```

Converts a `DynamicFrame` into a form that fits within a relational database. Relationalizing a `DynamicFrame` is especially useful when you want to move data from a NoSQL environment like DynamoDB into a relational database like MySQL.

The transform generates a list of frames by unnesting nested columns and pivoting array columns. You can join the pivoted array columns to the root table by using the join key that is generated during the unnest phase.

- `root_table_name` – The name for the root table.
- `staging_path` – The path where the method can store partitions of pivoted tables in CSV format (optional). Pivoted tables are read back from this path.
- `options` – A dictionary of optional parameters.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use `relationalize` to flatten a nested schema in a `DynamicFrame`

This code example uses the `relationalize` method to flatten a nested schema into a form that fits into a relational database.

Example dataset

The example uses a `DynamicFrame` called `legislators_combined` with the following schema. `legislators_combined` has multiple nested fields such as `links`, `images`, and `contact_details`, which will be flattened by the `relationalize` transform.

```
root
|-- role: string
|-- seats: int
|-- org_name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- type: string
|-- sort_name: string
|-- area_id: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- on_behalf_of_id: string
|-- other_names: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- name: string
|   |   |-- lang: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- name: string
|-- birth_date: string
|-- organization_id: string
|-- gender: string
|-- classification: string
|-- legislative_period_id: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- image: string
|-- given_name: string
|-- start_date: string
|-- family_name: string
|-- id: string
|-- death_date: string
|-- end_date: string
```

Example code

```

# Example: Use relationalize to flatten
# a nested schema into a format that fits
# into a relational database.
# Replace DOC-EXAMPLE-S3-BUCKET/tmpDir with your own location.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Apply relationalize and inspect new tables
legislators_relationalized = legislators_combined.relationalize(
    "l_root", "s3://DOC-EXAMPLE-BUCKET/tmpDir"
)
legislators_relationalized.keys()

# Compare the schema of the contact_details
# nested field to the new relationalized table that
# represents it
legislators_combined.select_fields("contact_details").printSchema()
legislators_relationalized.select("l_root_contact_details").toDF().where(
    "id = 10 or id = 75"
).orderBy(["id", "index"]).show()

```

Output

The following output lets you compare the schema of the nested field called `contact_details` to the table that the `relationalize` transform created. Notice that the table records link back to the main table using a foreign key called `id` and an `index` column that represents the positions of the array.

```

dict_keys(['l_root', 'l_root_images', 'l_root_links', 'l_root_other_names',
'l_root_contact_details', 'l_root_identifiers'])

root
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string

```

```
+---+-----+-----+-----+-----+
| id|index|contact_details.val.type|contact_details.val.value|
+---+-----+-----+-----+-----+
| 10|  0|                fax|          202-225-4160|
| 10|  1|                phone|          202-225-3436|
| 75|  0|                fax|          202-225-6791|
| 75|  1|                phone|          202-225-2861|
| 75|  2|            twitter|          RepSamFarr|
+---+-----+-----+-----+-----+
```

rename_field

```
rename_field(oldName, newName, transformation_ctx="", info="",
stageThreshold=0, totalThreshold=0)
```

Renames a field in this `DynamicFrame` and returns a new `DynamicFrame` with the field renamed.

- `oldName` – The full path to the node you want to rename.

If the old name has dots in it, `RenameField` doesn't work unless you place backticks around it (```). For example, to replace `this.old.name` with `thisNewName`, you would call `rename_field` as follows.

```
newDyF = oldDyF.rename_field("`this.old.name`", "thisNewName")
```

- `newName` – The new name, as a full path.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use `rename_field` to rename fields in a `DynamicFrame`

This code example uses the `rename_field` method to rename fields in a `DynamicFrame`. Notice that the example uses method chaining to rename multiple fields at the same time.

Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

Example code

```
# Example: Use rename_field to rename fields
# in a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Inspect the original orgs schema
orgs = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="organizations_json"
)
print("Original orgs schema: ")
orgs.printSchema()

# Rename fields and view the new schema
orgs = orgs.rename_field("id", "org_id").rename_field("name", "org_name")
print("New orgs schema with renamed fields: ")
orgs.printSchema()
```

Output

```
Original orgs schema:
root
 |-- identifiers: array
 |   |-- element: struct
 |   |   |-- scheme: string
 |   |   |-- identifier: string
 |-- other_names: array
 |   |-- element: struct
 |   |   |-- lang: string
```

```

|   |   |-- note: string
|   |   |-- name: string
|-- id: string
|-- classification: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- image: string
|-- seats: int
|-- type: string

```

New orgs schema with renamed fields:

```

root
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- classification: string
|-- org_id: string
|-- org_name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string

|-- type: string

```

resolveChoice

```

resolveChoice(specs = None, choice = "" , database = None , table_name = None , transformation_ctx="", info="", stageThreshold=0, totalThreshold=0, catalog_id = None)

```

Resolves a choice type within this DynamicFrame and returns the new DynamicFrame.

- `specs` – A list of specific ambiguities to resolve, each in the form of a tuple: (`field_path`, `action`).

There are two ways to use `resolveChoice`. The first is to use the `specs` argument to specify a sequence of specific fields and how to resolve them. The other mode for `resolveChoice` is to use the `choice` argument to specify a single resolution for all `ChoiceTypes`.

Values for `specs` are specified as tuples made up of (`field_path`, `action`) pairs. The `field_path` value identifies a specific ambiguous element, and the `action` value identifies the corresponding resolution. The following are the possible actions:

- `cast: type` – Attempts to cast all values to the specified type. For example: `cast:int`.
- `make_cols` – Converts each distinct type to a column with the name `columnName_type`. It resolves a potential ambiguity by flattening the data. For example, if `columnA` could be an `int` or a `string`, the resolution would be to produce two columns named `columnA_int` and `columnA_string` in the resulting `DynamicFrame`.
- `make_struct` – Resolves a potential ambiguity by using a `struct` to represent the data. For example, if data in a column could be an `int` or a `string`, the `make_struct` action produces a column of structures in the resulting `DynamicFrame`. Each structure contains both an `int` and a `string`.
- `project: type` – Resolves a potential ambiguity by projecting all the data to one of the possible data types. For example, if data in a column could be an `int` or a `string`, using a `project:string` action produces a column in the resulting `DynamicFrame` where all the `int` values have been converted to strings.

If the `field_path` identifies an array, place empty square brackets after the name of the array to avoid ambiguity. For example, suppose you are working with data structured as follows:

```
"myList": [  
  { "price": 100.00 },  
  { "price": "$100.00" }  
]
```

You can select the numeric rather than the string version of the price by setting the `field_path` to `"myList[].price"`, and setting the `action` to `"cast:double"`.

Note

You can only use one of the specs and choice parameters. If the specs parameter is not None, then the choice parameter must be an empty string. Conversely, if the choice is not an empty string, then the specs parameter must be None.

- `choice` – Specifies a single resolution for all `ChoiceTypes`. You can use this in cases where the complete list of `ChoiceTypes` is unknown before runtime. In addition to the actions listed previously for specs, this argument also supports the following action:
 - `match_catalog` – Attempts to cast each `ChoiceType` to the corresponding type in the specified Data Catalog table.
- `database` – The Data Catalog database to use with the `match_catalog` action.
- `table_name` – The Data Catalog table to use with the `match_catalog` action.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). When set to None (default value), it uses the catalog ID of the calling account.

Example: Use `resolveChoice` to handle a column that contains multiple types

This code example uses the `resolveChoice` method to specify how to handle a `DynamicFrame` column that contains values of multiple types. The example demonstrates two common ways to handle a column with different types:

- Cast the column to a single data type.
- Retain all types in separate columns.

Example dataset

Note

To access the dataset that is used in this example, see [Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

The example uses a DynamicFrame called `medicare` with the following schema:

```
root
|-- drg definition: string
|-- provider id: choice
|   |-- long
|   |-- string
|-- provider name: string
|-- provider street address: string
|-- provider city: string
|-- provider state: string
|-- provider zip code: long
|-- hospital referral region description: string
|-- total discharges: long
|-- average covered charges: string
|-- average total payments: string
|-- average medicare payments: string
```

Example code

```
# Example: Use resolveChoice to handle
# a column that contains multiple types

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load the input data and inspect the "provider id" column
medicare = glueContext.create_dynamic_frame.from_catalog(
    database="payments", table_name="medicare_hospital_provider_csv"
)
print("Inspect the provider id column:")
```

```

medicare.toDF().select("provider id").show()

# Cast provider id to type long
medicare_resolved_long = medicare.resolveChoice(specs=[("provider id", "cast:long")])
print("Schema after casting provider id to type long:")
medicare_resolved_long.printSchema()
medicare_resolved_long.toDF().select("provider id").show()

# Create separate columns
# for each provider id type
medicare_resolved_cols = medicare.resolveChoice(choice="make_cols")
print("Schema after creating separate columns for each type:")
medicare_resolved_cols.printSchema()
medicare_resolved_cols.toDF().select("provider id_long", "provider id_string").show()

```

Output

Inspect the 'provider id' column:

```

+-----+
|provider id|

only showing top 20 rows

select_fields

select_fields(paths, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)

Returns a new `DynamicFrame` that contains the selected fields.

- `paths` – A list of strings. Each string is a path to a top-level node that you want to select.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use `select_fields` to create a new `DynamicFrame` with chosen fields

The following code example shows how to use the `select_fields` method to create a new `DynamicFrame` with a chosen list of fields from an existing `DynamicFrame`.

Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use select_fields to select specific fields from a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
```

```
# Create a DynamicFrame and view its schema
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()

# Create a new DynamicFrame with chosen fields
names = persons.select_fields(paths=["family_name", "given_name"])
print("Schema for the names DynamicFrame, created with select_fields:")
names.printSchema()
names.toDF().show()
```

Output

```
Schema for the persons DynamicFrame:

simplify_ddb_json

simplify_ddb_json(): DynamicFrame

Simplifies nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new simplified `DynamicFrame`. If there're multiple types or Map type in a List type, the elements in the List will not be simplified. Note that this is a specific type of

transform that behaves differently from the regular `unnest` transform and requires the data to already be in the DynamoDB JSON structure. For more information, see [DynamoDB JSON](#).

For example, the schema of a reading an export with the DynamoDB JSON structure might look like the following:

```

root
|-- Item: struct
|   |-- parentMap: struct
|   |   |-- M: struct
|   |   |   |-- childMap: struct
|   |   |   |   |-- M: struct
|   |   |   |   |   |-- appName: struct
|   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |-- packageName: struct
|   |   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |   |-- updatedAt: struct
|   |   |   |   |   |   |   |   |-- N: string
|   |   |-- strings: struct
|   |   |   |-- SS: array
|   |   |   |   |-- element: string
|   |   |-- numbers: struct
|   |   |   |-- NS: array
|   |   |   |   |-- element: string
|   |   |-- binaries: struct
|   |   |   |-- BS: array
|   |   |   |   |-- element: string
|   |   |-- isDDBJson: struct
|   |   |   |-- BOOL: boolean
|   |   |-- nullValue: struct
|   |   |   |-- NULL: boolean

```

The `simplify_ddb_json()` transform would convert this to:

```

root
|-- parentMap: struct
|   |-- childMap: struct
|   |   |-- appName: string
|   |   |-- packageName: string
|   |   |-- updatedAt: string
|-- strings: array
|   |-- element: string
|-- numbers: array

```

```
|    |-- element: string
|-- binaries: array
|    |-- element: string
|-- isDDBJson: boolean
|-- nullValue: null
```

Example: Use `simplify_ddb_json` to invoke a DynamoDB JSON simplify

This code example uses the `simplify_ddb_json` method to use the Amazon Glue DynamoDB export connector, invoke a DynamoDB JSON simplify, and print the number of partitions.

Example code

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type = "dynamodb",
    connection_options = {
        'dynamodb.export': 'ddb',
        'dynamodb.tableArn': '<table arn>',
        'dynamodb.s3.bucket': '<bucket name>',
        'dynamodb.s3.prefix': '<bucket prefix>',
        'dynamodb.s3.bucketOwner': '<account_id of bucket>'
    }
)

simplified = dynamicFrame.simplify_ddb_json()
print(simplified.getNumPartitions())
```

spigot

`spigot(path, options={})`

Writes sample records to a specified destination to help you verify the transformations performed by your job.

- `path` – The path of the destination to write to (required).

- `options` – Key-value pairs that specify options (optional). The "topk" option specifies that the first k records should be written. The "prob" option specifies the probability (as a decimal) of choosing any given record. You can use it in selecting records to write.
- `transformation_ctx` – A unique string that is used to identify state information (optional).

Example: Use `spigot` to write sample fields from a `DynamicFrame` to Amazon S3

This code example uses the `spigot` method to write sample records to an Amazon S3 bucket after applying the `select_fields` transform.

Example dataset

Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

The example uses a `DynamicFrame` called `persons` with the following schema:

```
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- sort_name: string
|-- images: array
```

```
|   |-- element: struct
|   |   |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- death_date: string
```

Example code

```
# Example: Use spigot to write sample records
# to a destination during a transformation
# from pyspark.context import SparkContext.
# Replace DOC-EXAMPLE-BUCKET with your own location.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load table data into a DynamicFrame
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)

# Perform the select_fields on the DynamicFrame
persons = persons.select_fields(paths=["family_name", "given_name", "birth_date"])

# Use spigot to write a sample of the transformed data
# (the first 10 records)
spigot_output = persons.spigot(
    path="s3://DOC-EXAMPLE-BUCKET", options={"topk": 10}
)

# Example: Use spigot to write sample records
# to a destination during a transformation
# from pyspark.context import SparkContext.
# Replace DOC-EXAMPLE-BUCKET with your own location.
```

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load table data into a DynamicFrame
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)

# Perform the select_fields on the DynamicFrame
persons = persons.select_fields(paths=["family_name", "given_name", "birth_date"])

# Use spigot to write a sample of the transformed data
# (the first 10 records)
spigot_output = persons.spigot(
    path="s3://DOC-EXAMPLE-BUCKET", options={"topk": 10}
)
```

Output

The following is an example of the data that spigot writes to Amazon S3. Because the example code specified `options={"topk": 10}`, the sample data contains the first 10 records.

```
{"family_name": "Collins", "given_name": "Michael", "birth_date": "1944-10-15"}
{"family_name": "Huizenga", "given_name": "Bill", "birth_date": "1969-01-31"}
{"family_name": "Clawson", "given_name": "Curtis", "birth_date": "1959-09-28"}
{"family_name": "Solomon", "given_name": "Gerald", "birth_date": "1930-08-14"}
{"family_name": "Rigell", "given_name": "Edward", "birth_date": "1960-05-28"}
{"family_name": "Crapo", "given_name": "Michael", "birth_date": "1951-05-20"}
{"family_name": "Hutto", "given_name": "Earl", "birth_date": "1926-05-12"}
{"family_name": "Ertel", "given_name": "Allen", "birth_date": "1937-11-07"}
{"family_name": "Minish", "given_name": "Joseph", "birth_date": "1916-09-01"}
{"family_name": "Andrews", "given_name": "Robert", "birth_date": "1957-08-04"}
```

split_fields

```
split_fields(paths, name1, name2, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)
```

Returns a new `DynamicFrameCollection` that contains two `DynamicFrames`. The first `DynamicFrame` contains all the nodes that have been split off, and the second contains the nodes that remain.

- `paths` – A list of strings, each of which is a full path to a node that you want to split into a new `DynamicFrame`.
- `name1` – A name string for the `DynamicFrame` that is split off.
- `name2` – A name string for the `DynamicFrame` that remains after the specified nodes have been split off.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use `split_fields` to split selected fields into a separate `DynamicFrame`

This code example uses the `split_fields` method to split a list of specified fields into a separate `DynamicFrame`.

Example dataset

The example uses a `DynamicFrame` called `l_root_contact_details` that is from a collection named `legislators_relationalized`.

`l_root_contact_details` has the following schema and entries.

```
root
|-- id: long
```

```
 |-- index: int
 |-- contact_details.val.type: string
 |-- contact_details.val.value: string

+---+-----+-----+-----+-----+
| id|index|contact_details.val.type|contact_details.val.value|
+---+-----+-----+-----+
| 1|  0|                phone|          202-225-5265|
| 1|  1|            twitter|          kathyhochul|
| 2|  0|                phone|          202-225-3252|
| 2|  1|            twitter|          repjackyroser|
| 3|  0|                fax|          202-225-1314|
| 3|  1|                phone|          202-225-3772|
...

```

Example code

```
# Example: Use split_fields to split selected
# fields into a separate DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load the input DynamicFrame and inspect its schema
frame_to_split = legislators_relationalized.select("l_root_contact_details")
print("Inspect the input DynamicFrame schema:")
frame_to_split.printSchema()

# Split id and index fields into a separate DynamicFrame
split_fields_collection = frame_to_split.split_fields(["id", "index"], "left", "right")

# Inspect the resulting DynamicFrames
print("Inspect the schemas of the DynamicFrames created with split_fields:")
split_fields_collection.select("left").printSchema()
split_fields_collection.select("right").printSchema()

```

Output

```
Inspect the input DynamicFrame's schema:
```

```

root

```

Inspect the schemas of the `DynamicFrames` created with `split_fields`:

```

root
|-- id: long
|-- index: int

```

```

root
|-- contact_details.val.type: string
|-- contact_details.val.value: string

```

split_rows

split_rows(comparison_dict, name1, name2, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)

Splits one or more rows in a `DynamicFrame` off into a new `DynamicFrame`.

The method returns a new `DynamicFrameCollection` that contains two `DynamicFrames`. The first `DynamicFrame` contains all the rows that have been split off, and the second contains the rows that remain.

- `comparison_dict` – A dictionary where the key is a path to a column, and the value is another dictionary for mapping comparators to values that the column values are compared to. For example, `{"age": {">": 10, "<": 20}}` splits off all rows whose value in the age column is greater than 10 and less than 20.
- `name1` – A name string for the `DynamicFrame` that is split off.
- `name2` – A name string for the `DynamicFrame` that remains after the specified nodes have been split off.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use `split_rows` to split rows in a `DynamicFrame`

This code example uses the `split_rows` method to split rows in a `DynamicFrame` based on the `id` field value.

Example dataset

The example uses a `DynamicFrame` called `l_root_contact_details` that is selected from a collection named `legislators_relationalized`.

`l_root_contact_details` has the following schema and entries.

```
root
|-- id: long
|-- index: int
|-- contact_details.val.type: string
|-- contact_details.val.value: string
```

only showing top 20 rows

unbox

```
unbox(path, format, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0, **options)
```

Unboxes (reformats) a string field in a `DynamicFrame` and returns a new `DynamicFrame` that contains the unboxed `DynamicRecords`.

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in an Apache Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `path` – A full path to the string node you want to unbox.
- `format` – A format specification (optional). You use this for an Amazon S3 or Amazon Glue connection that supports multiple formats. For the formats that are supported, see [Data format options for inputs and outputs in Amazon Glue for Spark](#).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `options` – One or more of the following:
 - `separator` – A string that contains the separator character.
 - `escaper` – A string that contains the escape character.
 - `skipFirst` – A Boolean value that indicates whether to skip the first instance.
 - `withSchema` – A string containing a JSON representation of the node's schema. The format of a schema's JSON representation is defined by the output of `StructType.json()`.
 - `withHeader` – A Boolean value that indicates whether a header is included.

Example: Use unbox to unbox a string field into a struct

This code example uses the `unbox` method to *unbox*, or reformat, a string field in a `DynamicFrame` into a field of type `struct`.

Example dataset

The example uses a DynamicFrame called `mapped_with_string` with the following schema and entries.

Notice the field named `AddressString`. This is the field that the example unboxes into a struct.

```

+-----+-----+-----+-----+

```

only showing top 20 rows

union

```
union(frame1, frame2, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)
```

Union two DynamicFrames. Returns DynamicFrame containing all records from both input DynamicFrames. This transform may return different results from the union of two DataFrames with equivalent data. If you need the Spark DataFrame union behavior, consider using `toDF`.

- `frame1` – First DynamicFrame to union.
- `frame2` – Second DynamicFrame to union.
- `transformation_ctx` – (optional) A unique string that is used to identify stats / state information
- `info` – (optional) Any string to be associated with errors in the transformation
- `stageThreshold` – (optional) Max number of errors in the transformation until processing will error out
- `totalThreshold` – (optional) Max number of errors total until processing will error out.

unnest

```
unnest(transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)
```

Unnests nested objects in a DynamicFrame, which makes them top-level objects, and returns a new unnested DynamicFrame.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use unnest to turn nested fields into top-level fields

This code example uses the `unnest` method to flatten all of the nested fields in a `DynamicFrame` into top-level fields.

Example dataset

The example uses a `DynamicFrame` called `mapped_medicare` with the following schema. Notice that the `Address` field is the only field that contains nested data.

```
root
|-- Average Total Payments: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string
|-- Hospital Referral Region Description: string
|-- Address: struct
|   |-- Zip.Code: string
|   |-- City: string
|   |-- Array: array
|   |   |-- element: string
|   |-- State: string
|   |-- Street: string
|-- Provider Id: string
|-- Total Discharges: string
|-- Provider Name: string
```

Example code

```
# Example: Use unnest to unnest nested
# objects in a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Unnest all nested fields
unnested = mapped_medicare.unnest()
unnested.printSchema()
```

Output

```
root
|-- Average Total Payments: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string
|-- Hospital Referral Region Description: string
|-- Address.Zip.Code: string
|-- Address.City: string
|-- Address.Array: array
|   |-- element: string
|-- Address.State: string
|-- Address.Street: string
|-- Provider Id: string
|-- Total Discharges: string
|-- Provider Name: string
```

unnest_ddb_json

Unnests nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new unnested `DynamicFrame`. Columns that are of an array of struct types will not be unnested. Note that this is a specific type of unnesting transform that behaves differently from the regular `unnest` transform and requires the data to already be in the DynamoDB JSON structure. For more information, see [DynamoDB JSON](#).

unnest_ddb_json(transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional: zero by default, indicating that the process should not error out).
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional: zero by default, indicating that the process should not error out).

For example, the schema of a reading an export with the DynamoDB JSON structure might look like the following:

```
root
|-- Item: struct
|   |-- ColA: struct
|   |   |-- S: string
|   |-- ColB: struct
|   |   |-- S: string
|   |-- ColC: struct
|   |   |-- N: string
|   |-- ColD: struct
|   |   |-- L: array
|   |   |   |-- element: null
```

The `unnest_ddb_json()` transform would convert this to:

```
root
|-- ColA: string
|-- ColB: string
|-- ColC: string
|-- ColD: array
|   |-- element: null
```

The following code example shows how to use the Amazon Glue DynamoDB export connector, invoke a DynamoDB JSON unnest, and print the number of partitions:

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dynamicFrame = glue_context.create_dynamic_frame.from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.export": "ddb",
```

```

        "dynamodb.tableArn": "<test_source>",
        "dynamodb.s3.bucket": "<bucket name>",
        "dynamodb.s3.prefix": "<bucket prefix>",
        "dynamodb.s3.bucketOwner": "<account_id>",
    }
)
unnested = dynamicFrame.unnest_ddb_json()
print(unnested.getNumPartitions())

job.commit()

```

write

write(connection_type, connection_options, format, format_options, accumulator_size)

Gets a [DataSink\(object\)](#) of the specified connection type from the [GlueContext class](#) of this DynamicFrame, and uses it to format and write the contents of this DynamicFrame. Returns the new DynamicFrame formatted and written as specified.

- `connection_type` – The connection type to use. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, and `oracle`.
- `connection_options` – The connection option to use (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

Warning

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from Amazon Secrets Manager or the Amazon Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
    "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-path"}
```

- `format` – A format specification (optional). This is used for an Amazon Simple Storage Service (Amazon S3) or an Amazon Glue connection that supports multiple formats. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `accumulator_size` – The accumulable size to use, in bytes (optional).

— errors —

- [assertErrorThreshold](#)
- [errorsAsDynamicFrame](#)
- [errorsCount](#)
- [stageErrorsCount](#)

assertErrorThreshold

`assertErrorThreshold()` – An assert for errors in the transformations that created this `DynamicFrame`. Returns an `Exception` from the underlying `DataFrame`.

errorsAsDynamicFrame

`errorsAsDynamicFrame()` – Returns a `DynamicFrame` that has error records nested inside.

Example: Use errorsAsDynamicFrame to view error records

The following code example shows how to use the `errorsAsDynamicFrame` method to view an error record for a `DynamicFrame`.

Example dataset

The example uses the following dataset that you can upload to Amazon S3 as JSON. Notice that the second record is malformed. Malformed data typically breaks file parsing when you use SparkSQL. However, `DynamicFrame` recognizes malformation issues and turns malformed lines into error records that you can handle individually.

```
{"id": 1, "name": "george", "surname": "washington", "height": 178}
{"id": 2, "name": "benjamin", "surname": "franklin",
{"id": 3, "name": "alexander", "surname": "hamilton", "height": 171}
{"id": 4, "name": "john", "surname": "jay", "height": 190}
```

Example code

```
# Example: Use errorsAsDynamicFrame to view error records.
# Replace s3://DOC-EXAMPLE-S3-BUCKET/error_data.json with your location.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create errors DynamicFrame, view schema
errors = glueContext.create_dynamic_frame.from_options(
    "s3", {"paths": ["s3://DOC-EXAMPLE-S3-BUCKET/error_data.json"]}, "json"
)
print("Schema of errors DynamicFrame:")
errors.printSchema()

# Show that errors only contains valid entries from the dataset
print("errors contains only valid records from the input dataset (2 of 4 records)")
errors.toDF().show()

# View errors
print("Errors count:", str(errors.errorsCount()))
print("Errors:")
errors.errorsAsDynamicFrame().toDF().show()

# View error fields and error data
error_record = errors.errorsAsDynamicFrame().toDF().head()

error_fields = error_record["error"]
print("Error fields: ")
print(error_fields.asDict().keys())

print("\nError record data:")
for key in error_fields.asDict().keys():
    print("\n", key, ": ", str(error_fields[key]))
```

Output

```
Schema of errors DynamicFrame:
root
```

```
 |-- id: int
 |-- name: string
 |-- surname: string
 |-- height: int
```

errors contains only valid records from the input dataset (2 of 4 records)

```
+---+-----+-----+-----+
| id| name|  surname|height|
+---+-----+-----+-----+
| 1|george|washington| 178|
| 4| john|      jay| 190|
+---+-----+-----+-----+
```

Errors count: 1

Errors:

```
+-----+
|           error|
+-----+
|[[ File "/tmp/20...|
+-----+
```

Error fields:

```
dict_keys(['callsite', 'msg', 'stackTrace', 'input', 'bytesread', 'source',
'dynamicRecord'])
```

Error record data:

```
callsite : Row(site=' File "/tmp/2060612586885849088", line 549, in <module>\n
sys.exit(main())\n File "/tmp/2060612586885849088", line 523, in main\n   response

dynamicRecord : Row(id=2, name='benjamin', surname='franklin')

Comprehensive DynamicFrame examples

The following examples demonstrate various ways to create and work with DynamicFrames beyond basic Glue catalog scenarios.

Loading from PostgreSQL with SQL SELECT query

This example shows how to load data from a PostgreSQL database using a custom SQL SELECT query:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

# Load specific data from PostgreSQL with custom query
postgres_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="postgresql",
    connection_options={
        "url": "jdbc:postgresql://your-postgres-host:5432/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "(SELECT customer_id, customer_name, email FROM customers WHERE
active = true) AS filtered_customers"
    }
)
```

Loading specific columns to avoid full table scans

This example demonstrates how to load only specific columns from a large database table:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

# Load only specific columns from a large table
selected_columns_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="mysql",
    connection_options={
        "url": "jdbc:mysql://your-mysql-host:3306/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "(SELECT order_id, customer_id FROM large_orders_table) AS
selected_data"
    }
)

# Alternative approach using column selection in query
efficient_load_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="postgresql",
```

```
connection_options={
    "url": "jdbc:postgresql://your-postgres-host:5432/your-database",
    "user": "your-username",
    "password": "your-password",
    "query": "SELECT product_id, product_name FROM products WHERE category =
'electronics'"
}
)
```

Row-level filtering via JDBC connections

This example shows how to use row-level filtering to load only specific rows from a database table:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

# Load filtered rows using WHERE clause
filtered_rows_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="postgresql",
    connection_options={
        "url": "jdbc:postgresql://your-postgres-host:5432/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "(SELECT * FROM transactions WHERE transaction_date >= '2024-01-01'
AND amount > 100) AS recent_large_transactions"
    }
)

# Using partitionColumn for parallel loading with filtering
partitioned_load_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="mysql",
    connection_options={
        "url": "jdbc:mysql://your-mysql-host:3306/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "sales_data",
        "partitionColumn": "sale_date",
        "lowerBound": "2024-01-01",
        "upperBound": "2024-12-31",
        "numPartitions": "10"
    }
)
```

```
)
```

Creating DynamicFrame from in-memory Python data

This example demonstrates how to create a DynamicFrame from Python lists, tuples, or dictionaries:

```
from awsglue.context import GlueContext
from awsglue.dynamicframe import DynamicFrame
from pyspark.context import SparkContext
from pyspark.sql import Row

sc = SparkContext()
glueContext = GlueContext(sc)

# Method 1: From list of tuples
data_tuples = [
    ("John", "Doe", 30, "Engineer"),
    ("Jane", "Smith", 25, "Designer"),
    ("Bob", "Johnson", 35, "Manager")
]

# Convert to RDD of Rows
rdd = sc.parallelize([Row(first_name=row[0], last_name=row[1], age=row[2], job=row[3])
    for row in data_tuples])
df = glueContext.spark_session.createDataFrame(rdd)
dyf_from_tuples = DynamicFrame.fromDF(df, glueContext, "employees_from_tuples")

# Method 2: From list of dictionaries
data_dicts = [
    {"product_id": 1, "product_name": "Laptop", "price": 999.99, "category":
    "Electronics"},
    {"product_id": 2, "product_name": "Book", "price": 19.99, "category": "Education"},
    {"product_id": 3, "product_name": "Chair", "price": 149.99, "category":
    "Furniture"}
]

df_from_dicts = glueContext.spark_session.createDataFrame(data_dicts)
dyf_from_dicts = DynamicFrame.fromDF(df_from_dicts, glueContext, "products_from_dicts")

# Method 3: From nested data structures
nested_data = [
    {
```

```

    "customer_id": 1,
    "customer_info": {
      "name": "Alice Brown",
      "email": "alice@example.com"
    },
    "orders": [
      {"order_id": 101, "amount": 250.00},
      {"order_id": 102, "amount": 175.50}
    ]
  }
]

```

```

df_nested = glueContext.spark_session.createDataFrame(nested_data)
dyf_nested = DynamicFrame.fromDF(df_nested, glueContext, "customers_with_orders")

```

Performance optimization for large datasets

When working with large datasets, consider these performance optimization techniques:

```

# Use partitioning for parallel reads
large_table_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="postgresql",
    connection_options={
        "url": "jdbc:postgresql://your-postgres-host:5432/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "large_table",
        "partitionColumn": "id",
        "lowerBound": "1",
        "upperBound": "1000000",
        "numPartitions": "20"
    }
)

# Use pushdown predicates to filter at source
filtered_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="mysql",
    connection_options={
        "url": "jdbc:mysql://your-mysql-host:3306/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "transactions"
    },
    push_down_predicate="transaction_date >= '2024-01-01'"
)

```

```
)
```

errorsCount

`errorsCount()` – Returns the total number of errors in a `DynamicFrame`.

stageErrorsCount

`stageErrorsCount` – Returns the number of errors that occurred in the process of generating this `DynamicFrame`.

DynamicFrameCollection class

A `DynamicFrameCollection` is a dictionary of [DynamicFrame class](#) objects, in which the keys are the names of the `DynamicFrames` and the values are the `DynamicFrame` objects.

`__init__`

`__init__(dynamic_frames, glue_ctx)`

- `dynamic_frames` – A dictionary of [DynamicFrame class](#) objects.
- `glue_ctx` – A [GlueContext class](#) object.

Keys

`keys()` – Returns a list of the keys in this collection, which generally consists of the names of the corresponding `DynamicFrame` values.

Values

`values(key)` – Returns a list of the `DynamicFrame` values in this collection.

Select

`select(key)`

Returns the `DynamicFrame` that corresponds to the specified key (which is generally the name of the `DynamicFrame`).

- `key` – A key in the `DynamicFrameCollection`, which usually represents the name of a `DynamicFrame`.

Map

map(callable, transformation_ctx="")

Uses a passed-in function to create and return a new `DynamicFrameCollection` based on the `DynamicFrames` in this collection.

- `callable` – A function that takes a `DynamicFrame` and the specified transformation context as parameters and returns a `DynamicFrame`.
- `transformation_ctx` – A transformation context to be used by the callable (optional).

Flatmap

flatmap(f, transformation_ctx="")

Uses a passed-in function to create and return a new `DynamicFrameCollection` based on the `DynamicFrames` in this collection.

- `f` – A function that takes a `DynamicFrame` as a parameter and returns a `DynamicFrame` or `DynamicFrameCollection`.
- `transformation_ctx` – A transformation context to be used by the function (optional).

DynamicFrameWriter class

methods

- [`__init__`](#)
- [`from_options`](#)
- [`from_catalog`](#)
- [`from_jdbc_conf`](#)

`__init__`

`__init__(glue_context)`

- `glue_context` – The [`GlueContext` class](#) to use.

from_options

```
from_options(frame, connection_type, connection_options={}, format=None,
             format_options={}, transformation_ctx="")
```

Writes a `DynamicFrame` using the specified connection and format.

- `frame` – The `DynamicFrame` to write.
- `connection_type` – The connection type. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, and `oracle`.
- `connection_options` – Connection options, such as path and database table (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

Warning

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from Amazon Secrets Manager or the Amazon Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
                     "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
                     path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#).

- `format` – A format specification (optional). This is used for an Amazon Simple Storage Service (Amazon S3) or an Amazon Glue connection that supports multiple formats. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.

- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – A transformation context to use (optional).

from_catalog

```
from_catalog(frame, name_space, table_name, redshift_tmp_dir="", transformation_ctx="")
```

Writes a `DynamicFrame` using the specified catalog database and table name.

- `frame` – The `DynamicFrame` to write.
- `name_space` – The database to use.
- `table_name` – The `table_name` to use.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).
- `additional_options` – Additional options provided to Amazon Glue.

To write to Lake Formation governed tables, you can use these additional options:

- `transactionId` – (String) The transaction ID at which to do the write to the Governed table. This transaction can not be already committed or aborted, or the write will fail.
- `callDeleteObjectsOnCancel` – (Boolean, optional) If set to `true` (default), Amazon Glue automatically calls the `DeleteObjectsOnCancel` API after the object is written to Amazon S3. For more information, see [DeleteObjectsOnCancel](#) in the *Amazon Lake Formation Developer Guide*.

Example: Writing to a governed table in Lake Formation

```
txId = glueContext.start_transaction(read_only=False)
glueContext.write_dynamic_frame.from_catalog(
    frame=dyf,
    database = db,
    table_name = tbl,
    transformation_ctx = "datasource0",
    additional_options={"transactionId":txId})
...
glueContext.commit_transaction(txId)
```

from_jdbc_conf

```
from_jdbc_conf(frame, catalog_connection, connection_options={},
redshift_tmp_dir = "", transformation_ctx="")
```

Writes a `DynamicFrame` using the specified JDBC connection information.

- `frame` – The `DynamicFrame` to write.
- `catalog_connection` – A catalog connection to use.
- `connection_options` – Connection options, such as path and database table (optional).
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).

Example for write_dynamic_frame

This example writes the output locally using a `connection_type` of `S3` with a POSIX path argument in `connection_options`, which allows writing to local storage.

```
glueContext.write_dynamic_frame.from_options(\
frame = dyf_splitFields,\
connection_options = {'path': '/home/glue/GlueLocalOutput/'},\
connection_type = 's3',\
format = 'json')
```

DynamicFrameReader class

— methods —

- [__init__](#)
- [from_rdd](#)
- [from_options](#)
- [from_catalog](#)

__init__

__init__(glue_context)

- `glue_context` – The [GlueContext class](#) to use.

from_rdd

from_rdd(data, name, schema=None, sampleRatio=None)

Reads a `DynamicFrame` from a Resilient Distributed Dataset (RDD).

- `data` – The dataset to read from.
- `name` – The name to read from.
- `schema` – The schema to read (optional).
- `sampleRatio` – The sample ratio (optional).

from_options

from_options(connection_type, connection_options={}, format=None, format_options={}, transformation_ctx="")

Reads a `DynamicFrame` using the specified connection and format.

- `connection_type` – The connection type. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, `dynamodb`, and `snowflake`.
- `connection_options` – Connection options, such as path and database table (optional). For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#). For a `connection_type` of `s3`, Amazon S3 paths are defined in an array.

```
connection_options = {"paths": [ "s3://amzn-s3-demo-bucket/object_a", "s3://amzn-s3-  
demo-bucket/object_b" ]}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

Warning

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from Amazon Secrets Manager or the Amazon Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
  "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
  path"}
```

For a JDBC connection that performs parallel reads, you can set the hashfield option. For example:

```
connection_options = {"url": "jdbc-url/database", "user": "username",
  "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
  path" , "hashfield": "month"}
```

For more information, see [Reading from JDBC tables in parallel](#).

- `format` – A format specification (optional). This is used for an Amazon Simple Storage Service (Amazon S3) or an Amazon Glue connection that supports multiple formats. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-Filtering Using Pushdown Predicates](#).

from_catalog

```
from_catalog(database, table_name, redshift_tmp_dir="",
transformation_ctx="", push_down_predicate="", additional_options={})
```

Reads a `DynamicFrame` using the specified catalog namespace and table name.

- `database` – The database to read from.
- `table_name` – The name of the table to read from.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional if not reading data from Redshift).
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-filtering using pushdown predicates](#).

- `additional_options` – Additional options provided to Amazon Glue.
- To use a JDBC connection that performs parallel reads, you can set the `hashfield`, `hashexpression`, or `hashpartitions` options. For example:

```
additional_options = {"hashfield": "month"}
```

For more information, see [Reading from JDBC tables in parallel](#).

- To pass a catalog expression to filter based on the index columns, you can see the `catalogPartitionPredicate` option.

`catalogPartitionPredicate` — You can pass a catalog expression to filter based on the index columns. This pushes down the filtering to the server side. For more information, see [Amazon Glue Partition Indexes](#). Note that `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

For more information, see [Managing partitions for ETL output in Amazon Glue](#).

GlueContext class

Wraps the Apache Spark [SparkContext](#) object, and thereby provides mechanisms for interacting with the Apache Spark platform.

`__init__`

`__init__(sparkContext)`

- `sparkContext` – The Apache Spark context to use.

Creating

- [__init__](#)
- [getSource](#)
- [create_dynamic_frame_from_rdd](#)
- [create_dynamic_frame_from_catalog](#)
- [create_dynamic_frame_from_options](#)
- [create_sample_dynamic_frame_from_catalog](#)

- [create_sample_dynamic_frame_from_options](#)
- [add_ingestion_time_columns](#)
- [create_data_frame_from_catalog](#)
- [create_data_frame_from_options](#)
- [forEachBatch](#)

getSource

getSource(connection_type, transformation_ctx = "", **options)

Creates a DataSource object that can be used to read DynamicFrames from external sources.

- `connection_type` – The connection type to use, such as Amazon Simple Storage Service (Amazon S3), Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, and `dynamodb`.
- `transformation_ctx` – The transformation context to use (optional).
- `options` – A collection of optional name-value pairs. For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#).

The following is an example of using `getSource`.

```
>>> data_source = context.getSource("file", paths=["/in/path"])
>>> data_source.setFormat("json")
>>> myFrame = data_source.getFrame()
```

create_dynamic_frame_from_rdd

create_dynamic_frame_from_rdd(data, name, schema=None, sample_ratio=None, transformation_ctx="")

Returns a DynamicFrame that is created from an Apache Spark Resilient Distributed Dataset (RDD).

- `data` – The data source to use.
- `name` – The name of the data to use.
- `schema` – The schema to use (optional).

- `sample_ratio` – The sample ratio to use (optional).
- `transformation_ctx` – The transformation context to use (optional).

`create_dynamic_frame_from_catalog`

```
create_dynamic_frame_from_catalog(database, table_name, redshift_tmp_dir,
transformation_ctx = "", push_down_predicate= "", additional_options = {},
catalog_id = None)
```

Returns a `DynamicFrame` that is created using a Data Catalog database and table name. When using this method, you provide `format_options` through table properties on the specified Amazon Glue Data Catalog table and other options through the `additional_options` argument.

- `Database` – The database to read from.
- `table_name` – The name of the table to read from.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For supported sources and limitations, see [Optimizing reads with pushdown in Amazon Glue ETL](#). For more information, see [Pre-filtering using pushdown predicates](#).
- `additional_options` – A collection of optional name-value pairs. The possible options include those listed in [Connection types and options for ETL in Amazon Glue for Spark](#) except for `endpointUrl`, `streamName`, `bootstrap.servers`, `security.protocol`, `topicName`, `classification`, and `delimiter`. Another supported option is `catalogPartitionPredicate`:

`catalogPartitionPredicate` — You can pass a catalog expression to filter based on the index columns. This pushes down the filtering to the server side. For more information, see [Amazon Glue Partition Indexes](#). Note that `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

- `catalog_id` — The catalog ID (account ID) of the Data Catalog being accessed. When `None`, the default account ID of the caller is used.

create_dynamic_frame_from_options

```
create_dynamic_frame_from_options(connection_type, connection_options={},
format=None, format_options={}, transformation_ctx = "")
```

Returns a `DynamicFrame` created with the specified connection and format.

- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, and `dynamodb`.
- `connection_options` – Connection options, such as paths and database table (optional). For a `connection_type` of `s3`, a list of Amazon S3 paths is defined.

```
connection_options = {"paths": ["s3://aws-glue-target/temp"]}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

Warning

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from Amazon Secrets Manager or the Amazon Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
"password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#).

- `format` – A format specification. This is used for an Amazon S3 or an Amazon Glue connection that supports multiple formats. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.

- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For supported sources and limitations, see [Optimizing reads with pushdown in Amazon Glue ETL](#). For more information, see [Pre-Filtering Using Pushdown Predicates](#).

`create_sample_dynamic_frame_from_catalog`

```
create_sample_dynamic_frame_from_catalog(database, table_name, num,
redshift_tmp_dir, transformation_ctx = "", push_down_predicate= "",
additional_options = {}, sample_options = {}, catalog_id = None)
```

Returns a sample `DynamicFrame` that is created using a Data Catalog database and table name. The `DynamicFrame` only contains first `num` records from a datasource.

- `database` – The database to read from.
- `table_name` – The name of the table to read from.
- `num` – The maximum number of records in the returned sample dynamic frame.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-filtering using pushdown predicates](#).
- `additional_options` – A collection of optional name-value pairs. The possible options include those listed in [Connection types and options for ETL in Amazon Glue for Spark](#) except for `endpointUrl`, `streamName`, `bootstrap.servers`, `security.protocol`, `topicName`, `classification`, and `delimiter`.
- `sample_options` – Parameters to control sampling behavior (optional). Current available parameters for Amazon S3 sources:
 - `maxSamplePartitions` – The maximum number of partitions the sampling will read. Default value is 10
 - `maxSampleFilesPerPartition` – The maximum number of files the sampling will read in one partition. Default value is 10.

These parameters help to reduce the time consumed by file listing. For example, suppose the dataset has 1000 partitions, and each partition has 10 files. If you set `maxSamplePartitions = 10`, and `maxSampleFilesPerPartition = 10`, instead of listing all 10,000 files, the

sampling will only list and read the first 10 partitions with the first 10 files in each: $10 \times 10 = 100$ files in total.

- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). Set to `None` by default. `None` defaults to the catalog ID of the calling account in the service.

`create_sample_dynamic_frame_from_options`

```
create_sample_dynamic_frame_from_options(connection_type,  
connection_options={}, num, sample_options={}, format=None,  
format_options={}, transformation_ctx = "")
```

Returns a sample `DynamicFrame` created with the specified connection and format. The `DynamicFrame` only contains first `num` records from a datasource.

- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, and `dynamodb`.
- `connection_options` – Connection options, such as paths and database table (optional). For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#).
- `num` – The maximum number of records in the returned sample dynamic frame.
- `sample_options` – Parameters to control sampling behavior (optional). Current available parameters for Amazon S3 sources:
 - `maxSamplePartitions` – The maximum number of partitions the sampling will read. Default value is 10
 - `maxSampleFilesPerPartition` – The maximum number of files the sampling will read in one partition. Default value is 10.

These parameters help to reduce the time consumed by file listing. For example, suppose the dataset has 1000 partitions, and each partition has 10 files. If you set `maxSamplePartitions = 10`, and `maxSampleFilesPerPartition = 10`, instead of listing all 10,000 files, the sampling will only list and read the first 10 partitions with the first 10 files in each: $10 \times 10 = 100$ files in total.

- `format` – A format specification. This is used for an Amazon S3 or an Amazon Glue connection that supports multiple formats. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.

- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-filtering using pushdown predicates](#).

`add_ingestion_time_columns`

`add_ingestion_time_columns(dataFrame, timeGranularity = "")`

Appends ingestion time columns like `ingest_year`, `ingest_month`, `ingest_day`, `ingest_hour`, `ingest_minute` to the input `DataFrame`. This function is automatically generated in the script generated by the Amazon Glue when you specify a Data Catalog table with Amazon S3 as the target. This function automatically updates the partition with ingestion time columns on the output table. This allows the output data to be automatically partitioned on ingestion time without requiring explicit ingestion time columns in the input data.

- `dataFrame` – The `dataFrame` to append the ingestion time columns to.
- `timeGranularity` – The granularity of the time columns. Valid values are "day", "hour" and "minute". For example, if "hour" is passed in to the function, the original `dataFrame` will have "ingest_year", "ingest_month", "ingest_day", and "ingest_hour" time columns appended.

Returns the data frame after appending the time granularity columns.

Example:

```
dynamic_frame = DynamicFrame.fromDF(glueContext.add_ingestion_time_columns(dataFrame, "hour"))
```

`create_data_frame_from_catalog`

`create_data_frame_from_catalog(database, table_name, transformation_ctx = "", additional_options = {})`

Returns a `DataFrame` that is created using information from a Data Catalog table.

- `database` – The Data Catalog database to read from.

- `table_name` – The name of the Data Catalog table to read from.
- `transformation_ctx` – The transformation context to use (optional).
- `additional_options` – A collection of optional name-value pairs. The possible options include those listed in [Connection types and options for ETL in Amazon Glue for Spark](#) for streaming sources, such as `startingPosition`, `maxFetchTimeInMs`, and `startingOffsets`.
- `useSparkDataSource` – When set to true, forces Amazon Glue to use the native Spark Data Source API to read the table. The Spark Data Source API supports the following formats: AVRO, binary, CSV, JSON, ORC, Parquet, and text. In a Data Catalog table, you specify the format using the `classification` property. To learn more about the Spark Data Source API, see the official [Apache Spark documentation](#).

Using `create_data_frame_from_catalog` with `useSparkDataSource` has the following benefits:

- Directly returns a `DataFrame` and provides an alternative to `create_dynamic_frame_from_catalog().toDF()`.
- Supports Amazon Lake Formation table-level permission control for native formats.
- Supports reading data lake formats without Amazon Lake Formation table-level permission control. For more information, see [Using data lake frameworks with Amazon Glue ETL jobs](#).

When you enable `useSparkDataSource`, you can also add any of the [Spark Data Source options](#) in `additional_options` as needed. Amazon Glue passes these options directly to the Spark reader.

- `useCatalogSchema` – When set to true, Amazon Glue applies the Data Catalog schema to the resulting `DataFrame`. Otherwise, the reader infers the schema from the data. When you enable `useCatalogSchema`, you must also set `useSparkDataSource` to true.

Limitations

Consider the following limitations when you use the `useSparkDataSource` option:

- When you use `useSparkDataSource`, Amazon Glue creates a new `DataFrame` in a separate Spark session that is different from the original Spark session.
- Spark `DataFrame` partition filtering doesn't work with the following Amazon Glue features.
 - [Job bookmarks](#)
 - [Excluding Amazon S3 storage classes](#)

- [Catalog partition predicates](#)

To use partition filtering with these features, you can use the Amazon Glue pushdown predicate. For more information, see [Pre-filtering using pushdown predicates](#). Filtering on non-partitioned columns is not affected.

The following example script demonstrates the incorrect way to perform partition filtering with the `excludeStorageClasses` option.

```
// Incorrect partition filtering using Spark filter with excludeStorageClasses
read_df = glueContext.create_data_frame.from_catalog(
    database=database_name,
    table_name=table_name,
    additional_options = {
        "useSparkDataSource": True,
        "excludeStorageClasses" : ["GLACIER", "DEEP_ARCHIVE"]
    }
)

// Suppose year and month are partition keys.
// Filtering on year and month won't work, the filtered_df will still
// contain data with other year/month values.
filtered_df = read_df.filter("year == '2017 and month == '04' and 'state == 'CA'")
```

The following example script demonstrates the correct way to use a pushdown predicate in order to perform partition filtering with the `excludeStorageClasses` option.

```
// Correct partition filtering using the AWS Glue pushdown predicate
// with excludeStorageClasses
read_df = glueContext.create_data_frame.from_catalog(
    database=database_name,
    table_name=table_name,
    // Use AWS Glue pushdown predicate to perform partition filtering
    push_down_predicate = "(year=='2017' and month=='04')",
    additional_options = {
        "useSparkDataSource": True,
        "excludeStorageClasses" : ["GLACIER", "DEEP_ARCHIVE"]
    }
)

// Use Spark filter only on non-partitioned columns
```

```
filtered_df = read_df.filter("state == 'CA'")
```

Example: Creating a CSV table using the Spark data source reader

```
// Read a CSV table with '\t' as separator
read_df = glueContext.create_data_frame.from_catalog(
    database=<database_name>,
    table_name=<table_name>,
    additional_options = {"useSparkDataSource": True, "sep": '\t'}
)
```

create_data_frame_from_options

create_data_frame_from_options(connection_type, connection_options={}, format=None, format_options={}, transformation_ctx = "")

This API is now deprecated. Instead use the `getSource()` API. Returns a DataFrame created with the specified connection and format. Use this function only with Amazon Glue streaming sources.

- `connection_type` – The streaming connection type. Valid values include `kinesis` and `kafka`.
- `connection_options` – Connection options, which are different for Kinesis and Kafka. You can find the list of all connection options for each streaming data source at [Connection types and options for ETL in Amazon Glue for Spark](#). Note the following differences in streaming connection options:
 - Kinesis streaming sources require `streamARN`, `startingPosition`, `inferSchema`, and `classification`.
 - Kafka streaming sources require `connectionName`, `topicName`, `startingOffsets`, `inferSchema`, and `classification`.
- `format` – A format specification. This is used for an Amazon S3 or an Amazon Glue connection that supports multiple formats. For information about the supported formats, see [Data format options for inputs and outputs in Amazon Glue for Spark](#).
- `format_options` – Format options for the specified format. For information about the supported format options, see [Data format options for inputs and outputs in Amazon Glue for Spark](#).
- `transformation_ctx` – The transformation context to use (optional).

Example for Amazon Kinesis streaming source:

```
kinesis_options =
  { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
    "startingPosition": "TRIM_HORIZON",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kinesis",
  connection_options=kinesis_options)
```

Example for Kafka streaming source:

```
kafka_options =
  { "connectionName": "ConfluentKafka",
    "topicName": "kafka-auth-topic",
    "startingOffsets": "earliest",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kafka",
  connection_options=kafka_options)
```

forEachBatch

forEachBatch(frame, batch_function, options)

Applies the `batch_function` passed in to every micro batch that is read from the Streaming source.

- `frame` – The `DataFrame` containing the current micro batch.
- `batch_function` – A function that will be applied for every micro batch.
- `options` – A collection of key-value pairs that holds information about how to process micro batches. The following options are required:
 - `windowSize` – The amount of time to spend processing each batch.
 - `checkpointLocation` – The location where checkpoints are stored for the streaming ETL job.
 - `batchMaxRetries` – The maximum number of times to retry the batch if it fails. The default value is 3. This option is only configurable for Glue version 2.0 and above.

Example:

```
glueContext.forEachBatch(  
    frame = data_frame_datasource0,  
    batch_function = processBatch,  
    options = {  
        "windowSize": "100 seconds",  
        "checkpointLocation": "s3://kafka-auth-dataplane/confluent-test/output/  
checkpoint/"  
    }  
)  
  
def processBatch(data_frame, batchId):  
    if (data_frame.count() > 0):  
        datasource0 = DynamicFrame.fromDF(  
            glueContext.add_ingestion_time_columns(data_frame, "hour"),  
            glueContext, "from_data_frame"  
        )  
        additionalOptions_datasink1 = {"enableUpdateCatalog": True}  
        additionalOptions_datasink1["partitionKeys"] = ["ingest_yr", "ingest_mo",  
"ingest_day"]  
        datasink1 = glueContext.write_dynamic_frame.from_catalog(  
            frame = datasource0,  
            database = "tempdb",  
            table_name = "kafka-auth-table-output",  
            transformation_ctx = "datasink1",  
            additional_options = additionalOptions_datasink1  
        )
```

Working with datasets in Amazon S3

- [purge_table](#)
- [purge_s3_path](#)
- [transition_table](#)
- [transition_s3_path](#)

purge_table

```
purge_table(catalog_id=None, database="", table_name="", options={},  
transformation_ctx="")
```

Deletes files from Amazon S3 for the specified catalog's database and table. If all files in a partition are deleted, that partition is also deleted from the catalog. We don't support `purge_table` action on tables registered with Lake Formation.

If you want to be able to recover deleted objects, you can turn on [object versioning](#) on the Amazon S3 bucket. When an object is deleted from a bucket that doesn't have object versioning enabled, the object can't be recovered. For more information about how to recover deleted objects in a version-enabled bucket, see [How can I retrieve an Amazon S3 object that was deleted?](#) in the Amazon Web Services Support Knowledge Center.

- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). Set to `None` by default. `None` defaults to the catalog ID of the calling account in the service.
- `database` – The database to use.
- `table_name` – The name of the table to use.
- `options` – Options to filter files to be deleted and for manifest file generation.
 - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
 - `partitionPredicate` – Partitions satisfying this predicate are deleted. Files within the retention period in these partitions are not deleted. Set to `""` – empty by default.
 - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not deleted. The default is `Set()` – an empty set.
 - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully purged are recorded in `Success.csv`, and those that failed in `Failed.csv`
- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.

Example

```
glueContext.purge_table("database", "table", {"partitionPredicate": "(month=='march')",
"retentionPeriod": 1, "excludeStorageClasses": ["STANDARD_IA"], "manifestFilePath":
"s3://bucketmanifest/"})
```

purge_s3_path

purge_s3_path(s3_path, options={}, transformation_ctx="")

Deletes files from the specified Amazon S3 path recursively.

If you want to be able to recover deleted objects, you can turn on [object versioning](#) on the Amazon S3 bucket. When an object is deleted from a bucket that doesn't have object versioning turned on, the object can't be recovered. For more information about how to recover deleted objects in a bucket with versioning, see [How can I retrieve an Amazon S3 object that was deleted?](#) in the Amazon Web Services Support Knowledge Center.

- **s3_path** – The path in Amazon S3 of the files to be deleted in the format `s3://<bucket>/<prefix>/`
- **options** – Options to filter files to be deleted and for manifest file generation.
 - **retentionPeriod** – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
 - **excludeStorageClasses** – Files with storage class in the `excludeStorageClasses` set are not deleted. The default is `Set()` – an empty set.
 - **manifestFilePath** – An optional path for manifest file generation. All files that were successfully purged are recorded in `Success.csv`, and those that failed in `Failed.csv`
- **transformation_ctx** – The transformation context to use (optional). Used in the manifest file path.

Example

```
glueContext.purge_s3_path("s3://bucket/path/", {"retentionPeriod": 1,
"excludeStorageClasses": ["STANDARD_IA"], "manifestFilePath": "s3://bucketmanifest/"})
```

transition_table

```
transition_table(database, table_name, transition_to, options={},  
transformation_ctx="", catalog_id=None)
```

Transitions the storage class of the files stored on Amazon S3 for the specified catalog's database and table.

You can transition between any two storage classes. For the GLACIER and DEEP_ARCHIVE storage classes, you can transition to these classes. However, you would use an S3 RESTORE to transition from GLACIER and DEEP_ARCHIVE storage classes.

If you're running Amazon Glue ETL jobs that read files or partitions from Amazon S3, you can exclude some Amazon S3 storage class types. For more information, see [Excluding Amazon S3 Storage Classes](#).

- `database` – The database to use.
- `table_name` – The name of the table to use.
- `transition_to` – The [Amazon S3 storage class](#) to transition to.
- `options` – Options to filter files to be deleted and for manifest file generation.
 - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
 - `partitionPredicate` – Partitions satisfying this predicate are transitioned. Files within the retention period in these partitions are not transitioned. Set to "" – empty by default.
 - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not transitioned. The default is `Set()` – an empty set.
 - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully transitioned are recorded in `Success.csv`, and those that failed in `Failed.csv`
 - `accountId` – The Amazon Web Services account ID to run the transition transform. Mandatory for this transform.
 - `roleArn` – The Amazon role to run the transition transform. Mandatory for this transform.
- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.
- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). Set to `None` by default. `None` defaults to the catalog ID of the calling account in the service.

Example

```
glueContext.transition_table("database", "table", "STANDARD_IA", {"retentionPeriod": 1,
  "excludeStorageClasses": ["STANDARD_IA"], "manifestFilePath": "s3://bucketmanifest/",
  "accountId": "12345678901", "roleArn": "arn:aws:iam::123456789012:user/example-username"})
```

transition_s3_path

```
transition_s3_path(s3_path, transition_to, options={},
  transformation_ctx="")
```

Transitions the storage class of the files in the specified Amazon S3 path recursively.

You can transition between any two storage classes. For the GLACIER and DEEP_ARCHIVE storage classes, you can transition to these classes. However, you would use an S3 RESTORE to transition from GLACIER and DEEP_ARCHIVE storage classes.

If you're running Amazon Glue ETL jobs that read files or partitions from Amazon S3, you can exclude some Amazon S3 storage class types. For more information, see [Excluding Amazon S3 Storage Classes](#).

- `s3_path` – The path in Amazon S3 of the files to be transitioned in the format `s3://<bucket>/<prefix>/`
- `transition_to` – The [Amazon S3 storage class](#) to transition to.
- `options` – Options to filter files to be deleted and for manifest file generation.
 - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
 - `partitionPredicate` – Partitions satisfying this predicate are transitioned. Files within the retention period in these partitions are not transitioned. Set to "" – empty by default.
 - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not transitioned. The default is `Set()` – an empty set.
 - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully transitioned are recorded in `Success.csv`, and those that failed in `Failed.csv`
 - `accountId` – The Amazon Web Services account ID to run the transition transform. Mandatory for this transform.
 - `roleArn` – The Amazon role to run the transition transform. Mandatory for this transform.

- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.

Example

```
glueContext.transition_s3_path("s3://bucket/prefix/", "STANDARD_IA",
{"retentionPeriod": 1, "excludeStorageClasses": ["STANDARD_IA"],
"manifestFilePath": "s3://bucketmanifest/", "accountId": "12345678901", "roleArn":
"arn:aws:iam::123456789012:user/example-username"})
```

Extracting

- [extract_jdbc_conf](#)

`extract_jdbc_conf`

`extract_jdbc_conf(connection_name, catalog_id = None)`

Returns a dict with keys with the configuration properties from the Amazon Glue connection object in the Data Catalog.

- `user` – The database user name.
- `password` – The database password.
- `vendor` – Specifies a vendor (`mysql`, `postgresql`, `oracle`, `sqlserver`, etc.).
- `enforceSSL` – A boolean string indicating if a secure connection is required.
- `customJDBCCert` – Use a specific client certificate from the Amazon S3 path indicated.
- `skipCustomJDBCCertValidation` – A boolean string indicating if the `customJDBCCert` must be validated by a CA.
- `customJDBCCertString` – Additional information about the custom certificate, specific for the driver type.
- `url` – (Deprecated) JDBC URL with only protocol, server and port.
- `fullUrl` – JDBC URL as entered when the connection was created (Available in Amazon Glue version 3.0 or later).

Example retrieving JDBC configurations:

```
jdbc_conf = glueContext.extract_jdbc_conf(connection_name="your_glue_connection_name")
print(jdbc_conf)
>>> {'enforceSSL': 'false', 'skipCustomJDBCCertValidation': 'false', 'url':
'jdbc:mysql://myserver:3306', 'fullUrl': 'jdbc:mysql://myserver:3306/mydb',
'customJDBCCertString': '', 'user': 'admin', 'customJDBCCert': '', 'password': '1234',
'vendor': 'mysql'}
```

Transactions

- [start_transaction](#)
- [commit_transaction](#)
- [cancel_transaction](#)

start_transaction

start_transaction(read_only)

Start a new transaction. Internally calls the Lake Formation [startTransaction](#) API.

- `read_only` – (Boolean) Indicates whether this transaction should be read only or read and write. Writes made using a read-only transaction ID will be rejected. Read-only transactions do not need to be committed.

Returns the transaction ID.

commit_transaction

commit_transaction(transaction_id, wait_for_commit = True)

Attempts to commit the specified transaction. `commit_transaction` may return before the transaction has finished committing. Internally calls the Lake Formation [commitTransaction](#) API.

- `transaction_id` – (String) The transaction to commit.
- `wait_for_commit` – (Boolean) Determines whether the `commit_transaction` returns immediately. The default value is true. If false, `commit_transaction` polls and waits until the transaction is committed. The amount of wait time is restricted to 1 minute using exponential backoff with a maximum of 6 retry attempts.

Returns a Boolean to indicate whether the commit is done or not.

cancel_transaction

cancel_transaction(transaction_id)

Attempts to cancel the specified transaction. Returns a `TransactionCommittedException` exception if the transaction was previously committed. Internally calls the Lake Formation [CancelTransaction](#) API.

- `transaction_id` – (String) The transaction to cancel.

Writing

- [getSink](#)
- [write_dynamic_frame_from_options](#)
- [write_from_options](#)
- [write_dynamic_frame_from_catalog](#)
- [write_data_frame_from_catalog](#)
- [write_dynamic_frame_from_jdbc_conf](#)
- [write_from_jdbc_conf](#)

getSink

getSink(connection_type, format = None, transformation_ctx = "", **options)

Gets a `DataSink` object that can be used to write `DynamicFrames` to external sources. Check the SparkSQL format first to be sure to get the expected sink.

- `connection_type` – The connection type to use, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, `kinesis`, and `kafka`.
- `format` – The SparkSQL format to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `options` – A collection of name-value pairs used to specify the connection options. Some of the possible values are:
 - `user` and `password`: For authorization
 - `url`: The endpoint for the data store

- `dbtable`: The name of the target table
- `bulkSize`: Degree of parallelism for insert operations

The options that you can specify depends on the connection type. See [Connection types and options for ETL in Amazon Glue for Spark](#) for additional values and examples.

Example:

```
>>> data_sink = context.getSink("s3")
>>> data_sink.setFormat("json"),
>>> data_sink.writeFrame(myFrame)
```

`write_dynamic_frame_from_options`

```
write_dynamic_frame_from_options(frame, connection_type,
connection_options={}, format=None, format_options={}, transformation_ctx =
"")
```

Writes and returns a `DynamicFrame` using the specified connection and format.

- `frame` – The `DynamicFrame` to write.
- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, `kinesis`, and `kafka`.
- `connection_options` – Connection options, such as path and database table (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

Warning

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from Amazon Secrets Manager or the Amazon Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
  "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
  path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#).

- `format` – A format specification. This is used for an Amazon S3 or an Amazon Glue connection that supports multiple formats. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – A transformation context to use (optional).

`write_from_options`

```
write_from_options(frame_or_dfc, connection_type, connection_options={},
  format={}, format_options={}, transformation_ctx = "")
```

Writes and returns a `DynamicFrame` or `DynamicFrameCollection` that is created with the specified connection and format information.

- `frame_or_dfc` – The `DynamicFrame` or `DynamicFrameCollection` to write.
- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, and `oracle`.
- `connection_options` – Connection options, such as path and database table (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

⚠ Warning

Storing passwords in your script is not recommended. Consider using boto3 to retrieve them from Amazon Secrets Manager or the Amazon Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
  "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
  path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#).

- `format` – A format specification. This is used for an Amazon S3 or an Amazon Glue connection that supports multiple formats. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in Amazon Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – A transformation context to use (optional).

write_dynamic_frame_from_catalog

```
write_dynamic_frame_from_catalog(frame, database, table_name,
redshift_tmp_dir, transformation_ctx = "", additional_options = {},
catalog_id = None)
```

Writes and returns a `DynamicFrame` using information from a Data Catalog database and table.

- `frame` – The `DynamicFrame` to write.
- `Database` – The Data Catalog database that contains the table.
- `table_name` – The name of the Data Catalog table associated with the target.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).

- `additional_options` – A collection of optional name-value pairs.
- `catalog_id` — The catalog ID (account ID) of the Data Catalog being accessed. When `None`, the default account ID of the caller is used.

`write_data_frame_from_catalog`

```
write_data_frame_from_catalog(frame, database, table_name,  
redshift_tmp_dir, transformation_ctx = "", additional_options = {},  
catalog_id = None)
```

Writes and returns a `DataFrame` using information from a Data Catalog database and table. This method supports writing to data lake formats (Hudi, Iceberg, and Delta Lake). For more information, see [Using data lake frameworks with Amazon Glue ETL jobs](#).

- `frame` – The `DataFrame` to write.
- `Database` – The Data Catalog database that contains the table.
- `table_name` – The name of the Data Catalog table that is associated with the target.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `additional_options` – A collection of optional name-value pairs.
 - `useSparkDataSink` – When set to `true`, forces Amazon Glue to use the native Spark Data Sink API to write to the table. When you enable this option, you can add any [Spark Data Source options](#) to `additional_options` as needed. Amazon Glue passes these options directly to the Spark writer.
- `catalog_id` – The catalog ID (account ID) of the Data Catalog being accessed. When you don't specify a value, the default account ID of the caller is used.

Limitations

Consider the following limitations when you use the `useSparkDataSink` option:

- The [enableUpdateCatalog](#) option isn't supported when you use the `useSparkDataSink` option.

Example: Writing to a Hudi table using the Spark Data Source writer

```
hoodie_options = {
    'useSparkDataSink': True,
    'hoodie.table.name': <table_name>,
    'hoodie.datasource.write.storage.type': 'COPY_ON_WRITE',
    'hoodie.datasource.write.recordkey.field': 'product_id',
    'hoodie.datasource.write.table.name': <table_name>,
    'hoodie.datasource.write.operation': 'upsert',
    'hoodie.datasource.write.precombine.field': 'updated_at',
    'hoodie.datasource.write.hive_style_partitioning': 'true',
    'hoodie.upsert.shuffle.parallelism': 2,
    'hoodie.insert.shuffle.parallelism': 2,
    'hoodie.datasource.hive_sync.enable': 'true',
    'hoodie.datasource.hive_sync.database': <database_name>,
    'hoodie.datasource.hive_sync.table': <table_name>,
    'hoodie.datasource.hive_sync.use_jdbc': 'false',
    'hoodie.datasource.hive_sync.mode': 'hms'}

glueContext.write_data_frame.from_catalog(
    frame = <df_product_inserts>,
    database = <database_name>,
    table_name = <table_name>,
    additional_options = hoodie_options
)
```

write_dynamic_frame_from_jdbc_conf

```
write_dynamic_frame_from_jdbc_conf(frame, catalog_connection,
connection_options={}, redshift_tmp_dir = "", transformation_ctx = "",
catalog_id = None)
```

Writes and returns a `DynamicFrame` using the specified JDBC connection information.

- `frame` – The `DynamicFrame` to write.
- `catalog_connection` – A catalog connection to use.
- `connection_options` – Connection options, such as path and database table (optional). For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#).
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).
- `catalog_id` – The catalog ID (account ID) of the Data Catalog being accessed. When `None`, the default account ID of the caller is used.

`write_from_jdbc_conf`

```
write_from_jdbc_conf(frame_or_dfc, catalog_connection,  
connection_options={}, redshift_tmp_dir = "", transformation_ctx = "",  
catalog_id = None)
```

Writes and returns a `DynamicFrame` or `DynamicFrameCollection` using the specified JDBC connection information.

- `frame_or_dfc` – The `DynamicFrame` or `DynamicFrameCollection` to write.
- `catalog_connection` – A catalog connection to use.
- `connection_options` – Connection options, such as path and database table (optional). For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#).
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).
- `catalog_id` — The catalog ID (account ID) of the Data Catalog being accessed. When `None`, the default account ID of the caller is used.

Amazon Glue PySpark transforms reference

Amazon Glue provides the following built-in transforms that you can use in PySpark ETL operations. Your data passes from transform to transform in a data structure called a *DynamicFrame*, which is an extension to an Apache Spark SQL `DataFrame`. The `DynamicFrame` contains your data, and you reference its schema to process your data.

Most of these transforms also exist as methods of the `DynamicFrame` class. For more information, see [DynamicFrame transforms](#).

- [GlueTransform base class](#)
- [ApplyMapping class](#)
- [DropFields class](#)
- [DropNullFields class](#)
- [ErrorsAsDynamicFrame class](#)
- [EvaluateDataQuality class](#)
- [FillMissingValues class](#)
- [Filter class](#)

- [FindIncrementalMatches class](#)
- [FindMatches class](#)
- [FlatMap class](#)
- [Join class](#)
- [Map class](#)
- [MapToCollection class](#)
- [mergeDynamicFrame](#)
- [Relationalize class](#)
- [RenameField class](#)
- [ResolveChoice class](#)
- [SelectFields class](#)

- [UnnestFrame class](#)

GlueTransform base class

The base class that all the `aws glue . transforms` classes inherit from.

The classes all define a `__call__` method. They either override the `GlueTransform` class methods listed in the following sections, or they are called using the class name by default.

Methods

- [apply\(cls, *args, **kwargs\)](#)
- [name\(cls\)](#)
- [describeArgs\(cls\)](#)
- [describeReturn\(cls\)](#)
- [describeTransform\(cls\)](#)

- [describeErrors\(cls\)](#)
- [describe\(cls\)](#)

apply(cls, *args, **kwargs)

Applies the transform by calling the transform class, and returns the result.

- `cls` – The self class object.

name(cls)

Returns the name of the derived transform class.

- `cls` – The self class object.

describeArgs(cls)

- `cls` – The self class object.

Returns a list of dictionaries, each corresponding to a named argument, in the following format:

```
[
  {
    "name": "(name of argument)",
    "type": "(type of argument)",
    "description": "(description of argument)",
    "optional": "(Boolean, True if the argument is optional)",
    "defaultValue": "(Default value string, or None)(String; the default value, or None)"
  },
  ...
]
```

Raises a `NotImplementedError` exception when called in a derived transform where it is not implemented.

describeReturn(cls)

- `cls` – The self class object.

Returns a dictionary with information about the return type, in the following format:

```
{
  "type": "(return type)",
  "description": "(description of output)"
}
```

Raises a `NotImplementedError` exception when called in a derived transform where it is not implemented.

describeTransform(cls)

Returns a string describing the transform.

- `cls` – The `self` class object.

Raises a `NotImplementedError` exception when called in a derived transform where it is not implemented.

describeErrors(cls)

- `cls` – The `self` class object.

Returns a list of dictionaries, each describing a possible exception thrown by this transform, in the following format:

```
[
  {
    "type": "(type of error)",
    "description": "(description of error)"
  },
  ...
]
```

describe(cls)

- `cls` – The `self` class object.

Returns an object with the following format:

```
{
  "transform" : {
    "name" : cls.name( ),
    "args" : cls.describeArgs( ),
    "returns" : cls.describeReturn( ),
    "raises" : cls.describeErrors( ),
    "location" : "internal"
  }
}
```

ApplyMapping class

Applies a mapping in a `DynamicFrame`.

Example

We recommend that you use the [DynamicFrame.apply_mapping\(\)](#) method to apply a mapping in a `DynamicFrame`. To view a code example, see [Example: Use apply_mapping to rename fields and change field types](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

`__call__(frame, mappings, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`

Applies a declarative mapping to a specified `DynamicFrame`.

- `frame` – The `DynamicFrame` to apply the mapping to (required).
- `mappings` – A list of mapping tuples (required). Each consists of: (source column, source type, target column, target type).

If the source column has a dot "." in the name, you must place back-ticks "`" around it. For example, to map `this.old.name` (string) to `thisNewName`, you would use the following tuple:

```
("`this.old.name`", "string", "thisNewName", "string")
```

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns only the fields of the `DynamicFrame` that are specified in the "mapping" tuples.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` [apply](#).

name(cls)

Inherited from `GlueTransform` [name](#).

describeArgs(cls)

Inherited from `GlueTransform` [describeArgs](#).

describeReturn(cls)

Inherited from `GlueTransform` [describeReturn](#).

describeTransform(cls)

Inherited from `GlueTransform` [describeTransform](#).

describeErrors(cls)

Inherited from `GlueTransform` [describeErrors](#).

describe(cls)

Inherited from `GlueTransform` [describe](#).

DropFields class

Drops fields within a `DynamicFrame`.

Example

We recommend that you use the [`DynamicFrame.drop_fields\(\)`](#) method to drop fields from a `DynamicFrame`. To view a code example, see [Example: Use `drop_fields` to remove fields from a `DynamicFrame`](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

`__call__(frame, paths, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`

Drops nodes within a `DynamicFrame`.

- `frame` – The `DynamicFrame` to drop the nodes in (required).
- `paths` – A list of full paths to the nodes to drop (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` without the specified fields.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` [apply](#).

name(cls)

Inherited from `GlueTransform` [name](#).

describeArgs(cls)

Inherited from `GlueTransform` [describeArgs](#).

describeReturn(cls)

Inherited from `GlueTransform` [describeReturn](#).

describeTransform(cls)

Inherited from `GlueTransform` [describeTransform](#).

describeErrors(cls)

Inherited from `GlueTransform` [describeErrors](#).

describe(cls)

Inherited from `GlueTransform` [describe](#).

DropNullFields class

Drops all null fields in a `DynamicFrame` whose type is `NullType`. These are fields with missing or null values in every record in the `DynamicFrame` dataset.

Example

This example uses `DropNullFields` to create a new `DynamicFrame` where fields of type `NullType` have been dropped. In order to demonstrate `DropNullFields`, we add a new column named `empty_column` with type `null` to the already-loaded `persons` dataset.

Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use DropNullFields to create a new DynamicFrame without NullType fields

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from pyspark.sql.functions import lit
from pyspark.sql.types import NullType
from awsglue.dynamicframe import DynamicFrame
from awsglue.transforms import DropNullFields

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create DynamicFrame
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()

# Add new column "empty_column" with NullType
persons_with_nulls = persons.toDF().withColumn("empty_column",
    lit(None).cast(NullType()))
persons_with_nulls_dyf = DynamicFrame.fromDF(persons_with_nulls, glueContext,
    "persons_with_nulls")
print("Schema for the persons_with_nulls_dyf DynamicFrame:")
persons_with_nulls_dyf.printSchema()

# Remove the NullType field
persons_no_nulls = DropNullFields.apply(persons_with_nulls_dyf)
print("Schema for the persons_no_nulls DynamicFrame:")
persons_no_nulls.printSchema()
```

Output

```
Schema for the persons DynamicFrame:
root
 |-- family_name: string
 |-- name: string
 |-- links: array
 |    |-- element: struct
 |    |    |-- note: string
 |    |    |-- url: string
```

```
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- sort_name: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- death_date: string
```

Schema for the persons_with_nulls_dyf DynamicFrame:

```
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct

|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
```

```
|-- death_date: string
```

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

`__call__(frame, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`

Drops all null fields in a `DynamicFrame` whose type is `NullType`. These are fields with missing or null values in every record in the `DynamicFrame` dataset.

- `frame` – The `DynamicFrame` to drop null fields in (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` with no null fields.

`apply(cls, *args, **kwargs)`

- `cls` – `cls`

`name(cls)`

- `cls` – `cls`

describeArgs(cls)

- cls – cls

describeReturn(cls)

- cls – cls

describeTransform(cls)

- cls – cls

describeErrors(cls)

- cls – cls

describe(cls)

- cls – cls

ErrorsAsDynamicFrame class

Returns a `DynamicFrame` that contains nested records for errors that occurred while the source `DynamicFrame` was created.

Example

We recommend that you use the [`DynamicFrame.errorsAsDynamicFrame\(\)`](#) method to retrieve and view error records. To view a code example, see [Example: Use errorsAsDynamicFrame to view error records](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)

- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

`__call__(frame)`

Returns a `DynamicFrame` that contains nested error records that relate to the source `DynamicFrame`.

- `frame` – The source `DynamicFrame` (required).

`apply(cls, *args, **kwargs)`

- `cls` – `cls`

`name(cls)`

- `cls` – `cls`

`describeArgs(cls)`

- `cls` – `cls`

`describeReturn(cls)`

- `cls` – `cls`

`describeTransform(cls)`

- `cls` – `cls`

`describeErrors(cls)`

- `cls` – `cls`

describe(cls)

- cls – cls

EvaluateDataQuality class

Evaluates a data quality ruleset against a `DynamicFrame` and returns a new `DynamicFrame` with results of the evaluation.

Example

The following example code demonstrates how to evaluate data quality for a `DynamicFrame` and then view the data quality results.

```
from awsglue.transforms import *
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsgluedq.transforms import EvaluateDataQuality

#Create Glue context
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Define DynamicFrame
legislatorsAreas = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="areas_json")

# Create data quality ruleset
ruleset = """"Rules = [ColumnExists "id", IsComplete "id"]""""

# Evaluate data quality
dqResults = EvaluateDataQuality.apply(
    frame=legislatorsAreas,
    ruleset=ruleset,
    publishing_options={
        "dataQualityEvaluationContext": "legislatorsAreas",
        "enableDataQualityCloudWatchMetrics": True,
        "enableDataQualityResultsPublishing": True,
        "resultsS3Prefix": "amzn-s3-demo-bucket1",
    },
)
```

```
# Inspect data quality results
dqResults.printSchema()
dqResults.toDF().show()
```

Output

```
root
|-- Rule: string
|-- Outcome: string
|-- FailureReason: string
|-- EvaluatedMetrics: map
|   |-- keyType: string
|   |-- valueType: double

+-----+-----+-----+-----+
|Rule          |Outcome|FailureReason|EvaluatedMetrics|
+-----+-----+-----+-----+
|ColumnExists "id"    |Passed |null         |{}              |
|IsComplete "id"     |Passed |null         |{Column.first_name.Completeness -> 1.0}|
+-----+-----+-----+-----+
```

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(frame, ruleset, publishing_options = {})`

- `frame` – The `DynamicFrame` that you want evaluate the data quality of.
- `ruleset` – A Data Quality Definition Language (DQDL) ruleset in string format. To learn more about DQDL, see the [Data Quality Definition Language \(DQDL\) reference](#) guide.

- `publishing_options` – A dictionary that specifies the following options for publishing evaluation results and metrics:
 - `dataQualityEvaluationContext` – A string that specifies the namespace under which Amazon Glue should publish Amazon CloudWatch metrics and the data quality results. The aggregated metrics appear in CloudWatch, while the full results appear in the Amazon Glue Studio interface.
 - Required: No
 - Default value: `default_context`
 - `enableDataQualityCloudWatchMetrics` – Specifies whether the results of the data quality evaluation should be published to CloudWatch. You specify a namespace for the metrics using the `dataQualityEvaluationContext` option.
 - Required: No
 - Default value: `False`
 - `enableDataQualityResultsPublishing` – Specifies whether the data quality results should be visible on the **Data Quality** tab in the Amazon Glue Studio interface.
 - Required: No
 - Default value: `True`
 - `resultsS3Prefix` – Specifies the Amazon S3 location where Amazon Glue can write the data quality evaluation results.
 - Required: No
 - Default value: `""` (empty string)

`apply(cls, *args, **kwargs)`

Inherited from `GlueTransform` [apply](#).

`name(cls)`

Inherited from `GlueTransform` [name](#).

`describeArgs(cls)`

describe(cls)

Inherited from `GlueTransform` [describe](#).

FillMissingValues class

The `FillMissingValues` class locates null values and empty strings in a specified `DynamicFrame` and uses machine learning methods, such as linear regression and random forest, to predict the missing values. The ETL job uses the values in the input dataset to train the machine learning model, which then predicts what the missing values should be.

Tip

If you use incremental data sets, then each incremental set is used as the training data for the machine learning model, so the results might not be as accurate.

To import:

```
from awsglueml.transforms import FillMissingValues
```

Methods

- [Apply](#)

apply(frame, missing_values_column, output_column = "", transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Fills a dynamic frame's missing values in a specified column and returns a new frame with estimates in a new column. For rows without missing values, the specified column's value is duplicated to the new column.

- `frame` – The `DynamicFrame` in which to fill missing values. Required.

- `missing_values_column` – The column containing missing values (null values and empty strings). Required.
- `output_column` – The name of the new column that will contain estimated values for all rows whose value was missing. Optional; the default is the name of `missing_values_column` suffixed by `"_filled"`.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional; the default is zero).
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional; the default is zero).

Returns a new `DynamicFrame` with one additional column that contains estimations for rows with missing values and the present value for other rows.

Filter class

Builds a new `DynamicFrame` that contains records from the input `DynamicFrame` that satisfy a specified predicate function.

Example

We recommend that you use the [`DynamicFrame.filter\(\)`](#) method to filter records in a `DynamicFrame`. To view a code example, see [Example: Use filter to get a filtered selection of fields](#).

Methods

- [`__call__`](#)
- [`apply`](#)
- [`name`](#)
- [`describeArgs`](#)
- [`describeReturn`](#)
- [`describeTransform`](#)
- [`describeErrors`](#)
- [`describe`](#)

`__call__(frame, f, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Returns a new `DynamicFrame` that is built by selecting records from the input `DynamicFrame` that satisfy a specified predicate function.

- `frame` – The source `DynamicFrame` to apply the specified filter function to (required).
- `f` – The predicate function to apply to each `DynamicRecord` in the `DynamicFrame`. The function must take a `DynamicRecord` as its argument and return `True` if the `DynamicRecord` meets the filter requirements, or `False` if it doesn't (required).

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

`apply(cls, *args, **kwargs)`

Inherited from `GlueTransform` [apply](#).

`name(cls)`

Inherited from `GlueTransform` [name](#).

`describeArgs(cls)`

Inherited from `GlueTransform` [describeArgs](#).

`describeReturn(cls)`

Inherited from `GlueTransform` [describeReturn](#).

`describeTransform(cls)`

Inherited from `GlueTransform` [describeTransform](#).

describeErrors(cls)

Inherited from `GlueTransform` [describeErrors](#).

describe(cls)

Inherited from `GlueTransform` [describe](#).

FindIncrementalMatches class

Identifies matching records in the existing and incremental `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

To import:

```
from awsglueml.transforms import FindIncrementalMatches
```

Methods

- [Apply](#)

apply(existingFrame, incrementalFrame, transformId, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0, enforcedMatches = none, computeMatchConfidenceScores = 0)

Identifies matching records in the input `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

- `existingFrame` – The existing and pre-matched `DynamicFrame` to apply the `FindIncrementalMatches` transform. Required.
- `incrementalFrame` – The incremental `DynamicFrame` to apply the `FindIncrementalMatches` transform to match against the `existingFrame`. Required.
- `transformId` – The unique ID associated with the `FindIncrementalMatches` transform to apply on records in the `DynamicFrames`. Required.
- `transformation_ctx` – A unique string that is used to identify stats/state information. Optional.
- `info` – A string to be associated with errors in the transformation. Optional.
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out. Optional. The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out. Optional. The default is zero.
- `enforcedMatches` – The `DynamicFrame` used to enforce matches. Optional. The default is `None`.
- `computeMatchConfidenceScores` – A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is `false`.

Returns a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

FindMatches class

Identifies matching records in the input `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

To import:

```
from awsglueml.transforms import FindMatches
```

Methods

- [Apply](#)

`apply(frame, transformId, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0, enforcedMatches = none, computeMatchConfidenceScores = 0)`

Identifies matching records in the input `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

- `frame` – The `DynamicFrame` to apply the `FindMatches` transform. Required.
- `transformId` – The unique ID associated with the `FindMatches` transform to apply on records in the `DynamicFrame`. Required.
- `transformation_ctx` – A unique string that is used to identify stats/state information. Optional.
- `info` – A string to be associated with errors in the transformation. Optional.
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out. Optional. The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out. Optional. The default is zero.
- `enforcedMatches` – The `DynamicFrame` used to enforce matches. Optional. The default is `None`.
- `computeMatchConfidenceScores` – A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is `false`.

Returns a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

FlatMap class

Applies a transform to each `DynamicFrame` in a collection. Results are not flattened into a single `DynamicFrame`, but preserved as a collection.

Examples for FlatMap

The following example snippet demonstrates how to use the `ResolveChoice` transform on a collection of dynamic frames when applied to a `FlatMap`. The data used for input is in the JSON located at the placeholder Amazon S3 address `s3://bucket/path-for-data/sample.json` and contains the following data.

Example JSON data

```
[{
  "firstname": "Arnav",
  "lastname": "Desai",
  "address": {
    "street": "6 Anyroad Avenue",
    "city": "London",
    "state": "England",
    "country": "UK"
  },
  "phone": 17235550101,
  "affiliations": [
    "General Anonymous Example Products",
    "Example Independent Research",
    "Government Department of Examples"
  ]
},
{
  "firstname": "Mary",
```

```

    "lastname": "Major",
    "address": {
      "street": "7821 Spot Place",
      "city": "Centerville",
      "state": "OK",
      "country": "US"
    },
    "phone": 19185550023,
    "affiliations": [
      "Example Dot Com",
      "Example Independent Research",
      "Example.io"
    ]
  },
  {
    "firstname": "Paulo",
    "lastname": "Santos",
    "address": {
      "street": "123 Maple Street",
      "city": "London",
      "state": "Ontario",
      "country": "CA"
    },
    "phone": 12175550181,
    "affiliations": [
      "General Anonymous Example Products",
      "Example Dot Com"
    ]
  }
]}

```

Example Apply ResolveChoice to a DynamicFrameCollection and show output.

```

#Read DynamicFrame
datasource = glueContext.create_dynamic_frame_from_options("s3", connection_options =
  {"paths":["s3://bucket/path/to/file/mysamplejson.json"]}, format="json")
datasource.printSchema()
datasource.show()

## Split to create a DynamicFrameCollection
split_frame=datasource.split_fields(["firstname","lastname","address"],"personal_info","business")
split_frame.keys()
print("---")

```

```
## Use FlatMap to run ResolveChoice
kwargs = {"choice": "cast:string"}
flat = FlatMap.apply(split_frame, ResolveChoice, frame_name="frame",
                    transformation_ctx='tcx', **kwargs)
flat.keys()

##Select one of the DynamicFrames
personal_info = flat.select("personal_info")
personal_info.printSchema()
personal_info.show()
print("---")

business_info = flat.select("business_info")
business_info.printSchema()
business_info.show()
```

Important

When calling `FlatMap.apply`, the `frame_name` parameter **must** be "frame". No other value is currently accepted.

Example output

```
root
|-- firstname: string
|-- lastname: string
|-- address: struct
|   |-- street: string
|   |-- city: string
|   |-- state: string
|   |-- country: string
|-- phone: long
|-- affiliations: array
|   |-- element: string
---
{
  "firstname": "Mary",
  "lastname": "Major",
  "address": {
    "street": "7821 Spot Place",
    "city": "Centerville",
```

```
    "state": "OK",
    "country": "US"
  },
  "phone": 19185550023,
  "affiliations": [
    "Example Dot Com",
    "Example Independent Research",
    "Example.io"
  ]
}

{
  "firstname": "Paulo",
  "lastname": "Santos",
  "address": {
    "street": "123 Maple Street",
    "city": "London",
    "state": "Ontario",
    "country": "CA"
  },

Methods

- [__call__](#)
- [Apply](#)
- [Name](#)
- [describeArgs](#)

- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

`__call__(dfc, BaseTransform, frame_name, transformation_ctx = "", **base_kwargs)`

Applies a transform to each `DynamicFrame` in a collection and flattens the results.

- `dfc` – The `DynamicFrameCollection` over which to flatmap (required).
- `BaseTransform` – A transform derived from `GlueTransform` to apply to each member of the collection (required).
- `frame_name` – The argument name to pass the elements of the collection to (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `base_kwargs` – Arguments to pass to the base transform (required).

Returns a new `DynamicFrameCollection` created by applying the transform to each `DynamicFrame` in the source `DynamicFrameCollection`.

`apply(cls, *args, **kwargs)`

Inherited from `GlueTransform` [apply](#).

`name(cls)`

Inherited from `GlueTransform` [name](#).

`describeArgs(cls)`

Inherited from `GlueTransform` [describe](#).

Join class

Performs an equality join on two `DynamicFrames`.

Example

We recommend that you use the `DynamicFrame.join()` method to join `DynamicFrames`. To view a code example, see [Example: Use join to combine DynamicFrames](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

`__call__(frame1, frame2, keys1, keys2, transformation_ctx = "")`

Performs an equality join on two `DynamicFrames`.

- `frame1` – The first `DynamicFrame` to join (required).
- `frame2` – The second `DynamicFrame` to join (required).
- `keys1` – The keys to join on for the first frame (required).
- `keys2` – The keys to join on for the second frame (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).

Returns a new `DynamicFrame` that is created by joining the two `DynamicFrames`.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` [apply](#).

name(cls)

Inherited from `GlueTransform` [name](#).

describeArgs(cls)

Inherited from `GlueTransform` [describeArgs](#).

describeReturn(cls)

Map class

Builds a new `DynamicFrame` by applying a function to all records in the input `DynamicFrame`.

Example

We recommend that you use the [DynamicFrame.map\(\)](#) method to apply a function to all records in a `DynamicFrame`. To view a code example, see [Example: Use map to apply a function to every record in a DynamicFrame](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)

- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

`__call__(frame, f, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Returns a new `DynamicFrame` that results from applying the specified function to all `DynamicRecords` in the original `DynamicFrame`.

- `frame` – The original `DynamicFrame` to apply the mapping function to (required).
- `f` – The function to apply to all `DynamicRecords` in the `DynamicFrame`. The function must take a `DynamicRecord` as an argument and return a new `DynamicRecord` that is produced by the mapping (required).

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in an Apache Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` that results from applying the specified function to all `DynamicRecords` in the original `DynamicFrame`.

`apply(cls, *args, **kwargs)`

describe(cls)

Inherited from `GlueTransform` [describe](#).

MapToCollection class

Applies a transform to each `DynamicFrame` in the specified `DynamicFrameCollection`.

Methods

- [__call__](#)
- [Apply](#)
- [Name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

`__call__(dfc, BaseTransform, frame_name, transformation_ctx = "", **base_kwargs)`

Applies a transform function to each `DynamicFrame` in the specified `DynamicFrameCollection`.

- `dfc` – The `DynamicFrameCollection` over which to apply the transform function (required).
- `callable` – A callable transform function to apply to each member of the collection (required).

- `transformation_ctx` – A unique string that is used to identify state information (optional).

Returns a new `DynamicFrameCollection` created by applying the transform to each `DynamicFrame` in the source `DynamicFrameCollection`.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` [apply](#)

name(cls)

Inherited from `GlueTransform` [name](#).

describeArgs(cls)

Inherited from `GlueTransform` [describeArgs](#).

describeReturn(cls)

Inherited from `GlueTransform` [describeReturn](#).

Inherited from `GlueTransform` [describeTransform](#).

describeErrors(cls)

Inherited from `GlueTransform` [describeErrors](#).

describe(cls)

Inherited from `GlueTransform` [describe](#).

Relationalize class

Flattens a nested schema in a `DynamicFrame` and pivots out array columns from the flattened frame.

Example

We recommend that you use the [`DynamicFrame.relationalize\(\)`](#) method to relationalize a `DynamicFrame`. To view a code example, see [Example: Use relationalize to flatten a nested schema in a `DynamicFrame`](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(frame, staging_path=None, name='roottable', options=None, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`

Relationalizes a `DynamicFrame` and produces a list of frames that are generated by unnesting nested columns and pivoting array columns. You can join a pivoted array column to the root table by using the join key that is generated in the unnest phase.

- `frame` – The `DynamicFrame` to relationalize (required).
- `staging_path` – The path where the method can store partitions of pivoted tables in CSV format (optional). Pivoted tables are read back from this path.
- `name` – The name of the root table (optional).
- `options` – A dictionary of optional parameters. Currently unused.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

`apply(cls, *args, **kwargs)`

Inherited from `GlueTransform` [apply](#).

name(cls)

Inherited from `GlueTransform` [name](#).

describeArgs(cls)

Inherited from `GlueTransform` [describeArgs](#).

describeReturn(cls)

Inherited from `GlueTransform` [describeReturn](#).

describeTransform(cls)

Inherited from `GlueTransform` [describeTransform](#).

describeErrors(cls)

Inherited from `GlueTransform` [describeErrors](#).

describe(cls)

Inherited from `GlueTransform` [describe](#).

RenameField class

Renames a node within a `DynamicFrame`.

Example

We recommend that you use the [DynamicFrame.rename_field\(\)](#) method to rename a field in a `DynamicFrame`. To view a code example, see [Example: Use rename_field to rename fields in a DynamicFrame](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)

- [describe](#)

`__call__(frame, old_name, new_name, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`

Renames a node within a `DynamicFrame`.

- `frame` – The `DynamicFrame` in which to rename a node (required).
- `old_name` – The full path to the node to rename (required).

If the old name has dots in it, `RenameField` will not work unless you place backticks around it (```). For example, to replace `this.old.name` with `thisNewName`, you would call `RenameField` as follows:

```
newDyF = RenameField(oldDyF, "`this.old.name`", "thisNewName")
```

- `new_name` – The new name, including full path (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

ResolveChoice class

Resolves a choice type within a `DynamicFrame`.

Example

We recommend that you use the [`DynamicFrame.resolveChoice\(\)`](#) method to handle fields that contain multiple types in a `DynamicFrame`. To view a code example, see [Example: Use `resolveChoice` to handle a column that contains multiple types](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(frame, specs = none, choice = "", transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`

Provides information for resolving ambiguous types within a `DynamicFrame`. It returns the resulting `DynamicFrame`.

- `frame` – The `DynamicFrame` in which to resolve the choice type (required).
- `specs` – A list of specific ambiguities to resolve, each in the form of a tuple: (`path`, `action`). The `path` value identifies a specific ambiguous element, and the `action` value identifies the corresponding resolution.

You can only use one of the `spec` and `choice` parameters. If the `spec` parameter is not `None`, then the `choice` parameter must be an empty string. Conversely, if the `choice` is not an empty string, then the `spec` parameter must be `None`. If neither parameter is provided, Amazon Glue tries to parse the schema and use it to resolve ambiguities.

You can specify one of the following resolution strategies in the `action` portion of a `specs` tuple:

- `cast` – Allows you to specify a type to cast to (for example, `cast:int`).
- `make_cols` – Resolves a potential ambiguity by flattening the data. For example, if `columnA` could be an `int` or a `string`, the resolution is to produce two columns named `columnA_int` and `columnA_string` in the resulting `DynamicFrame`.
- `make_struct` – Resolves a potential ambiguity by using a struct to represent the data. For example, if data in a column could be an `int` or a `string`, using the `make_struct` action produces a column of structures in the resulting `DynamicFrame` with each containing both an `int` and a `string`.
- `project` – Resolves a potential ambiguity by retaining only values of a specified type in the resulting `DynamicFrame`. For example, if data in a `ChoiceType` column could be an `int` or a `string`, specifying a `project:string` action drops values from the resulting `DynamicFrame` that are not `string`.

If the `path` identifies an array, place empty square brackets after the name of the array to avoid ambiguity. For example, suppose you are working with data structured as follows:

```
"myList": [  
  { "price": 100.00 },  
  { "price": "$100.00" }  
]
```

You can select the numeric rather than the string version of the price by setting the `path` to `"myList[].price"`, and setting the `action` to `"cast:double"`.

- `choice` – The default resolution action if the `specs` parameter is `None`. If the `specs` parameter is not `None`, then this must not be set to anything but an empty string.

In addition to the specs actions previously described, this argument also supports the following action:

- `MATCH_CATALOG` – Attempts to cast each `ChoiceType` to the corresponding type in the specified Data Catalog table.
- `database` – The Amazon Glue Data Catalog database to use with the `MATCH_CATALOG` choice (required for `MATCH_CATALOG`).
- `table_name` – The Amazon Glue Data Catalog table name to use with the `MATCH_CATALOG` action (required for `MATCH_CATALOG`).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

SelectFields class

The `SelectFields` class creates a new `DynamicFrame` from an existing `DynamicFrame`, and keeps only the fields that you specify. `SelectFields` provides similar functionality to a SQL `SELECT` statement.

Example

We recommend that you use the [DynamicFrame.select_fields\(\)](#) method to select fields from a `DynamicFrame`. To view a code example, see [Example: Use select_fields to create a new DynamicFrame with chosen fields](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

`__call__(frame, paths, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`

Gets fields (nodes) in a `DynamicFrame`.

- `frame` – The `DynamicFrame` to select fields in (required).
- `paths` – A list of full paths to the fields to select (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` that contains only the specified fields.

`apply(cls, *args, **kwargs)`

SelectFromCollection class

Selects one `DynamicFrame` in a `DynamicFrameCollection`.

Example

This example uses `SelectFromCollection` to select a `DynamicFrame` from a `DynamicFrameCollection`.

Example dataset

The example selects two DynamicFrames from a DynamicFrameCollection called `split_rows_collection`. The following is the list of keys in `split_rows_collection`.

```
dict_keys(['high', 'low'])
```

Example code

```
# Example: Use SelectFromCollection to select
# DynamicFrames from a DynamicFrameCollection

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import SelectFromCollection

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Select frames and inspect entries
frame_low = SelectFromCollection.apply(dfc=split_rows_collection, key="low")
frame_low.toDF().show()

frame_high = SelectFromCollection.apply(dfc=split_rows_collection, key="high")
frame_high.toDF().show()
```

Output

```

Methods

- [__call__](#)
- [apply](#)
- [name](#)

- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(dfc, key, transformation_ctx = "")`

Gets one `DynamicFrame` from a `DynamicFrameCollection`.

- `dfc` – The `DynamicFrameCollection` that the `DynamicFrame` should be selected from (required).
- `key` – The key of the `DynamicFrame` to select (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).

Simplify_ddb_json class

Simplifies nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new simplified `DynamicFrame`.

Example

We recommend that you use the `DynamicFrame.simplify_ddb_json()` method to simplify nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure. To view a code example, see [Example: Use simplify_ddb_json to invoke a DynamoDB JSON simplify](#).

Spigot class

Writes sample records to a specified destination to help you verify the transformations performed by your Amazon Glue job.

Example

We recommend that you use the [DynamicFrame.spigot\(\)](#) method to write a subset of records from a `DynamicFrame` to a specified destination. To view a code example, see [Example: Use spigot to write sample fields from a DynamicFrame to Amazon S3](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(frame, path, options, transformation_ctx = "")`

Writes sample records to a specified destination during a transformation.

- `frame` – The `DynamicFrame` to spigot (required).
- `path` – The path of the destination to write to (required).
- `options` – JSON key-value pairs that specify options (optional). The "topk" option specifies that the first *k* records should be written. The "prob" option specifies the probability (as a decimal) of picking any given record. You use this in selecting records to write.
- `transformation_ctx` – A unique string that is used to identify state information (optional).

`SplitFields` class

Splits a `DynamicFrame` into two new ones, by specified fields.

Example

We recommend that you use the `DynamicFrame.split_fields()` method to split fields in a `DynamicFrame`. To view a code example, see [Example: Use `split_fields` to split selected fields into a separate `DynamicFrame`](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(frame, paths, name1 = none, name2 = none, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`

Splits one or more fields in a `DynamicFrame` off into a new `DynamicFrame`, and creates another new `DynamicFrame` that contains the fields that remain.

- `frame` – The source `DynamicFrame` to split into two new ones (required).
- `paths` – A list of full paths to the fields to be split (required).
- `name1` – The name to assign to the `DynamicFrame` that will contain the fields to be split off (optional). If no name is supplied, the name of the source frame is used with "1" appended.
- `name2` – The name to assign to the `DynamicFrame` that will contain the fields that remain after the specified fields are split off (optional). If no name is provided, the name of the source frame is used with "2" appended.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

`apply(cls, *args, **kwargs)`

`describe(cls)`

Inherited from `GlueTransform` [describe](#).

SplitRows class

Creates a `DynamicFrameCollection` that contains two `DynamicFrames`. One `DynamicFrame` contains only the specified rows to be split, and the other contains all remaining rows.

Example

We recommend that you use the `DynamicFrame.split_rows()` method to split rows in a `DynamicFrame`. To view a code example, see [Example: Use split_rows to split rows in a DynamicFrame](#).

Methods

- [__call__](#)

- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(frame, comparison_dict, name1="frame1", name2="frame2", transformation_ctx = "", info = none, stageThreshold = 0, totalThreshold = 0)`

Splits one or more rows in a `DynamicFrame` off into a new `DynamicFrame`.

- `frame` – The source `DynamicFrame` to split into two new ones (required).
- `comparison_dict` – A dictionary where the key is the full path to a column, and the value is another dictionary for mapping comparators to values that the column values are compared to. For example, `{"age": {">": 10, "<": 20}}` splits rows where the value of "age" is between 10 and 20, exclusive, from rows where "age" is outside that range (required).
- `name1` – The name to assign to the `DynamicFrame` that will contain the rows to be split off (optional).
- `name2` – The name to assign to the `DynamicFrame` that will contain the rows that remain after the specified rows are split off (optional).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

`apply(cls, *args, **kwargs)`

describe(cls)

Inherited from `GlueTransform` [describe](#).

Unbox class

Unboxes (reformats) a string field in a `DynamicFrame`.

Example

We recommend that you use the [`DynamicFrame.unbox\(\)`](#) method to unbox a field in a `DynamicFrame`. To view a code example, see [Example: Use unbox to unbox a string field into a struct](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)

- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(frame, path, format, transformation_ctx = "", info="", stageThreshold=0, totalThreshold=0, **options)`

Unboxes a string field in a `DynamicFrame`.

- `frame` – The `DynamicFrame` in which to unbox a field. (required).
- `path` – The full path to the `StringNode` to unbox (required).
- `format` – A format specification (optional). This is used for an Amazon S3 or Amazon Glue connection that supports multiple formats. For the formats that are supported, see [Data format options for inputs and outputs in Amazon Glue for Spark](#).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.
- `separator` – A separator token (optional).
- `escaper` – An escape token (optional).
- `skipFirst` – True if the first line of data should be skipped, or False if it should not be skipped (optional).
- `withSchema` – A string that contains a schema for the data to be unboxed (optional). This should always be created using `StructType.json`.
- `withHeader` – True if the data being unpacked includes a header, or False if not (optional).

`apply(cls, *args, **kwargs)`

UnnestFrame class

Unnests a `DynamicFrame`, flattens nested objects to top-level elements, and generates join keys for array objects.

Example

We recommend that you use the `DynamicFrame.unnest()` method to flatten nested structures in a `DynamicFrame`. To view a code example, see [Example: Use unnest to turn nested fields into top-level fields](#).

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)

- [describeErrors](#)
- [describe](#)

`__call__(frame, transformation_ctx = "", info="", stageThreshold=0, totalThreshold=0)`

Unnests a `DynamicFrame`, flattens nested objects to top-level elements, and generates join keys for array objects.

- `frame` – The `DynamicFrame` to unnest (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

`apply(cls, *args, **kwargs)`

Inherited from `GlueTransform` [describeErrors](#).

describe(cls)

Inherited from GlueTransform [describe](#).

FlagDuplicatesInColumn class

The FlagDuplicatesInColumn transform returns a new column with a specified value in each row that indicates whether the value in the row's source column matches a value in an earlier row of the source column. When matches are found, they are flagged as duplicates. The initial occurrence is not flagged, because it doesn't match an earlier row.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

datasource1 = spark.read.json("s3://${BUCKET}/json/zips/raw/data")

try:
    df_output = column.FlagDuplicatesInColumn.apply(
        data_frame=datasource1,
        spark_context=sc,
        source_column="city",
        target_column="flag_col",
        true_string="True",
        false_string="False"
    )
except:
    print("Unexpected Error happened ")
    raise
```

Output

The FlagDuplicatesInColumn transformation will add a new column `flag_col` to the `df_output` DataFrame. This column will contain a string value indicating whether the corresponding row has a duplicate value in the `city` column or not. If a row has a duplicate `city` value, the `flag_col` will contain the `true_string` value "True". If a row has a unique `city` value, the `flag_col` will contain the `false_string` value "False".

The resulting `df_output` DataFrame will contain all columns from the original datasource1` DataFrame, plus the additional flag_col` column indicating duplicate city` values.`

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(spark_context, data_frame, source_column, target_column, true_string=DEFAULT_TRUE_STRING, false_string=DEFAULT_FALSE_STRING)`

The `FlagDuplicatesInColumn` transform returns a new column with a specified value in each row that indicates whether the value in the row's source column matches a value in an earlier row of the source column. When matches are found, they are flagged as duplicates. The initial occurrence is not flagged, because it doesn't match an earlier row.

- `source_column` – Name of the source column.
- `target_column` – Name of the target column.
- `true_string` – String to be inserted in the target column when a source column value duplicates an earlier value in that column.
- `false_string` – String to be inserted in the target column when a source column value is distinct from earlier values in that column.

`apply(cls, *args, **kwargs)`

Inherited from `GlueTransform` [apply](#).

`name(cls)`

Inherited from `GlueTransform` [name](#).

describeArgs(cls)

Inherited from `GlueTransform` [describeArgs](#).

describeReturn(cls)

Inherited from `GlueTransform` [describeReturn](#).

describeTransform(cls)

Inherited from `GlueTransform` [describeTransform](#).

describeErrors(cls)

Inherited from `GlueTransform` [describeErrors](#).

describe(cls)

Inherited from `GlueTransform` [describe](#).

FormatPhoneNumber class

The `FormatPhoneNumber` transform returns a column in which a phone number string is converted into a formatted value.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsglue.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        ("408-341-5669",),
        ("4083415669",)
    ],
    ["phone"],
)
```

```
try:
    df_output = column_formatting.FormatPhoneNumber.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="phone",
        default_region="US"
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be:

```
...
+-----+
| phone|
+-----+
|(408) 341-5669|
|(408) 341-5669|
+-----+
...

```

The `FormatPhoneNumber` transformation takes the `source_column` as `"phone"` and the `default_region` as `"US"`.

The transformation successfully formats both phone numbers, regardless of their initial format, to the standard US format `(408) 341-5669`.

Methods

- [describeTransform](#)

- [describeErrors](#)
- [describe](#)

`__call__(spark_context, data_frame, source_column, phone_number_format=None, default_region=None, default_region_column=None)`

The `FormatPhoneNumber` transform returns a column in which a phone number string is converted into a formatted value.

- `source_column` – The name of an existing column.
- `phone_number_format` – The format to convert the phone number to. If no format is specified, the default is `E.164`, an internationally-recognized standard phone number format. Valid values include the following:
 - `E164` (omit the period after E)
- `default_region` – A valid region code consisting of two or three uppercase letters that specifies the region for the phone number when no country code is present in the number itself. At most, one of `defaultRegion` or `defaultRegionColumn` can be provided.
- `default_region_column` – The name of a column of the advanced data type `Country`. The region code from the specified column is used to determine the country code for the phone number when no country code is present in the number itself. At most, one of `defaultRegion` or `defaultRegionColumn` can be provided.

FormatCase class

The FormatCase transform changes each string in a column to the specified case type.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

datasource1 = spark.read.json("s3://${BUCKET}/json/zips/raw/data")

try:
    df_output = data_cleaning.FormatCase.apply(
        data_frame=datasource1,
        spark_context=sc,
        source_column="city",
        case_type="LOWER"
    )
except:
    print("Unexpected Error happened ")
    raise
```

Output

The FormatCase transformation will convert the values in the `city` column to lowercase based on the `case_type="LOWER"` parameter. The resulting `df_output` DataFrame will contain

all columns from the original ``datasource1`` DataFrame, but with the ``city`` column values in lowercase.

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(spark_context, data_frame, source_column, case_type)`

The `FormatCase` transform changes each string in a column to the specified case type.

- `source_column` – The name of an existing column.
- `case_type` – Supported case types are `CAPITAL`, `LOWER`, `UPPER`, `SENTENCE`.

`describeTransform(cls)`

Inherited from `GlueTransform` [describeTransform](#).

describeErrors(cls)

Inherited from GlueTransform [describeErrors](#).

describe(cls)

Inherited from GlueTransform [describe](#).

FillWithMode class

The `FillWithMode` transform formats a column according to the phone number format you specify. You can also specify tie-breaker logic, where some of the values are identical. For example, consider the following values: 1 2 2 3 3 4

A `modeType` of `MINIMUM` causes `FillWithMode` to return 2 as the mode value. If `modeType` is `MAXIMUM`, the mode is 3. For `AVERAGE`, the mode is 2.5.

Example

```
from awsglue.context import *
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (105.111, 13.12),
        (1055.123, 13.12),
        (None, 13.12),
        (13.12, 13.12),
        (None, 13.12),
    ],
    ["source_column_1", "source_column_2"],
)

try:
    df_output = data_quality.FillWithMode.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column_1",
        mode_type="MAXIMUM"
    )
```

```
df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output of the given code will be:

```
````
+-----+-----+
|source_column_1|source_column_2|
+-----+-----+
105.111	13.12
1055.123	13.12
1055.123	13.12
13.12	13.12
1055.123	13.12
+-----+-----+
````
```

The `FillWithMode` transformation from the `awsglue.data_quality` module is applied to the `input_df` DataFrame. It replaces the `null` values in the `source_column_1` column with the maximum value (`mode_type="MAXIMUM"`) from the non-null values in that column.

In this case, the maximum value in the `source_column_1` column is `1055.123`. Therefore, the `null` values in `source_column_1` are replaced by `1055.123` in the output DataFrame `df_output`.

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

__call__(spark_context, data_frame, source_column, mode_type)

The FillWithMode transform formats the case of strings in a column.

- `source_column` – The name of an existing column.
- `mode_type` – How to resolve tie values in the data. This value must be one of MINIMUM, NONE, AVERAGE, or MAXIMUM.

apply(cls, *args, **kwargs)

describe(cls)

Inherited from GlueTransform [describe](#).

FlagDuplicateRows class

The FlagDuplicateRows transform returns a new column with a specified value in each row that indicates whether that row is an exact match of an earlier row in the dataset. When matches are found, they are flagged as duplicates. The initial occurrence is not flagged, because it doesn't match an earlier row.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsglue.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (105.111, 13.12),
        (13.12, 13.12),
        (None, 13.12),
        (13.12, 13.12),
        (None, 13.12),
    ],
    ["source_column_1", "source_column_2"],
)

try:
    df_output = data_quality.FlagDuplicateRows.apply(
        data_frame=input_df,
        spark_context=sc,
        target_column="flag_row",
        true_string="True",
        false_string="False",
        target_index=1
    )
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be a PySpark DataFrame with an additional column `flag_row` that indicates whether a row is a duplicate or not, based on the `source_column_1` column. The resulting `df_output` DataFrame will contain the following rows:`

```
...
+-----+-----+-----+
|source_column_1|source_column_2|flag_row|
```

```
+-----+-----+-----+
| 105.111| 13.12| False|
| 13.12| 13.12| True|
| null| 13.12| True|
| 13.12| 13.12| True|
| null| 13.12| True|
+-----+-----+-----+
...

```

The `flag_row` column indicates whether a row is a duplicate or not. The `true_string` is set to "True", and the `false_string` is set to "False". The `target_index` is set to 1, which means that the `flag_row` column will be inserted at the second position (index 1) in the output DataFrame.

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(spark_context, data_frame, target_column, true_string=DEFAULT_TRUE_STRING, false_string=DEFAULT_FALSE_STRING, target_index=None)`

The `FlagDuplicateRows` transform returns a new column with a specified value in each row that indicates whether that row is an exact match of an earlier row in the dataset. When matches are found, they are flagged as duplicates. The initial occurrence is not flagged, because it doesn't match an earlier row.

- `true_string` – Value to be inserted if the row matches an earlier row.
- `false_string` – Value to be inserted if the row is unique.
- `target_column` – Name of the new column that is inserted in the dataset.

apply(cls, *args, **kwargs)

Inherited from GlueTransform [apply](#).

RemoveDuplicates class

The RemoveDuplicates transform deletes an entire row, if a duplicate value is encountered in a selected source column.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)
```

```

input_df = spark.createDataFrame(
    [
        (105.111, 13.12),
        (13.12, 13.12),
        (None, 13.12),
        (13.12, 13.12),
        (None, 13.12),
    ],
    ["source_column_1", "source_column_2"],
)

try:
    df_output = data_quality.RemoveDuplicates.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column_1"
    )
except:
    print("Unexpected Error happened ")
    raise

```

Output

The output will be a PySpark DataFrame with duplicates removed based on the `source_column_1` column. The resulting `df_output` DataFrame will contain the following rows:

```

...
+-----+-----+
|source_column_1|source_column_2|
+-----+-----+
| 105.111| 13.12|
| 13.12| 13.12|
| null| 13.12|
+-----+-----+
...

```

Note that the rows with `source_column_1` values of `13.12` and `null` appear only once in the output DataFrame, as the duplicates have been removed based on the `source_column_1` column.

MonthName class

The MonthName transform creates a new column containing the name of the month, from a string that represents a date.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

spark.conf.set("spark.sql.legacy.timeParserPolicy", "LEGACY")

input_df = spark.createDataFrame(
    [
        ("20-2018-12",),
        ("2018-20-12",),
        ("20182012",),
        ("12202018",),
        ("20122018",),
        ("20-12-2018",),
        ("12/20/2018",),
        ("02/02/02",),
        ("02 02 2009",),
        ("02/02/2009",),
        ("August/02/2009",),
        ("02/june/2009",),
        ("02/2020/june",),
        ("2013-02-21 06:35:45.658505",),
        ("August 02 2009",),
        ("2013/02/21",),
        (None,),
    ],
    ["column_1"],
)

try:
```

```

df_output = datetime_functions.MonthName.apply(
    data_frame=input_df,
    spark_context=sc,
    source_column="column_1",
    target_column="target_column"
)
df_output.show()
except:
    print("Unexpected Error happened ")
    raise

```

Output

The output will be:

```

...
+-----+-----+
| column_1|target_column|
+-----+-----+
|20-2018-12 | December |
|2018-20-12 | null |
| 20182012| null |
| 12202018| null |
| 20122018| null |
|20-12-2018 | December |
|12/20/2018 | December |
| 02/02/02 | February |
|02 02 2009 | February |
|02/02/2009 | February |
|August/02/2009| August |
|02/june/2009| null |
|02/2020/june| null |
|2013-02-21 06:35:45.658505| February |
|August 02 2009| August |
| 2013/02/21| February |
| null | null |
+-----+-----+
...

```

The MonthName transformation takes the `source_column` as `"column_1"` and the `target_column` as `"target_column"`. It attempts to extract the month name from the date/time strings in the `"column_1"` column and places it in the `"target_column"` column. If the date/

time string is in an unrecognized format or cannot be parsed, the `"target_column"` value is set to ``null``.

The transformation successfully extracts the month name from various date/time formats, such as "20-12-2018", "12/20/2018", "02/02/2009", "2013-02-21 06:35:45.658505", and "August 02 2009".

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(spark_context, data_frame, target_column, source_column=None, value=None)`

The `MonthName` transform creates a new column containing the name of the month, from a string that represents a date.

- `source_column` – The name of an existing column.
- `value` – A character string to evaluate..
- `target_column` – A name for the newly created column.

`apply(cls, *args, **kwargs)`

Inherited from `GlueTransform` [apply](#).

`name(cls)`

Inherited from `GlueTransform` [name](#).

`describeArgs(cls)`

Inherited from `GlueTransform` [describeArgs](#).

describeReturn(cls)

Inherited from GlueTransform [describeReturn](#).

describeTransform(cls)

Inherited from GlueTransform [describeTransform](#).

describeErrors(cls)

Inherited from GlueTransform [describeErrors](#).

describe(cls)

Inherited from GlueTransform [describe](#).

IsEven class

The IsEven transform returns a Boolean value in a new column that indicates whether the source column or value is even. If the source column or value is a decimal, the result is false.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [(5,), (0,), (-1,), (2,), (None,)],
    ["source_column"],
)

try:
    df_output = math_functions.IsEven.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column",
        target_column="target_column",
        value=None,
        true_string="Even",
```

```
        false_string="Not even",
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be:

```
...
+-----+-----+
|source_column|target_column|
+-----+-----+
| 5| Not even|
| 0| Even|
| -1| Not even|
| 2| Even|
| null| null|
+-----+-----+
...
```

The `IsEven` transformation takes the `source_column` as "source_column" and the `target_column` as "target_column". It checks if the value in the `"source_column"` is even or not. If the value is even, it sets the `"target_column"` value to the `true_string` "Even". If the value is odd, it sets the `"target_column"` value to the `false_string` "Not even". If the `"source_column"` value is `null`, the `"target_column"` value is set to `null`.

The transformation correctly identifies the even numbers (0 and 2) and sets the `"target_column"` value to "Even". For odd numbers (5 and -1), it sets the `"target_column"` value to "Not even". For the `null` value in `"source_column"`, the `"target_column"` value is set to `null`.

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)

- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

```
__call__(spark_context, data_frame, target_column, source_column=None,  
true_string=DEFAULT_TRUE_STRING, false_string=DEFAULT_FALSE_STRING, value=None)
```

The IsEven transform returns a Boolean value in a new column that indicates whether the source column or value is even. If the source column or value is a decimal, the result is false.

- `source_column` – The name of an existing column.
- `target_column` – The name of the new column to be created.
- `true_string` – A string that indicates whether the value is even.
- `false_string` – A string that indicates whether the value is not even.

CryptographicHash class

The CryptographicHash transform applies an algorithm to hash values in the column.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsglue.transforms import *

secret = "${SECRET}"
sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (1, "1234560000"),
        (2, "1234560001"),
        (3, "1234560002"),
        (4, "1234560003"),
        (5, "1234560004"),
        (6, "1234560005"),
        (7, "1234560006"),
        (8, "1234560007"),
        (9, "1234560008"),
        (10, "1234560009"),
    ],
    ["id", "phone"],
)

try:
    df_output = pii.CryptographicHash.apply(
        data_frame=input_df,
        spark_context=sc,
        source_columns=["id", "phone"],
        secret_id=secret,
        algorithm="HMAC_SHA256",
        output_format="BASE64",
    )
    df_output.show()
```

```
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be:

```
...
+---+-----+-----+-----+
| id| phone | id_hashed | phone_hashed |
+---+-----+-----+-----+
| 1| 1234560000 | QUI1zXTJiXmfIb... | juDBAmiRnn03g... |
| 2| 1234560001 | ZAUWiZ3dVTzCo... | vC8lgUqBVDMNQ... |
| 3| 1234560002 | ZP4VvZWkqYifu... | K13QAkgsWYpzB... |
| 4| 1234560003 | 3u8v03wQ8EQfj... | CPBzK1P8PZZkV... |
| 5| 1234560004 | eWkQJk4zA0Izx... | aLf7+mHcXqbLs... |
| 6| 1234560005 | xtI9fZCJZCvsa... | dy2DFgdYWmr0p... |

| 8| 1234560007 | H9V1pqvgkFhfS... | g9WKhagIXy9ht... |
| 9| 1234560008 | xDhEuHaxAUbU5... | b3uQLKPY+Q5vU... |
| 10| 1234560009 | GRN6nFXkxk349... | VJdsKt8VbxBbt... |
+---+-----+-----+-----+
...
```

The transformation computes the cryptographic hashes of the values in the `id` and `phone` columns using the specified algorithm and secret key, and encodes the hashes in Base64 format. The resulting `df_output` DataFrame contains all columns from the original `input_df` DataFrame, plus the additional `id_hashed` and `phone_hashed` columns with the computed hashes.

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)

- [describeErrors](#)
- [describe](#)

`__call__(spark_context, data_frame, source_columns, secret_id, algorithm=None, secret_version=None, create_secret_if_missing=False, output_format=None, entity_type_filter=None)`

The CryptographicHash transform applies an algorithm to hash values in the column.

- `source_columns` – An array of existing columns.
- `secret_id` – The ARN of the Secrets Manager secret key. The key used in the hash-based message authentication code (HMAC) prefix algorithm to hash the source columns.
- `secret_version` – Optional. Defaults to the latest secret version.
- `entity_type_filter` – Optional array of entity types. Can be used to encrypt only detected PII in free-text column.
- `create_secret_if_missing` – Optional boolean. If true will attempt to create the secret on behalf of the caller.
- `algorithm` – The algorithm used to hash your data. Valid enum values: MD5, SHA1, SHA256, SHA512, HMAC_MD5, HMAC_SHA1, HMAC_SHA256, HMAC_SHA512.

Decrypt class

The Decrypt transform decrypts inside of Amazon Glue. Your data can also be decrypted outside of Amazon Glue with the Amazon Encryption SDK. If the provided KMS key ARN does not match what was used to encrypt the column, the decrypt operation fails.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsglue.transforms import *

kms = "${KMS}"
sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (1, "1234560000"),
        (2, "1234560001"),
        (3, "1234560002"),
        (4, "1234560003"),
        (5, "1234560004"),
        (6, "1234560005"),
        (7, "1234560006"),
        (8, "1234560007"),
        (9, "1234560008"),
        (10, "1234560009"),
    ],
    ["id", "phone"],
)

try:
    df_encrypt = pii.Encrypt.apply(
        data_frame=input_df,
```

```

    spark_context=sc,
    source_columns=["phone"],
    kms_key_arn=kms
)
df_decrypt = pii.Decrypt.apply(
    data_frame=df_encrypt,
    spark_context=sc,
    source_columns=["phone"],
    kms_key_arn=kms
)
df_decrypt.show()
except:
    print("Unexpected Error happened ")
    raise

```

Output

The output will be a PySpark DataFrame with the original `id` column and the decrypted `phone` column:

```

...
+---+-----+
| id| phone|
+---+-----+
| 1| 1234560000|
| 2| 1234560001|
| 3| 1234560002|
| 4| 1234560003|
| 5| 1234560004|
| 6| 1234560005|
| 7| 1234560006|
| 8| 1234560007|
| 9| 1234560008|
| 10| 1234560009|
+---+-----+
...

```

The Encrypt transform takes the `source_columns` as `["phone"]` and the `kms_key_arn` as the value of the `\${KMS}` environment variable. The transformation encrypts the values in the `phone` column using the specified KMS key. The encrypted DataFrame `df_encrypt` is then passed to the Decrypt transform from the `awsglue.pii` module. It takes the `source_columns`

as `["phone"]` and the `kms_key_arn` as the value of the ``${KMS}`` environment variable. The transformation decrypts the encrypted values in the `phone` column using the same KMS key. The resulting `df_decrypt` DataFrame contains the original `id` column and the decrypted `phone` column.

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(spark_context, data_frame, source_columns, kms_key_arn)`

The Decrypt transform decrypts inside of Amazon Glue. Your data can also be decrypted outside of Amazon Glue with the Amazon Encryption SDK. If the provided KMS key ARN does not match what was used to encrypt the column, the decrypt operation fails.

- `source_columns` – An array of existing columns.
- `kms_key_arn` – The key ARN of the Amazon Key Management Service key to use to decrypt the source columns.

Encrypt class

The Encrypt transform encrypts source columns using the Amazon Key Management Service key. The Encrypt transform can encrypt up to 128 MiB per cell. It will attempt to preserve the format on decryption. To preserve the data type, the data type metadata must serialize to less than 1KB. Otherwise, you must set the `preserve_data_type` parameter to false. The data type metadata will be stored in plaintext in the encryption context.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

kms = "${KMS}"
sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (1, "1234560000"),
        (2, "1234560001"),
        (3, "1234560002"),
        (4, "1234560003"),
        (5, "1234560004"),
        (6, "1234560005"),
        (7, "1234560006"),
```

```

        (8, "1234560007"),
        (9, "1234560008"),
        (10, "1234560009"),
    ],
    ["id", "phone"],
)

try:
    df_encrypt = pii.Encrypt.apply(
        data_frame=input_df,
        spark_context=sc,
        source_columns=["phone"],
        kms_key_arn=kms
    )
except:
    print("Unexpected Error happened ")
    raise

```

Output

The output will be a PySpark DataFrame with the original `id` column and an additional column containing the encrypted values of the `phone` column.

```

...
+---+-----+-----+
| id| phone | phone_encrypted |
+---+-----+-----+
| 1| 1234560000| EncryptedData1234...abc |
| 2| 1234560001| EncryptedData5678...def |
| 3| 1234560002| EncryptedData9012...ghi |
| 4| 1234560003| EncryptedData3456...jkl |
| 5| 1234560004| EncryptedData7890...mno |
| 6| 1234560005| EncryptedData1234...pqr |
| 7| 1234560006| EncryptedData5678...stu |
| 8| 1234560007| EncryptedData9012...vwx |
| 9| 1234560008| EncryptedData3456...yz0 |
| 10| 1234560009| EncryptedData7890...123 |
+---+-----+-----+
...

```

The Encrypt transform takes the `source_columns` as `["phone"]` and the `kms_key_arn` as the value of the `\${KMS}` environment variable. The transformation encrypts the values

in the `phone` column using the specified KMS key. The resulting `df_encrypt` DataFrame contains the original `id` column, the original `phone` column, and an additional column named `phone_encrypted` containing the encrypted values of the `phone` column.

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(spark_context, data_frame, source_columns, kms_key_arn, entity_type_filter=None, preserve_data_type=None)`

The Encrypt transform encrypts source columns using the Amazon Key Management Service key.

- `source_columns` – An array of existing columns.
- `kms_key_arn` – The key ARN of the Amazon Key Management Service key to use to Encrypt the source columns.
- `entity_type_filter` – Optional array of entity types. Can be used to encrypt only detected PII in free-text column.
- `preserve_data_type` – Optional boolean. Defaults to true. If false, the data type will not be stored.

IntToIp class

The IntToIp transform converts the integer value of source column or other value to the corresponding IPv4 value in then target column, and returns the result in a new column.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (3221225473, ),
        (0, ),
        (1, ),
        (100, ),
        (168430090, ),
        (4294967295, ),
        (4294967294, ),
        (4294967296, ),
```

```

        (-1,),
        (None,),
    ],
    ["source_column_int"],
)

try:
    df_output = web_functions.IntToIp.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column_int",
        target_column="target_column",
        value=None
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise

```

Output

The output will be:

```

...
+-----+-----+
|source_column_int|target_column|
+-----+-----+
| 3221225473| 192.0.0.1 |
| 0| 0.0.0.0 |
| 1| 0.0.0.1 |
| 100| 0.0.0.100|
| 168430090 | 10.0.0.10 |
| 4294967295| 255.255.255.255|
| 4294967294| 255.255.255.254|
| 4294967296| null |
| -1| null |
| null| null |
+-----+-----+
...

```

The `IntToIp.apply` transformation takes the `source_column` as `"source_column_int"` and the `target_column` as `"target_column"` and converts the integer values in the

`source_column_int` column to their corresponding IPv4 address representation and stores the result in the `target_column` column.

For valid integer values within the range of IPv4 addresses (0 to 4294967295), the transformation successfully converts them to their IPv4 address representation (e.g., 192.0.0.1, 0.0.0.0, 10.0.0.10, 255.255.255.255).

For integer values outside the valid range (e.g., 4294967296, -1), the `target_column` value is set to `null`. For `null` values in the `source_column_int` column, the `target_column` value is also set to `null`.

Methods

- [__call__](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

`__call__(spark_context, data_frame, target_column, source_column=None, value=None)`

The IntToIp transform converts the integer value of source column or other value to the corresponding IPv4 value in then target column, and returns the result in a new column.

- `sourceColumn` – The name of an existing column.
- `value` – A character string to evaluate.
- `targetColumn` – The name of the new column to be created.

IpToInt class

The IpToInt transform converts the Internet Protocol version 4 (IPv4) value of the source column or other value to the corresponding integer value in the target column, and returns the result in a new column.

Example

For Amazon Glue 4.0 and above, create or update job arguments with key: `--enable-glue-di-transforms`, value: `true`

```
from pyspark.context import SparkContext
from awsgluedi.transforms import *

sc = SparkContext()

input_df = spark.createDataFrame(
    [
        ("192.0.0.1",),
        ("10.10.10.10",),
        ("1.2.3.4",),
        ("1.2.3.6",),
        ("http://12.13.14.15",),
        ("https://16.17.18.19",),
        ("1.2.3.4",),
    ]
```

```

        (None,),
        ("abc",),
        ("abc.abc.abc.abc",),
        ("321.123.123.123",),
        ("244.4.4.4",),
        ("255.255.255.255",),
    ],
    ["source_column_ip"],
)

df_output = web_functions.IpToInt.apply(
    data_frame=input_df,
    spark_context=sc,
    source_column="source_column_ip",
    target_column="target_column",
    value=None
)
df_output.show()

```

Output

The output will be:

```

...
+-----+-----+
|source_column_ip| target_column|
+-----+-----+
| 192.0.0.1| 3221225473|
| 10.10.10.10| 168427722|
| 1.2.3.4| 16909060|
| 1.2.3.6| 16909062|
|http://12.13.14.15| null|
|https://16.17.18.19| null|
| 1.2.3.4| 16909060|
| null| null|
| abc| null|
|abc.abc.abc.abc| null|
| 321.123.123.123| null|
| 244.4.4.4| 4102444804|
| 255.255.255.255| 4294967295|
+-----+-----+
...

```

The `IpToInt` transformation takes the `source_column`` as `"source_column_ip"``` and the `target_column`` as `"target_column"``` and converts the valid IPv4 address strings in the `source_column_ip`` column to their corresponding 32-bit integer representation and stores the result in the `target_column`` column.

For valid IPv4 address strings (e.g., "192.0.0.1", "10.10.10.10", "1.2.3.4"), the transformation successfully converts them to their integer representation (e.g., 3221225473, 168427722, 16909060). For strings that are not valid IPv4 addresses (e.g., URLs, non-IP strings like "abc", invalid IP formats like "abc.abc.abc.abc"), the `target_column`` value is set to `null``. For `null`` values in the `source_column_ip`` column, the `target_column`` value is also set to `null``.

Methods

Data integration transforms

For Amazon Glue 4.0 and above, create or update job arguments with key: `--enable-glue-di-transforms`, value: `true`.

Example job script:

```
from pyspark.context import SparkContext

from awsgluedi.transforms import *
sc = SparkContext()

input_df = spark.createDataFrame(
    [(5,), (0,), (-1,), (2,), (None,)],
    ["source_column"],
)

try:
    df_output = math_functions.IsEven.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column",
```

```
        target_column="target_column",
        value=None,
        true_string="Even",
        false_string="Not even",
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Example Sessions using Notebooks

```
%idle_timeout 2880
%glue_version 4.0
%worker_type G.1X
%number_of_workers 5
%region eu-west-1
```

```
%%configure
{
    "--enable-glue-di-transforms": "true"
}
```

```
from pyspark.context import SparkContext
from awsgluedi.transforms import *

sc = SparkContext()

input_df = spark.createDataFrame(
    [(5,), (0,), (-1,), (2,), (None,)],
    ["source_column"],
)

try:
    df_output = math_functions.IsEven.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column",
        target_column="target_column",
        value=None,
        true_string="Even",
        false_string="Not even",
```

```
)
df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Example Sessions using Amazon CLI

```
aws glue create-session --default-arguments "--enable-glue-di-transforms=true"
```

DI transforms:

- [FlagDuplicatesInColumn class](#)
- [FormatPhoneNumber class](#)
- [FormatCase class](#)

Maven: Bundle the plugin with your Spark applications

You can bundle the transforms dependency with your Spark applications and Spark distributions (version 3.3) by adding the plugin dependency in your Maven pom.xml while developing your Spark applications locally.

```
<repositories>
  ...
  <repository>
    <id>aws-glue-etl-artifacts</id>
    <url>https://aws-glue-etl-artifacts.s3.amazonaws.com/release/ </url>
```

```
</repository>
</repositories>
...
<dependency>
  <groupId>com.amazonaws</groupId>
  <artifactId>AWSGlueTransforms</artifactId>
  <version>4.0.0</version>
</dependency>
```

You can alternatively download the binaries from Amazon Glue Maven artifacts directly and include them in your Spark application as follows.

```
#!/bin/bash
sudo wget -v https://aws-glue-etl-artifacts.s3.amazonaws.com/release/com/amazonaws/
AWSGlueTransforms/4.0.0/AWSGlueTransforms-4.0.0.jar -P /usr/lib/spark/jars/
```

Programming Amazon Glue ETL scripts in Scala

You can find Scala code examples and utilities for Amazon Glue in the [Amazon Glue samples repository](#) on the GitHub website.

Amazon Glue supports an extension of the PySpark Scala dialect for scripting extract, transform, and load (ETL) jobs. The following sections describe how to use the Amazon Glue Scala library and the Amazon Glue API in ETL scripts, and provide reference documentation for the library.

Using Scala to program Amazon Glue ETL scripts

You can automatically generate a Scala extract, transform, and load (ETL) program using the Amazon Glue console, and modify it as needed before assigning it to a job. Or, you can write your own program from scratch. For more information, see [Configuring job properties for Spark jobs in Amazon Glue](#). Amazon Glue then compiles your Scala program on the server before running the associated job.

To ensure that your program compiles without errors and runs as expected, it's important that you load it on a development endpoint in a REPL (Read-Eval-Print Loop) or a Jupyter Notebook and test it there before running it in a job. Because the compile process occurs on the server, you will not have good visibility into any problems that happen there.

Testing a Scala ETL program in a Jupyter notebook on a development endpoint

To test a Scala program on an Amazon Glue development endpoint, set up the development endpoint as described in [Adding a development endpoint](#).

Next, connect it to a Jupyter Notebook that is either running locally on your machine or remotely on an Amazon EC2 notebook server. To install a local version of a Jupyter Notebook, follow the instructions in [Tutorial: Jupyter notebook in JupyterLab](#).

The only difference between running Scala code and running PySpark code on your Notebook is that you should start each paragraph on the Notebook with the the following:

```
%spark
```

This prevents the Notebook server from defaulting to the PySpark flavor of the Spark interpreter.

Testing a Scala ETL program in a Scala REPL

You can test a Scala program on a development endpoint using the Amazon GlueScala REPL. Follow the instructions in [Tutorial: Use a SageMaker AI notebook](#), except at the end of the SSH-to-REPL command, replace `-t gluepyspark` with `-t glue-spark-shell`. This invokes the Amazon Glue Scala REPL.

To close the REPL when you are finished, type `sys.exit`.

Scala script example - streaming ETL

Example

The following example script connects to Amazon Kinesis Data Streams, uses a schema from the Data Catalog to parse a data stream, joins the stream to a static dataset on Amazon S3, and outputs the joined results to Amazon S3 in parquet format.

```
// This script connects to an Amazon Kinesis stream, uses a schema from the data
// catalog to parse the stream,
// joins the stream to a static dataset on Amazon S3, and outputs the joined results to
// Amazon S3 in parquet format.

    }
} // end foreachBatch()
    .trigger(Trigger.ProcessingTime("100 seconds"))
    .option("checkpointLocation", "s3://amzn-s3-demo-bucket/checkpoint/")
    .start().awaitTermination() // start() returns type StreamingQuery
    Job.commit()
}
}

```

APIs in the Amazon Glue Scala library

Amazon Glue supports an extension of the PySpark Scala dialect for scripting extract, transform, and load (ETL) jobs. The following sections describe the APIs in the Amazon Glue Scala library.

com.amazonaws.services.glue

The **com.amazonaws.services.glue** package in the Amazon Glue Scala library contains the following APIs:

- [ChoiceOption](#)
- [DataSink](#)
- [DataSource trait](#)
- [DynamicFrame](#)
- [DynamicRecord](#)
- [GlueContext](#)
- [MappingSpec](#)
- [ResolveSpec](#)

com.amazonaws.services.glue.ml

The **com.amazonaws.services.glue.ml** package in the Amazon Glue Scala library contains the following APIs:

- [FillMissingValues](#)
- [FindIncrementalMatches](#)
- [FindMatches](#)

com.amazonaws.services.glue.dq

The **com.amazonaws.services.glue.dq** package in the Amazon Glue Scala library contains the following APIs:

- [EvaluateDataQuality](#)

com.amazonaws.services.glue.types

The **com.amazonaws.services.glue.types** package in the Amazon Glue Scala library contains the following APIs:

- [ArrayNode](#)
- [BinaryNode](#)

- [BooleanNode](#)
- [ByteNode](#)
- [DateNode](#)
- [DecimalNode](#)
- [DoubleNode](#)
- [DynamicNode](#)
- [FloatNode](#)
- [IntegerNode](#)
- [LongNode](#)
- [MapLikeNode](#)
- [MapNode](#)
- [NullNode](#)
- [ObjectNode](#)
- [ScalarNode](#)
- [ShortNode](#)
- [StringNode](#)
- [TimestampNode](#)

com.amazonaws.services.glue.util

The **com.amazonaws.services.glue.util** package in the Amazon Glue Scala library contains the following APIs:

- [GlueArgParser](#)
- [Job](#)

Amazon Glue Scala ChoiceOption APIs

Topics

- [ChoiceOption trait](#)
- [ChoiceOption object](#)
- [Case class ChoiceOptionWithResolver](#)
- [Case class MatchCatalogSchemaChoiceOption](#)

Package: com.amazonaws.services.glue

ChoiceOption trait

```
trait ChoiceOption extends Serializable
```

ChoiceOption object

ChoiceOption

```
object ChoiceOption
```

A general strategy to resolve choice applicable to all ChoiceType nodes in a DynamicFrame.

- val CAST
- val MAKE_COLS
- val MAKE_STRUCT
- val MATCH_CATALOG
- val PROJECT

Def apply

```
def apply(choice: String): ChoiceOption
```

Case class ChoiceOptionWithResolver

```
case class ChoiceOptionWithResolver(name: String, choiceResolver: ChoiceResolver)  
extends ChoiceOption {}
```

Case class MatchCatalogSchemaChoiceOption

```
case class MatchCatalogSchemaChoiceOption() extends ChoiceOption {}
```

Abstract DataSink class

Topics

- [Def writeDynamicFrame](#)

- [Def pyWriteDynamicFrame](#)
- [Def writeDataFrame](#)
- [Def pyWriteDataFrame](#)
- [Def setCatalogInfo](#)
- [Def supportsFormat](#)
- [Def setFormat](#)
- [Def withFormat](#)
- [Def setAccumulableSize](#)
- [Def getOutputErrorRecordsAccumulable](#)
- [Def errorsAsDynamicFrame](#)
- [DataSink object](#)

Package: com.amazonaws.services.glue

```
abstract class DataSink
```

The writer analog to a DataSource. DataSink encapsulates a destination and a format that a DynamicFrame can be written to.

Def writeDynamicFrame

```
def writeDynamicFrame( frame : DynamicFrame,  
                      callSite : CallSite = CallSite("Not provided", "")  
                      ) : DynamicFrame
```

Def pyWriteDynamicFrame

```
def pyWriteDynamicFrame( frame : DynamicFrame,  
                        site : String = "Not provided",  
                        info : String = "" )
```

Def writeDataFrame

```
def writeDataFrame(frame: DataFrame,  
                  glueContext: GlueContext,
```

```
callSite: CallSite = CallSite("Not provided", "")
): DataFrame
```

Def pyWriteDataFrame

```
def pyWriteDataFrame(frame: DataFrame,
    glueContext: GlueContext,
    site: String = "Not provided",
    info: String = ""
): DataFrame
```

Def setCatalogInfo

```
def setCatalogInfo(catalogDatabase: String,
    catalogTableName : String,
    catalogId : String = "")
```

Def supportsFormat

```
def supportsFormat( format : String ) : Boolean
```

Def setFormat

```
def setFormat( format : String,
    options : JsonOptions
) : Unit
```

Def withFormat

```
def withFormat( format : String,
    options : JsonOptions = JsonOptions.empty
) : DataSink
```

Def setAccumulableSize

```
def setAccumulableSize( size : Int ) : Unit
```

Def getOutputErrorRecordsAccumulable

```
def getOutputErrorRecordsAccumulable : Accumulable[List[OutputError], OutputError]
```

Def errorsAsDynamicFrame

```
def errorsAsDynamicFrame : DynamicFrame
```

DataSink object

```
object DataSink
```

Def recordMetrics

```
def recordMetrics( frame : DynamicFrame,  
                  ctxt : String  
                  ) : DynamicFrame
```

Amazon Glue Scala DataSource trait

Package: com.amazonaws.services.glue

A high-level interface for producing a DynamicFrame.

```
trait DataSource {  
  
  def getDynamicFrame : DynamicFrame  
  
  def getDynamicFrame( minPartitions : Int,  
                       targetPartitions : Int  
                       ) : DynamicFrame  
  
  def getDataFrame : DataFrame  
  
  /** @param num: the number of records for sampling.  
    * @param options: optional parameters to control sampling behavior. Current  
    available parameter for Amazon S3 sources in options:  
    * 1. maxSamplePartitions: the maximum number of partitions the sampling will  
    read.  
    * 2. maxSampleFilesPerPartition: the maximum number of files the sampling will  
    read in one partition.  */  
}
```

```
*/
def getSampleDynamicFrame(num:Int, options: JsonOptions = JsonOptions.empty):
DynamicFrame

def glueContext : GlueContext

def setFormat( format : String,
               options : String
               ) : Unit

def setFormat( format : String,
               options : JsonOptions
               ) : Unit

def supportsFormat( format : String ) : Boolean

def withFormat( format : String,
                options : JsonOptions = JsonOptions.empty
                ) : DataSource
}
```

Amazon Glue Scala DynamicFrame class

Package: `com.amazonaws.services.glue`

```
class DynamicFrame extends Serializable with Logging (
    val glueContext : GlueContext,
    _records : RDD[DynamicRecord],
    val name : String = s"",
    val transformationContext : String = DynamicFrame.UNDEFINED,
    callSite : CallSite = CallSite("Not provided", ""),
    stageThreshold : Long = 0,
    totalThreshold : Long = 0,
    prevErrors : => Long = 0,
    errorExpr : => Unit = {} )
```

A `DynamicFrame` is a distributed collection of self-describing [DynamicRecord](#) objects.

`DynamicFrames` are designed to provide a flexible data model for ETL (extract, transform, and load) operations. They don't require a schema to create, and you can use them to read and transform data that contains messy or inconsistent values and types. A schema can be computed on demand for those operations that need one.

`DynamicFrames` provide a range of transformations for data cleaning and ETL. They also support conversion to and from SparkSQL `DataFrames` to integrate with existing code and the many analytics operations that `DataFrames` provide.

The following parameters are shared across many of the Amazon Glue transformations that construct `DynamicFrames`:

- `transformationContext` — The identifier for this `DynamicFrame`. The `transformationContext` is used as a key for job bookmark state that is persisted across runs.
- `callSite` — Provides context information for error reporting. These values are automatically set when calling from Python.

- `stageThreshold` — The maximum number of error records that are allowed from the computation of this `DynamicFrame` before throwing an exception, excluding records that are present in the previous `DynamicFrame`.
- `totalThreshold` — The maximum number of total error records before an exception is thrown, including those from previous frames.

Val `errorsCount`

```
val errorsCount
```

The number of error records in this `DynamicFrame`. This includes errors from previous operations.

Def `applyMapping`

```
def applyMapping( mappings : Seq[Product4[String, String, String, String]],
                  caseSensitive : Boolean = true,
                  transformationContext : String = "",
                  callSite : CallSite = CallSite("Not provided", ""),
                  stageThreshold : Long = 0,
                  totalThreshold : Long = 0
                ) : DynamicFrame
```

- `mappings` — A sequence of mappings to construct a new `DynamicFrame`.
- `caseSensitive` — Whether to treat source columns as case sensitive. Setting this to false might help when integrating with case-insensitive stores like the Amazon Glue Data Catalog.

Selects, projects, and casts columns based on a sequence of mappings.

Each mapping is made up of a source column and type and a target column and type. Mappings can be specified as either a four-tuple (`source_path`, `source_type`, `target_path`, `target_type`) or a [MappingSpec](#) object containing the same information.

In addition to using mappings for simple projections and casting, you can use them to nest or unnest fields by separating components of the path with '.' (period).

For example, suppose that you have a `DynamicFrame` with the following schema.

```
{{{
```

```
root
|-- name: string
|-- age: int
|-- address: struct
|   |-- state: string
|   |-- zip: int
}}
```

You can make the following call to unnest the `state` and `zip` fields.

```
{{{
df.applyMapping(
  Seq(("name", "string", "name", "string"),
      ("age", "int", "age", "int"),
      ("address.state", "string", "state", "string"),
      ("address.zip", "int", "zip", "int")))
}}}
```

The resulting schema is as follows.

```
{{{
root
|-- name: string
|-- age: int
|-- state: string
|-- zip: int
}}}
```

You can also use `applyMapping` to re-nest columns. For example, the following inverts the previous transformation and creates a struct named `address` in the target.

```
{{{
df.applyMapping(
  Seq(("name", "string", "name", "string"),
      ("age", "int", "age", "int"),
      ("state", "string", "address.state", "string"),
      ("zip", "int", "address.zip", "int")))
}}}
```

Field names that contain '.' (period) characters can be quoted by using backticks (` `).

Note

Currently, you can't use the `applyMapping` method to map columns that are nested under arrays.

Def `assertErrorThreshold`

```
def assertErrorThreshold : Unit
```

An action that forces computation and verifies that the number of error records falls below `stageThreshold` and `totalThreshold`. Throws an exception if either condition fails.

Def `count`

```
lazy  
def count
```

Returns the number of elements in this `DynamicFrame`.

Def `dropField`

```
def dropField( path : String,  
              transformationContext : String = "",  
              callSite : CallSite = CallSite("Not provided", ""),  
              stageThreshold : Long = 0,  
              totalThreshold : Long = 0  
            ) : DynamicFrame
```

Returns a new `DynamicFrame` with the specified column removed.

Def `dropFields`

```
def dropFields( fieldNames : Seq[String], // The column names to drop.  
              transformationContext : String = "",  
              callSite : CallSite = CallSite("Not provided", ""),  
              stageThreshold : Long = 0,  
              totalThreshold : Long = 0  
            ) : DynamicFrame
```

Returns a new `DynamicFrame` with the specified columns removed.

You can use this method to delete nested columns, including those inside of arrays, but not to drop specific array elements.

Def dropNulls

```
def dropNulls( transformationContext : String = "",
               callSite : CallSite = CallSite("Not provided", ""),
               stageThreshold : Long = 0,
               totalThreshold : Long = 0 )
```

Returns a new `DynamicFrame` with all null columns removed.

Note

This only removes columns of type `NullType`. Individual null values in other columns are not removed or modified.

Def errorsAsDynamicFrame

```
def errorsAsDynamicFrame
```

Returns a new `DynamicFrame` containing the error records from this `DynamicFrame`.

Def filter

```
def filter( f : DynamicRecord => Boolean,
           errorMsg : String = "",
           transformationContext : String = "",
           callSite : CallSite = CallSite("Not provided"),
           stageThreshold : Long = 0,
           totalThreshold : Long = 0
         ) : DynamicFrame
```

Constructs a new `DynamicFrame` containing only those records for which the function 'f' returns true. The filter function 'f' should not mutate the input record.

Def getName

```
def getName : String
```

Returns the name of this `DynamicFrame`.

Def `getNumPartitions`

```
def getNumPartitions
```

Returns the number of partitions in this `DynamicFrame`.

Def `getSchemaIfComputed`

```
def getSchemaIfComputed : Option[Schema]
```

Returns the schema if it has already been computed. Does not scan the data if the schema has not already been computed.

Def `isSchemaComputed`

```
def isSchemaComputed : Boolean
```

Returns `true` if the schema has been computed for this `DynamicFrame`, or `false` if not. If this method returns `false`, then calling the `schema` method requires another pass over the records in this `DynamicFrame`.

Def `javaToPython`

```
def javaToPython : JavaRDD[Array[Byte]]
```

Def `join`

```
def join( keys1 : Seq[String],
          keys2 : Seq[String],
          frame2 : DynamicFrame,
          transformationContext : String = "",
          callSite : CallSite = CallSite("Not provided", ""),
          stageThreshold : Long = 0,
          totalThreshold : Long = 0
        ) : DynamicFrame
```

- `keys1` — The columns in this `DynamicFrame` to use for the join.

- `keys2` — The columns in `frame2` to use for the join. Must be the same length as `keys1`.
- `frame2` — The `DynamicFrame` to join against.

Returns the result of performing an equijoin with `frame2` using the specified keys.

Def map

```
def map( f : DynamicRecord => DynamicRecord,
        errorMsg : String = "",
        transformationContext : String = "",
        callSite : CallSite = CallSite("Not provided", ""),
        stageThreshold : Long = 0,
        totalThreshold : Long = 0
    ) : DynamicFrame
```

Returns a new `DynamicFrame` constructed by applying the specified function 'f' to each record in this `DynamicFrame`.

This method copies each record before applying the specified function, so it is safe to mutate the records. If the mapping function throws an exception on a given record, that record is marked as an error, and the stack trace is saved as a column in the error record.

Def mergeDynamicFrames

```
def mergeDynamicFrames( stageDynamicFrame: DynamicFrame, primaryKeys: Seq[String],
                       transformationContext: String = "",
                           options: JsonOptions = JsonOptions.empty, callSite: CallSite =
CallSite("Not provided"),
                       stageThreshold: Long = 0, totalThreshold: Long = 0):
DynamicFrame
```

- `stageDynamicFrame` — The staging `DynamicFrame` to merge.
- `primaryKeys` — The list of primary key fields to match records from the source and staging `DynamicFrames`.
- `transformationContext` — A unique string that is used to retrieve metadata about the current transformation (optional).
- `options` — A string of JSON name-value pairs that provide additional information for this transformation.

- `callSite` — Used to provide context information for error reporting.
- `stageThreshold` — A Long. The number of errors in the given transformation for which the processing needs to error out.
- `totalThreshold` — A Long. The total number of errors up to and including in this transformation for which the processing needs to error out.

Merges this `DynamicFrame` with a staging `DynamicFrame` based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not de-duplicated. If there is no matching record in the staging frame, all records (including duplicates) are retained from the source. If the staging frame has matching records, the records from the staging frame overwrite the records in the source in Amazon Glue.

The returned `DynamicFrame` contains record A in the following cases:

1. If A exists in both the source frame and the staging frame, then A in the staging frame is returned.
2. If A is in the source table and `A.primaryKeys` is not in the `stagingDynamicFrame` (that means A is not updated in the staging table).

The source frame and staging frame do not need to have the same schema.

Example

```
val mergedFrame: DynamicFrame = srcFrame.mergeDynamicFrames(stageFrame, Seq("id1", "id2"))
```

Def printSchema

```
def printSchema : Unit
```

Prints the schema of this `DynamicFrame` to `stdout` in a human-readable format.

Def recomputeSchema

```
def recomputeSchema : Schema
```

Forces a schema recomputation. This requires a scan over the data, but it might "tighten" the schema if there are some fields in the current schema that are not present in the data.

Returns the recomputed schema.

Def relationalize

```
def relationalize( rootTableName : String,
                  stagingPath : String,
                  options : JsonOptions = JsonOptions.empty,
                  transformationContext : String = "",
                  callSite : CallSite = CallSite("Not provided"),
                  stageThreshold : Long = 0,
                  totalThreshold : Long = 0
                ) : Seq[DynamicFrame]
```

- `rootTableName` — The name to use for the base `DynamicFrame` in the output. `DynamicFrames` that are created by pivoting arrays start with this as a prefix.
- `stagingPath` — The Amazon Simple Storage Service (Amazon S3) path for writing intermediate data.
- `options` — Relationalize options and configuration. Currently unused.

Flattens all nested structures and pivots arrays into separate tables.

You can use this operation to prepare deeply nested data for ingestion into a relational database. Nested structs are flattened in the same manner as the [Unnest](#) transform. Additionally, arrays are pivoted into separate tables with each array element becoming a row. For example, suppose that you have a `DynamicFrame` with the following data.

```
{"name": "Nancy", "age": 47, "friends": ["Fred", "Lakshmi"]}
{"name": "Stephanie", "age": 28, "friends": ["Yao", "Phil", "Alvin"]}
{"name": "Nathan", "age": 54, "friends": ["Nicolai", "Karen"]}
```

Run the following code.

```
{{{
  df.relationalize("people", "s3:/my_bucket/my_path", JsonOptions.empty)
}}}
```

This produces two tables. The first table is named "people" and contains the following.

```
{{{
```

```

{"name": "Nancy", "age": 47, "friends": 1}
{"name": "Stephanie", "age": 28, "friends": 2}
{"name": "Nathan", "age": 54, "friends": 3)
}}}
```

Here, the friends array has been replaced with an auto-generated join key. A separate table named `people.friends` is created with the following content.

```

{{{
  {"id": 1, "index": 0, "val": "Fred"}
  {"id": 1, "index": 1, "val": "Lakshmi"}
  {"id": 2, "index": 0, "val": "Yao"}
  {"id": 2, "index": 1, "val": "Phil"}
  {"id": 2, "index": 2, "val": "Alvin"}
  {"id": 3, "index": 0, "val": "Nicolai"}
  {"id": 3, "index": 1, "val": "Karen"}
}}}
```

In this table, 'id' is a join key that identifies which record the array element came from, 'index' refers to the position in the original array, and 'val' is the actual array entry.

The `relationalize` method returns the sequence of `DynamicFrames` created by applying this process recursively to all arrays.

Note

The Amazon Glue library automatically generates join keys for new tables. To ensure that join keys are unique across job runs, you must enable job bookmarks.

Def `renameField`

```

def renameField( oldName : String,
                 newName  : String,
                 transformationContext : String = "",
                 callSite   : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
                 ) : DynamicFrame
```

- `oldName` — The original name of the column.

- `newName` — The new name of the column.

Returns a new `DynamicFrame` with the specified field renamed.

You can use this method to rename nested fields. For example, the following code would rename `state` to `state_code` inside the `address` struct.

```
{{{
  df.renameField("address.state", "address.state_code")
}}}
```

Def repartition

```
def repartition( numPartitions : Int,
                 transformationContext : String = "",
                 callSite : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
                 ) : DynamicFrame
```

Returns a new `DynamicFrame` with `numPartitions` partitions.

Def resolveChoice

```
def resolveChoice( specs : Seq[Product2[String, String]] = Seq.empty[ResolveSpec],
                  choiceOption : Option[ChoiceOption] = None,
                  database : Option[String] = None,
                  tableName : Option[String] = None,
                  transformationContext : String = "",
                  callSite : CallSite = CallSite("Not provided", ""),
                  stageThreshold : Long = 0,
                  totalThreshold : Long = 0
                  ) : DynamicFrame
```

- `choiceOption` — An action to apply to all `ChoiceType` columns not listed in the `specs` sequence.
- `database` — The Data Catalog database to use with the `match_catalog` action.
- `tableName` — The Data Catalog table to use with the `match_catalog` action.

Returns a new `DynamicFrame` by replacing one or more `ChoiceTypes` with a more specific type.

There are two ways to use `resolveChoice`. The first is to specify a sequence of specific columns and how to resolve them. These are specified as tuples made up of (column, action) pairs.

The following are the possible actions:

- `cast:type` — Attempts to cast all values to the specified type.
- `make_cols` — Converts each distinct type to a column with the name `columnName_type`.
- `make_struct` — Converts a column to a struct with keys for each distinct type.
- `project:type` — Retains only values of the specified type.

The other mode for `resolveChoice` is to specify a single resolution for all `ChoiceTypes`. You can use this in cases where the complete list of `ChoiceTypes` is unknown before execution. In addition to the actions listed preceding, this mode also supports the following action:

- `match_catalog` — Attempts to cast each `ChoiceType` to the corresponding type in the specified catalog table.

Examples:

Resolve the `user.id` column by casting to an int, and make the `address` field retain only structs.

```
{{{
  df.resolveChoice(specs = Seq(("user.id", "cast:int"), ("address", "project:struct")))
}}}
```

Resolve all `ChoiceTypes` by converting each choice to a separate column.

```
{{{
  df.resolveChoice(choiceOption = Some(ChoiceOption("make_cols")))
}}}
```

Resolve all `ChoiceTypes` by casting to the types in the specified catalog table.

```
{{{
  df.resolveChoice(choiceOption = Some(ChoiceOption("match_catalog")),
                  database = Some("my_database"),
                  tableName = Some("my_table"))
}}}
```

```
}}}
```

Def schema

```
def schema : Schema
```

Returns the schema of this `DynamicFrame`.

The returned schema is guaranteed to contain every field that is present in a record in this `DynamicFrame`. But in a small number of cases, it might also contain additional fields. You can use the [Unnest](#) method to "tighten" the schema based on the records in this `DynamicFrame`.

Def selectField

```
def selectField( fieldName : String,
                transformationContext : String = "",
                callSite : CallSite = CallSite("Not provided", ""),
                stageThreshold : Long = 0,
                totalThreshold : Long = 0
                ) : DynamicFrame
```

Returns a single field as a `DynamicFrame`.

Def selectFields

```
def selectFields( paths : Seq[String],
                 transformationContext : String = "",
                 callSite : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
                 ) : DynamicFrame
```

- `paths` — The sequence of column names to select.

Returns a new `DynamicFrame` containing the specified columns.

Note

You can only use the `selectFields` method to select top-level columns. You can use the [applyMapping](#) method to select nested columns.

Def show

```
def show( numRows : Int = 20 ) : Unit
```

- numRows — The number of rows to print.

Prints rows from this `DynamicFrame` in JSON format.

Def simplifyDDBJson

DynamoDB exports with the Amazon Glue DynamoDB export connector results in JSON files of specific nested structures. For more information, see [Data objects](#). `simplifyDDBJson` Simplifies nested columns in a `DynamicFrame` of this type of data, and returns a new simplified `DynamicFrame`. If there are multiple types or a Map type contained in a List type, the elements in the List will not be simplified. This method only supports data in the DynamoDB export JSON format. Consider `unnest` to perform similar changes on other kinds of data.

```
def simplifyDDBJson() : DynamicFrame
```

This method does not take any parameters.

Example input

Consider the following schema generated by a DynamoDB export:

```
root
|-- Item: struct
|   |-- parentMap: struct
|   |   |-- M: struct
|   |   |   |-- childMap: struct
|   |   |   |   |-- M: struct
|   |   |   |   |   |-- appName: struct
|   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |-- packageName: struct
|   |   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |   |-- updatedAt: struct
|   |   |   |   |   |   |   |   |-- N: string
|   |   |-- strings: struct
|   |   |   |-- SS: array
|   |   |   |   |-- element: string
|   |-- numbers: struct
```

```

|   |   |-- NS: array
|   |   |   |-- element: string
|   |-- binaries: struct
|   |   |-- BS: array
|   |   |   |-- element: string
|   |-- isDDBJson: struct
|   |   |-- BOOL: boolean
|   |-- nullValue: struct
|   |   |-- NULL: boolean

```

Example code

```

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext import scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.export" -> "ddb",
        "dynamodb.tableArn" -> "ddbTableARN",
        "dynamodb.s3.bucket" -> "exportBucketLocation",
        "dynamodb.s3.prefix" -> "exportBucketPrefix",
        "dynamodb.s3.bucketOwner" -> "exportBucketAccountID",
      ))
    ).getDynamicFrame()

    val simplified = dynamicFrame.simplifyDDBJson()
    simplified.printSchema()

    Job.commit()
  }
}

```

```
}

```

Example output

The `simplifyDDBJson` transform will simplify this to:

```
root
|-- parentMap: struct
|   |-- childMap: struct
|   |   |-- appName: string
|   |   |-- packageName: string
|   |   |-- updatedAt: string
|-- strings: array
|   |-- element: string
|-- numbers: array
|   |-- element: string
|-- binaries: array
|   |-- element: string
|-- isDDBJson: boolean
|-- nullValue: null

```

Def spigot

```
def spigot( path : String,
            options : JsonOptions = new JsonOptions("{}"),
            transformationContext : String = "",
            callSite : CallSite = CallSite("Not provided"),
            stageThreshold : Long = 0,
            totalThreshold : Long = 0
            ) : DynamicFrame

```

Passthrough transformation that returns the same records but writes out a subset of records as a side effect.

- `path` — The path in Amazon S3 to write output to, in the form `s3://bucket//path`.
- `options` — An optional `JsonOptions` map describing the sampling behavior.

Returns a `DynamicFrame` that contains the same records as this one.

By default, writes 100 arbitrary records to the location specified by `path`. You can customize this behavior by using the `options` map. Valid keys include the following:

- `topk` — Specifies the total number of records written out. The default is 100.
- `prob` — Specifies the probability (as a decimal) that an individual record is included. Default is 1.

For example, the following call would sample the dataset by selecting each record with a 20 percent probability and stopping after 200 records have been written.

```

{{{
  df.spigot("s3://my_bucket/my_path", JsonOptions(Map("topk" -> 200, "prob" ->
    0.2)))
}}}
```

Def `splitFields`

```

def splitFields( paths : Seq[String],
                 transformationContext : String = "",
                 callSite : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
                 ) : Seq[DynamicFrame]
```

- `paths` — The paths to include in the first `DynamicFrame`.

Returns a sequence of two `DynamicFrames`. The first `DynamicFrame` contains the specified paths, and the second contains all other columns.

Example

This example takes a `DynamicFrame` created from the `persons` table in the `legislators` database in the Amazon Glue Data Catalog and splits the `DynamicFrame` into two, with the specified fields going into the first `DynamicFrame` and the remaining fields going into a second `DynamicFrame`. The example then chooses the first `DynamicFrame` from the result.

```

val InputFrame = glueContext.getCatalogSource(database="legislators",
  tableName="persons",
  transformationContext="InputFrame").getDynamicFrame()

val SplitField_collection = InputFrame.splitFields(paths=Seq("family_name", "name",
  "links.note",
  "links.url", "gender", "image", "identifiers.scheme", "identifiers.identifier",
  "other_names.lang",
```

```
"other_names.note", "other_names.name"), transformationContext="SplitField_collection")  
  
val ResultFrame = SplitField_collection(0)
```

Def splitRows

```
def splitRows( paths : Seq[String],  
              values : Seq[Any],  
              operators : Seq[String],  
              transformationContext : String,  
              callSite : CallSite,  
              stageThreshold : Long,  
              totalThreshold : Long  
            ) : Seq[DynamicFrame]
```

Splits rows based on predicates that compare columns to constants.

- `paths` — The columns to use for comparison.
- `values` — The constant values to use for comparison.
- `operators` — The operators to use for comparison.

Returns a sequence of two `DynamicFrame`s. The first contains rows for which the predicate is true and the second contains those for which it is false.

Predicates are specified using three sequences: `paths` contains the (possibly nested) column names, `values` contains the constant values to compare to, and `operators` contains the operators to use for comparison. All three sequences must be the same length: The *n*th operator is used to compare the *n*th column with the *n*th value.

Each operator must be one of `!="`, `"="`, `"<="`, `"<"`, `">="`, or `">"`.

As an example, the following call would split a `DynamicFrame` so that the first output frame would contain records of people over 65 from the United States, and the second would contain all other records.

```
{{{  
  df.splitRows(Seq("age", "address.country"), Seq(65, "USA"), Seq(">=", "="))  
}}}
```

Def stageErrorsCount

```
def stageErrorsCount
```

Returns the number of error records created while computing this `DynamicFrame`. This excludes errors from previous operations that were passed into this `DynamicFrame` as input.

Def toDF

```
def toDF( specs : Seq[ResolveSpec] = Seq.empty[ResolveSpec] ) : DataFrame
```

Converts this `DynamicFrame` to an Apache Spark SQL `DataFrame` with the same schema and records.

Note

Because `DataFrames` don't support `ChoiceTypes`, this method automatically converts `ChoiceType` columns into `StructTypes`. For more information and options for resolving choice, see [resolveChoice](#).

Def unbox

```
def unbox( path : String,  
          format : String,  
          optionString : String = "{}",  
          transformationContext : String = "",  
          callSite : CallSite = CallSite("Not provided"),  
          stageThreshold : Long = 0,  
          totalThreshold : Long = 0  
        ) : DynamicFrame
```

- `path` — The column to parse. Must be a string or binary.
- `format` — The format to use for parsing.
- `optionString` — Options to pass to the format, such as the CSV separator.

Parses an embedded string or binary column according to the specified format. Parsed columns are nested under a struct with the original column name.

For example, suppose that you have a CSV file with an embedded JSON column.

```
name, age, address
Sally, 36, {"state": "NE", "city": "Omaha"}
...
```

After an initial parse, you would get a `DynamicFrame` with the following schema.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address: string
}}}
```

You can call `unbox` on the address column to parse the specific components.

```
{{{
  df.unbox("address", "json")
}}}
```

This gives us a `DynamicFrame` with the following schema.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address: struct
  |   |-- state: string
  |   |-- city: string
}}}
```

Def unnest

```
def unnest( transformationContext : String = "",
            callSite : CallSite = CallSite("Not Provided"),
            stageThreshold : Long = 0,
            totalThreshold : Long = 0
            ) : DynamicFrame
```

Returns a new `DynamicFrame` with all nested structures flattened. Names are constructed using the '.' (period) character.

For example, suppose that you have a `DynamicFrame` with the following schema.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address: struct
  |     |-- state: string
  |     |-- city: string
  }}}}
```

The following call unnests the address struct.

```
{{{
  df.unnest()
  }}}}
```

The resulting schema is as follows.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address.state: string
  |-- address.city: string
  }}}}
```

This method also unnests nested structs inside of arrays. But for historical reasons, the names of such fields are prepended with the name of the enclosing array and ".val".

Def `unnestDDBJson`

```
unnestDDBJson(transformationContext : String = "",
              callSite : CallSite = CallSite("Not Provided"),
              stageThreshold : Long = 0,
              totalThreshold : Long = 0): DynamicFrame
```

Unnests nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new unnested `DynamicFrame`. Columns that are of an array of struct types will not be unnested. Note that this is a specific type of unnesting transform that behaves differently from the regular `unnest` transform and requires the data to already be in the DynamoDB JSON structure. For more information, see [DynamoDB JSON](#).

For example, the schema of a reading an export with the DynamoDB JSON structure might look like the following:

```
root
|-- Item: struct
|   |-- ColA: struct
|   |   |-- S: string
|   |-- ColB: struct
|   |   |-- S: string
|   |-- ColC: struct
|   |   |-- N: string
|   |-- ColD: struct
|   |   |-- L: array
|   |   |   |-- element: null
```

The `unnestDDBJson()` transform would convert this to:

```
root
|-- ColA: string
|-- ColB: string
|-- ColC: string
|-- ColD: array
|   |-- element: null
```

The following code example shows how to use the Amazon Glue DynamoDB export connector, invoke a DynamoDB JSON `unnest`, and print the number of partitions:

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
```

```

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.export" -> "ddb",
        "dynamodb.tableArn" -> "<test_source>",
        "dynamodb.s3.bucket" -> "<bucket name>",
        "dynamodb.s3.prefix" -> "<bucket prefix>",
        "dynamodb.s3.bucketOwner" -> "<account_id of bucket>",
      ))
    ).getDynamicFrame()

    val unnested = dynamicFrame.unnestDDBJson()
    print(unnested.getNumPartitions())

    Job.commit()
  }
}

```

Def withFrameSchema

```
def withFrameSchema( getSchema : () => Schema ) : DynamicFrame
```

- `getSchema` — A function that returns the schema to use. Specified as a zero-parameter function to defer potentially expensive computation.

Sets the schema of this `DynamicFrame` to the specified value. This is primarily used internally to avoid costly schema recomputation. The passed-in schema must contain all columns present in the data.

Def withName

```
def withName( name : String ) : DynamicFrame
```

- `name` — The new name to use.

Returns a copy of this `DynamicFrame` with a new name.

Def `withTransformationContext`

```
def withTransformationContext( ctx : String ) : DynamicFrame
```

Returns a copy of this `DynamicFrame` with the specified transformation context.

The `DynamicFrame` object

Package: `com.amazonaws.services.glue`

```
object DynamicFrame
```

Def `apply`

```
def apply( df : DataFrame,  
          glueContext : GlueContext  
          ) : DynamicFrame
```

Def `emptyDynamicFrame`

```
def emptyDynamicFrame( glueContext : GlueContext ) : DynamicFrame
```

Def `fromPythonRDD`

```
def fromPythonRDD( rdd : JavaRDD[Array[Byte]],  
                  glueContext : GlueContext  
                  ) : DynamicFrame
```

Def `ignoreErrors`

```
def ignoreErrors( fn : DynamicRecord => DynamicRecord ) : DynamicRecord
```

Def inlineErrors

```
def inlineErrors( msg : String,
                  callSite : CallSite
                  ) : (DynamicRecord => DynamicRecord)
```

Def newFrameWithErrors

```
def newFrameWithErrors( prevFrame : DynamicFrame,
                        rdd : RDD[DynamicRecord],
                        name : String = "",
                        transformationContext : String = "",
                        callSite : CallSite,
                        stageThreshold : Long,
                        totalThreshold : Long
                        ) : DynamicFrame
```

Amazon Glue Scala DynamicRecord class

- [Def equals](#)
- [DynamicRecord object](#)
- [RecordTraverser trait](#)

Package: com.amazonaws.services.glue

```
class DynamicRecord extends Serializable with Writable with Cloneable
```

A `DynamicRecord` is a self-describing data structure that represents a row of data in the dataset that is being processed. It is self-describing in the sense that you can get the schema of the row that is represented by the `DynamicRecord` by inspecting the record itself. A `DynamicRecord` is similar to a `Row` in Apache Spark.

Def addField

```
def addField( path : String,
              dynamicNode : DynamicNode
              ) : Unit
```

Adds a [DynamicNode](#) to the specified path.

- `path` — The path for the field to be added.
- `dynamicNode` — The [DynamicNode](#) to be added at the specified path.

Def dropField

```
def dropField(path: String, underRename: Boolean = false): Option[DynamicNode]
```

Drops a [DynamicNode](#) from the specified path and returns the dropped node if there is not an array in the specified path.

- `path` — The path to the field to drop.
- `underRename` — True if `dropField` is called as part of a rename transform, or false otherwise (false by default).

Returns a `scala.Option` `Option` ([DynamicNode](#)).

Def setError

```
def setError( error : Error )
```

Sets this record as an error record, as specified by the `error` parameter.

Returns a `DynamicRecord`.

Def isError

```
def isError
```

Checks whether this record is an error record.

Def getError

```
def getError
```

Gets the `Error` if the record is an error record. Returns `scala.Some Some (Error)` if this record is an error record, or otherwise `scala.None`.

Def clearError

```
def clearError
```

Set the `Error` to `scala.None.None`.

Def write

```
override def write( out : DataOutput ) : Unit
```

Def readFields

```
override def readFields( in : DataInput ) : Unit
```

Def clone

```
override def clone : DynamicRecord
```

Clones this record to a new `DynamicRecord` and returns it.

Def schema

```
def schema
```

Gets the Schema by inspecting the record.

Def getRoot

```
def getRoot : ObjectNode
```

Gets the root `ObjectNode` for the record.

Def toJson

```
def toJson : String
```

Gets the JSON string for the record.

Def getFieldNode

```
def getFieldNode( path : String ) : Option[DynamicNode]
```

Gets the field's value at the specified path as an option of `DynamicNode`.

Returns `scala.Some` `Some` ([DynamicNode](#)) if the field exists, or otherwise `scala.None` `None` .

Def getField

```
def getField( path : String ) : Option[Any]
```

Gets the field's value at the specified path as an option of `DynamicNode`.

Returns `scala.Some` `Some` (value).

Def hashCode

```
override def hashCode : Int
```

Def equals

```
override def equals( other : Any )
```

DynamicRecord object

```
object DynamicRecord
```

Def apply

```
def apply( row : Row,  
          schema : SparkStructType )
```

Apply method to convert an Apache Spark SQL Row to a [DynamicRecord](#).

- row — A Spark SQL Row.
- schema — The Schema of that row.

Returns a DynamicRecord.

RecordTraverser trait

```
trait RecordTraverser {  
  def nullValue(): Unit  
  def byteValue(value: Byte): Unit  
  def binaryValue(value: Array[Byte]): Unit  
  def booleanValue(value: Boolean): Unit  
  def shortValue(value: Short) : Unit  
  def intValue(value: Int) : Unit  
  def longValue(value: Long) : Unit  
  def floatValue(value: Float): Unit  
  def doubleValue(value: Double): Unit  
  def decimalValue(value: BigDecimal): Unit  
  def stringValue(value: String): Unit  
  def dateValue(value: Date): Unit  
  def timestampValue(value: Timestamp): Unit  
  def objectStart(length: Int): Unit  
  def objectKey(key: String): Unit  
  def objectEnd(): Unit  
  def mapStart(length: Int): Unit  
  def mapKey(key: String): Unit  
  def mapEnd(): Unit  
  def arrayStart(length: Int): Unit  
  def arrayEnd(): Unit
```

```
}
```

Amazon Glue Scala GlueContext APIs

Package: `com.amazonaws.services.glue`

```
class GlueContext extends SQLContext(sc) (  
    @transient val sc : SparkContext,  
    val defaultSourcePartitioner : PartitioningStrategy )
```

`GlueContext` is the entry point for reading and writing a [DynamicFrame](#) from and to Amazon Simple Storage Service (Amazon S3), the Amazon Glue Data Catalog, JDBC, and so on. This class provides utility functions to create [DataSource trait](#) and [DataSink](#) objects that can in turn be used to read and write `DynamicFrames`.

You can also use `GlueContext` to set a target number of partitions (default 20) in the `DynamicFrame` if the number of partitions created from the source is less than a minimum threshold for partitions (default 10).

`def addIngestionTimeColumns`

```
def addIngestionTimeColumns(  
    df : DataFrame,  
    timeGranularity : String = "") : DataFrame
```

Appends ingestion time columns like `ingest_year`, `ingest_month`, `ingest_day`, `ingest_hour`, `ingest_minute` to the input `DataFrame`. This function is automatically generated in the script generated by the Amazon Glue when you specify a Data Catalog table with Amazon S3 as the target. This function automatically updates the partition with ingestion time columns on the output table. This allows the output data to be automatically partitioned on ingestion time without requiring explicit ingestion time columns in the input data.

- `dataFrame` – The `dataFrame` to append the ingestion time columns to.
- `timeGranularity` – The granularity of the time columns. Valid values are "day", "hour" and "minute". For example, if "hour" is passed in to the function, the original `dataFrame` will have "ingest_year", "ingest_month", "ingest_day", and "ingest_hour" time columns appended.

Returns the data frame after appending the time granularity columns.

Example:

```
glueContext.addIngestionTimeColumns(dataFrame, "hour")
```

def createDataFrameFromOptions

```
def createDataFrameFromOptions( connectionType : String,  
                                connectionOptions : JsonOptions,  
                                transformationContext : String = "",  
                                format : String = null,  
                                formatOptions : JsonOptions = JsonOptions.empty  
                                ) : DataSource
```

Returns a DataFrame created with the specified connection and format. Use this function only with Amazon Glue streaming sources.

- `connectionType` – The streaming connection type. Valid values include `kinesis` and `kafka`.
- `connectionOptions` – Connection options, which are different for Kinesis and Kafka. You can find the list of all connection options for each streaming data source at [Connection types and options for ETL in Amazon Glue for Spark](#). Note the following differences in streaming connection options:
 - Kinesis streaming sources require `streamARN`, `startingPosition`, `inferSchema`, and `classification`.
 - Kafka streaming sources require `connectionName`, `topicName`, `startingOffsets`, `inferSchema`, and `classification`.
- `transformationContext` – The transformation context to use (optional).
- `format` – A format specification (optional). This is used for an Amazon S3 or an Amazon Glue connection that supports multiple formats. For information about the supported formats, see [Data format options for inputs and outputs in Amazon Glue for Spark](#)
- `formatOptions` – Format options for the specified format. For information about the supported format options, see [Data format options](#).

Example for Amazon Kinesis streaming source:

```
val data_frame_datasource0 =  
glueContext.createDataFrameFromOptions(transformationContext = "datasource0",  
                                        connectionType = "kinesis",
```

```
connectionOptions = JsonOptions("""{"streamName": "example_stream", "startingPosition":
  "TRIM_HORIZON", "inferSchema": "true", "classification": "json"}"""))
```

Example for Kafka streaming source:

```
val data_frame_datasource0 =
glueContext.createDataFrameFromOptions(transformationContext = "datasource0",
  connectionType = "kafka",
  connectionOptions = JsonOptions("""{"connectionName": "example_connection",
  "topicName": "example_topic", "startingPosition": "earliest", "inferSchema": "false",
  "classification": "json", "schema":"`column1` STRING, `column2` STRING}"""))
```

forEachBatch

forEachBatch(frame, batch_function, options)

Applies the `batch_function` passed in to every micro batch that is read from the Streaming source.

- `frame` – The `DataFrame` containing the current micro batch.
- `batch_function` – A function that will be applied for every micro batch.
- `options` – A collection of key-value pairs that holds information about how to process micro batches. The following options are required:
 - `windowSize` – The amount of time to spend processing each batch.
 - `checkpointLocation` – The location where checkpoints are stored for the streaming ETL job.
 - `batchMaxRetries` – The maximum number of times to retry the batch if it fails. The default value is 3. This option is only configurable for Glue version 2.0 and above.

Example:

```
glueContext.forEachBatch(data_frame_datasource0, (dataFrame: Dataset[Row], batchId:
  Long) =>
  {
    if (dataFrame.count() > 0)
      {
        val datasource0 = DynamicFrame(glueContext.addIngestionTimeColumns(dataFrame,
  "hour"), glueContext)
        // @type: DataSink
```

```

        // @args: [database = "tempdb", table_name = "fromoptionsoutput",
stream_batch_time = "100 seconds",
        //      stream_checkpoint_location = "s3://from-options-testing-eu-central-1/
fromOptionsOutput/checkpoint/",
        //      transformation_ctx = "datasink1"]
        // @return: datasink1
        // @inputs: [frame = datasource0]
        val options_datasink1 = JsonOptions(
            Map("partitionKeys" -> Seq("ingest_year", "ingest_month", "ingest_day",
"ingest_hour"),
            "enableUpdateCatalog" -> true))
        val datasink1 = glueContext.getCatalogSink(
            database = "tempdb",
            tableName = "fromoptionsoutput",
            redshiftTmpDir = "",
            transformationContext = "datasink1",
            additionalOptions = options_datasink1).writeDynamicFrame(datasource0)
    }
}, JsonOptions("""{"windowSize" : "100 seconds",
    "checkpointLocation" : "s3://from-options-testing-eu-central-1/
fromOptionsOutput/checkpoint/"}"""))

```

def getCatalogSink

```

def getCatalogSink( database : String,
    tableName : String,
    redshiftTmpDir : String = "",
    transformationContext : String = ""
    additionalOptions: JsonOptions = JsonOptions.empty,
    catalogId: String = null
) : DataSink

```

Creates a [DataSink](#) that writes to a location specified in a table that is defined in the Data Catalog.

- `database` — The database name in the Data Catalog.
- `tableName` — The table name in the Data Catalog.
- `redshiftTmpDir` — The temporary staging directory to be used with certain data sinks. Set to empty by default.
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `additionalOptions` – Additional options provided to Amazon Glue.

- `catalogId` — The catalog ID (account ID) of the Data Catalog being accessed. When null, the default account ID of the caller is used.

Returns the `DataSink`.

def getCatalogSource

```
def getCatalogSource( database : String,
                      tableName : String,
                      redshiftTmpDir : String = "",
                      transformationContext : String = ""
                      pushDownPredicate : String = " "
                      additionalOptions: JsonOptions = JsonOptions.empty,
                      catalogId: String = null
                      ) : DataSource
```

Creates a [DataSource trait](#) that reads data from a table definition in the Data Catalog.

- `database` — The database name in the Data Catalog.
- `tableName` — The table name in the Data Catalog.
- `redshiftTmpDir` — The temporary staging directory to be used with certain data sinks. Set to empty by default.
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `pushDownPredicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-filtering using pushdown predicates](#).
- `additionalOptions` – A collection of optional name-value pairs. The possible options include those listed in [Connection types and options for ETL in Amazon Glue for Spark](#) except for `endpointUrl`, `streamName`, `bootstrap.servers`, `security.protocol`, `topicName`, `classification`, and `delimiter`. Another supported option is `catalogPartitionPredicate`:

`catalogPartitionPredicate` — You can pass a catalog expression to filter based on the index columns. This pushes down the filtering to the server side. For more information, see [Amazon Glue Partition Indexes](#). Note that `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

- `catalogId` — The catalog ID (account ID) of the Data Catalog being accessed. When null, the default account ID of the caller is used.

Returns the `DataSource`.

Example for streaming source

```
val data_frame_datasource0 = glueContext.getCatalogSource(
  database = "tempdb",
  tableName = "test-stream-input",
  redshiftTmpDir = "",
  transformationContext = "datasource0",
  additionalOptions = JsonOptions("""{
    "startingPosition": "TRIM_HORIZON", "inferSchema": "false"}""")
).getDataFrame()
```

def getJDBCSink

```
def getJDBCSink( catalogConnection : String,
  options : JsonOptions,
  redshiftTmpDir : String = "",
  transformationContext : String = "",
  catalogId: String = null
) : DataSink
```

Creates a [DataSink](#) that writes to a JDBC database that is specified in a `Connection` object in the Data Catalog. The `Connection` object has information to connect to a JDBC sink, including the URL, user name, password, VPC, subnet, and security groups.

- `catalogConnection` — The name of the connection in the Data Catalog that contains the JDBC URL to write to.
- `options` — A string of JSON name-value pairs that provide additional information that is required to write to a JDBC data store. This includes:
 - `dbtable` (required) — The name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used. The following example shows an `options` parameter that points to a schema named `test` and a table named `test_table` in database `test_db`.

```
options = JsonOptions("""{"dbtable": "test.test_table", "database": "test_db"}""")
```

- *database* (required) — The name of the JDBC database.
- Any additional options passed directly to the SparkSQL JDBC writer. For more information, see [Redshift data source for Spark](#).
- *redshiftTmpDir* — A temporary staging directory to be used with certain data sinks. Set to empty by default.
- *transformationContext* — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- *catalogId* — The catalog ID (account ID) of the Data Catalog being accessed. When null, the default account ID of the caller is used.

Example code:

```
getJDBCSink(catalogConnection = "my-connection-name", options =
  JsonOptions("""{"dbtable": "my-jdbc-table", "database": "my-jdbc-db"}"""),
  redshiftTmpDir = "", transformationContext = "datasink4")
```

Returns the `DataSink`.

def getSink

```
def getSink( connectionType : String,
             connectionOptions : JsonOptions,
             transformationContext : String = ""
           ) : DataSink
```

Creates a [DataSink](#) that writes data to a destination like Amazon Simple Storage Service (Amazon S3), JDBC, or the Amazon Glue Data Catalog, or an Apache Kafka or Amazon Kinesis data stream.

- *connectionType* — The type of the connection. See [the section called "Connection parameters"](#).
- *connectionOptions* — A string of JSON name-value pairs that provide additional information to establish the connection with the data sink. See [the section called "Connection parameters"](#).
- *transformationContext* — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.

Returns the `DataSink`.

def getSinkWithFormat

```
def getSinkWithFormat( connectionType : String,
                       options : JsonOptions,
                       transformationContext : String = "",
                       format : String = null,
                       formatOptions : JsonOptions = JsonOptions.empty
                       ) : DataSink
```

Creates a [DataSink](#) that writes data to a destination like Amazon S3, JDBC, or the Data Catalog, or an Apache Kafka or Amazon Kinesis data stream. Also sets the format for the data to be written out to the destination.

- `connectionType` — The type of the connection. See [the section called “Connection parameters”](#).
- `options` — A string of JSON name-value pairs that provide additional information to establish a connection with the data sink. See [the section called “Connection parameters”](#).
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `format` — The format of the data to be written out to the destination.
- `formatOptions` — A string of JSON name-value pairs that provide additional options for formatting data at the destination. See [Data format options](#).

Returns the `DataSink`.

def getSource

```
def getSource( connectionType : String,
               connectionOptions : JsonOptions,
               transformationContext : String = ""
               pushDownPredicate
               ) : DataSource
```

Creates a [DataSource trait](#) that reads data from a source like Amazon S3, JDBC, or the Amazon Glue Data Catalog. Also supports Kafka and Kinesis streaming data sources.

- `connectionType` — The type of the data source. See [the section called “Connection parameters”](#).

- `connectionOptions` — A string of JSON name-value pairs that provide additional information for establishing a connection with the data source. For more information, see [the section called “Connection parameters”](#).

A Kinesis streaming source requires the following connection options: `streamARN`, `startingPosition`, `inferSchema`, and `classification`.

A Kafka streaming source requires the following connection options: `connectionName`, `topicName`, `startingOffsets`, `inferSchema`, and `classification`.

- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `pushDownPredicate` — Predicate on partition columns.

Returns the `DataSource`.

Example for Amazon Kinesis streaming source:

```
val kinesisOptions = jsonOptions()
data_frame_datasource0 = glueContext.getSource("kinesis",
  kinesisOptions).getDataFrame()

private def jsonOptions(): JsonOptions = {
  new JsonOptions(
    s"""{"streamARN": "arn:aws:kinesis:eu-central-1:123456789012:stream/
fromOptionsStream",
      |"startingPosition": "TRIM_HORIZON",
      |"inferSchema": "true",
      |"classification": "json"}""").stripMargin)
}
```

Example for Kafka streaming source:

```
val kafkaOptions = jsonOptions()
val data_frame_datasource0 = glueContext.getSource("kafka",
  kafkaOptions).getDataFrame()

private def jsonOptions(): JsonOptions = {
  new JsonOptions(
    s"""{"connectionName": "ConfluentKafka",
      |"topicName": "kafka-auth-topic",
```

```
    |"startingOffsets": "earliest",  
    |"inferSchema": "true",  
    |"classification": "json"}""").stripMargin)  
}
```

def getSourceWithFormat

```
def getSourceWithFormat( connectionType : String,  
                        options : JsonOptions,  
                        transformationContext : String = "",  
                        format : String = null,  
                        formatOptions : JsonOptions = JsonOptions.empty  
                        ) : DataSource
```

Creates a [DataSource trait](#) that reads data from a source like Amazon S3, JDBC, or the Amazon Glue Data Catalog, and also sets the format of data stored in the source.

- `connectionType` – The type of the data source. See [the section called “Connection parameters”](#).
- `options` – A string of JSON name-value pairs that provide additional information for establishing a connection with the data source. See [the section called “Connection parameters”](#).
- `transformationContext` – The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `format` – The format of the data that is stored at the source. When the `connectionType` is "s3", you can also specify `format`. Can be one of "avro", "csv", "grokLog", "ion", "json", "xml", "parquet", or "orc".
- `formatOptions` – A string of JSON name-value pairs that provide additional options for parsing data at the source. See [Data format options](#).

Returns the DataSource.

Examples

Create a DynamicFrame from a data source that is a comma-separated values (CSV) file on Amazon S3:

```
val datasource0 = glueContext.getSourceWithFormat(  
    connectionType="s3",
```

```
options =JsonOptions(s""""{"paths": [ "s3://csv/nycflights.csv"]}""""),
transformationContext = "datasource0",
format = "csv",
formatOptions=JsonOptions(s""""{"withHeader":"true","separator": ","}""""))
).getDynamicFrame()
```

Create a DynamicFrame from a data source that is a PostgreSQL using a JDBC connection:

```
val datasource0 = glueContext.getSourceWithFormat(
  connectionType="postgresql",
  options =JsonOptions(s""""{
    "url":"jdbc:postgresql://databasePostgres-1.rds.amazonaws.com:5432/testdb",
    "dbtable": "public.company",
    "redshiftTmpDir":"","
    "user":"username",
    "password":"password123"
  }""""),
  transformationContext = "datasource0").getDynamicFrame()
```

Create a DynamicFrame from a data source that is a MySQL using a JDBC connection:

```
val datasource0 = glueContext.getSourceWithFormat(
  connectionType="mysql",
  options =JsonOptions(s""""{
    "url":"jdbc:mysql://databaseMySQL-1.rds.amazonaws.com:3306/testdb",
    "dbtable": "athenatest_nycflights13_csv",
    "redshiftTmpDir":"","
    "user":"username",
    "password":"password123"
  }""""),
  transformationContext = "datasource0").getDynamicFrame()
```

def getSparkSession

```
def getSparkSession : SparkSession
```

Gets the SparkSession object associated with this GlueContext. Use this SparkSession object to register tables and UDFs for use with DataFrame created from DynamicFrames.

Returns the SparkSession.

def startTransaction

```
def startTransaction(readOnly: Boolean):String
```

Start a new transaction. Internally calls the Lake Formation [startTransaction](#) API.

- `readOnly` – (Boolean) Indicates whether this transaction should be read only or read and write. Writes made using a read-only transaction ID will be rejected. Read-only transactions do not need to be committed.

Returns the transaction ID.

def commitTransaction

```
def commitTransaction(transactionId: String, waitForCommit: Boolean): Boolean
```

Attempts to commit the specified transaction. `commitTransaction` may return before the transaction has finished committing. Internally calls the Lake Formation [commitTransaction](#) API.

- `transactionId` – (String) The transaction to commit.
- `waitForCommit` – (Boolean) Determines whether the `commitTransaction` returns immediately. The default value is true. If false, `commitTransaction` polls and waits until the transaction is committed. The amount of wait time is restricted to 1 minute using exponential backoff with a maximum of 6 retry attempts.

Returns a Boolean to indicate whether the commit is done or not.

def cancelTransaction

```
def cancelTransaction(transactionId: String): Unit
```

Attempts to cancel the specified transaction. Internally calls the Lake Formation [CancelTransaction](#) API.

- `transactionId` – (String) The transaction to cancel.

Returns a `TransactionCommittedException` exception if the transaction was previously committed.

def this

```
def this( sc : SparkContext,  
         minPartitions : Int,  
         targetPartitions : Int )
```

Creates a `GlueContext` object using the specified `SparkContext`, minimum partitions, and target partitions.

- `sc` — The `SparkContext`.
- `minPartitions` — The minimum number of partitions.
- `targetPartitions` — The target number of partitions.

Returns the `GlueContext`.

def this

```
def this( sc : SparkContext )
```

Creates a `GlueContext` object with the provided `SparkContext`. Sets the minimum partitions to 10 and target partitions to 20.

- `sc` — The `SparkContext`.

Returns the `GlueContext`.

def this

```
def this( sparkContext : JavaSparkContext )
```

Creates a `GlueContext` object with the provided `JavaSparkContext`. Sets the minimum partitions to 10 and target partitions to 20.

- `sparkContext` — The `JavaSparkContext`.

Returns the `GlueContext`.

MappingSpec

Package: `com.amazonaws.services.glue`

MappingSpec case class

```
case class MappingSpec( sourcePath: SchemaPath,
                       sourceType: DataType,
                       targetPath: SchemaPath,
                       targetType: DataType
                       ) extends Product4[String, String, String, String] {
  override def _1: String = sourcePath.toString
  override def _2: String = ExtendedTypeName.fromDataType(sourceType)
  override def _3: String = targetPath.toString
  override def _4: String = ExtendedTypeName.fromDataType(targetType)
}
```

- `sourcePath` — The `SchemaPath` of the source field.
- `sourceType` — The `DataType` of the source field.
- `targetPath` — The `SchemaPath` of the target field.
- `targetType` — The `DataType` of the target field.

A `MappingSpec` specifies a mapping from a source path and a source data type to a target path and a target data type. The value at the source path in the source frame appears in the target frame at the target path. The source data type is cast to the target data type.

It extends from `Product4` so that you can handle any `Product4` in your `applyMapping` interface.

MappingSpec object

```
object MappingSpec
```

The `MappingSpec` object has the following members:

Val `orderingByTarget`

```
val orderingByTarget: Ordering[MappingSpec]
```

Def apply

```
def apply( sourcePath : String,  
          sourceType : DataType,  
          targetPath : String,  
          targetType : DataType  
        ) : MappingSpec
```

Creates a MappingSpec.

- `sourcePath` — A string representation of the source path.
- `sourceType` — The source `DataType`.
- `targetPath` — A string representation of the target path.
- `targetType` — The target `DataType`.

Returns a MappingSpec.

Def apply

```
def apply( sourcePath : String,  
          sourceTypeString : String,  
          targetPath : String,  
          targetTypeString : String  
        ) : MappingSpec
```

Creates a MappingSpec.

- `sourcePath` — A string representation of the source path.
- `sourceType` — A string representation of the source data type.
- `targetPath` — A string representation of the target path.
- `targetType` — A string representation of the target data type.

Returns a MappingSpec.

Def apply

```
def apply( product : Product4[String, String, String, String] ) : MappingSpec
```

Creates a MappingSpec.

- `product` — The Product4 of the source path, source data type, target path, and target data type.

Returns a MappingSpec.

Amazon Glue Scala ResolveSpec APIs

Topics

- [ResolveSpec object](#)
- [ResolveSpec case class](#)

Package: `com.amazonaws.services.glue`

ResolveSpec object

ResolveSpec

```
object ResolveSpec
```

Def

```
def apply( path : String,  
          action : String  
          ) : ResolveSpec
```

Creates a ResolveSpec.

- `path` — A string representation of the choice field that needs to be resolved.
- `action` — A resolution action. The action can be one of the following: `Project`, `KeepAsStruct`, or `Cast`.

Returns the ResolveSpec.

Def

```
def apply( product : Product2[String, String] ) : ResolveSpec
```

Creates a `ResolveSpec`.

- `product` — `Product2` of: source path, resolution action.

Returns the `ResolveSpec`.

ResolveSpec case class

```
case class ResolveSpec extends Product2[String, String] (  
    path : SchemaPath,  
    action : String )
```

Creates a `ResolveSpec`.

- `path` — The `SchemaPath` of the choice field that needs to be resolved.
- `action` — A resolution action. The action can be one of the following: `Project`, `KeepAsStruct`, or `Cast`.

ResolveSpec def methods

```
def _1 : String
```

```
def _2 : String
```

Amazon Glue Scala ArrayNode APIs

Package: `com.amazonaws.services.glue.types`

ArrayNode case class

ArrayNode

```
case class ArrayNode extends DynamicNode (  
    value : ArrayBuffer[DynamicNode] )
```

ArrayNode def methods

```
def add( node : DynamicNode )
```

```
def clone
```

```
def equals( other : Any )
```

```
def get( index : Int ) : Option[DynamicNode]
```

```
def getValue
```

```
def hashCode : Int
```

```
def isEmpty : Boolean
```

```
def nodeType
```

```
def remove( index : Int )
```

```
def this
```

```
def toIterator : Iterator[DynamicNode]
```

```
def toJson : String
```

```
def update( index : Int,  
            node : DynamicNode )
```

Amazon Glue Scala BinaryNode APIs

Package: `com.amazonaws.services.glue.types`

BinaryNode case class

BinaryNode

```
case class BinaryNode extends ScalarNode(value, TypeCode.BINARY) (  
    value : Array[Byte] )
```

BinaryNode val fields

- ordering

BinaryNode def methods

```
def clone
```

```
def equals( other : Any )
```

```
def hashCode : Int
```

Amazon Glue Scala BooleanNode APIs

Package: com.amazonaws.services.glue.types

BooleanNode case class

BooleanNode

```
case class BooleanNode extends ScalarNode(value, TypeCode.BOOLEAN) (  
    value : Boolean )
```

BooleanNode val fields

- ordering

BooleanNode def methods

```
def equals( other : Any )
```

Amazon Glue Scala ByteNode APIs

Package: com.amazonaws.services.glue.types

ByteNode case class

ByteNode

```
case class ByteNode extends ScalarNode(value, TypeCode.BYTE) (  
    value : Byte )
```

```
value : Byte )
```

ByteNode val fields

- ordering

ByteNode def methods

```
def equals( other : Any )
```

Amazon Glue Scala DateNode APIs

Package: com.amazonaws.services.glue.types

DateNode case class

DateNode

```
case class DateNode extends ScalarNode(value, TypeCode.DATE) (  
    value : Date )
```

DateNode val fields

- ordering

DateNode def methods

```
def equals( other : Any )
```

```
def this( value : Int )
```

Amazon Glue Scala DecimalNode APIs

Package: com.amazonaws.services.glue.types

DecimalNode case class

DecimalNode

```
case class DecimalNode extends ScalarNode(value, TypeCode.DECIMAL) (  
    value : Decimal )
```

```
value : BigDecimal )
```

DecimalNode val fields

- ordering

DecimalNode def methods

```
def equals( other : Any )
```

```
def this( value : Decimal )
```

Amazon Glue Scala DoubleNode APIs

Package: com.amazonaws.services.glue.types

DoubleNode case class

DoubleNode

```
case class DoubleNode extends ScalarNode(value, TypeCode.DOUBLE) (  
    value : Double )
```

DoubleNode val fields

- ordering

DoubleNode def methods

```
def equals( other : Any )
```

Amazon Glue Scala DynamicNode APIs

Topics

- [DynamicNode class](#)
- [DynamicNode object](#)

Package: com.amazonaws.services.glue.types

DynamicNode class

DynamicNode

```
class DynamicNode extends Serializable with Cloneable
```

DynamicNode def methods

```
def getValue : Any
```

Get plain value and bind to the current record:

```
def nodeType : TypeCode
```

```
def toJson : String
```

Method for debug:

```
def toRow( schema : Schema,  
           options : Map[String, ResolveOption]  
           ) : Row
```

```
def typeName : String
```

DynamicNode object

DynamicNode

```
object DynamicNode
```

DynamicNode def methods

```
def quote( field : String,  
           useQuotes : Boolean  
           ) : String
```

```
def quote( node : DynamicNode,  
           useQuotes : Boolean
```

```
) : String
```

EvaluateDataQuality class

Amazon Glue Data Quality is in preview release for Amazon Glue and is subject to change.

Package: `com.amazonaws.services.glue.dq`

```
object EvaluateDataQuality
```

Def apply

```
def apply(frame: DynamicFrame,  
          ruleset: String,  
          publishingOptions: JsonOptions = JsonOptions.empty): DynamicFrame
```

Evaluates a data quality ruleset against a `DynamicFrame`, and returns a new `DynamicFrame` with results of the evaluation. To learn more about Amazon Glue Data Quality, see [Amazon Glue Data Quality](#).

- `frame` – The `DynamicFrame` that you want to evaluate the data quality of.
- `ruleset` – A Data Quality Definition Language (DQDL) ruleset in string format. To learn more about DQDL, see the [Data Quality Definition Language \(DQDL\) reference](#) guide.
- `publishingOptions` – A dictionary that specifies the following options for publishing evaluation results and metrics:
 - `dataQualityEvaluationContext` – A string that specifies the namespace under which Amazon Glue should publish Amazon CloudWatch metrics and the data quality results. The aggregated metrics appear in CloudWatch, while the full results appear in the Amazon Glue Studio interface.
 - Required: No
 - Default value: `default_context`
 - `enableDataQualityCloudWatchMetrics` – Specifies whether the results of the data quality evaluation should be published to CloudWatch. You specify a namespace for the metrics using the `dataQualityEvaluationContext` option.
 - Required: No

- Default value: False
- `enableDataQualityResultsPublishing` – Specifies whether the data quality results should be visible on the **Data Quality** tab in the Amazon Glue Studio interface.
 - Required: No
 - Default value: True
- `resultsS3Prefix` – Specifies the Amazon S3 location where Amazon Glue can write the data quality evaluation results.
 - Required: No
 - Default value: "" (empty string)

Example

The following example code demonstrates how to evaluate data quality for a `DynamicFrame` before performing a `SelectFields` transform. The script verifies that all data quality rules pass before it attempts the transform.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.dq.EvaluateDataQuality

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    // @params: [JOB_NAME]
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    // Create DynamicFrame with data
    val Legislators_Area = glueContext.getCatalogSource(database="legislators",
    tableName="areas_json", transformationContext="S3bucket_node1").getDynamicFrame()

    // Define data quality ruleset
```

```
val DQ_Ruleset = """
  Rules = [ColumnExists "id"]
  """

// Evaluate data quality
val DQ_Results = EvaluateDataQuality.apply(frame=Legislators_Area,
ruleset=DQ_Ruleset, publishingOptions=JsonOptions("""{"dataQualityEvaluationContext":
"Legislators_Area", "enableDataQualityMetrics": "true",
"enableDataQualityResultsPublishing": "true"}"""))
  assert(DQ_Results.filter(_.getField("Outcome").contains("Failed")).count == 0,
"Failing DQ rules for Legislators_Area caused the job to fail.")

// Script generated for node Select Fields
val SelectFields_Results = Legislators_Area.selectFields(paths=Seq("id", "name"),
transformationContext="Legislators_Area")

Job.commit()
}
```

Amazon Glue Scala FloatNode APIs

Package: `com.amazonaws.services.glue.types`

FloatNode case class

FloatNode

```
case class FloatNode extends ScalarNode(value, TypeCode.FLOAT) (
  value : Float )
```

FloatNode val fields

- `ordering`

FloatNode def methods

```
def equals( other : Any )
```

FillMissingValues class

Package: `com.amazonaws.services.glue.ml`

```
object FillMissingValues
```

Def apply

```
def apply(frame: DynamicFrame,
          missingValuesColumn: String,
          outputColumn: String = "",
          transformationContext: String = "",
          callSite: CallSite = CallSite("Not provided", ""),
          stageThreshold: Long = 0,
          totalThreshold: Long = 0): DynamicFrame
```

Fills a dynamic frame's missing values in a specified column and returns a new frame with estimates in a new column. For rows without missing values, the specified column's value is duplicated to the new column.

- `frame` — The `DynamicFrame` in which to fill missing values. Required.
- `missingValuesColumn` — The column containing missing values (null values and empty strings). Required.
- `outputColumn` — The name of the new column that will contain estimated values for all rows whose value was missing. Optional; the default is the value of `missingValuesColumn` suffixed by `"_filled"`.
- `transformationContext` — A unique string that is used to identify state information (optional).
- `callSite` — Used to provide context information for error reporting. (optional).
- `stageThreshold` — The maximum number of errors that can occur in the transformation before it errors out (optional; the default is zero).
- `totalThreshold` — The maximum number of errors that can occur overall before processing errors out (optional; the default is zero).

Returns a new dynamic frame with one additional column that contains estimations for rows with missing values and the present value for other rows.

FindMatches class

Package: `com.amazonaws.services.glue.ml`

```
object FindMatches
```

Def apply

```
def apply(frame: DynamicFrame,
          transformId: String,
          transformationContext: String = "",
          callSite: CallSite = CallSite("Not provided", ""),
          stageThreshold: Long = 0,
          totalThreshold: Long = 0,
          enforcedMatches: DynamicFrame = null): DynamicFrame,
computeMatchConfidenceScores: Boolean
```

Find matches in an input frame and return a new frame with a new column containing a unique ID per match group.

- `frame` — The `DynamicFrame` in which to find matches. Required.
- `transformId` — A unique ID associated with the `FindMatches` transform to apply on the input frame. Required.
- `transformationContext` — Identifier for this `DynamicFrame`. The `transformationContext` is used as a key for the job bookmark state that is persisted across runs. Optional.
- `callSite` — Used to provide context information for error reporting. These values are automatically set when calling from Python. Optional.
- `stageThreshold` — The maximum number of error records allowed from the computation of this `DynamicFrame` before throwing an exception, excluding records present in the previous `DynamicFrame`. Optional. The default is zero.
- `totalThreshold` — The maximum number of total errors records before an exception is thrown, including those from previous frames. Optional. The default is zero.
- `enforcedMatches` — The frame for enforced matches. Optional. The default is `null`.
- `computeMatchConfidenceScores` — A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is `false`.

Returns a new dynamic frame with a unique identifier assigned to each group of matching records.

FindIncrementalMatches class

Package: com.amazonaws.services.glue.ml

```
object FindIncrementalMatches
```

Def apply

```
apply(existingFrame: DynamicFrame,
       incrementalFrame: DynamicFrame,
       transformId: String,
       transformationContext: String = "",
       callSite: CallSite = CallSite("Not provided", ""),
       stageThreshold: Long = 0,
       totalThreshold: Long = 0,
       enforcedMatches: DynamicFrame = null): DynamicFrame,
computeMatchConfidenceScores: Boolean
```

Find matches across the existing and incremental frames and return a new frame with a column containing a unique ID per match group.

- `existingframe` — An existing frame which has been assigned a matching ID for each group. Required.
- `incrementalframe` — An incremental frame used to find matches against the existing frame. Required.
- `transformId` — A unique ID associated with the FindIncrementalMatches transform to apply on the input frames. Required.
- `transformationContext` — Identifier for this DynamicFrame. The `transformationContext` is used as a key for the job bookmark state that is persisted across runs. Optional.
- `callSite` — Used to provide context information for error reporting. These values are automatically set when calling from Python. Optional.
- `stageThreshold` — The maximum number of error records allowed from the computation of this DynamicFrame before throwing an exception, excluding records present in the previous DynamicFrame. Optional. The default is zero.
- `totalThreshold` — The maximum number of total errors records before an exception is thrown, including those from previous frames. Optional. The default is zero.

- `enforcedMatches` — The frame for enforced matches. Optional. The default is `null`.
- `computeMatchConfidenceScores` — A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is `false`.

Returns a new dynamic frame with a unique identifier assigned to each group of matching records.

Amazon Glue Scala IntegerNode APIs

Package: `com.amazonaws.services.glue.types`

IntegerNode case class

IntegerNode

```
case class IntegerNode extends ScalarNode(value, TypeCode.INT) (  
    value : Int )
```

IntegerNode val fields

- `ordering`

IntegerNode def methods

```
def equals( other : Any )
```

Amazon Glue Scala LongNode APIs

Package: `com.amazonaws.services.glue.types`

LongNode case class

LongNode

```
case class LongNode extends ScalarNode(value, TypeCode.LONG) (  
    value : Long )
```

LongNode val fields

- `ordering`

LongNode def methods

```
def equals( other : Any )
```

Amazon Glue Scala MapLikeNode APIs

Package: `com.amazonaws.services.glue.types`

MapLikeNode class

MapLikeNode

```
class MapLikeNode extends DynamicNode (
    value : mutable.Map[String, DynamicNode] )
```

MapLikeNode def methods

```
def clear : Unit
```

```
def get( name : String ) : Option[DynamicNode]
```

```
def getValue
```

```
def has( name : String ) : Boolean
```

```
def isEmpty : Boolean
```

```
def put( name : String,
        node : DynamicNode
        ) : Option[DynamicNode]
```

```
def remove( name : String ) : Option[DynamicNode]
```

```
def toIterator : Iterator[(String, DynamicNode)]
```

```
def toJson : String
```

```
def toJson( useQuotes : Boolean ) : String
```

Example: Given this JSON:

```
{"foo": "bar"}
```

If `useQuotes == true`, `toJson` yields `{"foo": "bar"}`. If `useQuotes == false`, `toJson` yields `{foo: bar}` @return.

Amazon Glue Scala MapNode APIs

Package: `com.amazonaws.services.glue.types`

MapNode case class

MapNode

```
case class MapNode extends MapLikeNode(value) (  
    value : mutable.Map[String, DynamicNode] )
```

MapNode def methods

```
def clone
```

```
def equals( other : Any )
```

```
def hashCode : Int
```

```
def nodeType
```

```
def this
```

Amazon Glue Scala NullNode APIs

```

ScalarNode def methods

```
def apply( v : Any ) : DynamicNode
```

```
def compare( tv : Ordered[T],  
            other : T,  
            operator : String  
            ) : Boolean
```

```
def compareAny( v : Any,  
              y : Any,  
              o : String )
```

```
def withEscapedSpecialCharacters( jsonToEscape : String ) : String
```

Amazon Glue Scala ShortNode APIs

Package: `com.amazonaws.services.glue.types`

ShortNode case class

ShortNode

```
case class ShortNode extends ScalarNode(value, TypeCode.SHORT) (  
    value : Short )
```

ShortNode val fields

- ordering

ShortNode def methods

```
def equals( other : Any )
```

Amazon Glue Scala StringNode APIs

Package: com.amazonaws.services.glue.types

StringNode case class

StringNode

```
case class StringNode extends ScalarNode(value, TypeCode.STRING) (  
    value : String )
```

StringNode val fields

- ordering

StringNode def methods

```
def equals( other : Any )
```

```
def this( value : UTF8String )
```

Amazon Glue Scala TimestampNode APIs

Package: com.amazonaws.services.glue.types

TimestampNode case class

TimestampNode

```
case class TimestampNode extends ScalarNode(value, TypeCode.TIMESTAMP) (  
    value : Timestamp )
```

TimestampNode val fields

- ordering

TimestampNode def methods

```
def equals( other : Any )
```

```
def this( value : Long )
```

Amazon Glue Scala GlueArgParser APIs

Package: com.amazonaws.services.glue.util

GlueArgParser object

GlueArgParser

```
object GlueArgParser
```

This is strictly consistent with the Python version of `utils.getResolvedOptions` in the `AWSGlueDataplanePython` package.

GlueArgParser def methods

```
def getResolvedOptions( args : Array[String],  
                        options : Array[String]  
                        ) : Map[String, String]
```

```
def initParser( userOptionsSet : mutable.Set[String] ) : ArgumentParser
```

Example Retrieving arguments passed to a job

To retrieve job arguments, you can use the `getResolvedOptions` method. Consider the following example, which retrieves a job argument named `aws_region`.

```
val args = GlueArgParser.getResolvedOptions(sysArgs,  
      Seq("JOB_NAME","aws_region").toArray)  
Job.init(args("JOB_NAME"), glueContext, args.asJava)  
val region = args("aws_region")
```

```
println(region)
```

Amazon Glue Scala job APIs

Package: `com.amazonaws.services.glue.util`

Job object

Job

```
object Job
```

Job def methods

```
def commit
```

```
def init( jobName : String,  
         glueContext : GlueContext,  
         args : java.util.Map[String, String] = Map[String, String]()  
         ) : this.type
```

```
def init( jobName : String,  
         glueContext : GlueContext,  
         endpoint : String,  
         args : java.util.Map[String, String]  
         ) : this.type
```

```
def isInitialized
```

```
def reset
```

```
def runId
```

Features and optimizations for programming Amazon Glue for Spark ETL scripts

The following sections describe techniques and values that apply generally to Amazon Glue for Spark ETL (extract, transform, and load) programming in any language.

Topics

- [Connection types and options for ETL in Amazon Glue for Spark](#)
- [Data format options for inputs and outputs in Amazon Glue for Spark](#)
- [Amazon Glue Data Catalog support for Spark SQL jobs](#)
- [Using job bookmarks](#)
- [Using Sensitive Data Detection outside Amazon Glue Studio](#)
- [Amazon Glue Visual Job API](#)

Connection types and options for ETL in Amazon Glue for Spark

In Amazon Glue for Spark, various PySpark and Scala methods and transforms specify the connection type using a `connectionType` parameter. They specify connection options using a `connectionOptions` or `options` parameter.

The `connectionType` parameter can take the values shown in the following table. The associated `connectionOptions` (or `options`) parameter values for each type are documented in the following sections. Except where otherwise noted, the parameters apply when the connection is used as a source or sink.

For sample code that demonstrates setting and using connection options, see the homepage for each connection type.

| <code>connectionType</code> | Connects to |
|-----------------------------|--|
| dynamodb | Amazon DynamoDB database |
| kinesis | Amazon Kinesis Data Streams |
| s3 | Amazon S3 |
| documentdb | Amazon DocumentDB (with MongoDB compatibility) database |
| opensearch | Amazon OpenSearch Service . |
| redshift | Amazon Redshift database |
| kafka | Kafka or Amazon Managed Streaming for Apache Kafka |

| connectionType | Connects to |
|-------------------------------|--|
| azurecosmos | Azure Cosmos for NoSQL. |
| azuresql | Azure SQL. |
| bigquery | Google BigQuery. |
| mongodb | MongoDB database, including MongoDB Atlas. |
| sqlserver | Microsoft SQL Server database (see JDBC connections) |
| mysql | MySQL database (see JDBC connections) |
| oracle | Oracle database (see JDBC connections) |
| postgresql | PostgreSQL database (see JDBC connections) |
| saphana | SAP HANA. |
| snowflake | Snowflake data lake |
| teradata | Teradata Vantage. |
| vertica | Vertica. |
| custom.* | Spark, Athena, or JDBC data stores (see Custom and Amazon Web Services Marketplace connectionType values) |
| marketplace.* | Spark, Athena, or JDBC data stores (see Custom and Amazon Web Services Marketplace connectionType values) |

DynamoDB connections

You can use Amazon Glue for Spark to read from and write to tables in DynamoDB in Amazon Glue. You connect to DynamoDB using IAM permissions attached to your Amazon Glue job. Amazon Glue supports writing data into another Amazon account's DynamoDB table. For more information, see [the section called "Cross-account cross-Region access to DynamoDB tables"](#).

The original DynamoDB connector uses Glue DynamicFrame objects to work with the data extracted from DynamoDB. Amazon Glue 5.0+ introduces a new [DynamoDB connector with Spark DataFrame support](#) that provides native Spark DataFrame support.

In addition to the Amazon Glue DynamoDB ETL connector, you can read from DynamoDB using the DynamoDB export connector, that invokes a DynamoDB ExportTableToPointInTime request and stores it in an Amazon S3 location you supply, in the format of [DynamoDB JSON](#). Amazon Glue then creates a DynamicFrame object by reading the data from the Amazon S3 export location.

The DynamoDB writer is available in Amazon Glue version 1.0 or later versions. The Amazon Glue DynamoDB export connector is available in Amazon Glue version 2.0 or later versions. The new DataFrame-based DynamoDB connector is available in Amazon Glue version 5.0 or later versions.

For more information about DynamoDB, consult [Amazon DynamoDB](#) documentation.

 **Note**

The DynamoDB ETL reader does not support filters or pushdown predicates.

Configuring DynamoDB connections

To connect to DynamoDB from Amazon Glue, grant the IAM role associated with your Amazon Glue job permission to interact with DynamoDB. For more information about permissions necessary to read or write from DynamoDB, consult [Actions, resources, and condition keys for DynamoDB](#) in the IAM documentation.

In the following situations, you may need additional configuration:

- When using the DynamoDB export connector, you will need to configure IAM so your job can request DynamoDB table exports. Additionally, you will need to identify an Amazon S3 bucket for the export and provide appropriate permissions in IAM for DynamoDB to write to it, and for your Amazon Glue job to read from it. For more information, consult [Request a table export in DynamoDB](#).
- If your Amazon Glue job has specific Amazon VPC connectivity requirements, use the NETWORK Amazon Glue connection type to provide network options. Since access to DynamoDB is authorized by IAM, there is no need for a Amazon Glue DynamoDB connection type.

Reading from and writing to DynamoDB

The following code examples show how to read from (via the ETL connector) and write to DynamoDB tables. They demonstrate reading from one table and writing to another table.

Python

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame.from_options(
    connection_type="dynamodb",
    connection_options={"dynamodb.input.tableName": test_source,
                        "dynamodb.throughput.read.percent": "1.0",
                        "dynamodb.splits": "100"
    }
)
print(dyf.getNumPartitions())

glue_context.write_dynamic_frame_from_options(
    frame=dyf,
    connection_type="dynamodb",
    connection_options={"dynamodb.output.tableName": test_sink,
                        "dynamodb.throughput.write.percent": "1.0"
    }
)

job.commit()
```

Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
```

```
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.input.tableName" -> test_source,
        "dynamodb.throughput.read.percent" -> "1.0",
        "dynamodb.splits" -> "100"
      ))
    ).getDynamicFrame()

    print(dynamicFrame.getNumPartitions())

    val dynamoDbSink: DynamoDbDataSink = glueContext.getSinkWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.output.tableName" -> test_sink,
        "dynamodb.throughput.write.percent" -> "1.0"
      ))
    ).asInstanceOf[DynamoDbDataSink]

    dynamoDbSink.writeDynamicFrame(dynamicFrame)

    Job.commit()
  }
}
```

Using the DynamoDB export connector

The export connector performs better than the ETL connector when the DynamoDB table size is larger than 80 GB. In addition, given that the export request is conducted outside from the Spark

processes in an Amazon Glue job, you can enable [auto scaling of Amazon Glue jobs](#) to save DPU usage during the export request. With the export connector, you also do not need to configure the number of splits for Spark executor parallelism or DynamoDB throughput read percentage.

Note

DynamoDB has specific requirements to invoke the `ExportTableToPointInTime` requests. For more information, see [Requesting a table export in DynamoDB](#). For example, Point-in-Time-Restore (PITR) needs to be enabled on the table to use this connector. The DynamoDB connector also supports Amazon KMS encryption for DynamoDB exports to Amazon S3. Supplying your security configuration in the Amazon Glue job configuration enables Amazon KMS encryption for a DynamoDB export. The KMS key must be in the same Region as the Amazon S3 bucket.

Note that additional charges for DynamoDB export and Amazon S3 storage costs apply. Exported data in Amazon S3 persists after a job run finishes so you can reuse it without additional DynamoDB exports. A requirement for using this connector is that point-in-time recovery (PITR) is enabled for the table.

The DynamoDB ETL connector or export connector do not support filters or pushdown predicates to be applied at the DynamoDB source.

The following code examples show how to read from (via the export connector) and print the number of partitions.

Python

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame.from_options(
    connection_type="dynamodb",
    connection_options={
```

```
        "dynamodb.export": "ddb",
        "dynamodb.tableArn": test_source,
        "dynamodb.s3.bucket": bucket_name,
        "dynamodb.s3.prefix": bucket_prefix,
        "dynamodb.s3.bucketOwner": account_id_of_bucket,
    }
)
print(dyf.getNumPartitions())

job.commit()
```

Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.export" -> "ddb",
        "dynamodb.tableArn" -> test_source,
        "dynamodb.s3.bucket" -> bucket_name,
        "dynamodb.s3.prefix" -> bucket_prefix,
        "dynamodb.s3.bucketOwner" -> account_id_of_bucket,
      ))
    ).getDynamicFrame()

    print(dynamicFrame.getNumPartitions())

    Job.commit()
```

```
}  
  
}
```

These examples show how to do the read from (via the export connector) and print the number of partitions from an Amazon Glue Data Catalog table that has a dynamodb classification:

Python

```
import sys  
from pyspark.context import SparkContext  
from awsglue.context import GlueContext  
from awsglue.job import Job  
from awsglue.utils import getResolvedOptions  
  
args = getResolvedOptions(sys.argv, ["JOB_NAME"])  
glue_context= GlueContext(SparkContext.getOrCreate())  
job = Job(glue_context)  
job.init(args["JOB_NAME"], args)  
  
dynamicFrame = glue_context.create_dynamic_frame.from_catalog(  
    database=catalog_database,  
    table_name=catalog_table_name,  
    additional_options={  
        "dynamodb.export": "ddb",  
        "dynamodb.s3.bucket": s3_bucket,  
        "dynamodb.s3.prefix": s3_bucket_prefix  
    }  
)  
print(dynamicFrame.getNumPartitions())  
  
job.commit()
```

Scala

```
import com.amazonaws.services.glue.GlueContext  
import com.amazonaws.services.glue.util.GlueArgParser  
import com.amazonaws.services.glue.util.Job  
import com.amazonaws.services.glue.util.JsonOptions  
import com.amazonaws.services.glue.DynamoDbDataSink  
import org.apache.spark.SparkContext  
import scala.collection.JavaConverters._
```

```

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getCatalogSource(
      database = catalog_database,
      tableName = catalog_table_name,
      additionalOptions = JsonOptions(Map(
        "dynamodb.export" -> "ddb",
        "dynamodb.s3.bucket" -> s3_bucket,
        "dynamodb.s3.prefix" -> s3_bucket_prefix
      ))
    ).getDynamicFrame()
    print(dynamicFrame.getNumPartitions())
  }
}

```

Simplifying usage of DynamoDB export JSON

The DynamoDB exports with the Amazon Glue DynamoDB export connector results in JSON files of specific nested structures. For more information, see [Data objects](#). Amazon Glue supplies a `DynamicFrame` transformation, which can unnest such structures into an easier-to-use form for downstream applications.

The transform can be invoked in one of two ways. You can set the connection option `"dynamodb.simplifyDDBJson"` with the value `"true"` when calling a method to read from DynamoDB. You can also call the transform as a method independently available in the Amazon Glue library.

Consider the following schema generated by a DynamoDB export:

```

root
|-- Item: struct
|   |-- parentMap: struct
|   |   |-- M: struct
|   |   |   |-- childMap: struct
|   |   |   |   |-- M: struct
|   |   |   |   |   |-- appName: struct

```

```

|   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |-- packageName: struct
|   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |-- updatedAt: struct
|   |   |   |   |   |   |-- N: string
|   |-- strings: struct
|   |   |-- SS: array
|   |   |   |-- element: string
|   |-- numbers: struct
|   |   |-- NS: array
|   |   |   |-- element: string
|   |-- binaries: struct
|   |   |-- BS: array
|   |   |   |-- element: string
|   |-- isDDBJson: struct
|   |   |-- BOOL: boolean
|   |-- nullValue: struct
|   |   |-- NULL: boolean

```

The `simplifyDDBJson` transform will simplify this to:

```

root
|-- parentMap: struct
|   |-- childMap: struct
|   |   |-- appName: string
|   |   |-- packageName: string
|   |   |-- updatedAt: string
|-- strings: array
|   |-- element: string
|-- numbers: array
|   |-- element: string
|-- binaries: array
|   |-- element: string
|-- isDDBJson: boolean
|-- nullValue: null

```

Note

`simplifyDDBJson` is available in Amazon Glue 3.0 and later versions. The `unnestDDBJson` transform is also available to simplify DynamoDB export JSON. We encourage users to transition to `simplifyDDBJson` from `unnestDDBJson`.

Configuring parallelism in DynamoDB operations

To improve performance, you can tune certain parameters available for the DynamoDB connector. Your goal when tuning parallelism parameters is to maximize the use of the provisioned Amazon Glue workers. Then, if you need more performance, we recommend you to scale out your job by increasing the number of DPUs.

You can alter the parallelism in a DynamoDB read operation using the `dynamodb.splits` parameter when using the ETL connector. When reading with the export connector, you do not need to configure the number of splits for Spark executor parallelism. You can alter the parallelism in a DynamoDB write operation with `dynamodb.output.numParallelTasks`.

Reading with the DynamoDB ETL connector

We recommend you to calculate `dynamodb.splits` based on the maximum number of workers set in your job configuration and the following `numSlots` calculation. If autoscaling, the actual number of workers available may change under that cap. For more information about setting the maximum number of workers, see **Number of workers** (`NumberOfWorkers`) in [the section called "Configuring Spark job properties"](#).

- `numExecutors = NumberOfWorkers - 1`

For context, one executor is reserved for the Spark driver; other executors are used to process data.

- `numSlotsPerExecutor =`

Amazon Glue 3.0 and later versions

- 4 if `WorkerType` is G.1X
- 8 if `WorkerType` is G.2X
- 16 if `WorkerType` is G.4X
- 32 if `WorkerType` is G.8X

Amazon Glue 2.0 and legacy versions

- 8 if `WorkerType` is G.1X
- 16 if `WorkerType` is G.2X

- `numSlots = numSlotsPerExecutor * numExecutors`

We recommend you set `dynamodb.splits` to the number of slots available, `numSlots`.

Writing to DynamoDB

The `dynamodb.output.numParallelTasks` parameter is used to determine WCU per Spark task, using the following calculation:

$$\text{permittedWcuPerTask} = (\text{TableWCU} * \text{dynamodb.throughput.write.percent}) / \text{dynamodb.output.numParallelTasks}$$

The DynamoDB writer will function best if configuration accurately represents the number of Spark tasks writing to DynamoDB. In some cases, you may need to override the default calculation to improve write performance. If you do not specify this parameter, the permitted WCU per Spark task will be automatically calculated by the following formula:

- `numPartitions = dynamicframe.getNumPartitions()`
- `numSlots` (as defined previously in this section)
- `numParallelTasks = min(numPartitions, numSlots)`
- Example 1. DPU=10, WorkerType=Standard. Input DynamicFrame has 100 RDD partitions.
 - `numPartitions = 100`
 - `numExecutors = (10 - 1) * 2 - 1 = 17`
 - `numSlots = 4 * 17 = 68`
 - `numParallelTasks = min(100, 68) = 68`
- Example 2. DPU=10, WorkerType=Standard. Input DynamicFrame has 20 RDD partitions.
 - `numPartitions = 20`
 - `numExecutors = (10 - 1) * 2 - 1 = 17`
 - `numSlots = 4 * 17 = 68`
 - `numParallelTasks = min(20, 68) = 20`

Note

Jobs on legacy Amazon Glue versions and those using Standard workers require different methods to calculate the number of slots. If you need to performance tune these jobs, we recommend you transition to supported Amazon Glue versions.

DynamoDB connection option reference

Designates a connection to Amazon DynamoDB.

Connection options differ for a source connection and a sink connection.

"connectionType": "dynamodb" with the ETL connector as source

Use the following connection options with "connectionType": "dynamodb" as a source, when using the Amazon Glue DynamoDB ETL connector:

- "dynamodb.input.tableName": (Required) The DynamoDB table to read from.
- "dynamodb.throughput.read.percent": (Optional) The percentage of read capacity units (RCU) to use. The default is set to "0.5". Acceptable values are from "0.1" to "1.5", inclusive.
 - 0.5 represents the default read rate, meaning that Amazon Glue will attempt to consume half of the read capacity of the table. If you increase the value above 0.5, Amazon Glue increases the request rate; decreasing the value below 0.5 decreases the read request rate. (The actual read rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)
 - When the DynamoDB table is in on-demand mode, Amazon Glue handles the read capacity of the table as 40000. For exporting a large table, we recommend switching your DynamoDB table to on-demand mode.
- "dynamodb.splits": (Optional) Defines how many splits we partition this DynamoDB table into while reading. The default is set to "1". Acceptable values are from "1" to "1,000,000", inclusive.

1 represents there is no parallelism. We highly recommend that you specify a larger value for better performance by using the below formula. For more information on appropriately setting a value, see [the section called "DynamoDB parallelism"](#).

- "dynamodb.sts.roleArn": (Optional) The IAM role ARN to be assumed for cross-account access. This parameter is available in Amazon Glue 1.0 or later.
- "dynamodb.sts.roleSessionName": (Optional) STS session name. The default is set to "glue-dynamodb-read-sts-session". This parameter is available in Amazon Glue 1.0 or later.

"connectionType": "dynamodb" with the Amazon Glue DynamoDB export connector as source

Use the following connection options with "connectionType": "dynamodb" as a source, when using the Amazon Glue DynamoDB export connector, which is available only for Amazon Glue version 2.0 onwards:

- "dynamodb.export": (Required) A string value:
 - If set to `ddb` enables the Amazon Glue DynamoDB export connector where a new `ExportTableToPointInTimeRequest` will be invoked during the Amazon Glue job. A new export will be generated with the location passed from `dynamodb.s3.bucket` and `dynamodb.s3.prefix`.
 - If set to `s3` enables the Amazon Glue DynamoDB export connector but skips the creation of a new DynamoDB export and instead uses the `dynamodb.s3.bucket` and `dynamodb.s3.prefix` as the Amazon S3 location of a past export of that table.
- "dynamodb.tableArn": (Required) The DynamoDB table to read from.
- "dynamodb.unnestDDBJson": (Optional) Default: `false`. Valid values: `boolean`. If set to `true`, performs an `unnest` transformation of the DynamoDB JSON structure that is present in exports. It is an error to set "dynamodb.unnestDDBJson" and "dynamodb.simplifyDDBJson" to `true` at the same time. In Amazon Glue 3.0 and later versions, we recommend you use "dynamodb.simplifyDDBJson" for better behavior when simplifying DynamoDB Map types. For more information, see [the section called "Simplifying usage of DynamoDB export JSON"](#).
- "dynamodb.simplifyDDBJson": (Optional) Default: `false`. Valid values: `boolean`. If set to `true`, performs a transformation to simplify the schema of the DynamoDB JSON structure that is present in exports. This has the same purpose as the "dynamodb.unnestDDBJson" option but provides better support for DynamoDB Map types or even nested Map types in your DynamoDB table. This option is available in Amazon Glue 3.0 and later versions. It is an error to set "dynamodb.unnestDDBJson" and "dynamodb.simplifyDDBJson" to `true` at the same time. For more information, see [the section called "Simplifying usage of DynamoDB export JSON"](#).
- "dynamodb.s3.bucket": (Optional) Indicates the Amazon S3 bucket location in which the DynamoDB `ExportTableToPointInTime` process is to be conducted. The file format for the export is DynamoDB JSON.
- "dynamodb.s3.prefix": (Optional) Indicates the Amazon S3 prefix location inside the Amazon S3 bucket in which the DynamoDB `ExportTableToPointInTime` loads are to be stored. If neither `dynamodb.s3.prefix` nor `dynamodb.s3.bucket` are specified, these

values will default to the Temporary Directory location specified in the Amazon Glue job configuration. For more information, see [Special Parameters Used by Amazon Glue](#).

- `"dynamodb.s3.bucketOwner"`: Indicates the bucket owner needed for cross-account Amazon S3 access.
- `"dynamodb.sts.roleArn"`: (Optional) The IAM role ARN to be assumed for cross-account access and/or cross-Region access for the DynamoDB table. Note: The same IAM role ARN will be used to access the Amazon S3 location specified for the `ExportTableToPointInTime` request.
- `"dynamodb.sts.roleSessionName"`: (Optional) STS session name. The default is set to `"glue-dynamodb-read-sts-session"`.
- `"dynamodb.exportTime"` (Optional) Valid values: strings representing ISO-8601 instants. A point-in-time at which the export should be made.
- `"dynamodb.sts.region"`: (Required if making a cross-region call using a regional endpoint) The region hosting the DynamoDB table you want to read.

"connectionType": "dynamodb" with the ETL connector as sink

Use the following connection options with `"connectionType": "dynamodb"` as a sink:

- `"dynamodb.output.tableName"`: (Required) The DynamoDB table to write to.
- `"dynamodb.throughput.write.percent"`: (Optional) The percentage of write capacity units (WCU) to use. The default is set to `"0.5"`. Acceptable values are from `"0.1"` to `"1.5"`, inclusive.
 - `0.5` represents the default write rate, meaning that Amazon Glue will attempt to consume half of the write capacity of the table. If you increase the value above `0.5`, Amazon Glue increases the request rate; decreasing the value below `0.5` decreases the write request rate. (The actual write rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table).
- When the DynamoDB table is in on-demand mode, Amazon Glue handles the write capacity of the table as `40000`. For importing a large table, we recommend switching your DynamoDB table to on-demand mode.
- `"dynamodb.output.numParallelTasks"`: (Optional) Defines how many parallel tasks write into DynamoDB at the same time. Used to calculate permissive WCU per Spark task. In most cases, Amazon Glue will calculate a reasonable default for this value. For more information, see [the section called "DynamoDB parallelism"](#).
- `"dynamodb.output.retry"`: (Optional) Defines how many retries we perform when there is a `ProvisionedThroughputExceededException` from DynamoDB. The default is set to `"10"`.

- "dynamodb.sts.roleArn": (Optional) The IAM role ARN to be assumed for cross-account access.
- "dynamodb.sts.roleSessionName": (Optional) STS session name. The default is set to "glue-dynamodb-write-sts-session".

Cross-account cross-Region access to DynamoDB tables

Amazon Glue ETL jobs support both cross-region and cross-account access to DynamoDB tables. Amazon Glue ETL jobs support both reading data from another Amazon Account's DynamoDB table, and writing data into another Amazon Web Services Account's DynamoDB table. Amazon Glue also supports both reading from a DynamoDB table in another region, and writing into a DynamoDB table in another region. This section gives instructions on setting up the access, and provides an example script.

The procedures in this section reference an IAM tutorial for creating an IAM role and granting access to the role. The tutorial also discusses assuming a role, but here you will instead use a job script to assume the role in Amazon Glue. This tutorial also contains information about general cross-account practices. For more information, see [Tutorial: Delegate Access Across Amazon Web Services Accounts Using IAM Roles](#) in the *IAM User Guide*.

Create a role

Follow [step 1 in the tutorial](#) to create an IAM role in account A. When defining the permissions of the role, you can choose to attach existing policies such as `AmazonDynamoDBReadOnlyAccess`, or `AmazonDynamoDBFullAccess` to allow the role to read/write DynamoDB. The following example shows creating a role named `DynamoDBCrossAccessRole`, with the permission policy `AmazonDynamoDBFullAccess`.

Grant access to the role

Follow [step 2 in the tutorial](#) in the *IAM User Guide* to allow account B to switch to the newly-created role. The following example creates a new policy with the following statement:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
```

```
"Effect": "Allow",
"Action": "sts:AssumeRole",
"Resource": "arn:aws:iam::111122223333:role/DynamoDBCrossAccessRole"
}
}
```

Then, you can attach this policy to the group/role/user you would like to use to access DynamoDB.

Assume the role in the Amazon Glue job script

Now, you can log in to account B and create an Amazon Glue job. To create a job, refer to the instructions at [Configuring job properties for Spark jobs in Amazon Glue](#).

In the job script you need to use the `dynamodb.sts.roleArn` parameter to assume the `DynamoDBCrossAccessRole` role. Assuming this role allows you to get the temporary credentials, which need to be used to access DynamoDB in account B. Review these example scripts.

For a cross-account read across regions (ETL connector):

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame_from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.region": "us-east-1",
        "dynamodb.input.tableName": "test_source",
        "dynamodb.sts.roleArn": "<DynamoDBCrossAccessRole's ARN>"
    }
)
dyf.show()
job.commit()
```

For a cross-account read across regions (ELT connector):

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame_from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.export": "ddb",
        "dynamodb.tableArn": "<test_source ARN>",
        "dynamodb.sts.roleArn": "<DynamoDBCrossAccessRole's ARN>"
    }
)
dyf.show()
job.commit()
```

For a read and cross-account write across regions:

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame_from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.region": "us-east-1",
        "dynamodb.input.tableName": "test_source"
    }
)
dyf.show()
```

```
glue_context.write_dynamic_frame_from_options(  
    frame=dyf,  
    connection_type="dynamodb",  
    connection_options={  
        "dynamodb.region": "us-west-2",  
        "dynamodb.output.tableName": "test_sink",  
        "dynamodb.sts.roleArn": "<DynamoDBCrossAccessRole's ARN>"  
    }  
)  
  
job.commit()
```

DynamoDB connector with Spark DataFrame support

DynamoDB connector with Spark DataFrame support allows you to read from and write to tables in DynamoDB using Spark DataFrame APIs. The connector setup steps are the same as for DynamicFrame-based connector and can be found [here](#).

In order to load in the DataFrame-based connector library, make sure to attach a DynamoDB connection to the Glue job.

Note

Glue console UI currently does not support creating a DynamoDB connection. You can use Glue CLI ([CreateConnection](#)) to create a DynamoDB connection:

```
aws glue create-connection \  
  --connection-input '{ \  
    "Name": "my-dynamodb-connection", \  
    "ConnectionType": "DYNAMODB", \  
    "ConnectionProperties": {}, \  
    "ValidateCredentials": false, \  
    "ValidateForComputeEnvironments": ["SPARK"] \  
  }'
```

Upon creating the DynamoDB connection, you can attach it to your Glue job via CLI ([CreateJob](#), [UpdateJob](#)) or directly in the "Job details" page:

Connections

Additional network connections [Info](#)

Choose a VPC configuration to access Amazon S3 data sources located in your virtual private cloud (VPC). You can create and manage Network connections in [AWS Glue](#). [↗](#)

Choose options ▼

my-dynamodb-connection ✕
No description available.

Current connections

These are the connections currently associated with the job.

| Name | Type | VPC | Subnet | Security Groups | Version |
|------------------------|----------|------|--------|-----------------|---------|
| my-dynamodb-connection | DYNAMODB | None | - | - | 2 |

Upon ensuring a connection with DYNAMODB Type is attached to your Glue job, you can utilize the following read, write, and export operations from the DataFrame-based connector.

Reading from and writing to DynamoDB with the DataFrame-based connector

The following code examples show how to read from and write to DynamoDB tables via the DataFrame-based connector. They demonstrate reading from one table and writing to another table.

Python

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
spark = glue_context.spark_session
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

# Read from DynamoDB
df = spark.read.format("dynamodb") \
    .option("dynamodb.input.tableName", "test-source") \
```

```
.option("dynamodb.throughput.read.ratio", "0.5") \  
.option("dynamodb.consistentRead", "false") \  
.load()  
  
print(df.rdd.getNumPartitions())  
  
# Write to DynamoDB  
df.write \  
.format("dynamodb") \  
.option("dynamodb.output.tableName", "test-sink") \  
.option("dynamodb.throughput.write.ratio", "0.5") \  
.option("dynamodb.item.size.check.enabled", "true") \  
.save()  
  
job.commit()
```

Scala

```
import com.amazonaws.services.glue.GlueContext  
import com.amazonaws.services.glue.util.GlueArgParser  
import com.amazonaws.services.glue.util.Job  
import org.apache.spark.SparkContext  
import scala.collection.JavaConverters._  
  
object GlueApp {  
  def main(sysArgs: Array[String]): Unit = {  
  
    val glueContext = new GlueContext(SparkContext.getOrCreate())  
    val spark = glueContext.getSparkSession  
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)  
    Job.init(args("JOB_NAME"), glueContext, args.asJava)  
  
    val df = spark.read  
      .format("dynamodb")  
      .option("dynamodb.input.tableName", "test-source")  
      .option("dynamodb.throughput.read.ratio", "0.5")  
      .option("dynamodb.consistentRead", "false")  
      .load()  
  
    print(df.rdd.getNumPartitions)  
  
    df.write  
      .format("dynamodb")
```

```

        .option("dynamodb.output.tableName", "test-sink")
        .option("dynamodb.throughput.write.ratio", "0.5")
        .option("dynamodb.item.size.check.enabled", "true")
        .save()

    job.commit()
}
}

```

Using DynamoDB export via the DataFrame-based connector

The export operation is preferred to read operation for DynamoDB table sizes larger than 80 GB. The following code examples show how to read from a table, export to S3, and print the number of partitions via the DataFrame-based connector.

Note

The DynamoDB export functionality is available through the Scala `DynamoDBExport` object. Python users can access it via Spark's JVM interop or use the AWS SDK for Python (boto3) with the `DynamoDB ExportTableToPointInTime` API.

Scala

```

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.{GlueArgParser, Job}
import org.apache.spark.SparkContext
import glue.spark.dynamodb.DynamoDBExport
import scala.collection.JavaConverters._

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val spark = glueContext.getSparkSession
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val options = Map(
      "dynamodb.export" -> "ddb",
      "dynamodb.tableArn" -> "arn:aws:dynamodb:us-east-1:123456789012:table/my-
table",

```

```

    "dynamodb.s3.bucket" -> "my-s3-bucket",
    "dynamodb.s3.prefix" -> "my-s3-prefix",
    "dynamodb.simplifyDDBJson" -> "true"
  )
  val df = DynamoDBExport.fullExport(spark, options)

  print(df.rdd.getNumPartitions)
  df.count()

  Job.commit()
}
}

```

Configuration Options

Read options

| Option | Description | Default |
|---|---|---------|
| <code>dynamodb.input.tableName</code> | DynamoDB table name (required) | - |
| <code>dynamodb.throughput.read</code> | The read capacity units (RCU) to use. If unspecified, <code>dynamodb.throughput.read.ratio</code> is used for calculation. | - |
| <code>dynamodb.throughput.read.ratio</code> | The ratio of read capacity units (RCU) to use | 0.5 |
| <code>dynamodb.table.read.capacity</code> | The read capacity of the on-demand table used for calculating the throughput. This parameter is effective only in on-demand capacity tables. Default to warm throughput read units. | - |
| <code>dynamodb.splits</code> | Defines how many segments used in parallel scan operations. If not provided, connector will calculate a reasonable default value. | - |

| Option | Description | Default |
|--------------------------------------|--|---------|
| <code>dynamodb.consistentRead</code> | Whether to use strongly consistent reads | FALSE |
| <code>dynamodb.input.retry</code> | Defines how many retries we perform when there is a retryable exception. | 10 |

Write options

| Option | Description | Default |
|---|---|---------|
| <code>dynamodb.output.tableName</code> | DynamoDB table name (required) | - |
| <code>dynamodb.throughput.write</code> | The write capacity units (WCU) to use. If unspecified, <code>dynamodb.throughput.write.ratio</code> is used for calculation. | - |
| <code>dynamodb.throughput.write.ratio</code> | The ratio of write capacity units (WCU) to use | 0.5 |
| <code>dynamodb.table.write.capacity</code> | The write capacity of the on-demand table used for calculating the throughput. This parameter is effective only in on-demand capacity tables. Default to warm throughput write units. | - |
| <code>dynamodb.item.size.check.enabled</code> | If true, the connector calculate the item size and abort if the size exceeds the maximum size, before writing to DynamoDB table. | TRUE |
| <code>dynamodb.output.retry</code> | Defines how many retries we perform when there is a retryable exception. | 10 |

Export options

| Option | Description | Default |
|--|---|--------------------|
| <code>dynamodb.export</code> | If set to <code>ddb</code> enables the Amazon Glue DynamoDB export connector where a new <code>ExportTableToPointInTimeRequest</code> will be invoked during the Amazon Glue job. A new export will be generated with the location passed from <code>dynamodb.s3.bucket</code> and <code>dynamodb.s3.prefix</code> . If set to <code>s3</code> enables the Amazon Glue DynamoDB export connector but skips the creation of a new DynamoDB export and instead uses the <code>dynamodb.s3.bucket</code> and <code>dynamodb.s3.prefix</code> as the Amazon S3 location of the past exported of that table. | <code>ddb</code> |
| <code>dynamodb.tableArn</code> | The DynamoDB table to read from. Required if <code>dynamodb.export</code> is set to <code>ddb</code> . | |
| <code>dynamodb.simplifyDBObject</code> | If set to <code>true</code> , performs a transformation to simplify the schema of the DynamoDB JSON structure that is present in exports. | <code>FALSE</code> |
| <code>dynamodb.s3.bucket</code> | The S3 bucket to store temporary data during DynamoDB export (required) | |
| <code>dynamodb.s3.prefix</code> | The S3 prefix to store temporary data during DynamoDB export | |
| <code>dynamodb.s3.bucketOwner</code> | Indicate the bucket owner needed for cross-account Amazon S3 access | |
| <code>dynamodb.s3.sse.algorithm</code> | Type of encryption used on the bucket where temporary data will be stored. Valid values are <code>AES256</code> and <code>KMS</code> . | |

| Option | Description | Default |
|---------------------------------------|---|---------|
| <code>dynamodb.s3.sse.kmsKeyId</code> | The ID of the Amazon KMS managed key used to encrypt the S3 bucket where temporary data will be stored (if applicable). | |
| <code>dynamodb.exportTime</code> | A point-in-time at which the export should be made. Valid values: strings representing ISO-8601 instants. | |

General options

| Option | Description | Default |
|---|--|--|
| <code>dynamodb.sts.roleArn</code> | The IAM role ARN to be assumed for cross-account access | - |
| <code>dynamodb.sts.roleSessionName</code> | STS session name | <code>glue-dynamodb-sts-session</code> |
| <code>dynamodb.sts.region</code> | Region for the STS client (for cross-region role assumption) | Same as <code>region</code> option |

Kinesis connections

You can use a Kinesis connection to read and write to Amazon Kinesis data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. You can read information from Kinesis into a Spark DataFrame, then convert it to an Amazon Glue DynamicFrame. You can write DynamicFrames to Kinesis in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kinesis streaming source, the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading

from the Kinesis streaming source. If you use `getSource`, `getSourceWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kinesis using the following arguments for the specified methods in the `GlueContext` class.

- Scala
 - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
 - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
 - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
 - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
 - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
 - `options`: Use with `getSource`, `getSink`

For notes and restrictions about Streaming ETL jobs, consult [the section called “Streaming ETL notes and restrictions”](#).

Configure Kinesis

To connect to a Kinesis data stream in an Amazon Glue Spark job, you will need some prerequisites:

- If reading, the Amazon Glue job must have Read access level IAM permissions to the Kinesis data stream.
- If writing, the Amazon Glue job must have Write access level IAM permissions to the Kinesis data stream.

In certain cases, you will need to configure additional prerequisites:

- If your Amazon Glue job is configured with **Additional network connections** (typically to connect to other datasets) and one of those connections provides Amazon VPC **Network options**, this will direct your job to communicate over Amazon VPC. In this case you will also need to configure your Kinesis data stream to communicate over Amazon VPC. You can do this

by creating an interface VPC endpoint between your Amazon VPC and Kinesis data stream. For more information, see [Using Kinesis Data Streams with Interface VPC Endpoints](#).

- When specifying Amazon Kinesis Data Streams in another account, you must setup the roles and policies to allow cross-account access. For more information, see [Example: Read From a Kinesis Stream in a Different Account](#).

For more information about Streaming ETL job prerequisites, consult [the section called "Streaming ETL jobs"](#).

Example: Reading from Kinesis streams

Example: Reading from Kinesis streams

Used in conjunction with [the section called "forEachBatch"](#).

Example for Amazon Kinesis streaming source:

```
kinesis_options =
  { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
    "startingPosition": "TRIM_HORIZON",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kinesis",
  connection_options=kinesis_options)
```

Example: Writing to Kinesis streams

Example: Reading from Kinesis streams

Used in conjunction with [the section called "forEachBatch"](#).

Example for Amazon Kinesis streaming source:

```
kinesis_options =
  { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
    "startingPosition": "TRIM_HORIZON",
    "inferSchema": "true",
    "classification": "json"
  }
```

```
}  
data_frame_datasource0 =  
  glueContext.create_data_frame.from_options(connection_type="kinesis",  
  connection_options=kinesis_options)
```

Kinesis connection option reference

Designates connection options for Amazon Kinesis Data Streams.

Use the following connection options for Kinesis streaming data sources:

- "streamARN" (Required) Used for Read/Write. The ARN of the Kinesis data stream.
- "classification" (Required for read) Used for Read. The file format used by the data in the record. Required unless provided through the Data Catalog.
- "streamName" – (Optional) Used for Read. The name of a Kinesis data stream to read from. Used with `endpointUrl`.
- "endpointUrl" – (Optional) Used for Read. Default: "https://kinesis.us-east-1.amazonaws.com". The Amazon endpoint of the Kinesis stream. You do not need to change this unless you are connecting to a special region.
- "partitionKey" – (Optional) Used for Write. The Kinesis partition key used when producing records.
- "delimiter" (Optional) Used for Read. The value separator used when `classification` is CSV. Default is ",".
- "startingPosition": (Optional) Used for Read. The starting position in the Kinesis data stream to read data from. The possible values are "latest", "trim_horizon", "earliest", or a Timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where Z represents a UTC timezone offset with a +/-). For example "2023-04-04T08:00:00-04:00". The default value is "latest". Note: the Timestamp string in UTC Format for "startingPosition" is supported only for Amazon Glue version 4.0 or later.
- "failOnDataLoss": (Optional) Fail the job if any active shard is missing or expired. The default value is "false".
- "awsSTSRoleARN": (Optional) Used for Read/Write. The Amazon Resource Name (ARN) of the role to assume using Amazon Security Token Service (Amazon STS). This role must have permissions for describe or read record operations for the Kinesis data stream. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSSessionName".

- `"awsSTSSessionName"`: (Optional) Used for Read/Write. An identifier for the session assuming the role using Amazon STS. You must use this parameter when accessing a data stream in a different account. Used in conjunction with `"awsSTSRoleARN"`.
- `"awsSTSEndpoint"`: (Optional) The Amazon STS endpoint to use when connecting to Kinesis with an assumed role. This allows using the regional Amazon STS endpoint in a VPC, which is not possible with the default global endpoint.
- `"maxFetchTimeInMs"`: (Optional) Used for Read. The maximum time spent for the job executor to read records for the current batch from the Kinesis data stream, specified in milliseconds (ms). Multiple `GetRecords` API calls may be made within this time. The default value is `1000`.
- `"maxFetchRecordsPerShard"`: (Optional) Used for Read. The maximum number of records to fetch per shard in the Kinesis data stream per microbatch. Note: The client can exceed this limit if the streaming job has already read extra records from Kinesis (in the same `get-records` call). If `maxFetchRecordsPerShard` needs to be strict then it needs to be a multiple of `maxRecordPerRead`. The default value is `100000`.
- `"maxRecordPerRead"`: (Optional) Used for Read. The maximum number of records to fetch from the Kinesis data stream in each `getRecords` operation. The default value is `10000`.
- `"addIdleTimeBetweenReads"`: (Optional) Used for Read. Adds a time delay between two consecutive `getRecords` operations. The default value is `"False"`. This option is only configurable for Glue version 2.0 and above.
- `"idleTimeBetweenReadsInMs"`: (Optional) Used for Read. The minimum time delay between two consecutive `getRecords` operations, specified in ms. The default value is `1000`. This option is only configurable for Glue version 2.0 and above.
- `"describeShardInterval"`: (Optional) Used for Read. The minimum time interval between two `ListShards` API calls for your script to consider resharding. For more information, see [Strategies for Resharding](#) in *Amazon Kinesis Data Streams Developer Guide*. The default value is `1s`.
- `"numRetries"`: (Optional) Used for Read. The maximum number of retries for Kinesis Data Streams API requests. The default value is `3`.
- `"retryIntervalMs"`: (Optional) Used for Read. The cool-off time period (specified in ms) before retrying the Kinesis Data Streams API call. The default value is `1000`.
- `"maxRetryIntervalMs"`: (Optional) Used for Read. The maximum cool-off time period (specified in ms) between two retries of a Kinesis Data Streams API call. The default value is `10000`.

- **"avoidEmptyBatches"**: (Optional) Used for Read. Avoids creating an empty microbatch job by checking for unread data in the Kinesis data stream before the batch is started. The default value is "False".
- **"schema"**: (Required when inferSchema set to false) Used for Read. The schema to use to process the payload. If classification is avro the provided schema must be in the Avro schema format. If the classification is not avro the provided schema must be in the DDL schema format.

The following are schema examples.

Example in DDL schema format

```
`column1` INT, `column2` STRING , `column3` FLOAT
```

Example in Avro schema format

```
{
  "type": "array",
  "items":
  {
    "type": "record",
    "name": "test",
    "fields":
    [
      {
        "name": "_id",
        "type": "string"
      },
      {
        "name": "index",
        "type":
        [
          "int",
          "string",
          "float"
        ]
      }
    ]
  }
}
```

- **"inferSchema"**: (Optional) Used for Read. The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within foreachbatch.

- "avroSchema": (Deprecated) Used for Read. Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the schema parameter.
- "addRecordTimestamp": (Optional) Used for Read. When this option is set to 'true', the data output will contain an additional column named "__src_timestamp" that indicates the time when the corresponding record received by the stream. The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.
- "emitConsumerLagMetrics": (Optional) Used for Read. When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the stream and the time it arrives in Amazon Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.
- "fanoutConsumerARN": (Optional) Used for Read. The ARN of a Kinesis stream consumer for the stream specified in streamARN. Used to enable enhanced fan-out mode for your Kinesis connection. For more information on consuming a Kinesis stream with enhanced fan-out, see [the section called "Using enhanced fan-out in Kinesis streaming jobs"](#).
- "recordMaxBufferedTime" – (Optional) Used for Write. Default: 1000 (ms). Maximum time a record is buffered while waiting to be written.
- "aggregationEnabled" – (Optional) Used for Write. Default: true. Specifies if records should be aggregated before sending them to Kinesis.
- "aggregationMaxSize" – (Optional) Used for Write. Default: 51200 (bytes). If a record is larger than this limit, it will bypass the aggregator. Note Kinesis enforces a limit of 50KB on record size. If you set this beyond 50KB, oversize records will be rejected by Kinesis.
- "aggregationMaxCount" – (Optional) Used for Write. Default: 4294967295. Maximum number of items to pack into an aggregated record.
- "producerRateLimit" – (Optional) Used for Write. Default: 150 (%). Limits per-shard throughput sent from a single producer (such as your job), as a percentage of the backend limit.
- "collectionMaxCount" – (Optional) Used for Write. Default: 500. Maximum number of items to pack into an PutRecords request.
- "collectionMaxSize" – (Optional) Used for Write. Default: 5242880 (bytes). Maximum amount of data to send with a PutRecords request.

Using enhanced fan-out in Kinesis streaming jobs

An enhanced fan-out consumer is able to receive records from a Kinesis stream with dedicated throughput that can be greater than typical consumers. This is done by optimizing the transfer protocol used to provide data to a Kinesis consumer, such as your job. For more information about Kinesis Enhanced Fan-Out, see [the Kinesis documentation](#).

In enhanced fan-out mode, the `maxRecordPerRead` and `idleTimeBetweenReadsInMs` connection options no longer apply, as those parameters are not configurable when using enhanced fan-out. The configuration options for retries perform as described.

Use the following procedures to enable and disable enhanced fan-out for your streaming job. You should register a stream consumer for each job that will consume data from your stream.

To enable enhanced fan-out consumption on your job:

1. Register a stream consumer for your job using the Kinesis API. Follow the instructions to *register a consumer with enhanced fan-out using the Kinesis Data Streams API* in the [Kinesis documentation](#). You will only need to follow the first step - calling [RegisterStreamConsumer](#). Your request should return an ARN, `consumerARN`.
2. Set the connection option `fanoutConsumerARN` to `consumerARN` in your connection method arguments.
3. Restart your job.

To disable enhanced fan-out consumption on your job:

1. Remove the `fanoutConsumerARN` connection option from your method call.
2. Restart your job.
3. Follow the instructions to *deregister a consumer* in the [Kinesis documentation](#). These instructions apply to the console, but can also be achieved through the Kinesis API. For more information about stream consumer deregistration through the Kinesis API, consult [DeregisterStreamConsumer](#) in the Kinesis documentation.

Amazon S3 connections

You can use Amazon Glue for Spark to read and write files in Amazon S3. Amazon Glue for Spark supports many common data formats stored in Amazon S3 out of the box, including CSV, Avro,

JSON, Orc and Parquet. For more information about supported data formats, see [the section called “Data format options”](#). Each data format may support a different set of Amazon Glue features. Consult the page for your data format for the specifics of feature support. Additionally, you can read and write versioned files stored in the Hudi, Iceberg and Delta Lake data lake frameworks. For more information about data lake frameworks, see [the section called “Data lake frameworks”](#).

With Amazon Glue you can partition your Amazon S3 objects into a folder structure while writing, then retrieve it by partition to improve performance using simple configuration. You can also set configuration to group small files together when transforming your data to improve performance. You can read and write bzip2 and gzip archives in Amazon S3.

Topics

- [Configuring S3 connections](#)
- [Amazon S3 connection option reference](#)
- [Deprecated connection syntaxes for data formats](#)
- [Excluding Amazon S3 storage classes](#)
- [Managing partitions for ETL output in Amazon Glue](#)
- [Reading input files in larger groups](#)
- [Amazon VPC endpoints for Amazon S3](#)

Configuring S3 connections

To connect to Amazon S3 in a Amazon Glue with Spark job, you will need some prerequisites:

- The Amazon Glue job must have IAM permissions for relevant Amazon S3 buckets.

In certain cases, you will need to configure additional prerequisites:

- When configuring cross-account access, appropriate access controls on the Amazon S3 bucket.
- For security reasons, you may choose to route your Amazon S3 requests through an Amazon VPC. This approach can introduce bandwidth and availability challenges. For more information, see [the section called “Amazon VPC endpoints for Amazon S3”](#).

Amazon S3 connection option reference

Designates a connection to Amazon S3.

Since Amazon S3 manages files rather than tables, in addition to specifying the connection properties provided in this document, you will need to specify additional configuration about your file type. You specify this information through data format options. For more information about format options, see [the section called "Data format options"](#). You can also specify this information by integrating with the Amazon Glue Data Catalog.

For an example of the distinction between connection options and format options, consider how the [the section called "create_dynamic_frame_from_options"](#) method takes `connection_type`, `connection_options`, `format` and `format_options`. This section specifically discusses parameters provided to `connection_options`.

Use the following connection options with `"connectionType": "s3"`:

- `"paths"`: (Required) A list of the Amazon S3 paths to read from.
- `"exclusions"`: (Optional) A string containing a JSON list of Unix-style glob patterns to exclude. For example, `"[\\\"**\\.pdf\\\"]"` excludes all PDF files. For more information about the glob syntax that Amazon Glue supports, see [Include and Exclude Patterns](#).
- `"compressionType"`: or `"compression"`: (Optional) Specifies how the data is compressed. Use `"compressionType"` for Amazon S3 sources and `"compression"` for Amazon S3 targets. This is generally not necessary if the data has a standard file extension. Possible values are `"gzip"` and `"bzip2"`). Additional compression formats may be supported for specific formats. For the specifics of feature support, consult the data format page.
- `"groupFiles"`: (Optional) Grouping files is turned on by default when the input contains more than 50,000 files. To turn on grouping with fewer than 50,000 files, set this parameter to `"inPartition"`. To disable grouping when there are more than 50,000 files, set this parameter to `"none"`.
- `"groupSize"`: (Optional) The target group size in bytes. The default is computed based on the input data size and the size of your cluster. When there are fewer than 50,000 input files, `"groupFiles"` must be set to `"inPartition"` for this to take effect.
- `"recurse"`: (Optional) If set to true, recursively reads files in all subdirectories under the specified paths.
- `"maxBand"`: (Optional, advanced) This option controls the duration in milliseconds after which the s3 listing is likely to be consistent. Files with modification timestamps falling within the last `maxBand` milliseconds are tracked specially when using `JobBookmarks` to account for Amazon S3 eventual consistency. Most users don't need to set this option. The default is 900000 milliseconds, or 15 minutes.

- "maxFilesInBand": (Optional, advanced) This option specifies the maximum number of files to save from the last maxBand seconds. If this number is exceeded, extra files are skipped and only processed in the next job run. Most users don't need to set this option.
- "isFailFast": (Optional) This option determines if an Amazon Glue ETL job throws reader parsing exceptions. If set to true, jobs fail fast if four retries of the Spark task fail to parse the data correctly.
- "catalogPartitionPredicate": (Optional) Used for Read. The contents of a SQL WHERE clause. Used when reading from Data Catalog tables with a very large quantity of partitions. Retrieves matching partitions from Data Catalog indices. Used with push_down_predicate, an option on the [the section called "create_dynamic_frame_from_catalog"](#) method (and other similar methods). For more information, see [the section called "Catalog partition predicates"](#).
- "partitionKeys": (Optional) Used for Write. An array of column label strings. Amazon Glue will partition your data as specified by this configuration. For more information, see [the section called "Writing partitions"](#).
- "excludeStorageClasses": (Optional) Used for Read. An array of strings specifying Amazon S3 storage classes. Amazon Glue will exclude Amazon S3 objects based on this configuration. For more information, see [the section called "Excluding Amazon S3 storage classes"](#).

Deprecated connection syntaxes for data formats

Certain data formats can be accessed using a specific connection type syntax. This syntax is deprecated. We recommend you specify your formats using the s3 connection type and the format options provided in [the section called "Data format options"](#) instead.

"connectionType": "Orc"

Designates a connection to files stored in Amazon S3 in the [Apache Hive Optimized Row Columnar \(ORC\)](#) file format.

Use the following connection options with "connectionType": "orc":

- paths: (Required) A list of the Amazon S3 paths to read from.
- (Other option name/value pairs): Any additional options, including formatting options, are passed directly to the SparkSQL DataSource.

"connectionType": "parquet"

Designates a connection to files stored in Amazon S3 in the [Apache Parquet](#) file format.

Use the following connection options with "connectionType": "parquet":

- **paths:** (Required) A list of the Amazon S3 paths to read from.
- *(Other option name/value pairs):* Any additional options, including formatting options, are passed directly to the SparkSQL DataSource.

Excluding Amazon S3 storage classes

If you're running Amazon Glue ETL jobs that read files or partitions from Amazon Simple Storage Service (Amazon S3), you can exclude some Amazon S3 storage class types.

The following storage classes are available in Amazon S3:

- **STANDARD** — For general-purpose storage of frequently accessed data.
- **INTELLIGENT_TIERING** — For data with unknown or changing access patterns.
- **STANDARD_IA** and **ONEZONE_IA** — For long-lived, but less frequently accessed data.
- **GLACIER**, **DEEP_ARCHIVE**, and **REDUCED_REDUNDANCY** — For long-term archive and digital preservation.

For more information, see [Amazon S3 Storage Classes](#) in the *Amazon S3 Developer Guide*.

The examples in this section show how to exclude the **GLACIER** and **DEEP_ARCHIVE** storage classes. These classes allow you to list files, but they won't let you read the files unless they are restored. (For more information, see [Restoring Archived Objects](#) in the *Amazon S3 Developer Guide*.)

By using storage class exclusions, you can ensure that your Amazon Glue jobs will work on tables that have partitions across these storage class tiers. Without exclusions, jobs that read data from these tiers fail with the following error: `AmazonS3Exception: The operation is not valid for the object's storage class.`

There are different ways that you can filter Amazon S3 storage classes in Amazon Glue.

Topics

- [Excluding Amazon S3 storage classes when creating a Dynamic Frame](#)

- [Excluding Amazon S3 storage classes on a Data Catalog table](#)

Excluding Amazon S3 storage classes when creating a Dynamic Frame

To exclude Amazon S3 storage classes while creating a dynamic frame, use `excludeStorageClasses` in `additionalOptions`. Amazon Glue automatically uses its own Amazon S3 Lister implementation to list and exclude files corresponding to the specified storage classes.

The following Python and Scala examples show how to exclude the `GLACIER` and `DEEP_ARCHIVE` storage classes when creating a dynamic frame.

Python example:

```
glueContext.create_dynamic_frame.from_catalog(  
    database = "my_database",  
    tableName = "my_table_name",  
    redshift_tmp_dir = "",  
    transformation_ctx = "my_transformation_context",  
    additional_options = {  
        "excludeStorageClasses" : ["GLACIER", "DEEP_ARCHIVE"]  
    }  
)
```

Scala example:

```
val* *df = glueContext.getCatalogSource(  
    nameSpace, tableName, "", "my_transformation_context",  
    additionalOptions = JsonOptions(  
        Map("excludeStorageClasses" -> List("GLACIER", "DEEP_ARCHIVE"))  
    )  
)  
.getDynamicFrame()
```

Excluding Amazon S3 storage classes on a Data Catalog table

You can specify storage class exclusions to be used by an Amazon Glue ETL job as a table parameter in the Amazon Glue Data Catalog. You can include this parameter in the `CreateTable` operation using the Amazon Command Line Interface (Amazon CLI) or programmatically using the API. For more information, see [Table Structure](#) and [CreateTable](#).

You can also specify excluded storage classes on the Amazon Glue console.

To exclude Amazon S3 storage classes (console)

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane on the left, choose **Tables**.
3. Choose the table name in the list, and then choose **Edit table**.
4. In **Table properties**, add **excludeStorageClasses** as a key and `["GLACIER", "DEEP_ARCHIVE"]` as a value.
5. Choose **Apply**.

Managing partitions for ETL output in Amazon Glue

Partitioning is an important technique for organizing datasets so they can be queried efficiently. It organizes data in a hierarchical directory structure based on the distinct values of one or more columns.

For example, you might decide to partition your application logs in Amazon Simple Storage Service (Amazon S3) by date, broken down by year, month, and day. Files that correspond to a single day's worth of data are then placed under a prefix such as `s3://my_bucket/logs/year=2018/month=01/day=23/`. Systems like Amazon Athena, Amazon Redshift Spectrum, and now Amazon Glue can use these partitions to filter data by partition value without having to read all the underlying data from Amazon S3.

Crawlers not only infer file types and schemas, they also automatically identify the partition structure of your dataset when they populate the Amazon Glue Data Catalog. The resulting partition columns are available for querying in Amazon Glue ETL jobs or query engines like Amazon Athena.

After you crawl a table, you can view the partitions that the crawler created. In the Amazon Glue console, choose **Tables** in the left navigation pane. Choose the table created by the crawler, and then choose **View Partitions**.

For Apache Hive-style partitioned paths in `key=val` style, crawlers automatically populate the column name using the key name. Otherwise, it uses default names like `partition_0`, `partition_1`, and so on. You can change the default names on the console. To do so, navigate to the table. Check if indexes exist under the **Indexes** tab. If that's the case, you need to delete them to proceed (you can recreate them using the new column names afterwards). Then, choose **Edit Schema**, and modify the names of the partition columns there.

In your ETL scripts, you can then filter on the partition columns. Because the partition information is stored in the Data Catalog, use the `from_catalog` API calls to include the partition columns in the `DynamicFrame`. For example, use `create_dynamic_frame.from_catalog` instead of `create_dynamic_frame.from_options`.

Partitioning is an optimization technique that reduces data scan. For more information about the process of identifying when this technique is appropriate, consult [Reduce the amount of data scan](#) in the *Best practices for performance tuning Amazon Glue for Apache Spark jobs* guide on Amazon Prescriptive Guidance.

Pre-filtering using pushdown predicates

In many cases, you can use a pushdown predicate to filter on partitions without having to list and read all the files in your dataset. Instead of reading the entire dataset and then filtering in a `DynamicFrame`, you can apply the filter directly on the partition metadata in the Data Catalog. Then you only list and read what you actually need into a `DynamicFrame`.

For example, in Python, you could write the following.

```
glue_context.create_dynamic_frame.from_catalog(  
    database = "my_S3_data_set",  
    table_name = "catalog_data_table",  
    push_down_predicate = my_partition_predicate)
```

This creates a `DynamicFrame` that loads only the partitions in the Data Catalog that satisfy the predicate expression. Depending on how small a subset of your data you are loading, this can save a great deal of processing time.

The predicate expression can be any Boolean expression supported by Spark SQL. Anything you could put in a `WHERE` clause in a Spark SQL query will work. For example, the predicate expression `pushDownPredicate = "(year=='2017' and month=='04')"` loads only the partitions in the Data Catalog that have both year equal to 2017 and month equal to 04. For more information, see the [Apache Spark SQL documentation](#), and in particular, the [Scala SQL functions reference](#).

Server-side filtering using catalog partition predicates

The `push_down_predicate` option is applied after listing all the partitions from the catalog and before listing files from Amazon S3 for those partitions. If you have a lot of partitions

for a table, catalog partition listing can still incur additional time overhead. To address this overhead, you can use server-side partition pruning with the `catalogPartitionPredicate` option that uses [partition indexes](#) in the Amazon Glue Data Catalog. This makes partition filtering much faster when you have millions of partitions in one table. You can use both `push_down_predicate` and `catalogPartitionPredicate` in `additional_options` together if your `catalogPartitionPredicate` requires predicate syntax that is not yet supported with the catalog partition indexes.

Python:

```
dynamic_frame = glueContext.create_dynamic_frame.from_catalog(  
    database=dbname,  
    table_name=tablename,  
    transformation_ctx="datasource0",  
    push_down_predicate="day>=10 and customer_id like '10%'",  
    additional_options={"catalogPartitionPredicate":"year='2021' and month='06'"}  
)
```

Scala:

```
val dynamicFrame = glueContext.getCatalogSource(  
    database = dbname,  
    tableName = tablename,  
    transformationContext = "datasource0",  
    pushDownPredicate="day>=10 and customer_id like '10%'",  
    additionalOptions = JsonOptions("""{  
        "catalogPartitionPredicate": "year='2021' and month='06'"}""")  
).getDynamicFrame()
```

Note

The `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

Writing partitions

By default, a `DynamicFrame` is not partitioned when it is written. All of the output files are written at the top level of the specified output path. Until recently, the only way to write a `DynamicFrame` into partitions was to convert it to a Spark SQL `DataFrame` before writing.

However, `DynamicFrames` now support native partitioning using a sequence of keys, using the `partitionKeys` option when you create a sink. For example, the following Python code writes out a dataset to Amazon S3 in the Parquet format, into directories partitioned by the type field. From there, you can process these partitions using other systems, such as Amazon Athena.

```
glue_context.write_dynamic_frame.from_options(  
    frame = projectedEvents,  
    connection_type = "s3",  
    connection_options = {"path": "$outpath", "partitionKeys": ["type"]},  
    format = "parquet")
```

Reading input files in larger groups

You can set properties of your tables to enable an Amazon Glue ETL job to group files when they are read from an Amazon S3 data store. These properties enable each ETL task to read a group of input files into a single in-memory partition, this is especially useful when there is a large number of small files in your Amazon S3 data store. When you set certain properties, you instruct Amazon Glue to group files within an Amazon S3 data partition and set the size of the groups to be read. You can also set these options when reading from an Amazon S3 data store with the `create_dynamic_frame.from_options` method.

To enable grouping files for a table, you set key-value pairs in the `parameters` field of your table structure. Use JSON notation to set a value for the parameter field of your table. For more information about editing the properties of a table, see [Viewing and managing table details](#).

You can use this method to enable grouping for tables in the Data Catalog with Amazon S3 data stores.

groupFiles

Set **groupFiles** to `inPartition` to enable the grouping of files within an Amazon S3 data partition. Amazon Glue automatically enables grouping if there are more than 50,000 input files, as in the following example.

```
'groupFiles': 'inPartition'
```

groupSize

Set **groupSize** to the target size of groups in bytes. The **groupSize** property is optional, if not provided, Amazon Glue calculates a size to use all the CPU cores in the cluster while still reducing the overall number of ETL tasks and in-memory partitions.

For example, the following sets the group size to 1 MB.

```
'groupSize': '1048576'
```

Note that the groupsize should be set with the result of a calculation. For example $1024 * 1024 = 1048576$.

recurse

Set **recurse** to `True` to recursively read files in all subdirectories when specifying paths as an array of paths. You do not need to set **recurse** if paths is an array of object keys in Amazon S3, or if the input format is parquet/orc, as in the following example.

```
'recurse': True
```

If you are reading from Amazon S3 directly using the `create_dynamic_frame.from_options` method, add these connection options. For example, the following attempts to group files into 1 MB groups.

```
df = glueContext.create_dynamic_frame.from_options("s3", {'paths': ["s3://s3path/"],  
'recurse': True, 'groupFiles': 'inPartition', 'groupSize': '1048576'}, format="json")
```

Note

`groupFiles` is supported for DynamicFrames created from the following data formats: csv, ion, grokLog, json, and xml. This option is not supported for avro, parquet, and orc.

Amazon VPC endpoints for Amazon S3

For security reasons, many Amazon customers run their applications within an Amazon Virtual Private Cloud environment (Amazon VPC). With Amazon VPC, you can launch Amazon EC2 instances into a virtual private cloud, which is logically isolated from other networks—including the public internet. With an Amazon VPC, you have control over its IP address range, subnets, routing tables, network gateways, and security settings.

Note

If you created your Amazon account after 2013-12-04, you already have a default VPC in each Amazon Region. You can immediately start using your default VPC without any additional configuration.

For more information, see [Your Default VPC and Subnets](#) in the Amazon VPC User Guide.

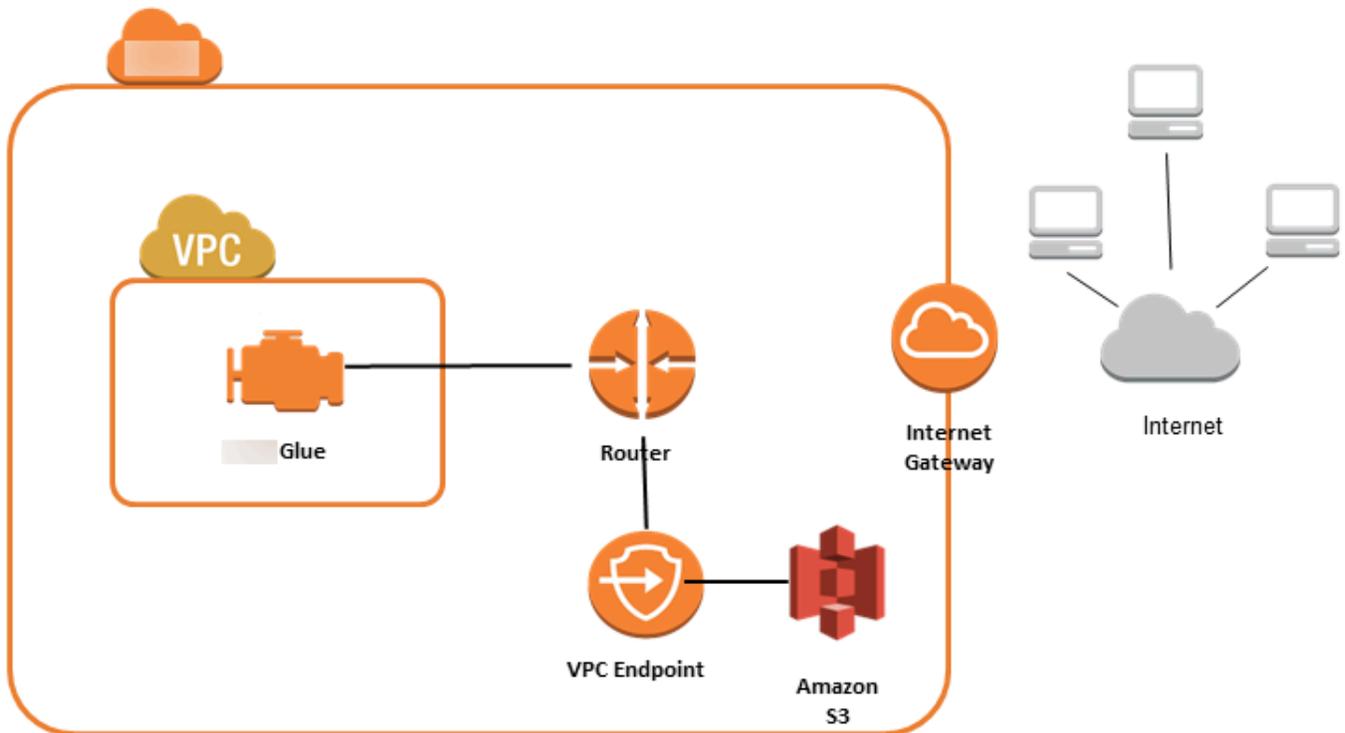

Many customers have legitimate privacy and security concerns about sending and receiving data across the public internet. Customers can address these concerns by using a virtual private network (VPN) to route all Amazon S3 network traffic through their own corporate network infrastructure. However, this approach can introduce bandwidth and availability challenges.

VPC endpoints for Amazon S3 can alleviate these challenges. A VPC endpoint for Amazon S3 enables Amazon Glue to use private IP addresses to access Amazon S3 with no exposure to the public internet. Amazon Glue does not require public IP addresses, and you don't need an internet gateway, a NAT device, or a virtual private gateway in your VPC. You use endpoint policies to control access to Amazon S3. Traffic between your VPC and the Amazon service does not leave the Amazon network.

When you create a VPC endpoint for Amazon S3, any requests to an Amazon S3 endpoint within the Region (for example, *s3.us-west-2.amazonaws.com*) are routed to a private Amazon S3 endpoint within the Amazon network. You don't need to modify your applications running on Amazon EC2 instances in your VPC—the endpoint name remains the same, but the route to Amazon S3 stays entirely within the Amazon network, and does not access the public internet.

For more information about VPC endpoints, see [VPC Endpoints](#) in the Amazon VPC User Guide.

The following diagram shows how Amazon Glue can use a VPC endpoint to access Amazon S3.

To set up access for Amazon S3

1. Sign in to the Amazon Web Services Management Console and open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. In the left navigation pane, choose **Endpoints**.
3. Choose **Create Endpoint**, and follow the steps to create an Amazon S3 VPC endpoint of type Gateway.

Amazon DocumentDB connections

You can use Amazon Glue for Spark to read from and write to tables in Amazon DocumentDB. You can connect to Amazon DocumentDB using credentials stored in Amazon Secrets Manager through a Amazon Glue connection.

For more information about Amazon DocumentDB, consult the [Amazon DocumentDB documentation](#).

Note

Amazon DocumentDB elastic clusters are not currently supported when using the Amazon Glue connector. For more information about elastic clusters, see [Using Amazon DocumentDB elastic clusters](#).

Reading and writing to Amazon DocumentDB collections

Note

When you create an ETL job that connects to Amazon DocumentDB, for the `Connections` job property, you must designate a connection object that specifies the virtual private cloud (VPC) in which Amazon DocumentDB is running. For the connection object, the connection type must be JDBC, and the JDBC URL must be `mongo://<DocumentDB_host>:27017`.

Note

These code samples were developed for Amazon Glue 3.0. To migrate to Amazon Glue 4.0, consult [the section called "MongoDB"](#). The `uri` parameter has changed.

Note

When using Amazon DocumentDB, `retryWrites` must be set to `false` in certain situations, such as when the document written specifies `_id`. For more information, consult [Functional Differences with MongoDB](#) in the Amazon DocumentDB documentation.

The following Python script demonstrates using connection types and connection options for reading and writing to Amazon DocumentDB.

```
import sys
```

```
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext, SparkConf
from awsglue.context import GlueContext
from awsglue.job import Job
import time

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

job = Job(glueContext)
job.init(args['JOB_NAME'], args)

output_path = "s3://some_bucket/output/" + str(time.time()) + "/"
documentdb_uri = "mongodb://<mongo-instanced-ip-address>:27017"
documentdb_write_uri = "mongodb://<mongo-instanced-ip-address>:27017"

read_docdb_options = {
    "uri": documentdb_uri,
    "database": "test",
    "collection": "coll",
    "username": "username",
    "password": "1234567890",
    "ssl": "true",
    "ssl.domain_match": "false",
    "partitioner": "MongoSamplePartitioner",
    "partitionerOptions.partitionSizeMB": "10",
    "partitionerOptions.partitionKey": "_id"
}

write_documentdb_options = {
    "retryWrites": "false",
    "uri": documentdb_write_uri,
    "database": "test",
    "collection": "coll",
    "username": "username",
    "password": "pwd"
}

# Get DynamicFrame from DocumentDB
```

```
dynamic_frame2 =
  glueContext.create_dynamic_frame.from_options(connection_type="documentdb",
  connection_options=read_docdb_options)

# Write DynamicFrame to MongoDB and DocumentDB
glueContext.write_dynamic_frame.from_options(dynamic_frame2,
  connection_type="documentdb",

  connection_options=write_documentdb_options)

job.commit()
```

The following Scala script demonstrates using connection types and connection options for reading and writing to Amazon DocumentDB.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamicFrame
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {
  val DOC_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  val DOC_WRITE_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  lazy val documentDBJsonOption = jsonOptions(DOC_URI)
  lazy val writeDocumentDBJsonOption = jsonOptions(DOC_WRITE_URI)
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    // Get DynamicFrame from DocumentDB
    val resultFrame2: DynamicFrame = glueContext.getSource("documentdb",
    documentDBJsonOption).getDynamicFrame()

    // Write DynamicFrame to DocumentDB
    glueContext.getSink("documentdb", writeJsonOption).writeDynamicFrame(resultFrame2)
```

```
    Job.commit()
  }

  private def jsonOptions(uri: String): JsonOptions = {
    new JsonOptions(
      s""""{"uri": "${uri}",
        |"database":"test",
        |"collection":"coll",
        |"username": "username",
        |"password": "pwd",
        |"ssl":"true",
        |"ssl.domain_match":"false",
        |"partitioner": "MongoSamplePartitioner",
        |"partitionerOptions.partitionSizeMB": "10",
        |"partitionerOptions.partitionKey": "_id"}"""".stripMargin)
    }
  }
```

Amazon DocumentDB connection option reference

Designates a connection to Amazon DocumentDB (with MongoDB compatibility).

Connection options differ for a source connection and a sink connection.

"connectionType": "Documentdb" as source

Use the following connection options with "connectionType": "documentdb" as a source:

- "uri": (Required) The Amazon DocumentDB host to read from, formatted as `mongodb://<host>:<port>`.
- "database": (Required) The Amazon DocumentDB database to read from.
- "collection": (Required) The Amazon DocumentDB collection to read from.
- "username": (Required) The Amazon DocumentDB user name.
- "password": (Required) The Amazon DocumentDB password.
- "ssl": (Required if using SSL) If your connection uses SSL, then you must include this option with the value "true".
- "ssl.domain_match": (Required if using SSL) If your connection uses SSL, then you must include this option with the value "false".

- "batchSize": (Optional): The number of documents to return per batch, used within the cursor of internal batches.
- "partitioner": (Optional): The class name of the partitioner for reading input data from Amazon DocumentDB. The connector provides the following partitioners:
 - MongoDefaultPartitioner (default) (Not supported in Amazon Glue 4.0)
 - MongoSamplePartitioner (Not supported in Amazon Glue 4.0)
 - MongoShardedPartitioner
 - MongoSplitVectorPartitioner
 - MongoPaginateByCountPartitioner
 - MongoPaginateBySizePartitioner (Not supported in Amazon Glue 4.0)
- "partitionerOptions" (Optional): Options for the designated partitioner. The following options are supported for each partitioner:
 - MongoSamplePartitioner: partitionKey, partitionSizeMB, samplesPerPartition
 - MongoShardedPartitioner: shardkey
 - MongoSplitVectorPartitioner: partitionKey, partitionSizeMB
 - MongoPaginateByCountPartitioner: partitionKey, numberOfPartitions
 - MongoPaginateBySizePartitioner: partitionKey, partitionSizeMB

For more information about these options, see [Partitioner Configuration](#) in the MongoDB documentation.

"connectionType": "Documentdb" as sink

Use the following connection options with "connectionType": "documentdb" as a sink:

- "uri": (Required) The Amazon DocumentDB host to write to, formatted as `mongodb://<host>:<port>`.
- "database": (Required) The Amazon DocumentDB database to write to.
- "collection": (Required) The Amazon DocumentDB collection to write to.
- "username": (Required) The Amazon DocumentDB user name.
- "password": (Required) The Amazon DocumentDB password.
- "extendedBsonTypes": (Optional) If `true`, allows extended BSON types when writing data to Amazon DocumentDB. The default is `true`.

- "replaceDocument": (Optional) If `true`, replaces the whole document when saving datasets that contain an `_id` field. If `false`, only fields in the document that match the fields in the dataset are updated. The default is `true`.
- "maxBatchSize": (Optional): The maximum batch size for bulk operations when saving data. The default is 512.
- "retryWrites": (Optional): Automatically retry certain write operations a single time if Amazon Glue encounters a network error.

OpenSearch Service connections

You can use Amazon Glue for Spark to read from and write to tables in OpenSearch Service in Amazon Glue 4.0 and later versions. You can define what to read from OpenSearch Service with an OpenSearch query. You connect to OpenSearch Service using HTTP basic authentication credentials stored in Amazon Secrets Manager through a Amazon Glue connection. This feature is not compatible with OpenSearch Service serverless.

For more information about Amazon OpenSearch Service, see the [Amazon OpenSearch Service documentation](#).

Configuring OpenSearch Service connections

To connect to OpenSearch Service from Amazon Glue, you will need to create and store your OpenSearch Service credentials in a Amazon Secrets Manager secret, then associate that secret with a OpenSearch Service Amazon Glue connection.

Prerequisites:

- Identify the domain endpoint, *aosEndpoint* and port, *aosPort* you would like to read from, or create the resource by following instructions in the Amazon OpenSearch Service documentation. For more information on creating a domain, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

An Amazon OpenSearch Service domain endpoint will have the following default form, `https://search-domainName-unstructuredIdContent.region.es.amazonaws.com`. For more information on identifying your domain endpoint, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

Identify or generate HTTP basic authentication credentials, *aosUser* and *aosPassword* for your domain.

To configure a connection to OpenSearch Service:

1. In Amazon Secrets Manager, create a secret using your OpenSearch Service credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key USERNAME with the value *aosUser*.
 - When selecting **Key/value pairs**, create a pair for the key PASSWORD with the value *aosPassword*.
2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in Amazon Glue.
 - When selecting a **Connection type**, select OpenSearch Service.
 - When selecting a Domain endpoint, provide *aosEndpoint*.
 - When selecting a port, provide *aosPort*.
 - When selecting an **Amazon Secret**, provide *secretName*.

After creating a Amazon Glue OpenSearch Service connection, you will need to perform the following steps before running your Amazon Glue job:

- Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.
- In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from OpenSearch Service indexes

Prerequisites:

- A OpenSearch Service index you would like to read from, *aosIndex*.
- A Amazon Glue OpenSearch Service connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to OpenSearch Service*. You will need the name of the Amazon Glue connection, *connectionName*.

This example reads an index from Amazon OpenSearch Service. You will need to provide the pushdown parameter.

For example:

```
opensearch_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="opensearch",  
    connection_options={  
        "connectionName": "connectionName",  
        "opensearch.resource": "aosIndex",  
        "pushdown": "true",  
    }  
)
```

You can also provide a query string to filter the results returned in your DynamicFrame. You will need to configure `opensearch.query`.

`opensearch.query` can take a URL query parameter string *queryString* or a query DSL JSON object *queryObject*. For more information about the query DSL, see [Query DSL](#) in the OpenSearch documentation. To provide a URL query parameter string, prepend `?q=` to your query, as you would in a fully qualified URL. To provide a query DSL object, string escape the JSON object before providing it.

For example:

```
    queryObject = "{ \"query\": { \"multi_match\": { \"query\": \"Sample\", \"fields\":  
[ \"sample\" ] } } }"  
    queryString = "?q=queryString"  
  
    opensearch_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="opensearch",  
    connection_options={  
        "connectionName": "connectionName",  
        "opensearch.resource": "aosIndex",  
        "opensearch.query": queryString,  
        "pushdown": "true",  
    }  
)
```

For more information about how to build a query outside of its specific syntax, see [Query string syntax](#) in the OpenSearch documentation.

When reading from OpenSearch collections that contain array type data, you must specify which fields are array type in your method call using the `opensearch.read.field.as.array.include` parameter.

For example, when reading the following document, you will encounter the `genre` and `actor` array fields:

```
{
  "_index": "movies",
  "_id": "2",
  "_version": 1,
  "_seq_no": 0,
  "_primary_term": 1,
  "found": true,
  "_source": {
    "director": "Frankenheimer, John",
    "genre": [
      "Drama",
      "Mystery",
      "Thriller",
      "Crime"
    ],
    "year": 1962,
    "actor": [
      "Lansbury, Angela",
      "Sinatra, Frank",
      "Leigh, Janet",
      "Harvey, Laurence",
      "Silva, Henry",
      "Frees, Paul",
      "Gregory, James",
      "Bissell, Whit",
      "McGiver, John",
      "Parrish, Leslie",
      "Edwards, James",
      "Flowers, Bess",
      "Dhiegh, Khigh",
      "Payne, Julie",
      "Kleeb, Helen",
      "Gray, Joe",
      "Nalder, Reggie",
      "Stevens, Bert",
      "Masters, Michael",
```

```
        "Lowell, Tom"
    ],
    "title": "The Manchurian Candidate"
}
}
```

In this case, you would include those field names in your method call. For example:

```
"opensearch.read.field.as.array.include": "genre,actor"
```

If your array field is nested inside of your document structure, refer to it using dot notation: "genre,actor,foo.bar.baz". This would specify an array baz included in your source document through the embedded document foo containing the embedded document bar.

Writing to OpenSearch Service tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to OpenSearch Service. If the index already has information, Amazon Glue will append data from your DynamicFrame. You will need to provide the pushdown parameter.

Prerequisites:

- A OpenSearch Service table you would like to write to. You will need identification information for the table. Let's call this *tableName*.
- A Amazon Glue OpenSearch Service connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to OpenSearch Service*. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
glueContext.write_dynamic_frame.from_options(  
    frame=dynamicFrame,  
    connection_type="opensearch",  
    connection_options={  
        "connectionName": "connectionName",  
        "opensearch.resource": "aosIndex",  
    },  
)
```

OpenSearch Service connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a Amazon Glue OpenSearch Service connection configured to provide auth and network location information to your connection method.
- `opensearch.resource` — Required. Used for Read/Write. Valid Values: OpenSearch index names. The name of the index your connection method will interact with.
- `opensearch.query` — Used for Read. Valid Values: String escaped JSON or, when this string begins with `?`, the search part of a URL. An OpenSearch query that filters what should be retrieved when reading. For more information on using this parameter, consult the previous section [the section called “Read from OpenSearch Service”](#).
- `pushdown` — Required if. Used for Read. Valid Values: boolean. Instructs Spark to pass read queries down to OpenSearch so the database only returns relevant documents.
- `opensearch.read.field.as.array.include` — Required if reading array type data. Used for Read. Valid Values: comma separated lists of field names. Specifies fields to read as arrays from OpenSearch documents. For more information on using this parameter, consult the previous section [the section called “Read from OpenSearch Service”](#).

Redshift connections

You can use Amazon Glue for Spark to read from and write to tables in Amazon Redshift databases. When connecting to Amazon Redshift databases, Amazon Glue moves data through Amazon S3 to achieve maximum throughput, using the Amazon Redshift SQL COPY and UNLOAD commands. In Amazon Glue 4.0 and later, you can use the [Amazon Redshift integration for Apache Spark](#) to read and write with optimizations and features specific to Amazon Redshift beyond those available when connecting through previous versions.

Learn about how Amazon Glue is making it easier than ever for Amazon Redshift users to migrate to Amazon Glue for serverless data integration and ETL.

Configuring Redshift connections

To use Amazon Redshift clusters in Amazon Glue, you will need some prerequisites:

- An Amazon S3 directory to use for temporary storage when reading from and writing to the database.
- An Amazon VPC enabling communication between your Amazon Redshift cluster, your Amazon Glue job and your Amazon S3 directory.

- Appropriate IAM permissions on the Amazon Glue job and Amazon Redshift cluster.

Configuring IAM roles

Set up the role for the Amazon Redshift cluster

Your Amazon Redshift cluster needs to be able to read and write to Amazon S3 in order to integrate with Amazon Glue jobs. To allow this, you can associate IAM roles with the Amazon Redshift cluster you want to connect to. Your role should have a policy allowing read from and write to your Amazon S3 temporary directory. Your role should have a trust relationship allowing the `redshift.amazonaws.com` service to `AssumeRole`.

To associate an IAM role with Amazon Redshift

1. **Prerequisites:** An Amazon S3 bucket or directory used for the temporary storage of files.
2. Identify which Amazon S3 permissions your Amazon Redshift cluster will need. When moving data to and from an Amazon Redshift cluster, Amazon Glue jobs issue `COPY` and `UNLOAD` statements against Amazon Redshift. If your job modifies a table in Amazon Redshift, Amazon Glue will also issue `CREATE LIBRARY` statements. For information on specific Amazon S3 permissions required for Amazon Redshift to execute these statements, refer to the Amazon Redshift documentation: [Amazon Redshift: Permissions to access other Amazon Resources](#).
3. In the IAM console, create an IAM policy with the necessary permissions. For more information about creating a policy [Creating IAM policies](#).
4. In the IAM console, create a role and trust relationship allowing Amazon Redshift to assume the role. Follow the instructions in the IAM documentation [To create a role for an Amazon service \(console\)](#)
 - When asked to choose an Amazon service use case, choose "Redshift - Customizable".
 - When asked to attach a policy, choose the policy you previously defined.

Note

For more information about configuring roles for Amazon Redshift, see [Authorizing Amazon Redshift to access other Amazon services on your behalf](#) in the Amazon Redshift documentation.

- In the Amazon Redshift console, associate the role with your Amazon Redshift cluster. Follow the instructions in [the Amazon Redshift documentation](#).

Select the highlighted option in the Amazon Redshift console to configure this setting:

The screenshot shows the Amazon Redshift console interface for a cluster named 'flight-2016'. The breadcrumb navigation is 'Amazon Redshift > Clusters > flight-2016'. The cluster title 'flight-2016' is prominently displayed. Below the title are several buttons: 'Actions' (with an upward arrow), 'Edit', 'Add partner integration', and 'Query data' (with a downward arrow). The 'Actions' dropdown menu is open, showing a list of options: 'Manage cluster', 'Resize', 'Reboot', 'Pause', 'Delete', 'Defer maintenance', 'Modify publicly accessible setting', 'Backup and disaster recovery', 'Restore table', 'Create snapshot', 'Configure cross-region snapshot', 'Relocate', 'Permissions', 'Manage IAM roles' (highlighted with a red box), 'Change admin user password', and 'Manage tags'. The 'General information' section on the left includes fields for 'Cluster identifier' (flight-2016), 'Cluster namespace' (redacted), 'Cluster configuration' (Production), 'Status' (Available with a green checkmark), 'Date created' (redacted), 'Storage used' (0.25% of 160 GB), and 'Multi-AZ' (No). The right side of the console shows fields for 'Endpoint', 'JDBC URL', and 'ODBC URL' (with a driver name partially visible).

Note

By default, Amazon Glue jobs pass Amazon Redshift temporary credentials that are created using the role that you specified to run the job. We do not recommend using these credentials. For security purposes, these credentials expire after 1 hour.

Set up the role for the Amazon Glue job

The Amazon Glue job needs a role to access the Amazon S3 bucket. You do not need IAM permissions for the Amazon Redshift cluster, your access is controlled by connectivity in Amazon VPC and your database credentials.

Set up Amazon VPC

To set up access for Amazon Redshift data stores

1. Sign in to the Amazon Web Services Management Console and open the Amazon Redshift console at <https://console.amazonaws.cn/redshiftv2/>.
2. In the left navigation pane, choose **Clusters**.
3. Choose the cluster name that you want to access from Amazon Glue.
4. In the **Cluster Properties** section, choose a security group in **VPC security groups** to allow Amazon Glue to use. Record the name of the security group that you chose for future reference. Choosing the security group opens the Amazon EC2 console **Security Groups** list.
5. Choose the security group to modify and navigate to the **Inbound** tab.
6. Add a self-referencing rule to allow Amazon Glue components to communicate. Specifically, add or confirm that there is a rule of **Type All TCP**, **Protocol** is TCP, **Port Range** includes all ports, and whose **Source** is the same security group name as the **Group ID**.

The inbound rule looks similar to the following:

| Type | Protocol | Port range | Source |
|---------|----------|------------|--------------------------------|
| All TCP | TCP | 0–65535 | <i>database-security-group</i> |

For example:

Security Group: sg-19e1b768

Description

Inbound

Outbound

Tags

Edit

| Type ⓘ | Protocol ⓘ | Port Range ⓘ | Source ⓘ |
|--------|------------|--------------|-----------|
| SSH | TCP | 22 | 0.0.0.0/0 |
| HTTPS | TCP | 443 | 0.0.0.0/0 |

7. Add a rule for outbound traffic also. Either open outbound traffic to all ports, for example:

| Type | Protocol | Port range | Destination |
|-------------|----------|------------|-------------|
| All Traffic | ALL | ALL | 0.0.0.0/0 |

Or create a self-referencing rule where **Type** All TCP, **Protocol** is TCP, **Port Range** includes all ports, and whose **Destination** is the same security group name as the **Group ID**. If using an Amazon S3 VPC endpoint, also add an HTTPS rule for Amazon S3 access. The *s3-prefix-list-id* is required in the security group rule to allow traffic from the VPC to the Amazon S3 VPC endpoint.

For example:

| Type | Protocol | Port range | Destination |
|---------|----------|------------|--------------------------|
| All TCP | TCP | 0–65535 | <i>security-group</i> |
| HTTPS | TCP | 443 | <i>s3-prefix-list-id</i> |

Set up Amazon Glue

You will need to create an Amazon Glue Data Catalog connection that provides Amazon VPC connection information.

To configure Amazon Redshift Amazon VPC connectivity to Amazon Glue in the console

1. Create a Data Catalog connection by following the steps in: [the section called “Adding an Amazon Glue connection”](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
 - When selecting a **Connection type**, select **Amazon Redshift**.
 - When selecting a **Redshift cluster**, select your cluster by name.
 - Provide default connection information for a Amazon Redshift user on your cluster.
 - Your Amazon VPC settings will be automatically configured.

Note

You will need to manually provide `PhysicalConnectionRequirements` for your Amazon VPC when creating an **Amazon Redshift** connection through the Amazon SDK.

2. In your Amazon Glue job configuration, provide `connectionName` as an **Additional network connection**.

Example: Reading from Amazon Redshift tables

You can read from Amazon Redshift clusters and Amazon Redshift serverless environments.

Prerequisites: An Amazon Redshift table you would like to read from. Follow the steps in the previous section [the section called "Configure Redshift"](#) after which you should have the Amazon S3 URI for a temporary directory, `temp-s3-dir` and an IAM role, `rs-role-name`, (in account `role-account-id`).

Using the Data Catalog

Additional Prerequisites: A Data Catalog Database and Table for the Amazon Redshift table you would like to read from. For more information about Data Catalog, see [Data discovery and cataloging](#). After creating a entry for your Amazon Redshift table you will identify your connection with a `redshift-dc-database-name` and `redshift-table-name`.

Configuration: In your function options you will identify your Data Catalog Table with the database and `table_name` parameters. You will identify your Amazon S3 temporary directory with `redshift_tmp_dir`. You will also provide `rs-role-name` using the `aws_iam_role` key in the `additional_options` parameter.

```
glueContext.create_dynamic_frame.from_catalog(  
    database = "redshift-dc-database-name",  
    table_name = "redshift-table-name",  
    redshift_tmp_dir = args["temp-s3-dir"],  
    additional_options = {"aws_iam_role": "arn:aws:iam::role-account-id:role/rs-  
role-name"})
```

Connecting directly

Additional Prerequisites: You will need the name of your Amazon Redshift table (*redshift-table-name*). You will need the JDBC connection information for the Amazon Redshift cluster storing that table. You will supply your connection information with *host*, *port*, *redshift-database-name*, *username* and *password*.

You can retrieve your connection information from the Amazon Redshift console when working with Amazon Redshift clusters. When using Amazon Redshift serverless, consult [Connecting to Amazon Redshift Serverless](#) in the Amazon Redshift documentation.

Configuration: In your function options you will identify your connection parameters with `url`, `dbtable`, `user` and `password`. You will identify your Amazon S3 temporary directory with `redshift_tmp_dir`. You can specify your IAM role using `aws_iam_role` when you use `from_options`. The syntax is similar to connecting through the Data Catalog, but you put the parameters in the `connection_options` map.

It is bad practice to hardcode passwords into Amazon Glue scripts. Consider storing your passwords in Amazon Secrets Manager and retrieving them in your script with SDK for Python (Boto3).

```
my_conn_options = {
    "url": "jdbc:redshift://host:port/redshift-database-name",
    "dbtable": "redshift-table-name",
    "user": "username",
    "password": "password",
    "redshiftTmpDir": args["temp-s3-dir"],
    "aws_iam_role": "arn:aws:iam::account id:role/rs-role-name"
}

df = glueContext.create_dynamic_frame.from_options("redshift", my_conn_options)
```

Example: Writing to Amazon Redshift tables

You can write to Amazon Redshift clusters and Amazon Redshift serverless environments.

Prerequisites: An Amazon Redshift cluster and follow the steps in the previous section [the section called "Configure Redshift"](#) after which you should have the Amazon S3 URI for a temporary

directory, *temp-s3-dir* and an IAM role, *rs-role-name*, (in account *role-account-id*). You will also need a DynamicFrame whose contents you would like to write to the database.

Using the Data Catalog

Additional Prerequisites A Data Catalog Database for the Amazon Redshift cluster and table you would like to write to. For more information about Data Catalog, see [Data discovery and cataloging](#). You will identify your connection with *redshift-dc-database-name* and the target table with *redshift-table-name*.

Configuration: In your function options you will identify your Data Catalog Database with the database parameter, then provide table with `table_name`. You will identify your Amazon S3 temporary directory with `redshift_tmp_dir`. You will also provide *rs-role-name* using the `aws_iam_role` key in the `additional_options` parameter.

```
glueContext.write_dynamic_frame.from_catalog(  
    frame = input dynamic frame,  
    database = "redshift-dc-database-name",  
    table_name = "redshift-table-name",  
    redshift_tmp_dir = args["temp-s3-dir"],  
    additional_options = {"aws_iam_role": "arn:aws:iam::account-id:role/rs-role-name"})
```

Connecting through a Amazon Glue connection

You can connect to Amazon Redshift directly using the `write_dynamic_frame.from_options` method. However, rather than insert your connection details directly into your script, you can reference connection details stored in a Data Catalog connection with the `from_jdbc_conf` method. You can do this without crawling or creating Data Catalog tables for your database. For more information about Data Catalog connections, see [Connecting to data](#).

Additional Prerequisites: A Data Catalog connection for your database, a Amazon Redshift table you would like to read from

Configuration: you will identify your Data Catalog connection with *dc-connection-name*. You will identify your Amazon Redshift database and table with *redshift-table-name* and *redshift-database-name*. You will provide your Data Catalog connection information with

catalog_connection and your Amazon Redshift information with dbtable and database. The syntax is similar to connecting through the Data Catalog, but you put the parameters in the connection_options map.

```
my_conn_options = {
    "dbtable": "redshift-table-name",
    "database": "redshift-database-name",
    "aws_iam_role": "arn:aws:iam::role-account-id:role/rs-role-name"
}

glueContext.write_dynamic_frame.from_jdbc_conf(
    frame = input_dynamic_frame,
    catalog_connection = "dc-connection-name",
    connection_options = my_conn_options,
    redshift_tmp_dir = args["temp-s3-dir"])
```

Amazon Redshift connection option reference

The basic connection options used for all Amazon Glue JDBC connections to set up information like url, user and password are consistent across all JDBC types. For more information about standard JDBC parameters, see [the section called "JDBC connection parameters"](#).

The Amazon Redshift connection type takes some additional connection options:

- "redshiftTmpDir": (Required) The Amazon S3 path where temporary data can be staged when copying out of the database.
- "aws_iam_role": (Optional) ARN for an IAM role. The Amazon Glue job will pass this role to the Amazon Redshift cluster to grant the cluster permissions needed to complete instructions from the job.

Additional connection options available in Amazon Glue 4.0+

You can also pass options for the new Amazon Redshift connector through Amazon Glue connection options. For a complete list of supported connector options, see the *Spark SQL parameters* section in [Amazon Redshift integration for Apache Spark](#).

For your convenience, we reiterate certain new options here:

| Name | Required | Default | Description |
|------------------------------|----------|---------|---|
| autopushdown | No | TRUE | Applies predicate and query pushdown by capturing and analyzing the Spark logical plans for SQL operations. The operations are translated into a SQL query, and then run in Amazon Redshift to improve performance. |
| autopushdown.s3_result_cache | No | FALSE | Caches the SQL query to unload data for Amazon S3 path mapping in memory so that the same query doesn't need to run again in the same Spark session. Only supported when autopushdown is enabled. |
| unload_s3_format | No | PARQUET | PARQUET - Unloads the query results in Parquet format.

TEXT - Unloads the query results in pipe-delimited text format. |

| Name | Required | Default | Description |
|------------------|----------|---------|---|
| sse_kms_key | No | N/A | The Amazon SSE-KMS key to use for encryption during UNLOAD operations instead of the default encryption for Amazon. |
| extracopyoptions | No | N/A | <p>A list of extra options to append to the Amazon Redshift COPY command when loading data, such as TRUNCATECOLUMNS or MAXERROR n (for other options see COPY: Optional parameters).</p> <p>Note that because these options are appended to the end of the COPY command, only options that make sense at the end of the command can be used. That should cover most possible use cases.</p> |

| Name | Required | Default | Description |
|---------------------------------|----------|---------|---|
| csvnullstring
(experimental) | No | NULL | The String value to write for nulls when using the CSV tempformat . This should be a value that doesn't appear in your actual data. |

These new parameters can be used in the following ways.

New options for performance improvement

The new connector introduces some new performance improvement options:

- autopushdown: Enabled by default.
- autopushdown.s3_result_cache: Disabled by default.
- unload_s3_format: PARQUET by default.

For information about using these options, see [Amazon Redshift integration for Apache Spark](#).

We recommend that you don't turn on `autopushdown.s3_result_cache` when you have mixed read and write operations because the cached results might contain stale information. The option `unload_s3_format` is set to PARQUET by default for the UNLOAD command, to improve performance and reduce storage cost. To use the UNLOAD command default behavior, reset the option to TEXT.

New encryption option for reading

By default, the data in the temporary folder that Amazon Glue uses when it reads data from the Amazon Redshift table is encrypted using SSE-S3 encryption. To use customer managed keys from Amazon Key Management Service (Amazon KMS) to encrypt your data, you can set up (`"sse_kms_key" # kmsKey`) where `kmsKey` is the [key ID from Amazon KMS](#), instead of the legacy setting option (`"extraunloadoptions" # s"ENCRYPTED KMS_KEY_ID '$kmsKey'"`) in Amazon Glue version 3.0.

```
datasource0 = glueContext.create_dynamic_frame.from_catalog(
```

```

database = "database-name",
table_name = "table-name",
redshift_tmp_dir = args["TempDir"],
additional_options = {"sse_kms_key": "<KMS_KEY_ID>"},
transformation_ctx = "datasource0"
)

```

Support IAM-based JDBC URL

The new connector supports an IAM-based JDBC URL so you don't need to pass in a user/password or secret. With an IAM-based JDBC URL, the connector uses the job runtime role to access to the Amazon Redshift data source.

Step 1: Attach the following minimal required policy to your Amazon Glue job runtime role.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "redshift:GetClusterCredentials",
      "Resource": [
        "arn:aws:redshift:us-east-1:111122223333:dbgroup:<cluster name>/
*",
        "arn:aws:redshift:*:111122223333:dbuser:*/*",
        "arn:aws:redshift:us-east-1:111122223333:dbname:<cluster name>/
<database name>"
      ]
    },
    {
      "Sid": "VisualEditor1",
      "Effect": "Allow",
      "Action": "redshift:DescribeClusters",
      "Resource": "*"
    }
  ]
}

```

Step 2: Use the IAM-based JDBC URL as follows. Specify a new option `DbUser` with the Amazon Redshift user name that you're connecting with.

```
conn_options = {
    // IAM-based JDBC URL
    "url": "jdbc:redshift:iam://<cluster name>:<region>/<database name>",
    "dbtable": dbtable,
    "redshiftTmpDir": redshiftTmpDir,
    "aws_iam_role": aws_iam_role,
    "DbUser": "<Redshift User name>" // required for IAM-based JDBC URL
}

redshift_write = glueContext.write_dynamic_frame.from_options(
    frame=dyf,
    connection_type="redshift",
    connection_options=conn_options
)

redshift_read = glueContext.create_dynamic_frame.from_options(
    connection_type="redshift",
    connection_options=conn_options
)
```

Note

A `DynamicFrame` currently only supports an IAM-based JDBC URL with a `DbUser` in the `GlueContext.create_dynamic_frame.from_options` workflow.

Migrating from Amazon Glue version 3.0 to version 4.0

In Amazon Glue 4.0, ETL jobs have access to a new Amazon Redshift Spark connector and a new JDBC driver with different options and configuration. The new Amazon Redshift connector and driver are written with performance in mind, and keep transactional consistency of your data. These products are documented in the Amazon Redshift documentation. For more information, see:

- [Amazon Redshift integration for Apache Spark](#)
- [Amazon Redshift JDBC driver, version 2.1](#)

Table/column names and identifiers restriction

The new Amazon Redshift Spark connector and driver have a more restricted requirement for the Redshift table name. For more information, see [Names and identifiers](#) to define your Amazon Redshift table name. The job bookmark workflow might not work with a table name that doesn't match the rules and with certain characters, such as a space.

If you have legacy tables with names that don't conform to the [Names and identifiers](#) rules and see issues with bookmarks (jobs reprocessing old Amazon Redshift table data), we recommend that you rename your table names. For more information, see [ALTER TABLE examples](#).

Default tempformat change in Dataframe

The Amazon Glue version 3.0 Spark connector defaults the tempformat to CSV while writing to Amazon Redshift. To be consistent, in Amazon Glue version 3.0, the `DynamicFrame` still defaults the tempformat to use CSV. If you've previously used Spark Dataframe APIs directly with the Amazon Redshift Spark connector, you can explicitly set the tempformat to CSV in the `DataframeReader` /`Writer` options. Otherwise, tempformat defaults to AVRO in the new Spark connector.

Behavior change: map Amazon Redshift data type REAL to Spark data type FLOAT instead of DOUBLE

In Amazon Glue version 3.0, Amazon Redshift REAL is converted to a Spark `DOUBLE` type. The new Amazon Redshift Spark connector has updated the behavior so that the Amazon Redshift `REAL` type is converted to, and back from, the Spark `FLOAT` type. If you have a legacy use case where you still want the Amazon Redshift `REAL` type to be mapped to a Spark `DOUBLE` type, you can use the following workaround:

- For a `DynamicFrame`, map the `Float` type to a `Double` type with `DynamicFrame.ApplyMapping`. For a `Dataframe`, you need to use `cast`.

Code example:

```
dyf_cast = dyf.apply_mapping([('a', 'long', 'a', 'long'), ('b', 'float', 'b', 'double')])
```

Handling VARBYTE Data Type

When working with Amazon Glue 3.0 and Amazon Redshift data types, Amazon Glue 3.0 converts Amazon Redshift VARBYTE to Spark STRING type. However, the latest Amazon Redshift Spark connector doesn't support the VARBYTE data type. To work around this limitation, you can [create a Redshift view](#) that transforms VARBYTE columns to a supported data type. Then, use the new connector to load data from this view instead of the original table, which ensures compatibility while maintaining access to your VARBYTE data.

Example for Redshift query:

```
CREATE VIEW view_name AS SELECT FROM_VARBYTE(varbyte_column, 'hex') FROM table_name
```

Kafka connections

You can use a Kafka connection to read and write to Kafka data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. The connection supports a Kafka cluster or an Amazon Managed Streaming for Apache Kafka cluster. You can read information from Kafka into a Spark DataFrame, then convert it to a Amazon Glue DynamicFrame. You can write DynamicFrames to Kafka in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kafka streaming source, or `getCatalogSink` or `write_dynamic_frame_from_catalog` to write records to Kafka, and the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kafka streaming source. If you use `getSource`, `getCatalogSink`, `getSourceWithFormat`, `getSinkWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, or `write_dynamic_frame_from_catalog`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kafka using the following arguments for the specified methods in the `GlueContext` class.

- Scala
 - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
 - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
 - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python

- `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
- `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
- `options`: Use with `getSource`, `getSink`

For notes and restrictions about streaming ETL jobs, consult [the section called “Streaming ETL notes and restrictions”](#).

Topics

- [Configure Kafka](#)
- [Example: Reading from Kafka streams](#)
- [Example: Writing to Kafka streams](#)
- [Kafka connection option reference](#)

Configure Kafka

There are no Amazon prerequisites to connecting to Kafka streams available through the internet.

You can create a Amazon Glue Kafka connection to manage your connection credentials. For more information, see [the section called “Creating a connection for a Kafka data stream”](#). In your Amazon Glue job configuration, provide `connectionName` as an **Additional network connection**, then, in your method call, provide `connectionName` to the `connectionName` parameter.

In certain cases, you will need to configure additional prerequisites:

- If using Amazon Managed Streaming for Apache Kafka with IAM authentication, you will need appropriate IAM configuration.
- If using Amazon Managed Streaming for Apache Kafka within an Amazon VPC, you will need appropriate Amazon VPC configuration. You will need to create a Amazon Glue connection that provides Amazon VPC connection information. You will need your job configuration to include the Amazon Glue connection as an **Additional network connection**.

For more information about Streaming ETL job prerequisites, consult [the section called “Streaming ETL jobs”](#).

Example: Reading from Kafka streams

Used in conjunction with [the section called "forEachBatch"](#).

Example for Kafka streaming source:

```
kafka_options =
  { "connectionName": "ConfluentKafka",
    "topicName": "kafka-auth-topic",
    "startingOffsets": "earliest",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kafka",
  connection_options=kafka_options)
```

Example: Writing to Kafka streams

Examples for writing to Kafka:

Example with the `getSink` method:

```
data_frame_datasource0 =
glueContext.getSink(
  connectionType="kafka",
  connectionOptions={
    JsonOptions("""{
      "connectionName": "ConfluentKafka",
      "classification": "json",
      "topic": "kafka-auth-topic",
      "typeOfData": "kafka"}
    """))},
transformationContext="dataframe_ApacheKafka_node1711729173428")
.getDataFrame()
```

Example with the `write_dynamic_frame.from_options` method:

```
kafka_options =
  { "connectionName": "ConfluentKafka",
    "topicName": "kafka-auth-topic",
    "classification": "json"
  }
```

```
data_frame_datasource0 =  
    glueContext.write_dynamic_frame.from_options(connection_type="kafka",  
        connection_options=kafka_options)
```

Kafka connection option reference

When reading, use the following connection options with "connectionType": "kafka":

- "bootstrap.servers" (Required) A list of bootstrap server URLs, for example, as `b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094`. This option must be specified in the API call or defined in the table metadata in the Data Catalog.
- "security.protocol" (Required) The protocol used to communicate with brokers. The possible values are "SSL" or "PLAINTEXT".
- "topicName" (Required) A comma-separated list of topics to subscribe to. You must specify one and only one of "topicName", "assign" or "subscribePattern".
- "assign": (Required) A JSON string specifying the specific TopicPartitions to consume. You must specify one and only one of "topicName", "assign" or "subscribePattern".

Example: `'{"topicA":[0,1],"topicB":[2,4]}'`

- "subscribePattern": (Required) A Java regex string that identifies the topic list to subscribe to. You must specify one and only one of "topicName", "assign" or "subscribePattern".

Example: `'topic.*'`

- "classification" (Required) The file format used by the data in the record. Required unless provided through the Data Catalog.
- "delimiter" (Optional) The value separator used when classification is CSV. Default is `","`.
- "startingOffsets": (Optional) The starting position in the Kafka topic to read data from. The possible values are "earliest" or "latest". The default value is "latest".
- "startingTimestamp": (Optional, supported only for Amazon Glue version 4.0 or later) The Timestamp of the record in the Kafka topic to read data from. The possible value is a Timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where Z represents a UTC timezone offset with a +/-). For example: `"2023-04-04T08:00:00-04:00"`.

Note: Only one of 'startingOffsets' or 'startingTimestamp' can be present in the Connection Options list of the Amazon Glue streaming script, including both these properties will result in job failure.

- "endingOffsets": (Optional) The end point when a batch query is ended. Possible values are either "latest" or a JSON string that specifies an ending offset for each TopicPartition.

For the JSON string, the format is {"topicA":{"0":23,"1":-1},"topicB":{"0":-1}}. The value -1 as an offset represents "latest".
- "pollTimeoutMs": (Optional) The timeout in milliseconds to poll data from Kafka in Spark job executors. The default value is 600000.
- "numRetries": (Optional) The number of times to retry before failing to fetch Kafka offsets. The default value is 3.
- "retryIntervalMs": (Optional) The time in milliseconds to wait before retrying to fetch Kafka offsets. The default value is 10.
- "maxOffsetsPerTrigger": (Optional) The rate limit on the maximum number of offsets that are processed per trigger interval. The specified total number of offsets is proportionally split across topicPartitions of different volumes. The default value is null, which means that the consumer reads all offsets until the known latest offset.
- "minPartitions": (Optional) The desired minimum number of partitions to read from Kafka. The default value is null, which means that the number of spark partitions is equal to the number of Kafka partitions.
- "includeHeaders": (Optional) Whether to include the Kafka headers. When the option is set to "true", the data output will contain an additional column named "glue_streaming_kafka_headers" with type `Array[Struct(key: String, value: String)]`. The default value is "false". This option is available in Amazon Glue version 3.0 or later.
- "schema": (Required when inferSchema set to false) The schema to use to process the payload. If classification is avro the provided schema must be in the Avro schema format. If the classification is not avro the provided schema must be in the DDL schema format.

The following are schema examples.

Example in DDL schema format

```
'column1' INT, 'column2' STRING , 'column3' FLOAT
```

Example in Avro schema format

```
{  
  "type":"array",
```

```
"items":
{
  "type":"record",
  "name":"test",
  "fields":
  [
    {
      "name":"_id",
      "type":"string"
    },
    {
      "name":"index",
      "type":
      [
        "int",
        "string",
        "float"
      ]
    }
  ]
}
]
```

- **"inferSchema"**: (Optional) The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within `foreachbatch`.
- **"avroSchema"**: (Deprecated) Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the `schema` parameter.
- **"addRecordTimestamp"**: (Optional) When this option is set to 'true', the data output will contain an additional column named `"__src_timestamp"` that indicates the time when the corresponding record received by the topic. The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.
- **"emitConsumerLagMetrics"**: (Optional) When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the topic and the time it arrives in Amazon Glue to CloudWatch. The metric's name is `"glue.driver.streaming.maxConsumerLagInMs"`. The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.

When writing, use the following connection options with `"connectionType": "kafka"`:

- "connectionName" (Required) Name of the Amazon Glue connection used to connect to the Kafka cluster (similar to Kafka source).
- "topic" (Required) If a topic column exists then its value is used as the topic when writing the given row to Kafka, unless the topic configuration option is set. That is, the topic configuration option overrides the topic column.
- "partition" (Optional) If a valid partition number is specified, that partition will be used when sending the record.

If no partition is specified but a key is present, a partition will be chosen using a hash of the key.

If neither key nor partition is present, a partition will be chosen based on sticky partitioning those changes when at least batch.size bytes are produced to the partition.

- "key" (Optional) Used for partitioning if partition is null.
- "classification" (Optional) The file format used by the data in the record. We only support JSON, CSV and Avro.

With Avro format, we can provide a custom avroSchema to serialize with, but note that this needs to be provided on the source for deserializing as well. Else, by default it uses the Apache AvroSchema for serializing.

Additionally, you can fine-tune the Kafka sink as required by updating the [Kafka producer configuration parameters](#). Note that there is no allow listing on connection options, all the key-value pairs are persisted on the sink as is.

However, there is a small deny list of options that will not take effect. For more information, see [Kafka specific configurations](#).

Azure Cosmos DB connections

You can use Amazon Glue for Spark to read from and write to existing containers in Azure Cosmos DB using the NoSQL API in Amazon Glue 4.0 and later versions. You can define what to read from Azure Cosmos DB with a SQL query. You connect to Azure Cosmos DB using an Azure Cosmos DB Key stored in Amazon Secrets Manager through a Amazon Glue connection.

For more information about Azure Cosmos DB for NoSQL, consult [the Azure documentation](#).

Configuring Azure Cosmos DB connections

To connect to Azure Cosmos DB from Amazon Glue, you will need to create and store your Azure Cosmos DB Key in a Amazon Secrets Manager secret, then associate that secret with a Azure Cosmos DB Amazon Glue connection.

Prerequisites:

- In Azure, you will need to identify or generate an Azure Cosmos DB Key for use by Amazon Glue, `cosmosKey`. For more information, see [Secure access to data in Azure Cosmos DB](#) in the Azure documentation.

To configure a connection to Azure Cosmos DB:

1. In Amazon Secrets Manager, create a secret using your Azure Cosmos DB Key. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, `secretName` for the next step.
 - When selecting **Key/value pairs**, create a pair for the key `spark.cosmos.accountKey` with the value `cosmosKey`.
2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, `connectionName`, for future use in Amazon Glue.
 - When selecting a **Connection type**, select Azure Cosmos DB.
 - When selecting an **Amazon Secret**, provide `secretName`.

After creating a Amazon Glue Azure Cosmos DB connection, you will need to perform the following steps before running your Amazon Glue job:

- Grant the IAM role associated with your Amazon Glue job permission to read `secretName`.
- In your Amazon Glue job configuration, provide `connectionName` as an **Additional network connection**.

Reading from Azure Cosmos DB for NoSQL containers

Prerequisites:

- A Azure Cosmos DB for NoSQL container you would like to read from. You will need identification information for the container.

An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.

- A Amazon Glue Azure Cosmos DB connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to Azure Cosmos DB*. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
azurecosmos_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="azurecosmos",  
    connection_options={  
        "connectionName": connectionName,  
        "spark.cosmos.database": cosmosDBName,  
        "spark.cosmos.container": cosmosContainerName,  
    }  
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query.

For example:

```
azurecosmos_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="azurecosmos",  
    connection_options={  
        "connectionName": "connectionName",  
        "spark.cosmos.database": cosmosDBName,  
        "spark.cosmos.container": cosmosContainerName,  
        "spark.cosmos.read.customQuery": "query"  
    }  
)
```

Writing to Azure Cosmos DB for NoSQL containers

This example writes information from an existing `DynamicFrame`, *dynamicFrame* to Azure Cosmos DB. If the container already has information, Amazon Glue will append data from your `DynamicFrame`. If the information in the container has a different schema from the information you write, you will run into errors.

Prerequisites:

- A Azure Cosmos DB table you would like to write to. You will need identification information for the container. **You must create the container before calling the connection method.**

An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.

- A Amazon Glue Azure Cosmos DB connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to Azure Cosmos DB*. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
azurecosmos_write = glueContext.write_dynamic_frame.from_options(  
    frame=dynamicFrame,  
    connection_type="azurecosmos",  
    connection_options={  
        "connectionName": connectionName,  
        "spark.cosmos.database": cosmosDBName,  
        "spark.cosmos.container": cosmosContainerName  
    }  
)
```

Azure Cosmos DB connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a Amazon Glue Azure Cosmos DB connection configured to provide auth and network location information to your connection method.
- `spark.cosmos.database` — Required. Used for Read/Write. Valid Values: database names. Azure Cosmos DB for NoSQL database name.

- `spark.cosmos.container` — Required. Used for Read/Write. Valid Values: container names. Azure Cosmos DB for NoSQL container name.
- `spark.cosmos.read.customQuery` — Used for Read. Valid Values: SELECT SQL queries. Custom query to select documents to be read.

Azure SQL connections

You can use Amazon Glue for Spark to read from and write to tables on Azure SQL Managed Instances in Amazon Glue 4.0 and later versions. You can define what to read from Azure SQL with a SQL query. You connect to Azure SQL using user and password credentials stored in Amazon Secrets Manager through a Amazon Glue connection.

For more information about Azure SQL, consult the [Azure SQL documentation](#).

Configuring Azure SQL connections

To connect to Azure SQL from Amazon Glue, you will need to create and store your Azure SQL credentials in a Amazon Secrets Manager secret, then associate that secret with a Azure SQL Amazon Glue connection.

To configure a connection to Azure SQL:

1. In Amazon Secrets Manager, create a secret using your Azure SQL credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key `user` with the value *azuresqlUsername*.
 - When selecting **Key/value pairs**, create a pair for the key `password` with the value *azuresqlPassword*.
2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in Amazon Glue.
 - When selecting a **Connection type**, select Azure SQL.
 - When providing **Azure SQL URL**, provide a JDBC endpoint URL.

The URL must be in the following format:

```
jdbc:sqlserver://databaseServerName:databasePort;databaseName=azuresqlDBName
```

Amazon Glue requires the following URL properties:

- `databaseName` – A default database in Azure SQL to connect to.

For more information about JDBC URLs for Azure SQL Managed Instances, see the [Microsoft documentation](#).

- When selecting an **Amazon Secret**, provide *secretName*.

After creating a Amazon Glue Azure SQL connection, you will need to perform the following steps before running your Amazon Glue job:

- Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.
- In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from Azure SQL tables

Prerequisites:

- A Azure SQL table you would like to read from. You will need identification information for the table, *databaseName* and *tableIdentifier*.

An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in *connectionName*, schema and table name through the `dbtable`.

- A Amazon Glue Azure SQL connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to Azure SQL* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
azuresql_read_table = glueContext.create_dynamic_frame.from_options(  
    connection_type="azuresql",  
    connection_options={
```

```
        "connectionName": "connectionName",
        "dbtable": "tableIdentifier"
    }
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query.

For example:

```
azuresql_read_query = glueContext.create_dynamic_frame.from_options(
    connection_type="azuresql",
    connection_options={
        "connectionName": "connectionName",
        "query": "query"
    }
)
```

Writing to Azure SQL tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to Azure SQL. If the table already has information, Amazon Glue will append data from your DynamicFrame.

Prerequisites:

- A Azure SQL table you would like to write to. You will need identification information for the table, *databaseName* and *tableIdentifier*.

An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in *connectionName*, schema and table name through the *dbtable*.

- Azure SQL auth information. Complete the steps in the previous procedure, *To configure a connection to Azure SQL* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
azuresql_write = glueContext.write_dynamic_frame.from_options(
    connection_type="azuresql",
```

```
connection_options={
  "connectionName": "connectionName",
  "dbtable": "tableIdentifier"
}
```

Azure SQL connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a Amazon Glue Azure SQL connection configured to provide auth information to your connection method.
- `databaseName` — Used for Read/Write. Valid Values: Azure SQL database names. The name of the database in Azure SQL to connect to.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. Valid Values: Names of Azure SQL tables, or period separated schema/table name combinations. Used to specify the table and schema that identify the table to connect to. The default schema is "public". If your table is in a non-default schema, provide this information in the form *schemaName.tableName*.
- `query` — Used for Read. A Transact-SQL SELECT query defining what should be retrieved when reading from Azure SQL. For more information, see the [Microsoft documentation](#).

BigQuery connections

You can use Amazon Glue for Spark to read from and write to tables in Google BigQuery in Amazon Glue 4.0 and later versions. You can read from BigQuery with a Google SQL query. You connect to BigQuery using credentials stored in Amazon Secrets Manager through a Amazon Glue connection.

For more information about Google BigQuery, see the [Google Cloud BigQuery website](#).

Configuring BigQuery connections

To connect to Google BigQuery from Amazon Glue, you will need to create and store your Google Cloud Platform credentials in a Amazon Secrets Manager secret, then associate that secret with a Google BigQuery Amazon Glue connection.

To configure a connection to BigQuery:

1. In Google Cloud Platform, create and identify relevant resources:
 - Create or identify a GCP project containing BigQuery tables you would like to connect to.

- Enable the BigQuery API. For more information, see [Use the BigQuery Storage Read API to read table data](#).
2. In Google Cloud Platform, create and export service account credentials:

You can use the BigQuery credentials wizard to expedite this step: [Create credentials](#).

To create a service account in GCP, follow the tutorial available in [Create service accounts](#).

- When selecting **project**, select the project containing your BigQuery table.
- When selecting GCP IAM roles for your service account, add or create a role that would grant appropriate permissions to run BigQuery jobs to read, write or create BigQuery tables.

To create credentials for your service account, follow the tutorial available in [Create a service account key](#).

- When selecting key type, select **JSON**.

You should now have downloaded a JSON file with credentials for your service account. It should look similar to the following:

```
{
  "type": "service_account",
  "project_id": "*****",
  "private_key_id": "*****",
  "private_key": "*****",
  "client_email": "*****",
  "client_id": "*****",
  "auth_uri": "https://accounts.google.com/o/oauth2/auth",
  "token_uri": "https://oauth2.googleapis.com/token",
  "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
  "client_x509_cert_url": "*****",
  "universe_domain": "googleapis.com"
}
```

3. Upload your credentials JSON file to an appropriately secure Amazon S3 location. Retain the path to the file, *s3secretpath* for future steps.
4. In Amazon Secrets Manager, create a secret using your Google Cloud Platform credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets](#)

[Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

When creating Key/value pairs, specify keys and values as followings:

- For `token_uri`, `client_x509_cert_url`, `private_key_id`, `project_id`, `universe_domain`, `auth_provider_x509_cert_url`, `auth_uri`, `client_email`, `private_key`, `type`, `client_id` keys, specify the corresponding values in the downloaded JSON file.
 - For `spark.hadoop.google.cloud.auth.service.account.json.keyfile` key, specify the *s3secretpath*.
5. In the Amazon Glue Data Catalog, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
 - When selecting a **Connection type**, select Google BigQuery.
 - When selecting an **Amazon Secret**, provide *secretName*.
 6. Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.
 7. In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from BigQuery tables

Prerequisites:

- A BigQuery table you would like to read from. You will need the BigQuery table and dataset names, in the form `[dataset].[table]`. Let's call this *tableName*.
- The billing project for the BigQuery table. You will need the name of the project, *parentProject*. If there is no billing parent project, use the project containing the table.
- BigQuery auth information. Complete the steps *To manage your connection credentials with Amazon Glue* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
bigquery_read = glueContext.create_dynamic_frame.from_options(
```

```
connection_type="bigquery",
connection_options={
    "connectionName": "connectionName",
    "parentProject": "parentProject",
    "sourceType": "table",
    "table": "tableName",
}
```

You can also provide a query, to filter the results returned to your DynamicFrame. You will need to configure query, sourceType, viewsEnabled and materializationDataset.

For example:

Additional prerequisites:

You will need to create or identify a BigQuery dataset, *materializationDataset*, where BigQuery can write materialized views for your queries.

You will need to grant appropriate GCP IAM permissions to your service account to create tables in *materializationDataset*.

```
glueContext.create_dynamic_frame.from_options(
    connection_type="bigquery",
    connection_options={
        "connectionName": "connectionName",
        "materializationDataset": materializationDataset,
        "parentProject": "parentProject",
        "viewsEnabled": "true",
        "sourceType": "query",
        "query": "select * from bqtest.test"
    }
)
```

Writing to BigQuery tables

This example writes directly to the BigQuery service. BigQuery also supports the "indirect" writing method. For more information about configuring indirect writes, see [the section called "Using indirect write with Google BigQuery"](#).

Prerequisites:

- A BigQuery table you would like to write to. You will need the BigQuery table and dataset names, in the form `[dataset].[table]`. You can also provide a new table name that will automatically be created. Let's call this *tableName*.
- The billing project for the BigQuery table. You will need the name of the project, *parentProject*. If there is no billing parent project, use the project containing the table.
- BigQuery auth information. Complete the steps *To manage your connection credentials with Amazon Glue* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
bigquery_write = glueContext.write_dynamic_frame.from_options(  
    frame=frameToWrite,  
    connection_type="bigquery",  
    connection_options={  
        "connectionName": "connectionName",  
        "parentProject": "parentProject",  
        "writeMethod": "direct",  
        "table": "tableName",  
    }  
)
```

BigQuery connection option reference

- `project` — Default: Google Cloud service account default. Used for Read/Write. The name of a Google Cloud project associated with your table.
- `table` — (Required) Used for Read/Write. The name of your BigQuery table in the format `[[project:]dataset.]`.
- `dataset` — Required when not defined through the `table` option. Used for Read/Write. The name of the dataset containing your BigQuery table.
- `parentProject` — Default: Google Cloud service account default. Used for Read/Write. The name of a Google Cloud project associated with `project` used for billing.
- `sourceType` — Used for Read. Required when reading. Valid Values: `table`, `query` Informs Amazon Glue of whether you will read by table or by query.
- `materializationDataset` — Used for Read. Valid Values: strings. The name of a BigQuery dataset used to store materializations for views.

- `viewsEnabled` — Used for Read. Default: `false`. Valid Values: `true`, `false`. Configures whether BigQuery will use views.
- `query` — Used for Read. Used when `viewsEnabled` is `true`. A GoogleSQL DQL query.
- `temporaryGcsBucket` — Used for Write. Required when `writeMethod` is set to default (`indirect`). Name of a Google Cloud Storage bucket used to store an intermediate form of your data while writing to BigQuery.
- `writeMethod` — Default: `indirect`. Valid Values: `direct`, `indirect`. Used for Write. Specifies the method used to write your data.
 - If set to `direct`, your connector will write using the BigQuery Storage Write API.
 - If set to `indirect`, you connector will write to Google Cloud Storage, then transfer it to BigQuery using a load operation. Your Google Cloud service account will need appropriate GCS permissions.

Using indirect write with Google BigQuery

This example uses indirect write, which writes data to Google Cloud Storage and copies it to Google BigQuery.

Prerequisites:

You will need a temporary Google Cloud Storage bucket, *temporaryBucket*.

The GCP IAM role for Amazon Glue's GCP service account will need appropriate GCS permissions to access *temporaryBucket*.

Additional Configuration:

To configure indirect write with BigQuery:

1. Assess [the section called "Configuring BigQuery"](#) and locate or redownload your GCP credentials JSON file. Identify *secretName*, the Amazon Secrets Manager secret for the Google BigQuery Amazon Glue connection used in your job.
2. Upload your credentials JSON file to an appropriately secure Amazon S3 location. Retain the path to the file, *s3secretpath* for future steps.
3. Edit *secretName*, adding the `spark.hadoop.google.cloud.auth.service.account.json.keyfile` key. Set the value to *s3secretpath*.

4. Grant your Amazon Glue job Amazon S3 IAM permissions to access *s3secretpath*.

You can now provide your temporary GCS bucket location to your write method. You do not need to provide `writeMethod`, as `indirect` is historically the default.

```
bigquery_write = glueContext.write_dynamic_frame.from_options(  
    frame=frameToWrite,  
    connection_type="bigquery",  
    connection_options={  
        "connectionName": "connectionName",  
        "parentProject": "parentProject",  
        "temporaryGcsBucket": "temporaryBucket",  
        "table": "tableName",  
    }  
)
```

JDBC connections

Certain, typically relational, database types support connecting through the JDBC standard. For more information about JDBC, see the [Java JDBC API](#) documentation. Amazon Glue natively supports connecting to certain databases through their JDBC connectors - the JDBC libraries are provided in Amazon Glue Spark jobs. When connecting to these database types using Amazon Glue libraries, you have access to a standard set of options.

The JDBC `connectionType` values include the following:

- "connectionType": "sqlserver": Designates a connection to a Microsoft SQL Server database.
- "connectionType": "mysql": Designates a connection to a MySQL database.
- "connectionType": "oracle": Designates a connection to an Oracle database.
- "connectionType": "postgresql": Designates a connection to a PostgreSQL database.
- "connectionType": "redshift": Designates a connection to an Amazon Redshift database. For more information, see [the section called "Redshift connections"](#).

The following table lists the JDBC driver versions that Amazon Glue supports.

| Product | JDBC driver versions for Glue 5.1 | JDBC driver versions for Glue 5.0 | JDBC driver versions for Glue 4.0 | JDBC driver versions for Glue 3.0 | JDBC driver versions for Glue 0.9, 1.0, 2.0 |
|----------------------|-----------------------------------|-----------------------------------|-----------------------------------|-----------------------------------|---|
| Microsoft SQL Server | 10.2.0 | 10.2.0 | 9.4.0 | 7.x | 6.x |
| MySQL | 8.0.33 | 8.0.33 | 8.0.23 | 8.0.23 | 5.1 |
| Oracle Database | 23.3.0.23.09 | 23.3.0.23.09 | 21.7 | 21.1 | 11.2 |
| PostgreSQL | 42.7.3 | 42.7.3 | 42.3.6 | 42.2.18 | 42.1.x |
| Amazon Redshift * | redshift-jdbc42-2.1.0.29 | redshift-jdbc42-2.1.0.29 | redshift-jdbc42-2.1.0.16 | redshift-jdbc41-1.2.12.1017 | redshift-jdbc41-1.2.12.1017 |

* For the Amazon Redshift connection type, all other option name/value pairs that are included in connection options for a JDBC connection, including formatting options, are passed directly to the underlying SparkSQL DataSource. In Amazon Glue with Spark jobs in Amazon Glue 4.0 and later versions, the Amazon Glue native connector for Amazon Redshift uses the Amazon Redshift integration for Apache Spark. For more information see [Amazon Redshift integration for Apache Spark](#). In previous versions, see [Amazon Redshift data source for Spark](#).

To configure your Amazon VPC to connect to Amazon RDS data stores using JDBC, refer to [the section called "Setting up Amazon VPC to connect to Amazon RDS data stores"](#).

Note

Amazon Glue jobs are only associated with one subnet during a run. This may impact your ability to connect to multiple data sources through the same job. This behavior is not limited to JDBC sources.

Topics

- [Use custom JDBC driver](#)
- [Reading from JDBC tables in parallel](#)
- [Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from Amazon Glue](#)

JDBC connection option reference

If you already have a JDBC Amazon Glue connection defined, you can reuse the configuration properties defined in it, such as: url, user and password; so you don't have to specify them in the code as connection options. This feature is available in Amazon Glue 3.0 and later versions. To do so, use the following connection properties:

- "useConnectionProperties": Set it to "true" to indicate you want to use the configuration from a connection.
- "connectionName": Enter the connection name to retrieve the configuration from, the connection must be defined in the same region as the job.

Use these connection options with JDBC connections:

- "url": (Required) The JDBC URL for the database.
- "dbtable": (Required) The database table to read from. For JDBC data stores that support schemas within a database, specify schema.table-name. If a schema is not provided, then the default "public" schema is used.
- "user": (Required) The user name to use when connecting.
- "password": (Required) The password to use when connecting.
- (Optional) The following options allow you to supply a custom JDBC driver. Use these options if you must use a driver that Amazon Glue does not natively support.

ETL jobs can use different JDBC driver versions for the data source and target, even if the source and target are the same database product. This allows you to migrate data between source and target databases with different versions. To use these options, you must first upload the JAR file of the JDBC driver to Amazon S3.

- "customJdbcDriverS3Path": The Amazon S3 path of the custom JDBC driver.
- "customJdbcDriverClassName": The class name of JDBC driver.

- "bulkSize": (Optional) Used to configure parallel inserts for speeding up bulk loads into JDBC targets. Specify an integer value for the degree of parallelism to use when writing or inserting data. This option is helpful for improving the performance of writes into databases such as the Arch User Repository (AUR).
- "hashfield" (Optional) A string, used to specify the name of a column in the JDBC table to be used to divide the data into partitions when reading from JDBC tables in parallel. Provide "hashfield" OR "hashexpression". For more information, see [the section called "Reading from JDBC in parallel"](#).
- "hashexpression" (Optional) A SQL select clause returning a whole number. Used to divide the data in a JDBC table into partitions when reading from JDBC tables in parallel. Provide "hashfield" OR "hashexpression". For more information, see [the section called "Reading from JDBC in parallel"](#).
- "hashpartitions" (Optional) A positive integer. Used to specify the number of parallel reads of the JDBC table when reading from JDBC tables in parallel. Default: 7. For more information, see [the section called "Reading from JDBC in parallel"](#).
- "sampleQuery": (Optional) A custom SQL query statement. Used to specify a subset of information in a table to retrieve a sample of the table contents. **When configured without regard to your data, it can be less efficient than DynamicFrame methods, causing timeouts or out of memory errors.** For more information, see [the section called "Use sampleQuery"](#).
- "enablePartitioningForSampleQuery": (Optional) A boolean. Default: false. Used to enable reading from JDBC tables in parallel when specifying sampleQuery. **If set to true, sampleQuery must end with "where" or "and" for Amazon Glue to append partitioning conditions.** For more information, see [the section called "Use sampleQuery"](#).
- "sampleSize": (Optional) A positive integer. Limits the number of rows returned by the sample query. Works only when enablePartitioningForSampleQuery is true. If partitioning is not enabled, you should instead directly add "limit x" in the sampleQuery to limit the size. For more information, see [the section called "Use sampleQuery"](#).

Use sampleQuery

This section explains how to use sampleQuery, sampleSize and enablePartitioningForSampleQuery.

sampleQuery can be an efficient way to sample a few rows of your dataset. By default, the query is run by a single executor. When configured without regard to your data, it can be less efficient than DynamicFrame methods, causing timeouts or out of memory errors. Running SQL

on the underlying database as part of your ETL pipeline is generally only needed for performance purposes. If you are trying to preview a few rows of your dataset, consider using [the section called "show"](#). If you are trying to transform your dataset using SQL, consider using [the section called "toDF"](#) to define a SparkSQL transform against your data in a DataFrame form.

While your query may manipulate a variety of tables, `dbtable` remains required.

Using `sampleQuery` to retrieve a sample of your table

When using default `sampleQuery` behavior to retrieve a sample of your data, Amazon Glue does not expect substantial throughput, so it runs your query on a single executor. In order to limit the data you provide and not cause performance problems, we suggest you provide SQL with a `LIMIT` clause.

Example Use `sampleQuery` without partitioning

The following code example shows how to use `sampleQuery` without partitioning.

```
//A full sql query statement.
val query = "select name from $tableName where age > 0 limit 1"
val connectionOptions = JsonOptions(Map(
  "url" -> url,
  "dbtable" -> tableName,
  "user" -> user,
  "password" -> password,
  "sampleQuery" -> query ))
val dyf = glueContext.getSource("mysql", connectionOptions)
    .getDynamicFrame()
```

Using `sampleQuery` against larger datasets

If you're reading a large dataset, you might need to enable JDBC partitioning to query a table in parallel. For more information, see [the section called "Reading from JDBC in parallel"](#). To use `sampleQuery` with JDBC partitioning, set `enablePartitioningForSampleQuery` to `true`. Enabling this feature requires you to make some changes to your `sampleQuery`.

When using JDBC partitioning with `sampleQuery`, your query must end with "where" or "and" for Amazon Glue to append partitioning conditions.

If you would like to limit the results of your `sampleQuery` when reading from JDBC tables in parallel, set the "sampleSize" parameter rather than specifying a `LIMIT` clause.

Example Use sampleQuery with JDBC partitioning

The following code example shows how to use sampleQuery with JDBC partitioning.

```
//note that the query should end with "where" or "and" if use with JDBC partitioning.
val query = "select name from $tableName where age > 0 and"

//Enable JDBC partitioning by setting hashfield.
//to use sampleQuery with partitioning, set enablePartitioningForSampleQuery.
//use sampleSize to limit the size of returned data.
val connectionOptions = JsonOptions(Map(
  "url" -> url,
  "dbtable" -> tableName,
  "user" -> user,
  "password" -> password,
  "hashfield" -> primaryKey,
  "sampleQuery" -> query,
  "enablePartitioningForSampleQuery" -> true,
  "sampleSize" -> "1" ))
val dyf = glueContext.getSource("mysql", connectionOptions)
    .getDynamicFrame()
```

Notes and Restrictions:

Sample queries cannot be used together with job bookmarks. The bookmark state will be ignored when configuration for both are provided.

Use custom JDBC driver

The following code examples show how to read from and write to JDBC databases with custom JDBC drivers. They demonstrate reading from one version of a database product, and writing to a later version of the same product.

Python

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext, SparkConf
from awsglue.context import GlueContext
from awsglue.job import Job
import time
from pyspark.sql.types import StructType, StructField, IntegerType, StringType
```

```
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

# Construct JDBC connection options
connection_mysql5_options = {
  "url": "jdbc:mysql://<jdbc-host-name>:3306/db",
  "dbtable": "test",
  "user": "admin",
  "password": "pwd"}

connection_mysql8_options = {
  "url": "jdbc:mysql://<jdbc-host-name>:3306/db",
  "dbtable": "test",
  "user": "admin",
  "password": "pwd",
  "customJdbcDriverS3Path": "s3://amzn-s3-demo-bucket/mysql-connector-
java-8.0.17.jar",
  "customJdbcDriverClassName": "com.mysql.cj.jdbc.Driver"}

connection_oracle11_options = {
  "url": "jdbc:oracle:thin:@//<jdbc-host-name>:1521/ORCL",
  "dbtable": "test",
  "user": "admin",
  "password": "pwd"}

connection_oracle18_options = {
  "url": "jdbc:oracle:thin:@//<jdbc-host-name>:1521/ORCL",
  "dbtable": "test",
  "user": "admin",
  "password": "pwd",
  "customJdbcDriverS3Path": "s3://amzn-s3-demo-bucket/ojdbc10.jar",
  "customJdbcDriverClassName": "oracle.jdbc.OracleDriver"}

# Read from JDBC databases with custom driver
df_mysql8 = glueContext.create_dynamic_frame.from_options(connection_type="mysql",
  connection_options=connection_mysql8_options)

# Read DynamicFrame from MySQL 5 and write to MySQL 8
df_mysql5 = glueContext.create_dynamic_frame.from_options(connection_type="mysql",
  connection_options=connection_mysql5_options)
```

```

glueContext.write_from_options(frame_or_dfc=df_mysql5, connection_type="mysql",
                               connection_options=connection_mysql8_options)

# Read DynamicFrame from Oracle 11 and write to Oracle 18
df_oracle11 =
  glueContext.create_dynamic_frame.from_options(connection_type="oracle",

        connection_options=connection_oracle11_options)
glueContext.write_from_options(frame_or_dfc=df_oracle11, connection_type="oracle",
                               connection_options=connection_oracle18_options)

```

"${customJdbcDriverClassName}"""".stripMargin)
}
}
```

Reading from JDBC tables in parallel

You can set properties of your JDBC table to enable Amazon Glue to read data in parallel. When you set certain properties, you instruct Amazon Glue to run parallel SQL queries against logical partitions of your data. You can control partitioning by setting a hash field or a hash expression. You can also control the number of parallel reads that are used to access your data.

Reading from JDBC tables in parallel is an optimization technique that may improve performance. For more information about the process of identifying when this technique is appropriate, consult [Reduce the amount of data scan](#) in the *Best practices for performance tuning Amazon Glue for Apache Spark jobs* guide on Amazon Prescriptive Guidance.

To enable parallel reads, you can set key-value pairs in the parameters field of your table structure. Use JSON notation to set a value for the parameter field of your table. For more information about editing the properties of a table, see [Viewing and managing table details](#). You can also enable parallel reads when you call the ETL (extract, transform, and load) methods `create_dynamic_frame_from_options` and `create_dynamic_frame_from_catalog`. For more information about specifying options in these methods, see [from_options](#) and [from_catalog](#).

You can use this method for JDBC tables, that is, most tables whose base data is a JDBC data store. These properties are ignored when reading Amazon Redshift and Amazon S3 tables.

hashfield

Set `hashfield` to the name of a column in the JDBC table to be used to divide the data into partitions. For best results, this column should have an even distribution of values to spread the data between partitions. This column can be of any data type. Amazon Glue generates non-overlapping queries that run in parallel to read the data partitioned by this column. For example, if your data is evenly distributed by month, you can use the month column to read each month of data in parallel.

```
'hashfield': 'month'
```

Amazon Glue creates a query to hash the field value to a partition number and runs the query for all partitions in parallel. To use your own query to partition a table read, provide a `hashexpression` instead of a `hashfield`.

hashexpression

Set `hashexpression` to an SQL expression (conforming to the JDBC database engine grammar) that returns a whole number. A simple expression is the name of any numeric column in the table. Amazon Glue generates SQL queries to read the JDBC data in parallel using the `hashexpression` in the `WHERE` clause to partition data.

For example, use the numeric column `customerID` to read data partitioned by a customer number.

```
'hashexpression': 'customerID'
```

To have Amazon Glue control the partitioning, provide a `hashfield` instead of a `hashexpression`.

hashpartitions

Set `hashpartitions` to the number of parallel reads of the JDBC table. If this property is not set, the default value is 7.

For example, set the number of parallel reads to 5 so that Amazon Glue reads your data with five queries (or fewer).

```
'hashpartitions': '5'
```

Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from Amazon Glue

When using JDBC to connect to databases in Amazon RDS, you will need to perform additional setup. To enable Amazon Glue components to communicate with Amazon RDS, you must set up access to your Amazon RDS data stores in Amazon VPC. To enable Amazon Glue to communicate between its components, specify a security group with a self-referencing inbound rule for all TCP ports. By creating a self-referencing rule, you can restrict the source to the same security group in the VPC. A self-referencing rule will not open the VPC to all networks. The default security group for your VPC might already have a self-referencing inbound rule for ALL Traffic.

To set up access between Amazon Glue and Amazon RDS data stores

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the Amazon RDS console, identify the security group(s) used to control access to your Amazon RDS database.

In the left navigation pane, choose **Databases**, then select the instance you would like to connect to from the list in the main pane.

In the database detail page, find **VPC security groups** on the **Connectivity & security** tab.

3. Based on your network architecture, identify which associated security group is best to modify to allow access for the Amazon Glue service. Save its name, *database-security-group* for future reference. If there is no appropriate security group, follow the directions to [Provide access to your DB instance in your VPC by creating a security group](#) in the Amazon RDS documentation.

4. Sign in to the Amazon Web Services Management Console and open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.

5. In the Amazon VPC console, identify how to update *database-security-group*.

In the left navigation pane, choose **Security groups**, then select *database-security-group* from the list in the main pane.

6. Identify the security group ID for *database-security-group*, *database-sg-id*. Save it for future reference.

In the security group detail page, find **Security group ID**.

7. Alter the inbound rules for *database-security-group*, add a self-referencing rule to allow Amazon Glue components to communicate. Specifically, add or confirm that there is a rule where **Type** is All TCP, **Protocol** is TCP, **Port Range** includes all ports, and **Source** is *database-sg-id*. Verify that the security group you have entered for **Source** is the same as the security group you are editing.

In the security group detail page, select **Edit inbound rules**.

The inbound rule looks similar to this:

| Type | Protocol | Port range | Source |
|---------|----------|------------|-----------------------|
| All TCP | TCP | 0–65535 | <i>database-sg-id</i> |

8. Add rules for outbound traffic.

In the security group detail page, select **Edit outbound rules**.

If your security group allows all outbound traffic, you do not need separate rules. For example:

| Type | Protocol | Port range | Destination |
|-------------|----------|------------|-------------|
| All Traffic | ALL | ALL | 0.0.0.0/0 |

If your network architecture is designed for you to restrict outbound traffic, create the following outbound rules:

Create a self-referencing rule where **Type** is All TCP, **Protocol** is TCP, **Port Range** includes all ports, and **Destination** is *database-sg-id*. Verify that the security group you have entered for **Destination** is the same as the security group you are editing.

If using an Amazon S3 VPC endpoint, add an HTTPS rule to allow traffic from the VPC to Amazon S3. Create a rule where **Type** is HTTPS, **Protocol** is TCP, **Port Range** is 443 and **Destination** is the ID of the managed prefix list for the Amazon S3 gateway endpoint, *s3-prefix-list-id*. For more information about prefix lists and Amazon S3 gateway endpoints, see [Gateway endpoints for Amazon S3](#) in the Amazon VPC documentation.

For example:

| Type | Protocol | Port range | Destination |
|---------|----------|------------|--------------------------|
| All TCP | TCP | 0–65535 | <i>database-sg-id</i> |
| HTTPS | TCP | 443 | <i>s3-prefix-list-id</i> |

MongoDB connections

You can use Amazon Glue for Spark to read from and write to tables in MongoDB and MongoDB Atlas in Amazon Glue 4.0 and later versions. You can connect to MongoDB using username and password credentials stored in Amazon Secrets Manager through a Amazon Glue connection.

For more information about MongoDB, consult the [MongoDB documentation](#).

Configuring MongoDB connections

To connect to MongoDB from Amazon Glue, you will need your MongoDB credentials, *mongodbUser* and *mongodbPass*.

To connect to MongoDB from Amazon Glue, you may need some prerequisites:

- If your MongoDB instance is in an Amazon VPC, configure Amazon VPC to allow your Amazon Glue job to communicate with the MongoDB instance without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that Amazon Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your MongoDB instance and this location. Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

You can then proceed to configure Amazon Glue for use with MongoDB.

To configure a connection to MongoDB:

1. Optionally, in Amazon Secrets Manager, create a secret using your MongoDB credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key `username` with the value *mongodbUser*.

When selecting **Key/value pairs**, create a pair for the key `password` with the value *mongodbPass*.

2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in Amazon Glue.

- When selecting a **Connection type**, select **MongoDB** or **MongoDB Atlas**.
- When selecting **MongoDB URL** or **MongoDB Atlas URL**, provide the hostname of your MongoDB instance.

A MongoDB URL is provided in the format
`mongodb://mongoHost:mongoPort/mongoDBName.`

A MongoDB Atlas URL is provided in the format `mongodb
+srv://mongoHost:mongoPort/mongoDBName.`

Providing the default database for the connection, *mongoDBName* is optional.

- If you chose to create an Secrets Manager secret, choose the Amazon Secrets Manager **Credential type**.

Then, in **Amazon Secret** provide *secretName*.

- If you choose to provide **Username and password**, provide *mongodbUser* and *mongodbPass*.

3. In the following situations, you may require additional configuration:

- For MongoDB instances hosted on Amazon in an Amazon VPC
 - You will need to provide Amazon VPC connection information to the Amazon Glue connection that defines your MongoDB security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a Amazon Glue MongoDB connection, you will need to perform the following actions before calling your connection method:

- If you chose to create an Secrets Manager secret, grant the IAM role associated with your Amazon Glue job permission to read *secretName*.
- In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection**.

To use your Amazon Glue MongoDB connection in Amazon Glue for Spark, provide the `connectionName` option in your connection method call. Alternatively, you can follow the steps in [the section called “Integrating with MongoDB”](#) to use the connection in conjunction with the Amazon Glue Data Catalog.

Reading from MongoDB using a Amazon Glue connection

Prerequisites:

- A MongoDB collection you would like to read from. You will need identification information for the collection.

A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.

- A Amazon Glue MongoDB connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to MongoDB* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
mongodb_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="mongodb",  
    connection_options={  
        "connectionName": "connectionName",  
        "database": "mongodbName",  
        "collection": "mongodbCollection",  
        "partitioner":  
        "com.mongodb.spark.sql.connector.read.partitionner.SinglePartitionPartitioner",  
        "partitionerOptions.partitionSizeMB": "10",  
        "partitionerOptions.partitionKey": "_id",  
        "disableUpdateUri": "false",  
    }  
)
```

Writing to MongoDB tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to MongoDB.

Prerequisites:

- A MongoDB collection you would like to write to. You will need identification information for the collection.

A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.

- A Amazon Glue MongoDB connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to MongoDB* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
glueContext.write_dynamic_frame.from_options(  
    frame=dynamicFrame,  
    connection_type="mongodb",  
    connection_options={  
        "connectionName": "connectionName",  
        "database": "mongodbName",  
        "collection": "mongodbCollection",  
        "disableUpdateUri": "false",  
        "retryWrites": "false",  
    },  
)
```

Reading and writing to MongoDB tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to MongoDB.

Prerequisites:

- A MongoDB collection you would like to read from. You will need identification information for the collection.

A MongoDB collection you would like to write to. You will need identification information for the collection.

A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.

- MongoDB auth information, *mongodbUser* and *mongodbPassword*.

For example:

Python

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext, SparkConf
from awsglue.context import GlueContext
from awsglue.job import Job
import time

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

job = Job(glueContext)
job.init(args['JOB_NAME'], args)

output_path = "s3://some_bucket/output/" + str(time.time()) + "/"
mongo_uri = "mongodb://<mongo-instanced-ip-address>:27017"
mongo_ssl_uri = "mongodb://<mongo-instanced-ip-address>:27017"
write_uri = "mongodb://<mongo-instanced-ip-address>:27017"

read_mongo_options = {
    "uri": mongo_uri,
    "database": "mongodbName",
    "collection": "mongodbCollection",
    "username": "mongodbUsername",
    "password": "mongodbPassword",
    "partitioner": "MongoSamplePartitioner",
    "partitionerOptions.partitionSizeMB": "10",
    "partitionerOptions.partitionKey": "_id"}

ssl_mongo_options = {
    "uri": mongo_ssl_uri,
    "database": "mongodbName",
    "collection": "mongodbCollection",
    "ssl": "true",
    "ssl.domain_match": "false"
}

write_mongo_options = {
```

```

    "uri": write_uri,
    "database": "mongodbName",
    "collection": "mongodbCollection",
    "username": "mongodbUsername",
    "password": "mongodbPassword",
  }

# Get DynamicFrame from MongoDB
dynamic_frame =
  glueContext.create_dynamic_frame.from_options(connection_type="mongodb",

  connection_options=read_mongo_options)

# Write DynamicFrame to MongoDB
glueContext.write_dynamic_frame.from_options(dynamicFrame,
  connection_type="mongodb", connection_options=write_mongo_options)

job.commit()

```

Scala

```

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser

      |"password": "mongodbPassword",
      |"ssl": "true",
      |"ssl.domain_match": "false",
      |"partitioner": "MongoSamplePartitioner",
      |"partitionerOptions.partitionSizeMB": "10",
      |"partitionerOptions.partitionKey": "_id"}"""".stripMargin)
  }
}

```

MongoDB connection option reference

Designates a connection to MongoDB. Connection options differ for a source connection and a sink connection.

These connection properties are shared between source and sink connections:

- `connectionName` — Used for Read/Write. The name of a Amazon Glue MongoDB connection configured to provide auth and networking information to your connection method. When a Amazon Glue connection is configured as described in the previous section, [the section called “Configuring MongoDB”](#), providing `connectionName` will replace the need to provide the `"uri"`, `"username"` and `"password"` connection options.
- `"uri"`: (Required) The MongoDB host to read from, formatted as `mongodb://<host>:<port>`. Used in Amazon Glue versions prior to Amazon Glue 4.0.
- `"connection.uri"`: (Required) The MongoDB host to read from, formatted as `mongodb://<host>:<port>`. Used in Amazon Glue 4.0 and later versions.

- "username": (Required) The MongoDB user name.
- "password": (Required) The MongoDB password.
- "database": (Required) The MongoDB database to read from. This option can also be passed in `additional_options` when calling `glue_context.create_dynamic_frame_from_catalog` in your job script.
- "collection": (Required) The MongoDB collection to read from. This option can also be passed in `additional_options` when calling `glue_context.create_dynamic_frame_from_catalog` in your job script.

"connectionType": "mongodb" as source

Use the following connection options with "connectionType": "mongodb" as a source:

- "ssl": (Optional) If `true`, initiates an SSL connection. The default is `false`.
- "ssl.domain_match": (Optional) If `true` and `ssl` is `true`, domain match check is performed. The default is `true`.
- "batchSize": (Optional): The number of documents to return per batch, used within the cursor of internal batches.
- "partitioner": (Optional): The class name of the partitioner for reading input data from MongoDB. The connector provides the following partitioners:
 - `MongoDefaultPartitioner` (default) (Not supported in Amazon Glue 4.0)
 - `MongoSamplePartitioner` (Requires MongoDB 3.2 or later) (Not supported in Amazon Glue 4.0)
 - `MongoShardedPartitioner` (Not supported in Amazon Glue 4.0)
 - `MongoSplitVectorPartitioner` (Not supported in Amazon Glue 4.0)
 - `MongoPaginateByCountPartitioner` (Not supported in Amazon Glue 4.0)
 - `MongoPaginateBySizePartitioner` (Not supported in Amazon Glue 4.0)
 - `com.mongodb.spark.sql.connector.read.partitioners.SinglePartitionPartitioner`
 - `com.mongodb.spark.sql.connector.read.partitioners.ShardedPartitioner`
 - `com.mongodb.spark.sql.connector.read.partitioners.PaginateIntoPartitionsPartitioner`
- "partitionerOptions" (Optional): Options for the designated partitioner. The following options are supported for each partitioner:
 - `MongoSamplePartitioner`: `partitionKey`, `partitionSizeMB`, `samplesPerPartition`

- `MongoShardedPartitioner`: `shardkey`
- `MongoSplitVectorPartitioner`: `partitionKey`, `partitionSizeMB`
- `MongoPaginateByCountPartitioner`: `partitionKey`, `numberOfPartitions`
- `MongoPaginateBySizePartitioner`: `partitionKey`, `partitionSizeMB`

For more information about these options, see [Partitioner Configuration](#) in the MongoDB documentation.

"connectionType": "mongodb" as sink

Use the following connection options with `"connectionType": "mongodb"` as a sink:

- `"ssl"`: (Optional) If `true`, initiates an SSL connection. The default is `false`.
- `"ssl.domain_match"`: (Optional) If `true` and `ssl` is `true`, domain match check is performed. The default is `true`.
- `"extendedBsonTypes"`: (Optional) If `true`, allows extended BSON types when writing data to MongoDB. The default is `true`.
- `"replaceDocument"`: (Optional) If `true`, replaces the whole document when saving datasets that contain an `_id` field. If `false`, only fields in the document that match the fields in the dataset are updated. The default is `true`.
- `"maxBatchSize"`: (Optional): The maximum batch size for bulk operations when saving data. The default is 512.
- `"retryWrites"`: (Optional): Automatically retry certain write operations a single time if Amazon Glue encounters a network error.

SAP HANA connections

You can use Amazon Glue for Spark to read from and write to tables in SAP HANA in Amazon Glue 4.0 and later versions. You can define what to read from SAP HANA with a SQL query. You connect to SAP HANA using JDBC credentials stored in Amazon Secrets Manager through a Amazon Glue SAP HANA connection.

For more information about SAP HANA JDBC, consult [the SAP HANA documentation](#).

Configuring SAP HANA connections

To connect to SAP HANA from Amazon Glue, you will need to create and store your SAP HANA credentials in a Amazon Secrets Manager secret, then associate that secret with a SAP HANA Amazon Glue connection. You will need to configure network connectivity between your SAP HANA service and Amazon Glue.

To connect to SAP HANA, you may need some prerequisites:

- If your SAP HANA service is in an Amazon VPC, configure Amazon VPC to allow your Amazon Glue job to communicate with the SAP HANA service without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that Amazon Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your SAP HANA endpoint and this location. Your job will need to establish a TCP connection with your SAP HANA JDBC port. For more information about SAP HANA ports, see the [SAP HANA documentation](#). Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

- There are no additional prerequisites if your SAP HANA endpoint is internet accessible.

To configure a connection to SAP HANA:

1. In Amazon Secrets Manager, create a secret using your SAP HANA credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key `username/USERNAME` with the value *saphanaUsername*.
 - When selecting **Key/value pairs**, create a pair for the key `password/PASSWORD` with the value *saphanaPassword*.
2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in Amazon Glue.
 - When selecting a **Connection type**, select SAP HANA.
 - When providing **SAP HANA URL**, provide the URL for your instance.

SAP HANA JDBC URLs are in the form

```
jdbc:sap://saphanaHostname:saphanaPort/?databaseName=saphanaDBName,Parameter
```

Amazon Glue requires the following JDBC URL parameters:

- *databaseName* – A default database in SAP HANA to connect to.
- When selecting an **Amazon Secret**, provide *secretName*.

After creating a Amazon Glue SAP HANA connection, you will need to perform the following steps before running your Amazon Glue job:

- Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.
- In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from SAP HANA tables

Prerequisites:

- A SAP HANA table you would like to read from. You will need identification information for the table.

A table can be specified with a SAP HANA table name and schema name, in the form *schemaName.tableName*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *tableIdentifier*. Note that the database is provided as a JDBC URL parameter in *connectionName*.

- A Amazon Glue SAP HANA connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to SAP HANA* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
saphana_read_table = glueContext.create_dynamic_frame.from_options(  
    connection_type="saphana",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableIdentifier",  
    }  
)
```

```
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query.

For example:

```
saphana_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="saphana",  
    connection_options={  
        "connectionName": "connectionName",  
        "query": "query"  
    }  
)
```

Writing to SAP HANA tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to SAP HANA. If the table already has information, Amazon Glue will error.

Prerequisites:

- A SAP HANA table you would like to write to.

A table can be specified with a SAP HANA table name and schema name, in the form *schemaName.tableName*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *tableIdentifier*. Note that the database is provided as a JDBC URL parameter in *connectionName*.

- SAP HANA auth information. Complete the steps in the previous procedure, *To configure a connection to SAP HANA* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
options = {  
    "connectionName": "connectionName",  
    "dbtable": 'tableIdentifier'  
}  
  
saphana_write = glueContext.write_dynamic_frame.from_options(  

```

```
frame=dynamicFrame,  
connection_type="saphana",  
connection_options=options  
)
```

SAP HANA connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a Amazon Glue SAP HANA connection configured to provide auth and networking information to your connection method.
- `databaseName` — Used for Read/Write. Valid Values: names of databases in SAP HANA. Name of database to connect to.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. Valid Values: contents of a SAP HANA SQL FROM clause. Identifies a table in SAP HANA to connect to. You may also provide other SQL than a table name, such as a subquery. For more information, see the [From clause](#) in the SAP HANA documentation.
- `query` — Used for Read. A SAP HANA SQL SELECT query defining what should be retrieved when reading from SAP HANA.

Snowflake connections

You can use Amazon Glue for Spark to read from and write to tables in Snowflake in Amazon Glue 4.0 and later versions. You can read from Snowflake with a SQL query. You can connect to Snowflake using a user and password. You can refer to Snowflake credentials stored in Amazon Secrets Manager through the Amazon Glue Data Catalog. Data Catalog Snowflake credentials for Amazon Glue for Spark are stored separately from Data Catalog Snowflake credentials for crawlers. You must choose a SNOWFLAKE type connection and not a JDBC type connection configured to connect to Snowflake.

For more information about Snowflake, see the [Snowflake website](#). For more information about Snowflake on Amazon, see [Snowflake Data Warehouse on Amazon Web Services](#).

Configuring Snowflake connections

There are no Amazon prerequisites to connecting to Snowflake databases available through the internet.

Optionally, you can perform the following configuration to manage your connection credentials with Amazon Glue.

To manage your connection credentials with Amazon Glue

1. In Snowflake, generate a user, *snowflakeUser* and password, *snowflakePassword*.
2. In Amazon Secrets Manager, create a secret using your Snowflake credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for *snowflakeUser* with the key USERNAME.
 - When selecting **Key/value pairs**, create a pair for *snowflakePassword* with the key PASSWORD.
 - When selecting **Key/value pairs**, you can provide your Snowflake warehouse with the key sfWarehouse.
 - When selecting **Key/value pairs**, you can provide additional Snowflake connection properties using their corresponding Spark property names as keys. Supported properties include:
 - sfDatabase - Snowflake database name
 - sfSchema - Snowflake schema name
 - sfRole - Snowflake role name
 - pem_private_key - Private key for key-pair authentication
3. In the Amazon Glue Data Catalog, create a connection by choosing **Connections**, then **Create connection**. Following the steps in the connection wizard to complete the process:
 - When selecting a **Data source**, select Snowflake, then choose **Next**.
 - Enter the connection details such as host and port. When entering the host **Snowflake URL**, provide the URL of your Snowflake instance. The URL will typically use a hostname in the form *account_identifier*.snowflakecomputing.com. However, the URL format may vary depending on your Snowflake account type (for example, Amazon, Azure, or Snowflake-hosted).
 - When selecting the IAM service role, choose from the drop-down menu. This is the IAM role from your account that will be used to access Amazon Secrets Manager and assign IP if VPC is specified.
 - When selecting an **Amazon Secret**, provide *secretName*.
4. In the next step in the wizard, set properties for your Snowflake connection.

5. In the final step in the wizard, review your settings and then complete the process to create your connection.

In the following situations, you may require the following:

- For Snowflake hosted on Amazon in an Amazon VPC
 - You will need appropriate Amazon VPC configuration for Snowflake. For more information on how to configure your Amazon VPC, consult [Amazon PrivateLink & Snowflake](#) in the Snowflake documentation.
 - You will need appropriate Amazon VPC configuration for Amazon Glue. [the section called “Configuring interface VPC endpoints \(Amazon PrivateLink\) for Amazon Glue”](#).
 - You will need to create a Amazon Glue Data Catalog connection that provides Amazon VPC connection information (in addition to the id of an Amazon Secrets Manager secret that defines your Snowflake security credentials). Your URL will change when using Amazon PrivateLink, as described in the Snowflake documentation linked in a previous item.
 - You will need your job configuration in include the Data Catalog connection as an **Additional network connection**.

Reading from Snowflake tables

Prerequisites: A Snowflake table you would like to read from. You will need the Snowflake table name, *tableName*. You will need your Snowflake url *snowflakeUrl*, username *snowflakeUser* and password *snowflakePassword*. If your Snowflake user does not have a default namespace set, you will need the Snowflake database name, *databaseName* and the schema name *schemaName*. Additionally, if your Snowflake user does not have a default warehouse set, you will need a warehouse name *warehouseName*.

For example:

Additional Prerequisites: Complete the steps *To manage your connection credentials with Amazon Glue* to configure *snowflakeUrl*, *snowflakeUsername* and *snowflakePassword*. To review these steps, see [the section called “Configuring Snowflake”](#), the previous section. To select which **Additional network connection** to connect with, we will use the *connectionName* parameter.

```
snowflake_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="snowflake",  
    connection_options={
```

```

        "connectionName": "connectionName",
        "dbtable": "tableName",
        "sfDatabase": "databaseName",
        "sfSchema": "schemaName",
        "sfWarehouse": "warehouseName",
    }
)

```

Additionally, you can use the autopushdown and query parameters to read a portion of a Snowflake table. This can be substantially more efficient than filtering your results after they have been loaded into Spark. Consider an example where all sales are stored in the same table, but you only need to analyze sales from a certain store on holidays. If that information is stored in the table, you could use predicate pushdown to retrieve the results as follows:

```

snowflake_node = glueContext.create_dynamic_frame.from_options(
    connection_type="snowflake",
    connection_options={
        "autopushdown": "on",
        "query": "select * from sales where store='1' and IsHoliday='TRUE'",
        "connectionName": "snowflake-glue-conn",
        "sfDatabase": "databaseName",
        "sfSchema": "schemaName",
        "sfWarehouse": "warehouseName",
    }
)

```

Writing to Snowflake tables

Prerequisites: A Snowflake database you would like to write to. You will need a current or desired table name, *tableName*. You will need your Snowflake url *snowflakeUrl*, username *snowflakeUser* and password *snowflakePassword*. If your Snowflake user does not have a default namespace set, you will need the Snowflake database name, *databaseName* and the schema name *schemaName*. Additionally, if your Snowflake user does not have a default warehouse set, you will need a warehouse name *warehouseName*.

For example:

Additional Prerequisites: Complete the steps *To manage your connection credentials with Amazon Glue* to configure *snowflakeUrl*, *snowflakeUsername* and *snowflakePassword*. To review these steps, see [the section called "Configuring Snowflake"](#), the previous section. To select which **Additional network connection** to connect with, we will use the *connectionName* parameter.

```
glueContext.write_dynamic_frame.from_options(  
    connection_type="snowflake",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableName",  
        "sfDatabase": "databaseName",  
        "sfSchema": "schemaName",  
        "sfWarehouse": "warehouseName",  
    },  
)
```

Snowflake connection option reference

The Snowflake connection type takes the following connection options:

You can retrieve some of the parameters in this section from a Data Catalog connection (sfUrl, sfUser, sfPassword), in which case you are not required to provide them. You can do this by providing the parameter connectionName.

You can retrieve connection parameters from Amazon Secrets Manager secrets using the secretId parameter. When using Secrets Manager, the following Spark properties can be automatically retrieved if present in the secret:

- sfUser (using key USERNAME or sfUser)
- sfPassword (using key PASSWORD or sfPassword)
- sfWarehouse (using key sfWarehouse)
- sfDatabase (using key sfDatabase)
- sfSchema (using key sfSchema)
- sfRole (using key sfRole)
- pem_private_key (using key pem_private_key)

Property Precedence Order: When the same property is specified in multiple locations, Amazon Glue uses the following precedence order (highest to lowest):

1. Explicitly provided connection options in your job code
2. Data Catalog connection properties
3. Amazon Secrets Manager secret values (when secretId is specified)

4. Snowflake user defaults

The following parameters are used generally when connecting to Snowflake.

- `sfDatabase` — Required if a user default is not set in Snowflake. Used for Read/Write. The database to use for the session after connecting.
- `sfSchema` — Required if a user default is not set in Snowflake. Used for Read/Write. The schema to use for the session after connecting.
- `sfWarehouse` — Required if a user default is not set in Snowflake. Used for Read/Write. The default virtual warehouse to use for the session after connecting.
- `sfRole` — Required if a user default is not set in Snowflake. Used for Read/Write. The default security role to use for the session after connecting.
- `sfUrl` — (Required) Used for Read/Write. Specifies the hostname for your account in the following format: `account_identifier.snowflakecomputing.com`. For more information about account identifiers, see [Account Identifiers](#) in the Snowflake documentation.
- `sfUser` — (Required) Used for Read/Write. Login name for the Snowflake user.
- `sfPassword` — (Required unless `pem_private_key` provided) Used for Read/Write. Password for the Snowflake user.
- `dbtable` — Required when working with full tables. Used for Read/Write. The name of the table to be read or the table to which data is written. When reading, all columns and records are retrieved.
- `pem_private_key` — Used for Read/Write. An unencrypted b64-encoded private key string. The private key for the Snowflake user. It is common to copy this out of a PEM file. For more information, see [Key-pair authentication and key-pair rotation](#) in the Snowflake documentation.
- `query` — Required when reading with a query. Used for Read. The exact query (SELECT statement) to run

The following options are used to configure specific behaviors during the process of connecting to Snowflake.

- `preactions` — Used for Read/Write. Valid Values: Semicolon separated list of SQL statements as String. SQL statements run before data is transferred between Amazon Glue and Snowflake. If a statement contains `%s`, the `%s` is replaced with the table name referenced for the operation.

- **postactions** — Used for Read/Write. SQL statements run after data is transferred between Amazon Glue and Snowflake. If a statement contains %s, the %s is replaced with the table name referenced for the operation.
- **autopushdown** — Default: "on". Valid Values: "on", "off". This parameter controls whether automatic query pushdown is enabled. If pushdown is enabled, then when a query is run on Spark, if part of the query can be "pushed down" to the Snowflake server, it is pushed down. This improves performance of some queries. For information about whether your query can be pushed down, consult [Pushdown](#) in the Snowflake documentation.

Additionally, some of the options available on the Snowflake Spark connector may be supported in Amazon Glue. For more information about options available on the Snowflake Spark connector, see [Setting Configuration Options for the Connector](#) in the Snowflake documentation.

Snowflake authentication methods

Amazon Glue supports the following authentication methods for connecting to Snowflake:

- **Username and Password Authentication:** Provide `sfUser` and `sfPassword` parameters.
- **Key-Pair Authentication:** Provide `sfUser` and `pem_private_key` parameters. When using key-pair authentication, the `sfPassword` parameter is not required.

Both authentication methods are fully supported and can be configured using any combination of connection options, Data Catalog connections, or Amazon Secrets Manager secrets.

Snowflake connector limitations

Connecting to Snowflake with Amazon Glue for Spark is subject to the following limitations.

- This connector does not support job bookmarks. For more information about job bookmarks, see [the section called "Tracking processed data using job bookmarks"](#).
- This connector does not support Snowflake reads and writes through tables in the Amazon Glue Data Catalog using the `create_dynamic_frame.from_catalog` and `write_dynamic_frame.from_catalog` methods.
- This connector supports username/password authentication and key-pair authentication. Other authentication methods (such as OAuth or SAML) are not currently supported.
- This connector is not supported within streaming jobs.

- This connector supports SELECT statement based queries when retrieving information (such as with the query parameter). Other kind of queries (such as SHOW, DESC, or DML statements) are not supported.
- Snowflake limits the size of query text (i.e. SQL statements) submitted through Snowflake clients to 1 MB per statement. For more details, see [Limits on Query Text Size](#).

Teradata Vantage connections

You can use Amazon Glue for Spark to read from and write to existing tables in Teradata Vantage in Amazon Glue 4.0 and later versions. You can define what to read from Teradata with a SQL query. You can connect to Teradata using username and password credentials stored in Amazon Secrets Manager through a Amazon Glue connection.

For more information about Teradata, consult the [Teradata documentation](#)

Configuring Teradata connections

To connect to Teradata from Amazon Glue, you will need to create and store your Teradata credentials in an Amazon Secrets Manager secret, then associate that secret with a Amazon Glue Teradata connection. If your Teradata instance is in an Amazon VPC, you will also need to provide networking options to your Amazon Glue Teradata connection.

To connect to Teradata from Amazon Glue, you may need some prerequisites:

- If you are accessing your Teradata environment through Amazon VPC, configure Amazon VPC to allow your Amazon Glue job to communicate with the Teradata environment. We discourage accessing the Teradata environment over the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that Amazon Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Teradata instance and this location. Your job will need to establish a TCP connection with your Teradata client port. For more information about Teradata ports, see the [Teradata documentation](#).

Based on your network layout, secure VPC connectivity may require changes in Amazon VPC and other networking services. For more information about Amazon connectivity, consult [Amazon Connectivity Options](#) in the Teradata documentation.

To configure a Amazon Glue Teradata connection:

1. In your Teradata configuration, identify or create a user and password Amazon Glue will connect with, *teradataUser* and *teradataPassword*. For more information, consult [Vantage Security Overview](#) in the Teradata documentation.
2. In Amazon Secrets Manager, create a secret using your Teradata credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key user with the value *teradataUsername*.
 - When selecting **Key/value pairs**, create a pair for the key password with the value *teradataPassword*.
3. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
 - When selecting a **Connection type**, select Teradata.
 - When providing **JDBC URL**, provide the URL for your instance. You can also hardcode certain comma separated connection parameters in your JDBC URL. The URL must conform to the following format:
`jdbc:teradata://teradataHostname/ParameterName=ParameterValue,ParameterName`

Supported URL parameters include:

 - DATABASE– name of database on host to access by default.
 - DBS_PORT– the database port, used when running on a nonstandard port.
 - When selecting a **Credential type**, select **Amazon Secrets Manager**, then set **Amazon Secret** to *secretName*.
4. In the following situations, you may require additional configuration:
 - For Teradata instances hosted on Amazon in an Amazon VPC
 - You will need to provide Amazon VPC connection information to the Amazon Glue connection that defines your Teradata security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a Amazon Glue Teradata connection, you will need to perform the following steps before calling your connection method.

- Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.
- In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from Teradata

Prerequisites:

- A Teradata table you would like to read from. You will need the table name, *tableName*.
- A Amazon Glue Teradata connection configured to provide auth information. Complete the steps *To configure a connection to Teradata* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
teradata_read_table = glueContext.create_dynamic_frame.from_options(  
    connection_type="teradata",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableName"  
    }  
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query.

For example:

```
teradata_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="teradata",  
    connection_options={  
        "connectionName": "connectionName",  
        "query": "query"  
    }  
)
```

Writing to Teradata tables

Prerequisites: A Teradata table you would like to write to, *tableName*. **You must create the table before calling the connection method.**

For example:

```
teradata_write = glueContext.write_dynamic_frame.from_options(  
    connection_type="teradata",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableName"  
    }  
)
```

Teradata connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a Amazon Glue Teradata connection configured to provide auth and networking information to your connection method.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. The name of a table your connection method will interact with.
- `query` — Used for Read. A SELECT SQL query defining what should be retrieved when reading from Teradata.

Teradata Vantage NOS connections

Teradata NOS (Native Object Store) connection is a new connection for Teradata Vantage which leverages Teradata WRITE_NOS query to read from existing tables and READ_NOS query to write to tables. These queries uses Amazon S3 as a staging directory, and therefore the Teradata NOS connector is faster than the existing Teradata connector (JDBC-based) especially in handling large amount of data.

You can use the Teradata NOS connection in Amazon Glue for Spark to read from and write to existing tables in Teradata Vantage in Amazon Glue 5.0 and later versions. You can define what to read from Teradata with a SQL query. You can connect to Teradata using username and password credentials stored in Amazon Secrets Manager through a Amazon Glue connection.

For more information about Teradata, consult the [Teradata documentation](#).

Topics

- [Creating a Teradata NOS connection](#)
- [Reading from Teradata tables](#)
- [Writing to Teradata tables](#)
- [Teradata connection option reference](#)
- [Provide Options in Amazon Glue Visual ETL UI](#)

Creating a Teradata NOS connection

To connect to Teradata NOS from Amazon Glue, you will need to create and store your Teradata credentials in an Amazon Secrets Manager secret, then associate that secret with a Amazon Glue Teradata NOS connection. If your Teradata instance is in an Amazon VPC, you will also need to provide networking options to your Amazon Glue Teradata NOS connection.

Prerequisites:

- If you are accessing your Teradata environment through Amazon VPC, configure Amazon VPC to allow your Amazon Glue job to communicate with the Teradata environment. We discourage accessing the Teradata environment over the public internet.
- In Amazon VPC, identify or create a VPC, Subnet and Security group that Amazon Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Teradata instance and this location. Your job will need to establish a TCP connection with your Teradata client port. For more information about Teradata ports, see the [Security Groups for Teradata Vantage](#).
- Based on your network layout, secure VPC connectivity may require changes in Amazon VPC and other networking services. For more information about Amazon connectivity, see [Amazon Connectivity Options](#) in the Teradata documentation.

To configure a Amazon Glue Teradata NOS connection:

1. In your Teradata configuration, identify or create a *teradataUsername* and *teradataPassword* Amazon Glue will connect with. For more information, see [Vantage Security Overview](#) in the Teradata documentation.
2. In Amazon Secrets Manager, create a secret using your Teradata credentials. To create a secret in Amazon Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret in the Amazon Secrets Manager](#) documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

- When selecting Key/value pairs, create a pair for the key USERNAME with the value *teradataUsername*.
 - When selecting Key/value pairs, create a pair for the key PASSWORD with the value *teradataPassword*.
3. In the Amazon Glue console, create a connection by following the steps in [Adding an Amazon Glue connection](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
- When selecting a **Connection type**, select Teradata Vantage NOS.
 - When providing JDBC URL, provide the URL for your instance. You can also hardcode certain comma separated connection parameters in your JDBC URL. The URL must conform to the following format: `jdbc:teradata://teradataHostname/ParameterName=ParameterValue,ParameterName=ParameterValue`.
 - Supported URL parameters include:
 - DATABASE– name of database on host to access by default.
 - DBS_PORT– the database port, used when running on a nonstandard port.
 - When selecting a **Credential type**, select Amazon Secrets Manager, then set **Amazon Secret** to *secretName*.
4. In the following situations, you may require additional configuration:
- For Teradata instances hosted on Amazon in an Amazon VPC, you will need to provide Amazon VPC connection information to the Amazon Glue connection that defines your Teradata security credentials. When creating or updating your connection, set **VPC**, **Subnet**, and **Security groups** in **Network options**.

After creating a Amazon Glue Teradata Vantage NOS connection, you will need to perform the following steps before calling your connection method.

1. Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.
2. In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection** Under **Connections**.

Reading from Teradata tables

Prerequisites:

- A Teradata table you would like to read from. You will need the table name, *tableName*.
- The Teradata environment has write access to the Amazon S3 path specified by `staging_fs_url` option, *stagingFsUrl*.
- The IAM role associated with Amazon Glue job has write access to the Amazon S3 location specified by `staging_fs_url` option.
- An Amazon Glue Teradata NOS connection configured to provide auth information. Complete the steps [To configure a Amazon Glue Teradata NOS connection](#): to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

Example:

```
teradata_read_table = glueContext.create_dynamic_frame.from_options(  
    connection_type= "teradatanos",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableName",  
        "staging_fs_url": "stagingFsUrl"  
    }  
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query. If you configure both `dbTable` and `query`, the connector fails to read the data. For example:

```
teradata_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="teradatanos",  
    connection_options={  
        "connectionName": "connectionName",  
        "query": "query",  
        "staging_fs_url": "stagingFsUrl"  
    }  
)
```

Additionally, you can use Spark DataFrame API to read from Teradata tables. For example:

```
options = {
  "url": "JDBC_URL",
  "dbtable": "tableName",
  "user": "teradataUsername", # or use "username" as key here
  "password": "teradataPassword",
  "staging_fs_url": "stagingFsUrl"
}
teradata_read_table = spark.read.format("teradata").option(**options).load()
```

Writing to Teradata tables

Prerequisites

- A Teradata table you would like to write to: *tableName*.
- The Teradata environment has read access to the Amazon S3 location specified by `staging_fs_url` option, *stagingFsUrl*.
- The IAM role associated with Amazon Glue job has write access to the Amazon S3 location specified by `staging_fs_url` option.
- An Amazon Glue Teradata connection configured to provide auth information. Complete the steps in [To configure a Amazon Glue Teradata NOS connection](#): to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.

For example:

```
teradata_write = glueContext.write_dynamic_frame.from_options(
  frame=dynamicFrame,
  connection_type= "teradata",
  connection_options={
    "connectionName": "connectionName",
    "dbtable": "tableName",
    "staging_fs_url": "stagingFsUrl"
  }
)
```

Teradata connection option reference

Connection and Operation Options:

- `connectionName` — Required. Used for Read/Write. The name of an Amazon Glue Teradata connection configured to provide auth and networking information to your connection method.
- `staging_fs_url` — Required. Used for Read/Write. A writable location in Amazon S3, to be used for unloaded data when reading from Teradata, and for Parquet data to be loaded into Redshift when writing to Teradata. The S3 bucket must be in the same region as the region of your Amazon Glue jobs.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. The name of a table your connection method will interact with.
- `query` — Used for Read. A SELECT SQL query defining what should be retrieved when reading from Teradata. You can not pass if `dbtable` option is provided.
- `clean_staging_s3_dir` — Optional. Used for Read/Write. If true, clean up the staging Amazon S3 objects after a read or a write. The default value is true.
- `pre_actions` — Optional. Used for Write. Semicolon-separated list of SQL commands that are executed before data is transferred between Spark and Teradata Vantage.
- `post_actions` — Optional. Used for Write. Semicolon-separated list of SQL commands that are executed after data is transferred between Spark and Teradata Vantage.
- `truncate` — Optional. Used for Write. If true, the connector truncates the table when writing in overwrite mode. If false, the connector drops the table when writing in overwrite mode. The default value is false.
- `create_table_script` — Optional. Used for Write. An SQL statement to create table when writing to Teradata Vantage. Useful when you want to create a table with custom metadata (e.g. CREATE MULTISET or SET table or change primary index). Note that the table name used in create table script should match with the table name specified in `dbtable` option.
- `partition_size_in_mb` — Optional. Used for Read. Maximum size of a Spark partition in megabytes while reading staging Amazon S3 objects. The default value is 128.

You can provide advanced options when creating a Teradata node. These options are the same as those available when programming Amazon Glue for Spark scripts.

See [the section called “Teradata Vantage connections”](#).

Authorization Options:

Below are options used to provide Amazon account credentials that the connector uses to access the staging Amazon S3 bucket. You can choose to (1) not provide any authorization options

at all, and use temporary credentials generated from your Amazon Glue execution role; or (2) provide an authorization object, `auth_object` you created; or (3) provide `aws_access_key_id` and `aws_secret_access_key` if using long term credentials, or provide `aws_access_key`, `aws_secret_access_key`, and `aws_session_token` if using temporary credentials.

- `auth_object` – Optional. Used for accessing the staging Amazon S3 bucket. An authorization object string created in Teradata instance. If provided, the connector will use this authorization object to access the staging Amazon S3 bucket. If not provided, and `aws_access_key_id` and `aws_secret_access_key` are also not provided, a temporary credential will be retrieved from Amazon Glue execution role and used by the connector. The Amazon account associated with this authorization object must be in the same region as your Amazon Glue jobs and your staging Amazon S3 bucket or configured with cross account trust.
- `aws_access_key_id` – Optional. Used for accessing the staging Amazon S3 bucket. Part of an Amazon account security credential. If `auth_object` is not provided, and `aws_access_key_id` is provided with `aws_secret_access_key`, the connector will use them to access staging Amazon S3 bucket. The Amazon account associated with this access key must be in the same region as your Amazon Glue jobs and your staging Amazon S3 bucket or configured with cross account trust.
- `aws_secret_access_key` – Optional. Used for accessing the staging Amazon S3 bucket. Part of an Amazon account security credential. If `auth_object` is not provided, and `aws_secret_access_key` is provided with `aws_access_key_id`, the connector will use them to access staging Amazon S3 bucket. The Amazon account associated with this secret key must be in the same region as your Amazon Glue jobs and your staging Amazon S3 bucket or configured with cross account trust.
- `aws_session_token` – Optional. Used for accessing the staging Amazon S3 bucket. Part of a temporary Amazon account security credential. Should be provided with `aws_access_key_id` and `aws_secret_access_key`.

Provide Options in Amazon Glue Visual ETL UI

You can provide all above options in your visual ETL job UI. For `connectionName` option, you should choose it from the Teradata Vantage NOS connection drop down list. For all other options, you should provide them through the Custom Teradata Vantage NOS properties as key value pairs.

Teradata Vantage NOS connection

Choose the AWS Glue connection for Teradata Vantage NOS, or [create a new connection](#).

Choose your Teradata Vantage NOS connection ↕ ↻

▼ Custom Teradata Vantage NOS properties

| Key | Value | |
|-------------------------|---------------------------|--------|
| staging_fs_url | s3://your_staging_bucket/ | Remove |
| dbtable | your_table | Remove |
| Add row | | |

Vertica connections

You can use Amazon Glue for Spark to read from and write to tables in Vertica in Amazon Glue 4.0 and later versions. You can define what to read from Vertica with a SQL query. You connect to Vertica using username and password credentials stored in Amazon Secrets Manager through a Amazon Glue connection.

For more information about Vertica, consult the [Vertica documentation](#).

Configuring Vertica connections

To connect to Vertica from Amazon Glue, you will need to create and store your Vertica credentials in a Amazon Secrets Manager secret, then associate that secret with a Vertica Amazon Glue connection. If your Vertica instance is in an Amazon VPC, you will also need to provide networking options to your Amazon Glue Vertica connection. You will need an Amazon S3 bucket or folder to use for temporary storage when reading from and writing to the database.

To connect to Vertica from Amazon Glue, you will need some prerequisites:

- An Amazon S3 bucket or folder to use for temporary storage when reading from and writing to the database, referred to by *tempS3Path*.

i Note

When using Vertica in Amazon Glue job data previews, temporary files may not be automatically removed from *tempS3Path*. To ensure the removal of temporary files, directly end the data preview session by choosing **End session** in the **Data preview** pane.

If you cannot guarantee the data preview session is ended directly, consider setting Amazon S3 Lifecycle configuration to remove old data. We recommend removing data older than 49 hours, based on maximum job runtime plus a margin. For more information about configuring Amazon S3 Lifecycle, see [Managing your storage lifecycle](#) in the Amazon S3 documentation.

- An IAM policy with appropriate permissions to your Amazon S3 path you can associate with your Amazon Glue job role.
- If your Vertica instance is in an Amazon VPC, configure Amazon VPC to allow your Amazon Glue job to communicate with the Vertica instance without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that Amazon Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Vertica instance and this location. Your job will need to establish a TCP connection with your Vertica client port, (default 5433). Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

You can then proceed to configure Amazon Glue for use with Vertica.

To configure a connection to Vertica:

1. In Amazon Secrets Manager, create a secret using your Vertica credentials, *verticaUsername* and *verticaPassword*. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key user with the value *verticaUsername*.
 - When selecting **Key/value pairs**, create a pair for the key password with the value *verticaPassword*.
2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
 - When selecting a **Connection type**, select Vertica.
 - When selecting **Vertica Host**, provide the hostname of your Vertica installation.

- When selecting **Vertica Port**, the port your Vertica installation is available through.
 - When selecting an **Amazon Secret**, provide *secretName*.
3. In the following situations, you may require additional configuration:
- For Vertica instances hosted on Amazon in an Amazon VPC
 - Provide Amazon VPC connection information to the Amazon Glue connection that defines your Vertica security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a Amazon Glue Vertica connection, you will need to perform the following steps before calling your connection method.

- Grant the IAM role associated with your Amazon Glue job permissions to *tempS3Path*.
- Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.
- In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from Vertica

Prerequisites:

- A Vertica table you would like to read from. You will need the Vertica database name, *dbName* and the table name, *tableName*.
- A Amazon Glue Vertica connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to Vertica* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.
- A Amazon S3 bucket or folder to use for temporary storage, mentioned previously. You will need the name, *tempS3Path*. You will need to connect to this location using the s3a protocol.

For example:

```
dynamicFrame = glueContext.create_dynamic_frame.from_options(  
    connection_type="vertica",  
    connection_options={  
        "connectionName": "connectionName",  
        "staging_fs_url": "s3a://tempS3Path",
```

```
        "db": "dbName",
        "table": "tableName",
    }
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame or to access a dataset from multiple tables.

For example:

```
dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="vertica",
    connection_options={
        "connectionName": "connectionName",
        "staging_fs_url": "s3a://tempS3Path",
        "db": "dbName",
        "query": "select * FROM tableName",
    },
)
```

Writing to Vertica tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to Vertica. If the table already has information, Amazon Glue will append data from your DynamicFrame.

Prerequisites:

- A current or desired table name, *tableName*, you would like to write to. You will also need the corresponding Vertica database name, *dbName*.
- A Amazon Glue Vertica connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to Vertica* to configure your auth information. You will need the name of the Amazon Glue connection, *connectionName*.
- A Amazon S3 bucket or folder to use for temporary storage, mentioned previously. You will need the name, *tempS3Path*. You will need to connect to this location using the s3a protocol.

For example:

```
glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="vertica",
```

```
connection_options={
  "connectionName": "connectionName",
  "staging_fs_url": "s3a://tempS3Path",
  "db": "dbName",
  "table": "tableName",
}
)
```

Vertica connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a Amazon Glue Vertica connection configured to provide auth and networking information to your connection method.
- `db` — Required. Used for Read/Write. The name of a database in Vertica your connection method will interact with.
- `dbSchema` — Required if needed to identify your table. Used for Read/Write. Default: `public`. The name of a schema your connection method will interact with.
- `table` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. The name of a table your connection method will interact with.
- `query` — Used for Read. A SELECT SQL query defining what should be retrieved when reading from Teradata.
- `staging_fs_url` — Required. Used for Read/Write. Valid Values: s3a URLs. The URL of a Amazon S3 bucket or folder to use for temporary storage.

DataFrame options for ETL in Amazon Glue 5.0 for Spark

A DataFrame is a Dataset organized into named columns similar to a table and supports functional-style (map/reduce/filter/etc.) operations and SQL operations (select, project, aggregate).

To create a DataFrame for a data source supported by Glue, the following are required:

- data source connector `ClassName`
- data source connection `Options`

Similarly, to write a DataFrame to a data sink supported by Glue, the same are required:

- data sink connector `ClassName`
- data sink connection `Options`

Note that Amazon Glue features such as job bookmarks and DynamicFrame options such as `connectionName` are not supported in DataFrame. For more details about DataFrame and the supported operations, see the Spark documentation for [DataFrame](#).

Specifying the connector ClassName

To specify the `ClassName` of a data source/sink, use the `.format` option to provide the corresponding connector `ClassName` that defines the data source/sink.

JDBC connectors

For JDBC connectors, specify `jdbc` as the value of the `.format` option and provide the JDBC driver `ClassName` in the `driver` option.

```
df = spark.read.format("jdbc").option("driver", "<DATA SOURCE JDBC DRIVER
CLASSNAME>")...

df.write.format("jdbc").option("driver", "<DATA SINK JDBC DRIVER CLASSNAME>")...
```

The following table lists the JDBC driver `ClassName` of the supported data source in Amazon Glue for DataFrames.

| Data source | Driver ClassName |
|-------------|---|
| PostgreSQL | <code>org.postgresql.Driver</code> |
| Oracle | <code>oracle.jdbc.driver.OracleDriver</code> |
| SQLServer | <code>com.microsoft.sqlserver.jdbc.SQLServerDriver</code> |
| MySQL | <code>com.mysql.jdbc.Driver</code> |
| SAPHana | <code>com.sap.db.jdbc.Driver</code> |
| Teradata | <code>com.teradata.jdbc.TeraDriver</code> |

Spark connectors

For spark connectors, specify the `ClassName` of the connector as the value of the `.format` option.

```
df = spark.read.format("<DATA SOURCE CONNECTOR CLASSNAME>")...  
  
df.write.format("<DATA SINK CONNECTOR CLASSNAME>")...
```

The following table lists the Spark connector `ClassName` of the supported data source in Amazon Glue for DataFrames.

| Data source | ClassName |
|--------------------|---|
| MongoDB/DocumentDB | glue.spark.mongodb |
| Redshift | io.github.spark_redshift_community.spark.redshift |
| AzureCosmos | cosmos.oltp |
| AzureSQL | com.microsoft.sqlserver.jdbc.spark |
| BigQuery | com.google.cloud.spark.bigquery |
| OpenSearch | org.opensearch.spark.sql |
| Snowflake | net.snowflake.spark.snowflake |
| Vertica | com.vertica.spark.datasource.VerticaSource |

Specifying the connection Options

To specify the `Options` of the connection to a data source/sink, use the `.option(<KEY>, <VALUE>)` to provide individual options or `.options(<MAP>)` to provide multiple options as a key-value map.

Each data source/sink supports its own set of connection `Options`. For details on the available `Options`, refer to the public documentation of the specific data source/sink Spark connector listed in the following table.

- [JDBC](#)
- [MongoDB/DocumentDB](#)
- [Redshift](#)

- [AzureCosmos](#)
- [AzureSQL](#)
- [BigQuery](#)
- [OpenSearch](#)
- [Snowflake](#)
- [Vertica](#)

Examples

The following examples read from PostgreSQL and write into Snowflake:

Python

Example:

```
from awsglue.context import GlueContext
from pyspark.sql import SparkSession

spark = SparkSession.builder.getOrCreate()

dataSourceClassName = "jdbc"
dataSourceOptions = {
    "driver": "org.postgresql.Driver",
    "url": "<url>",
    "user": "<user>",
    "password": "<password>",
    "dbtable": "<dbtable>",
}

dataframe = spark.read.format(className).options(**options).load()

dataSinkClassName = "net.snowflake.spark.snowflake"
dataSinkOptions = {
    "sfUrl": "<url>",
    "sfUsername": "<username>",
    "sfPassword": "<password>",
    "sfDatabase" -> "<database>",
    "sfSchema" -> "<schema>",
    "sfWarehouse" -> "<warehouse>"
}
```

```
dataframe.write.format(dataSinkClassName).options(**dataSinkOptions).save()
```

Scala

Example:

```
import org.apache.spark.sql.SparkSession

val spark = SparkSession.builder().getOrCreate()

val dataSourceClassName = "jdbc"
val dataSourceOptions = Map(
  "driver" -> "org.postgresql.Driver",
  "url" -> "<url>",
  "user" -> "<user>",
  "password" -> "<password>",
  "dbtable" -> "<dbtable>"
)

val dataframe =
  spark.read.format(dataSourceClassName).options(dataSourceOptions).load()

val dataSinkClassName = "net.snowflake.spark.snowflake"
val dataSinkOptions = Map(
  "sfUrl" -> "<url>",
  "sfUsername" -> "<username>",
  "sfPassword" -> "<password>",
  "sfDatabase" -> "<database>",
  "sfSchema" -> "<schema>",
  "sfWarehouse" -> "<warehouse>"
)

dataframe.write.format(dataSinkClassName).options(dataSinkOptions).save()
```

Custom and Amazon Web Services Marketplace connectionType values

These include the following:

- "connectionType": "marketplace.athena": Designates a connection to an Amazon Athena data store. The connection uses a connector from Amazon Web Services Marketplace.
- "connectionType": "marketplace.spark": Designates a connection to an Apache Spark data store. The connection uses a connector from Amazon Web Services Marketplace.

- "connectionType": "marketplace.jdbc": Designates a connection to a JDBC data store. The connection uses a connector from Amazon Web Services Marketplace.
- "connectionType": "custom.athena": Designates a connection to an Amazon Athena data store. The connection uses a custom connector that you upload to Amazon Glue Studio.
- "connectionType": "custom.spark": Designates a connection to an Apache Spark data store. The connection uses a custom connector that you upload to Amazon Glue Studio.
- "connectionType": "custom.jdbc": Designates a connection to a JDBC data store. The connection uses a custom connector that you upload to Amazon Glue Studio.

Connection options for type custom.jdbc or marketplace.jdbc

- `className` – String, required, driver class name.
- `connectionName` – String, required, name of the connection that is associated with the connector.
- `url` – String, required, JDBC URL with placeholders (`{}`) which are used to build the connection to the data source. The placeholder `{secretKey}` is replaced with the secret of the same name in Amazon Secrets Manager. Refer to the data store documentation for more information about constructing the URL.
- `secretId` or `user/password` – String, required, used to retrieve credentials for the URL.
- `dbTable` or `query` – String, required, the table or SQL query to get the data from. You can specify either `dbTable` or `query`, but not both.
- `partitionColumn` – String, optional, the name of an integer column that is used for partitioning. This option works only when it's included with `lowerBound`, `upperBound`, and `numPartitions`. This option works the same way as in the Spark SQL JDBC reader. For more information, see [JDBC To Other Databases](#) in the *Apache Spark SQL, DataFrames and Datasets Guide*.

The `lowerBound` and `upperBound` values are used to decide the partition stride, not for filtering the rows in table. All rows in the table are partitioned and returned.

Note

When using a query instead of a table name, you should validate that the query works with the specified partitioning condition. For example:

- If your query format is "SELECT col1 FROM table1", then test the query by appending a WHERE clause at the end of the query that uses the partition column.
- If your query format is "SELECT col1 FROM table1 WHERE col2=val", then test the query by extending the WHERE clause with AND and an expression that uses the partition column.

- `lowerBound` – Integer, optional, the minimum value of `partitionColumn` that is used to decide partition stride.
- `upperBound` – Integer, optional, the maximum value of `partitionColumn` that is used to decide partition stride.
- `numPartitions` – Integer, optional, the number of partitions. This value, along with `lowerBound` (inclusive) and `upperBound` (exclusive), form partition strides for generated WHERE clause expressions that are used to split the `partitionColumn`.

Important

Be careful with the number of partitions because too many partitions might cause problems on your external database systems.

- `filterPredicate` – String, optional, extra condition clause to filter data from source. For example:

```
BillingCity='Mountain View'
```

When using a *query* instead of a *table* name, you should validate that the query works with the specified `filterPredicate`. For example:

- If your query format is "SELECT col1 FROM table1", then test the query by appending a WHERE clause at the end of the query that uses the filter predicate.
- If your query format is "SELECT col1 FROM table1 WHERE col2=val", then test the query by extending the WHERE clause with AND and an expression that uses the filter predicate.
- `dataTypeMapping` – Dictionary, optional, custom data type mapping that builds a mapping from a **JDBC** data type to a **Glue** data type. For example, the option "dataTypeMapping": {"FLOAT": "STRING"} maps data fields of JDBC type FLOAT into the Java String type by calling the `ResultSet.getString()` method of the driver, and uses it to build Amazon Glue records. The `ResultSet` object is implemented by each driver, so the behavior is specific to the

driver you use. Refer to the documentation for your JDBC driver to understand how the driver performs the conversions.

- The Amazon Glue data types supported currently are:
 - DATE
 - STRING
 - TIMESTAMP
 - INT
 - FLOAT
 - LONG
 - BIGDECIMAL
 - BYTE
 - SHORT
 - DOUBLE

The JDBC data types supported are [Java8 java.sql.types](#).

The default data type mappings (from JDBC to Amazon Glue) are:

- DATE -> DATE
- VARCHAR -> STRING
- CHAR -> STRING
- LONGNVARCHAR -> STRING
- TIMESTAMP -> TIMESTAMP
- INTEGER -> INT
- FLOAT -> FLOAT
- REAL -> FLOAT
- BIT -> BOOLEAN
- BOOLEAN -> BOOLEAN
- BIGINT -> LONG
- DECIMAL -> BIGDECIMAL
- NUMERIC -> BIGDECIMAL

- TINYINT -> SHORT
- SMALLINT -> SHORT

- DOUBLE -> DOUBLE

If you use a custom data type mapping with the option `dataTypeMapping`, then you can override a default data type mapping. Only the JDBC data types listed in the `dataTypeMapping` option are affected; the default mapping is used for all other JDBC data types. You can add mappings for additional JDBC data types if needed. If a JDBC data type is not included in either the default mapping or a custom mapping, then the data type converts to the Amazon Glue `STRING` data type by default.

The following Python code example shows how to read from JDBC databases with Amazon Web Services Marketplace JDBC drivers. It demonstrates reading from a database and writing to an S3 location.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)
## @type: DataSource
## @args: [connection_type = "marketplace.jdbc", connection_options =
{"dataTypeMapping":{"INTEGER":"STRING"},"upperBound":"200","query":"select id,
name, department from department where id < 200","numPartitions":"4",
"partitionColumn":"id","lowerBound":"0","connectionName":"test-connection-
jdbc"},
transformation_ctx = "DataSource0"]
## @return: DataSource0
## @inputs: []
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
"marketplace.jdbc", connection_options = {"dataTypeMapping":{"INTEGER":"STRING"},
"upperBound":"200","query":"select id, name, department from department where
id < 200","numPartitions":"4","partitionColumn":"id","lowerBound":"0",
```

```

    "connectionName":"test-connection-jdbc"}, transformation_ctx = "DataSource0")
## @type: ApplyMapping
## @args: [mappings = [("department", "string", "department", "string"), ("name",
"string",
    "name", "string"), ("id", "int", "id", "int")], transformation_ctx =
"Transform0"]
## @return: Transform0
## @inputs: [frame = DataSource0]
Transform0 = ApplyMapping.apply(frame = DataSource0, mappings = [("department",
"string",
    "department", "string"), ("name", "string", "name", "string"), ("id", "int",
"id", "int")],
    transformation_ctx = "Transform0")
## @type: DataSink
## @args: [connection_type = "s3", format = "json", connection_options = {"path":
"s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0"]
## @return: DataSink0
## @inputs: [frame = Transform0]
DataSink0 = glueContext.write_dynamic_frame.from_options(frame = Transform0,
    connection_type = "s3", format = "json", connection_options = {"path":
"s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0")
job.commit()

```

Connection options for type `custom.athena` or `marketplace.athena`

- `className` – String, required, driver class name. When you're using the Athena-CloudWatch connector, this parameter value is the prefix of the class Name (for example, "com.amazonaws.athena.connectors"). The Athena-CloudWatch connector is composed of two classes: a metadata handler and a record handler. If you supply the common prefix here, then the API loads the correct classes based on that prefix.
- `tableName` – String, required, the name of the CloudWatch log stream to read. This code snippet uses the special view name `all_log_streams`, which means that the dynamic data frame returned will contain data from all log streams in the log group.
- `schemaName` – String, required, the name of the CloudWatch log group to read from. For example, `/aws-glue/jobs/output`.
- `connectionName` – String, required, name of the connection that is associated with the connector.

For additional options for this connector, see the [Amazon Athena CloudWatch Connector README](#) file on GitHub.

The following Python code example shows how to read from an Athena data store using an Amazon Web Services Marketplace connector. It demonstrates reading from Athena and writing to an S3 location.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)
## @type: DataSource
## @args: [connection_type = "marketplace.athena", connection_options =
  {"tableName":"all_log_streams","schemaName":"/aws-glue/jobs/output",
  "connectionName":"test-connection-athena"}, transformation_ctx = "DataSource0"]
## @return: DataSource0
## @inputs: []
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
  "marketplace.athena", connection_options = {"tableName":"all_log_streams",,
  "schemaName":"/aws-glue/jobs/output","connectionName":
  "test-connection-athena"}, transformation_ctx = "DataSource0")
## @type: ApplyMapping
## @args: [mappings = [("department", "string", "department", "string"), ("name",
"string",
  "name", "string"), ("id", "int", "id", "int")], transformation_ctx =
"Transform0"]
## @return: Transform0
## @inputs: [frame = DataSource0]
Transform0 = ApplyMapping.apply(frame = DataSource0, mappings = [("department",
"string",
  "department", "string"), ("name", "string", "name", "string"), ("id", "int",
"id", "int")],
```

```

    transformation_ctx = "Transform0")
## @type: DataSink
## @args: [connection_type = "s3", format = "json", connection_options = {"path":
    "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0"]
## @return: DataSink0
## @inputs: [frame = Transform0]
DataSink0 = glueContext.write_dynamic_frame.from_options(frame = Transform0,
    connection_type = "s3", format = "json", connection_options = {"path":
    "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0")
job.commit()

```

Connection options for type `custom.spark` or `marketplace.spark`

- `className` – String, required, connector class name.
- `secretId` – String, optional, used to retrieve credentials for the connector connection.
- `connectionName` – String, required, name of the connection that is associated with the connector.
- Other options depend on the data store. For example, OpenSearch configuration options start with the prefix `es`, as described in the [Elasticsearch for Apache Hadoop](#) documentation. Spark connections to Snowflake use options such as `sfUser` and `sfPassword`, as described in [Using the Spark Connector](#) in the *Connecting to Snowflake* guide.

The following Python code example shows how to read from an OpenSearch data store using a `marketplace.spark` connection.

```

import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

```

```

## @type: DataSource
## @args: [connection_type = "marketplace.spark", connection_options =
{"path":"test",
  "es.nodes.wan.only":"true","es.nodes":"https://<Amazon endpoint>",
  "connectionName":"test-spark-es","es.port":"443"}, transformation_ctx =
"DataSource0"]
## @return: DataSource0
## @inputs: []
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
  "marketplace.spark", connection_options = {"path":"test","es.nodes.wan.only":
  "true","es.nodes":"https://<Amazon endpoint>","connectionName":
  "test-spark-es","es.port":"443"}, transformation_ctx = "DataSource0")
## @type: DataSink
## @args: [connection_type = "s3", format = "json", connection_options = {"path":
  "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0"]
## @return: DataSink0
## @inputs: [frame = DataSource0]
DataSink0 = glueContext.write_dynamic_frame.from_options(frame = DataSource0,
  connection_type = "s3", format = "json", connection_options = {"path":
  "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0")
job.commit()

```

General options

The options in this section are provided as `connection_options`, but do not specifically apply to one connector.

The following parameters are used generally when configuring bookmarks. They may apply to Amazon S3 or JDBC workflows. For more information, see [the section called “Using job bookmarks”](#).

- `jobBookmarkKeys` — Array of column names.
- `jobBookmarkKeysSortOrder` — String defining how to compare values based on sort order. Valid values: "asc", "desc".
- `useS3ListImplementation` — Used to manage memory performance when listing Amazon S3 bucket contents. For more information, see [Optimize memory management in Amazon Glue](#).

Data format options for inputs and outputs in Amazon Glue for Spark

These pages offer information about feature support and configuration parameters for data formats supported by Amazon Glue for Spark. See the following for a description of the usage and applicability of this information.

Feature support across data formats in Amazon Glue

Each data format may support different Amazon Glue features. The following common features may or may not be supported based on your format type. Refer to the documentation for your data format to understand how to leverage our features to meet your requirements.

| | |
|-------------------|--|
| Read | Amazon Glue can recognize and interpret this data format without additional resources, such as connectors. |
| Write | Amazon Glue can write data in this format without additional resources. You can include third-party libraries in your job and use standard Apache Spark functions to write data, as you would in other Spark environments. For more information about including libraries, see the section called “Python libraries” . |
| Stream read | Amazon Glue can recognize and interpret this data format from an Apache Kafka, Amazon Managed Streaming for Apache Kafka or Amazon Kinesis message stream. We expect streams to present data in a consistent format, so they are read in as DataFrames . |
| Group small files | Amazon Glue can group files together to batch work sent to each node when performing Amazon Glue transforms. This can significantly improve performance for workloads involving large amounts of small files. For |

more information, see [the section called "Grouping input files"](#).

Job bookmarks Amazon Glue can track the progress of transforms performing the same work on the same dataset across job runs with job bookmarks. This can improve performance for workloads involving datasets where work only needs to be done on new data since the last job run. For more information, see [the section called "Tracking processed data using job bookmarks"](#).

Parameters used to interact with data formats in Amazon Glue

Certain Amazon Glue connection types support multiple format types, requiring you to specify information about your data format with a `format_options` object when using methods like `GlueContext.write_dynamic_frame.from_options`.

- `s3` – For more information, see Connection types and options for ETL in Amazon Glue: [S3 connection parameters](#). You can also view the documentation for the methods facilitating this connection type: [the section called "create_dynamic_frame_from_options"](#) and [the section called "write_dynamic_frame_from_options"](#) in Python and the corresponding Scala methods [the section called "getSourceWithFormat"](#) and [the section called "getSinkWithFormat"](#).
- `kinesis` – For more information, see Connection types and options for ETL in Amazon Glue: [Kinesis connection parameters](#). You can also view the documentation for the method facilitating this connection type: [the section called "create_data_frame_from_options"](#) and the corresponding Scala method [the section called "createDataFrameFromOptions"](#).
- `kafka` – For more information, see Connection types and options for ETL in Amazon Glue: [Kafka connection parameters](#). You can also view the documentation for the method facilitating this connection type: [the section called "create_data_frame_from_options"](#) and the corresponding Scala method [the section called "createDataFrameFromOptions"](#).

Some connection types do not require `format_options`. For example, in normal use, a JDBC connection to a relational database retrieves data in a consistent, tabular data format. Therefore, reading from a JDBC connection would not require `format_options`.

Some methods to read and write data in glue do not require `format_options`. For example, using `GlueContext.create_dynamic_frame.from_catalog` with Amazon Glue crawlers. Crawlers determine the shape of your data. When using crawlers, a Amazon Glue classifier will examine your data to make smart decisions about how to represent your data format. It will then store a representation of your data in the Amazon Glue Data Catalog, which can be used within a Amazon Glue ETL script to retrieve your data with the `GlueContext.create_dynamic_frame.from_catalog` method. Crawlers remove the need to manually specify information about your data format.

For jobs that access Amazon Lake Formation governed tables, Amazon Glue supports reading and writing all formats supported by Lake Formation governed tables. For the current list of supported formats for Amazon Lake Formation governed tables, see [Notes and Restrictions for Governed Tables](#) in the *Amazon Lake Formation Developer Guide*.

Note

For writing Apache Parquet, Amazon Glue ETL only supports writing to a governed table by specifying an option for a custom Parquet writer type optimized for Dynamic Frames. When writing to a governed table with the `parquet` format, you should add the key `useGlueParquetWriter` with a value of `true` in the table parameters.

Using the CSV format in Amazon Glue

Amazon Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the CSV data format, this document introduces you available features for using your data in Amazon Glue.

Amazon Glue supports using the comma-separated value (CSV) format. This format is a minimal, row-based data format. CSVs often don't strictly conform to a standard, but you can refer to [RFC 4180](#) and [RFC 7111](#) for more information.

You can use Amazon Glue to read CSVs from Amazon S3 and from streaming sources as well as write CSVs to Amazon S3. You can read and write bzip and gzip archives containing CSV files from S3. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common Amazon Glue features support the CSV format option.

| Read | Write | Streaming read | Group small files | Job bookmarks |
|-----------|-----------|----------------|-------------------|---------------|
| Supported | Supported | Supported | Supported | Supported |

Example: Read CSV files or folders from S3

Prerequisites: You will need the S3 paths (s3path) to the CSV files or folders that you want to read.

Configuration: In your function options, specify `format="csv"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can configure how the reader interacts with S3 in `connection_options`. For details, see [Connection types and options for ETL in Amazon Glue: S3 connection parameters](#). You can configure how the reader interprets CSV files in your `format_options`. For details, see [CSV Configuration Reference](#).

The following Amazon Glue ETL script shows the process of reading CSV files or folders from S3.

We provide a custom CSV reader with performance optimizations for common workflows through the `optimizePerformance` configuration key. To determine if this reader is right for your workload, see [the section called "Using optimized CSV reader"](#).

Python

For this example, use the [create_dynamic_frame.from_options](#) method.

```
# Example: Read CSV from S3
# For show, we handle a CSV with a header row. Set the withHeader option.
# Consider whether optimizePerformance is right for your workflow.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="csv",
    format_options={
        "withHeader": True,
        # "optimizePerformance": True,
    },
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\
    .format("csv")\
    .option("header", "true")\
    .load("s3://s3path")
```

Scala

For this example, use the [getSourceWithFormat](#) operation.

```
// Example: Read CSV from S3
// For show, we handle a CSV with a header row. Set the withHeader option.
```

```
// Consider whether optimizePerformance is right for your workflow.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      formatOptions=JsonOptions("""{"withHeader": true}"""),
      connectionType="s3",
      format="csv",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
val dataframe = spark.read
  .option("header", "true")
  .format("csv")
  .load("s3://s3path")
```

Example: Write CSV files and folders to S3

Prerequisites: You will need an initialized DataFrame (`dataFrame`) or a DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

Configuration: In your function options, specify `format="csv"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can configure how the writer interacts with S3 in `connection_options`. For details, see [Connection types and options for ETL in Amazon Glue: S3 connection parameters](#). You can configure how your operation writes the contents of your files in `format_options`. For details, see [CSV Configuration Reference](#). The following Amazon Glue ETL script shows the process of writing CSV files and folders to S3.

Python

For this example, use the [write_dynamic_frame.from_options](#) method.

```
# Example: Write CSV to S3
# For show, customize how we write string type values. Set quoteChar to -1 so our
# values are not quoted.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    connection_options={"path": "s3://s3path"},
    format="csv",
    format_options={
        "quoteChar": -1,
    },
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame.write\
    .format("csv")\
    .option("quote", None)\
    .mode("append")\
    .save("s3://s3path")
```

Scala

For this example, use the [getSinkWithFormat](#) method.

```
// Example: Write CSV to S3
// For show, customize how we write string type values. Set quoteChar to -1 so our
// values are not quoted.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
```

```
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="csv"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
dataFrame.write
  .format("csv")
  .option("quote", null)
  .mode("Append")
  .save("s3://s3path")
```

CSV configuration reference

You can use the following `format_options` wherever Amazon Glue libraries specify `format="csv"`:

- `separator` – Specifies the delimiter character. The default is a comma, but any other character can be specified.
 - **Type:** Text, **Default:** `,`
- `escaper` – Specifies a character to use for escaping. This option is used only when reading CSV files, not writing. If enabled, the character that immediately follows is used as-is, except for a small set of well-known escapes (`\n`, `\r`, `\t`, and `\0`).
 - **Type:** Text, **Default:** none
- `quoteChar` – Specifies the character to use for quoting. The default is a double quote. Set this to `-1` to turn off quoting entirely.
 - **Type:** Text, **Default:** `'"`

- `multiLine` – Specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to `True` if any record spans multiple lines. Enabling `multiLine` might decrease performance because it requires more cautious file-splitting while parsing.
 - **Type:** Boolean, **Default:** `false`
- `withHeader` – Specifies whether to treat the first line as a header. This option can be used in the `DynamicFrameReader` class.
 - **Type:** Boolean, **Default:** `false`
- `writeHeader` – Specifies whether to write the header to output. This option can be used in the `DynamicFrameWriter` class.
 - **Type:** Boolean, **Default:** `true`
- `skipFirst` – Specifies whether to skip the first data line.
 - **Type:** Boolean, **Default:** `false`
- `optimizePerformance` – Specifies whether to use the advanced SIMD CSV reader along with Apache Arrow-based columnar memory formats. Only available in Amazon Glue 3.0+.
 - **Type:** Boolean, **Default:** `false`
- `strictCheckForQuoting` – When writing CSVs, Glue may add quotes to values it interprets as strings. This is done to prevent ambiguity in what is written out. To save time when deciding what to write, Glue may quote in certain situations where quotes are not necessary. Enabling a strict check will perform a more intensive computation and will only quote when strictly necessary. Only available in Amazon Glue 3.0+.
 - **Type:** Boolean, **Default:** `false`

Optimize read performance with vectorized SIMD CSV reader

Amazon Glue version 3.0 adds an optimized CSV reader that can significantly speed up overall job performance compared to row-based CSV readers.

The optimized reader:

- Uses CPU SIMD instructions to read from disk
- Immediately writes records to memory in a columnar format (Apache Arrow)
- Divides the records into batches

This saves processing time when records would be batched or converted to a columnar format later on. Some examples are when changing schemas or retrieving data by column.

To use the optimized reader, set "optimizePerformance" to true in the format_options or table property.

```
glueContext.create_dynamic_frame.from_options(  
    frame = datasource1,  
    connection_type = "s3",  
    connection_options = {"paths": ["s3://s3path"]},  
    format = "csv",  
    format_options={  
        "optimizePerformance": True,  
        "separator": ",",  
    },  
    transformation_ctx = "datasink2")
```

Limitations for the vectorized CSV reader

Note the following limitations of the vectorized CSV reader:

- It doesn't support the `multiLine` and `escaper` format options. It uses the default escaper of double quote char ' " '. When these options are set, Amazon Glue automatically falls back to using the row-based CSV reader.
- It doesn't support creating a `DynamicFrame` with [ChoiceType](#).
- It doesn't support creating a `DynamicFrame` with [error records](#).
- It doesn't support reading CSV files with multibyte characters such as Japanese or Chinese characters.

Using the Parquet format in Amazon Glue

Amazon Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the Parquet data format, this document introduces you available features for using your data in Amazon Glue.

Amazon Glue supports using the Parquet format. This format is a performance-oriented, column-based data format. For an introduction to the format by the standard authority see, [Apache Parquet Documentation Overview](#).

You can use Amazon Glue to read Parquet files from Amazon S3 and from streaming sources as well as write Parquet files to Amazon S3. You can read and write bzip and gzip archives containing Parquet files from S3. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common Amazon Glue features support the Parquet format option.

| Read | Write | Streaming read | Group small files | Job bookmarks |
|-----------|-----------|----------------|-------------------|---------------|
| Supported | Supported | Supported | Unsupported | Supported* |

* Supported in Amazon Glue version 1.0+

Example: Read Parquet files or folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the Parquet files or folders that you want to read.

Configuration: In your function options, specify `format="parquet"`. In your `connection_options`, use the `paths` key to specify your `s3path`.

You can configure how the reader interacts with S3 in the `connection_options`. For details, see [Connection types and options for ETL in Amazon Glue: S3 connection parameters](#).

You can configure how the reader interprets Parquet files in your `format_options`. For details, see [Parquet Configuration Reference](#).

The following Amazon Glue ETL script shows the process of reading Parquet files or folders from S3:

Python

For this example, use the [create_dynamic_frame.from_options](#) method.

```
# Example: Read Parquet from S3

from pyspark.context import SparkContext
from awsglue.context import GlueContext
```

```
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type = "s3",
    connection_options = {"paths": ["s3://s3path/"]},
    format = "parquet"
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read.parquet("s3://s3path/")
```

Scala

For this example, use the [getSourceWithFormat](#) method.

```
// Example: Read Parquet from S3

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="parquet",
      options=JsonOptions("""{"paths": ["s3://s3path"]}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
spark.read.parquet("s3://s3path/")
```

Example: Write Parquet files and folders to S3

Prerequisites: You will need an initialized DataFrame (dataFrame) or DynamicFrame (dynamicFrame). You will also need your expected S3 output path, s3path.

Configuration: In your function options, specify format="parquet". In your connection_options, use the paths key to specify s3path.

You can further alter how the writer interacts with S3 in the connection_options. For details, see Connection types and options for ETL in Amazon Glue: [S3 connection parameters](#). You can configure how your operation writes the contents of your files in format_options. For details, see [Parquet Configuration Reference](#).

The following Amazon Glue ETL script shows the process of writing Parquet files and folders to S3.

We provide a custom Parquet writer with performance optimizations for DynamicFrames, through the useGlueParquetWriter configuration key. To determine if this writer is right for your workload, see [Glue Parquet Writer](#).

Python

For this example, use the [write_dynamic_frame.from_options](#) method.

```
# Example: Write Parquet to S3
# Consider whether useGlueParquetWriter is right for your workflow.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    format="parquet",
    connection_options={
        "path": "s3://s3path",
    },
    format_options={
        # "useGlueParquetWriter": True,
    },
)
```

```
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.parquet("s3://s3path/")
```

Scala

For this example, use the [getSinkWithFormat](#) method.

```
// Example: Write Parquet to S3
// Consider whether useGlueParquetWriter is right for your workflow.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="parquet"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
df.write.parquet("s3://s3path/")
```

Parquet configuration reference

You can use the following `format_options` wherever Amazon Glue libraries specify `format="parquet"`:

- `useGlueParquetWriter` – Specifies the use of a custom Parquet writer that has performance optimizations for `DynamicFrame` workflows. For usage details, see [Glue Parquet Writer](#).

- **Type:** Boolean, **Default:** false
- `compression` – Specifies the compression codec used. Values are fully compatible with `org.apache.parquet.hadoop.metadata.CompressionCodecName`.
 - **Type:** Enumerated Text, **Default:** "snappy"
 - Values: "uncompressed", "snappy", "gzip", and "lzo"
- `blockSize` – Specifies the size in bytes of a row group being buffered in memory. You use this for tuning performance. Size should divide exactly into a number of megabytes.
 - **Type:** Numerical, **Default:** 134217728
 - The default value is equal to 128 MB.
- `pageSize` – Specifies the size in bytes of a page. You use this for tuning performance. A page is the smallest unit that must be read fully to access a single record.
 - **Type:** Numerical, **Default:** 1048576
 - The default value is equal to 1 MB.

Note

Additionally, any options that are accepted by the underlying SparkSQL code can be passed to this format by way of the `connection_options` map parameter. For example, you can set a Spark configuration such as [mergeSchema](#) for the Amazon Glue Spark reader to merge the schema for all files.

Optimize write performance with Amazon Glue Parquet writer

Note

The Amazon Glue Parquet writer has historically been accessed through the `glueparquet` format type. This access pattern is no longer advocated. Instead, use the `parquet` type with `useGlueParquetWriter` enabled.

The Amazon Glue Parquet writer has performance enhancements that allow faster Parquet file writes. The traditional writer computes a schema before writing. The Parquet format doesn't store the schema in a quickly retrievable fashion, so this might take some time. With the Amazon Glue

Parquet writer, a pre-computed schema isn't required. The writer computes and modifies the schema dynamically, as data comes in.

Note the following limitations when you specify `useGlueParquetWriter`:

- The writer supports only schema evolution (such as adding or removing columns), but not changing column types, such as with `ResolveChoice`.
- The writer doesn't support writing empty `DataFrames`—for example, to write a schema-only file. When integrating with the Amazon Glue Data Catalog by setting `enableUpdateCatalog=True`, attempting to write an empty `DataFrame` will not update the Data Catalog. This will result in creating a table in the Data Catalog without a schema.

If your transform doesn't require these limitations, turning on the Amazon Glue Parquet writer should increase performance.

Using the XML format in Amazon Glue

Amazon Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the XML data format, this document introduces you available features for using your data in Amazon Glue.

Amazon Glue supports using the XML format. This format represents highly configurable, rigidly defined data structures that aren't row or column based. XML is highly standardized. For an introduction to the format by the standard authority, see [XML Essentials](#).

You can use Amazon Glue to read XML files from Amazon S3, as well as bzip and gzip archives containing XML files. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common Amazon Glue features support the XML format option.

| Read | Write | Streaming read | Group small files | Job bookmarks |
|-----------|-------------|----------------|-------------------|---------------|
| Supported | Unsupported | Unsupported | Supported | Supported |

Example: Read XML from S3

The XML reader takes an XML tag name. It examines elements with that tag within its input to infer a schema and populates a `DynamicFrame` with corresponding values. The Amazon Glue XML functionality behaves similarly to the [XML Data Source for Apache Spark](#). You might be able to gain insight around basic behavior by comparing this reader to that project's documentation.

Prerequisites: You will need the S3 paths (`s3path`) to the XML files or folders that you want to read, and some information about your XML file. You will also need the tag for the XML element you want to read, `xmlTag`.

Configuration: In your function options, specify `format="xml"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can further configure how the reader interacts with S3 in the `connection_options`. For details, see [Connection types and options for ETL in Amazon Glue: S3 connection parameters](#). In your `format_options`, use the `rowTag` key to specify `xmlTag`. You can further configure how the reader interprets XML files in your `format_options`. For details, see [XML Configuration Reference](#).

The following Amazon Glue ETL script shows the process of reading XML files or folders from S3.

Python

For this example, use the [create_dynamic_frame_from_options](#) method.

```
# Example: Read XML from S3
# Set the rowTag option to configure the reader.

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="xml",
    format_options={"rowTag": "xmlTag"},
)
```

You can also use `DataFrames` in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\  
  .format("xml")\  
  .option("rowTag", "xmlTag")\  
  .load("s3://s3path")
```

Scala

For this example, use the [getSourceWithFormat](#) operation.

```
// Example: Read XML from S3  
// Set the rowTag option to configure the reader.  
  
import com.amazonaws.services.glue.util.JsonOptions  
import com.amazonaws.services.glue.GlueContext  
import org.apache.spark.sql.SparkSession  
  
val glueContext = new GlueContext(SparkContext.getOrCreate())  
val sparkSession: SparkSession = glueContext.getSparkSession  
  
object GlueApp {  
  def main(sysArgs: Array[String]): Unit = {  
    val dynamicFrame = glueContext.getSourceWithFormat(  
      formatOptions=JsonOptions("""{"rowTag": "xmlTag"}"""),  
      connectionType="s3",  
      format="xml",  
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")  
    ).getDynamicFrame()  
  }  
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
val dataFrame = spark.read  
  .option("rowTag", "xmlTag")  
  .format("xml")  
  .load("s3://s3path")
```

XML configuration reference

You can use the following `format_options` wherever Amazon Glue libraries specify `format="xml"`:

- `rowTag` – Specifies the XML tag in the file to treat as a row. Row tags cannot be self-closing.
 - **Type:** Text, **Required**
- `encoding` – Specifies the character encoding. It can be the name or alias of a [Charset](#) supported by our runtime environment. We don't make specific guarantees around encoding support, but major encodings should work.
 - **Type:** Text, **Default:** "UTF-8"
- `excludeAttribute` – Specifies whether you want to exclude attributes in elements or not.
 - **Type:** Boolean, **Default:** false
- `treatEmptyValuesAsNulls` – Specifies whether to treat white space as a null value.
 - **Type:** Boolean, **Default:** false
- `attributePrefix` – A prefix for attributes to differentiate them from child element text. This prefix is used for field names.
 - **Type:** Text, **Default:** "_"
- `valueTag` – The tag used for a value when there are attributes in the element that have no child.
 - **Type:** Text, **Default:** "_VALUE"
- `ignoreSurroundingSpaces` – Specifies whether the white space that surrounds values should be ignored.
 - **Type:** Boolean, **Default:** false
- `withSchema` – Contains the expected schema, in situations where you want to override the inferred schema. If you don't use this option, Amazon Glue infers the schema from the XML data.
 - **Type:** Text, **Default:** Not applicable
 - The value should be a JSON object that represents a `StructType`.

Manually specify the XML schema

Manual XML schema example

This is an example of using the `withSchema` format option to specify the schema for XML data.

```
from awsglue.gluetypes import *

schema = StructType([
    Field("id", IntegerType()),
```

```

Field("name", StringType()),
Field("nested", StructType([
    Field("x", IntegerType()),
    Field("y", StringType()),
    Field("z", ChoiceType([IntegerType(), StringType()])))
]))
])

datasource0 = create_dynamic_frame_from_options(
    connection_type,
    connection_options={"paths": ["s3://xml_bucket/someprefix"]},
    format="xml",
    format_options={"withSchema": json.dumps(schema.jsonValue())},
    transformation_ctx = ""
)

```

Using the Avro format in Amazon Glue

Amazon Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the Avro data format, this document introduces you available features for using your data in Amazon Glue.

Amazon Glue supports using the Avro format. This format is a performance-oriented, row-based data format. For an introduction to the format by the standard authority see, [Apache Avro 1.8.2 Documentation](#).

You can use Amazon Glue to read Avro files from Amazon S3 and from streaming sources as well as write Avro files to Amazon S3. You can read and write bzip2 and gzip archives containing Avro files from S3. Additionally, you can write deflate, snappy, and xz archives containing Avro files. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common Amazon Glue operations support the Avro format option.

| Read | Write | Streaming read | Group small files | Job bookmarks |
|-----------|-----------|----------------|-------------------|---------------|
| Supported | Supported | Supported* | Unsupported | Supported |

*Supported with restrictions. For more information, see [the section called “Notes and restrictions for Avro streaming sources”](#).

Example: Read Avro files or folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the Avro files or folders that you want to read.

Configuration: In your function options, specify `format="avro"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can configure how the reader interacts with S3 in the `connection_options`. For details, see Data format options for ETL inputs and outputs in Amazon Glue: [the section called “S3 connection parameters”](#). You can configure how the reader interprets Avro files in your `format_options`. For details, see [Avro Configuration Reference](#).

The following Amazon Glue ETL script shows the process of reading Avro files or folders from S3:

Python

For this example, use the [create_dynamic_frame.from_options](#) method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="avro"
)
```

Scala

For this example, use the [getSourceWithFormat](#) operation.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.sql.SparkContext

object GlueApp {
    def main(sysArgs: Array[String]): Unit = {
```

```
val spark: SparkContext = new SparkContext()
val glueContext: GlueContext = new GlueContext(spark)

val dynamicFrame = glueContext.getSourceWithFormat(
    connectionType="s3",
    format="avro",
    options=JsonOptions("""{"paths": ["s3://s3path"]}""")
).getDynamicFrame()
}
```

Example: Write Avro files and folders to S3

Prerequisites: You will need an initialized DataFrame (dataFrame) or DynamicFrame (dynamicFrame). You will also need your expected S3 output path, s3path.

Configuration: In your function options, specify format="avro". In your connection_options, use the paths key to specify your s3path. You can further alter how the writer interacts with S3 in the connection_options. For details, see Data format options for ETL inputs and outputs in Amazon Glue: [the section called "S3 connection parameters"](#). You can alter how the writer interprets Avro files in your format_options. For details, see [Avro Configuration Reference](#).

The following Amazon Glue ETL script shows the process of writing Avro files or folders to S3.

Python

For this example, use the [write_dynamic_frame_from_options](#) method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    format="avro",
    connection_options={
        "path": "s3://s3path"
    }
)
```

Scala

For this example, use the [getSinkWithFormat](#) method.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="avro"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

Avro configuration reference

You can use the following `format_options` values wherever Amazon Glue libraries specify `format="avro"`:

- `version` — Specifies the version of Apache Avro reader/writer format to support. The default is "1.7". You can specify `format_options={"version": "1.8"}` to enable Avro logical type reading and writing. For more information, see the [Apache Avro 1.7.7 Specification](#) and [Apache Avro 1.8.2 Specification](#).

The Apache Avro 1.8 connector supports the following logical type conversions:

For the reader: this table shows the conversion between Avro data type (logical type and Avro primitive type) and Amazon Glue `DynamicFrame` data type for Avro reader 1.7 and 1.8.

| Avro Data Type:
Logical Type | Avro Data Type:
Avro Primitive Type | GlueDynamicFrame
Data Type:
Avro Reader 1.7 | GlueDynamicFrame
Data Type:
Avro Reader 1.8 |
|---|--|--|--|
| Decimal | bytes | BINARY | Decimal |
| Decimal | fixed | BINARY | Decimal |
| Date | int | INT | Date |
| Time (millisecond) | int | INT | INT |
| Time (microsecond) | long | LONG | LONG |
| Timestamp (millisecond) | long | LONG | Timestamp |
| Timestamp (microsecond) | long | LONG | LONG |
| Duration (not a logical type) | fixed of 12 | BINARY | BINARY |

For the writer: this table shows the conversion between Amazon Glue DynamicFrame data type and Avro data type for Avro writer 1.7 and 1.8.

| Amazon Glue DynamicFrame Data Type | Avro Data Type:
Avro Writer 1.7 | Avro Data Type:
Avro Writer 1.8 |
|---|--|--|
| Decimal | String | decimal |
| Date | String | date |
| Timestamp | String | timestamp-micros |

Avro Spark DataFrame support

In order to use Avro from the Spark DataFrame API, you need to install the Spark Avro plugin for the corresponding Spark version. The version of Spark available in your job is determined by your Amazon Glue version. For more information about Spark versions, see [the section called "Amazon Glue versions"](#). This plugin is maintained by Apache, we do not make specific guarantees of support.

In Amazon Glue 2.0 - use version 2.4.3 of the Spark Avro plugin. You can find this JAR on Maven Central, see [org.apache.spark:spark-avro_2.12:2.4.3](https://mvnrepository.com/artifact/org.apache.spark/spark-avro/2.12:2.4.3).

In Amazon Glue 3.0 - use version 3.1.1 of the Spark Avro plugin. You can find this JAR on Maven Central, see [org.apache.spark:spark-avro_2.12:3.1.1](https://mvnrepository.com/artifact/org.apache.spark/spark-avro/2.12:3.1.1).

To include extra JARs in a Amazon Glue ETL job, use the `--extra-jars` job parameter. For more information about job parameters, see [the section called "Job parameters"](#). You can also configure this parameter in the Amazon Web Services Management Console.

Using the grokLog format in Amazon Glue

Amazon Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in a loosely structured plaintext format, this document introduces you available features for using your data in Amazon Glue through Grok patterns.

Amazon Glue supports using Grok patterns. Grok patterns are similar to regular expression capture groups. They recognize patterns of character sequences in a plaintext file and give them a type and purpose. In Amazon Glue, their primary purpose is to read logs. For an introduction to the Grok by the authors, see [Logstash Reference: Grok filter plugin](#).

| Read | Write | Streaming read | Group small files | Job bookmarks |
|-----------|----------------|----------------|-------------------|---------------|
| Supported | Not Applicable | Supported | Supported | Unsupported |

grokLog configuration reference

You can use the following `format_options` values with `format="grokLog"`:

- `logFormat` — Specifies the Grok pattern that matches the log's format.
- `customPatterns` — Specifies additional Grok patterns used here.
- `MISSING` — Specifies the signal to use in identifying missing values. The default is ' - '.
- `LineCount` — Specifies the number of lines in each log record. The default is ' 1 ', and currently only single-line records are supported.
- `StrictMode` — A Boolean value that specifies whether strict mode is turned on. In strict mode, the reader doesn't do automatic type conversion or recovery. The default value is "false".

Using the Ion format in Amazon Glue

Amazon Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the Ion data format, this document introduces you available features for using your data in Amazon Glue.

Amazon Glue supports using the Ion format. This format represents data structures (that aren't row or column based) in interchangeable binary and plaintext representations. For an introduction to the format by the authors, see [Amazon Ion](#). (For more information, see the [Amazon Ion Specification](#).)

You can use Amazon Glue to read Ion files from Amazon S3. You can read bzip and gzip archives containing Ion files from S3. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common Amazon Glue operations support the Ion format option.

| Read | Write | Streaming read | Group small files | Job bookmarks |
|-----------|-------------|----------------|-------------------|---------------|
| Supported | Unsupported | Unsupported | Supported | Unsupported |

Example: Read Ion files and folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the Ion files or folders that you want to read.

Configuration: In your function options, specify `format="json"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can configure how the reader interacts with S3 in

the `connection_options`. For details, see [Connection types and options for ETL in Amazon Glue: the section called "S3 connection parameters"](#).

The following Amazon Glue ETL script shows the process of reading Ion files or folders from S3:

Python

For this example, use the [create_dynamic_frame.from_options](#) method.

```
# Example: Read ION from S3

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="ion"
)
```

Scala

For this example, use the [getSourceWithFormat](#) operation.

```
// Example: Read ION from S3

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="ion",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
  }
}
```

```
}
}
```

Ion configuration reference

There are no `format_options` values for `format="ion"`.

Using the JSON format in Amazon Glue

Amazon Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the JSON data format, this document introduces you to available features for using your data in Amazon Glue.

Amazon Glue supports using the JSON format. This format represents data structures with consistent shape but flexible contents, that aren't row or column based. JSON is defined by parallel standards issued by several authorities, one of which is ECMA-404. For an introduction to the format by a commonly referenced source, see [Introducing JSON](#).

You can use Amazon Glue to read JSON files from Amazon S3, as well as bzip and gzip compressed JSON files. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

| Read | Write | Streaming read | Group small files | Job bookmarks | |
|-----------|-----------|----------------|-------------------|---------------|--|
| Supported | Supported | Supported | Supported | Supported | |

Example: Read JSON files or folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the JSON files or folders you would like to read.

Configuration: In your function options, specify `format="json"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can further alter how your read operation will traverse S3 in the connection options, consult [the section called "S3 connection parameters"](#) for details. You can configure how the reader interprets JSON files in your `format_options`. For details, see [JSON Configuration Reference](#).

The following Amazon Glue ETL script shows the process of reading JSON files or folders from S3:

Python

For this example, use the [create_dynamic_frame.from_options](#) method.

```
# Example: Read JSON from S3
# For show, we handle a nested JSON file that we can limit with the JsonPath
  parameter
# For show, we also handle a JSON where a single entry spans multiple lines
# Consider whether optimizePerformance is right for your workflow.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="json",
    format_options={
        "jsonPath": "$.id",
        "multiline": True,
        # "optimizePerformance": True, -> not compatible with jsonPath, multiline
    }
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\
    .option("multiline", "true")\
    .json("s3://s3path")
```

Scala

For this example, use the [getSourceWithFormat](#) operation.

```
// Example: Read JSON from S3
// For show, we handle a nested JSON file that we can limit with the JsonPath
  parameter
// For show, we also handle a JSON where a single entry spans multiple lines
// Consider whether optimizePerformance is right for your workflow.
```

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      formatOptions=JsonOptions("""{"jsonPath": "$.id", "multiline": true,
"optimizePerformance":false}"""),
      connectionType="s3",
      format="json",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
val dataframe = spark.read
  .option("multiline", "true")
  .json("s3://s3path")
```

Example: Write JSON files and folders to S3

Prerequisites: You will need an initialized DataFrame (`dataFrame`) or DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

Configuration: In your function options, specify `format="json"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can further alter how the writer interacts with S3 in the `connection_options`. For details, see [Data format options for ETL inputs and outputs in Amazon Glue](#) : [the section called "S3 connection parameters"](#). You can configure how the writer interprets JSON files in your `format_options`. For details, see [JSON Configuration Reference](#).

The following Amazon Glue ETL script shows the process of writing JSON files or folders from S3:

Python

For this example, use the [write_dynamic_frame_from_options](#) method.

```
# Example: Write JSON to S3

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    connection_options={"path": "s3://s3path"},
    format="json"
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.json("s3://s3path/")
```

Scala

For this example, use the [getSinkWithFormat](#) method.

```
// Example: Write JSON to S3

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="json"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.json("s3://s3path")
```

Json configuration reference

You can use the following `format_options` values with `format="json"`:

- `jsonPath` — A [JsonPath](#) expression that identifies an object to be read into records. This is particularly useful when a file contains records nested inside an outer array. For example, the following `JsonPath` expression targets the `id` field of a JSON object.

```
format="json", format_options={"jsonPath": "$.id"}
```

- `multiline` — A Boolean value that specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to `"true"` if any record spans multiple lines. The default value is `"false"`, which allows for more aggressive file-splitting during parsing.
- `optimizePerformance` — A Boolean value that specifies whether to use the advanced SIMD JSON reader along with Apache Arrow based columnar memory formats. Only available in Amazon Glue 3.0. Not compatible with `multiline` or `jsonPath`. Providing either of those options will instruct Amazon Glue to fall back to the standard reader.
- `withSchema` — A String value that specifies a table schema in the format described in [the section called "Specify XML schema"](#). Only used with `optimizePerformance` when reading from non-Catalog connections.

Using vectorized SIMD JSON reader with Apache Arrow columnar format

Amazon Glue version 3.0 adds a vectorized reader for JSON data. It performs 2x faster under certain conditions, compared to the standard reader. This reader comes with certain limitations users should be aware of before use, documented in this section.

To use the optimized reader, set `"optimizePerformance"` to `True` in the `format_options` or `table` property. You will also need to provide `withSchema` unless reading from the catalog. `withSchema` expects an input as described in the [the section called "Specify XML schema"](#)

```
// Read from S3 data source
glueContext.create_dynamic_frame.from_options(
  connection_type = "s3",
  connection_options = {"paths": ["s3://s3path"]},
  format = "json",
  format_options={
    "optimizePerformance": True,
    "withSchema": SchemaString
  })

// Read from catalog table
glueContext.create_dynamic_frame.from_catalog(
  database = database,
  table_name = table,
  additional_options = {
    // The vectorized reader for JSON can read your schema from a catalog table
    // property.
    "optimizePerformance": True,
  })
```

For more information about the building a *SchemaString* in the Amazon Glue library, see [the section called "Types"](#).

Limitations for the vectorized CSV reader

Note the following limitations:

- JSON elements with nested objects or array values are not supported. If provided, Amazon Glue will fall back to the standard reader.
- A schema must be provided, either from the Catalog or with `withSchema`.
- Not compatible with `multiline` or `jsonPath`. Providing either of those options will instruct Amazon Glue to fall back to the standard reader.
- Providing input records that do not match the input schema will cause the reader to fail.
- [Error records](#) will not be created.
- JSON files with multi-byte characters (such as Japanese or Chinese characters) are not supported.

Using the ORC format in Amazon Glue

Amazon Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the ORC data format, this document introduces you available features for using your data in Amazon Glue.

Amazon Glue supports using the ORC format. This format is a performance-oriented, column-based data format. For an introduction to the format by the standard authority see, [Apache Orc](#).

You can use Amazon Glue to read ORC files from Amazon S3 and from streaming sources as well as write ORC files to Amazon S3. You can read and write bzip and gzip archives containing ORC files from S3. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common Amazon Glue operations support the ORC format option.

| Read | Write | Streaming read | Group small files | Job bookmarks |
|-----------|-----------|----------------|-------------------|---------------|
| Supported | Supported | Supported | Unsupported | Supported* |

*Supported in Amazon Glue version 1.0+

Example: Read ORC files or folders from S3

Prerequisites: You will need the S3 paths (s3path) to the ORC files or folders that you want to read.

Configuration: In your function options, specify `format="orc"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can configure how the reader interacts with S3 in the `connection_options`. For details, see [Connection types and options for ETL in Amazon Glue: the section called "S3 connection parameters"](#).

The following Amazon Glue ETL script shows the process of reading ORC files or folders from S3:

Python

For this example, use the [create_dynamic_frame.from_options](#) method.

```
from pyspark.context import SparkContext
```

```

from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="orc"
)

```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```

dataFrame = spark.read\
    .orc("s3://s3path")

```

Scala

For this example, use the [getSourceWithFormat](#) operation.

```

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.sql.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="orc",
      options=JsonOptions("""{"paths": ["s3://s3path"]}""")
    ).getDynamicFrame()
  }
}

```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```

val dataFrame = spark.read
    .orc("s3://s3path")

```

Example: Write ORC files and folders to S3

Prerequisites: You will need an initialized DataFrame (`dataFrame`) or DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

Configuration: In your function options, specify `format="orc"`. In your connection options, use the `paths` key to specify `s3path`. You can further alter how the writer interacts with S3 in the `connection_options`. For details, see Data format options for ETL inputs and outputs in Amazon Glue: [the section called "S3 connection parameters"](#). The following code example shows the process:

Python

For this example, use the [write_dynamic_frame.from_options](#) method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    format="orc",
    connection_options={
        "path": "s3://s3path"
    }
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.orc("s3://s3path/")
```

Scala

For this example, use the [getSinkWithFormat](#) method.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext
```

```
object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="orc"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.orc("s3://s3path/")
```

ORC configuration reference

There are no `format_options` values for `format="orc"`. However, any options that are accepted by the underlying SparkSQL code can be passed to it by way of the `connection_options` map parameter.

Using data lake frameworks with Amazon Glue ETL jobs

Open-source data lake frameworks simplify incremental data processing for files that you store in data lakes built on Amazon S3. Amazon Glue 3.0 and later supports the following open-source data lake frameworks:

- Apache Hudi
- Linux Foundation Delta Lake
- Apache Iceberg

We provide native support for these frameworks so that you can read and write data that you store in Amazon S3 in a transactionally consistent manner. There's no need to install a separate connector or complete extra configuration steps in order to use these frameworks in Amazon Glue ETL jobs.

When you manage datasets through the Amazon Glue Data Catalog, you can use Amazon Glue methods to read and write data lake tables with Spark DataFrames. You can also read and write Amazon S3 data using the Spark DataFrame API.

In this video, you can learn about the basics of how Apache Hudi, Apache Iceberg, and Delta Lake work. You'll see how to insert, update, and delete data in your data lake and how each of these frameworks works.

Topics

- [Limitations](#)
- [Using the Hudi framework in Amazon Glue](#)
- [Using the Delta Lake framework in Amazon Glue](#)
- [Using the Iceberg framework in Amazon Glue](#)

Limitations

Consider the following limitations before you use data lake frameworks with Amazon Glue.

- The following Amazon Glue `GlueContext` methods for `DynamicFrame` don't support reading and writing data lake framework tables. Use the `GlueContext` methods for `DataFrame` or Spark `DataFrame` API instead.
 - `create_dynamic_frame.from_catalog`
 - `write_dynamic_frame.from_catalog`
 - `getDynamicFrame`
 - `writeDynamicFrame`
- The following `GlueContext` methods for `DataFrame` are supported with Lake Formation permission control:
 - `create_data_frame.from_catalog`
 - `write_data_frame.from_catalog`
 - `getDataFrame`
 - `writeDataFrame`
- [Grouping small files](#) is not supported.
- [Job bookmarks](#) are not supported.
- Apache Hudi 0.10.1 for Amazon Glue 3.0 doesn't support Hudi Merge on Read (MoR) tables.

- ALTER TABLE ... RENAME TO is not available for Apache Iceberg 0.13.1 for Amazon Glue 3.0.

Limitations for data lake format tables managed by Lake Formation permissions

The data lake formats are integrated with Amazon Glue ETL via Lake Formation permissions. Creating a DynamicFrame using `create_dynamic_frame` is not supported. For more information, see the following examples:

- [Example: Read and write Iceberg table with Lake Formation permission control](#)
- [Example: Read and write Hudi table with Lake Formation permission control](#)
- [Example: Read and write Delta Lake table with Lake Formation permission control](#)

Note

The integration with Amazon Glue ETL via Lake Formation permissions for Apache Hudi, Apache Iceberg, and Delta Lake is supported only in Amazon Glue version 4.0.

Apache Iceberg has the best integration with Amazon Glue ETL via Lake Formation permissions. It supports almost all operations and includes SQL support.

Hudi supports most basic operations with the exception of administrative operations. This is because these operations generally are done via writing of dataframes and specified via `additional_options`. You need to use Amazon Glue APIs to create DataFrames for your operations as SparkSQL is not supported.

Delta Lake only supports the reading and appending and overwriting of table data. Delta Lake requires the use of their own libraries to be able to perform various tasks such as updates.

The following features are not available for Iceberg tables managed by Lake Formation permissions.

- Compaction using Amazon Glue ETL
- Spark SQL support via Amazon Glue ETL

The following are limitations of Hudi tables managed by Lake Formation permissions:

- Removal of orphaned files

The following are limitations of Delta Lake tables managed by Lake Formation permissions:

- All features other than inserting and reading from Delta Lake tables.

Using the Hudi framework in Amazon Glue

Amazon Glue 3.0 and later supports Apache Hudi framework for data lakes. Hudi is an open-source data lake storage framework that simplifies incremental data processing and data pipeline development. This topic covers available features for using your data in Amazon Glue when you transport or store your data in a Hudi table. To learn more about Hudi, see the official [Apache Hudi documentation](#).

You can use Amazon Glue to perform read and write operations on Hudi tables in Amazon S3, or work with Hudi tables using the Amazon Glue Data Catalog. Additional operations including insert, update, and all of the [Apache Spark operations](#) are also supported.

Note

The Apache Hudi 0.15.0 implementation in Amazon Glue 5.0 internally reverts [HUDI-7001](#). It does not exhibit the regression related to Complex Key gen when the record key consists of a single field. However this behavior differs from OSS Apache Hudi 0.15.0. Apache Hudi 0.10.1 for Amazon Glue 3.0 doesn't support Hudi Merge on Read (MoR) tables.

The following table lists the Hudi version that is included in each Amazon Glue version.

| Amazon Glue version | Supported Hudi version |
|---------------------|------------------------|
| 5.1 | 1.0.2 |
| 5.0 | 0.15.0 |
| 4.0 | 0.12.1 |
| 3.0 | 0.10.1 |

To learn more about the data lake frameworks that Amazon Glue supports, see [Using data lake frameworks with Amazon Glue ETL jobs](#).

Enabling Hudi

To enable Hudi for Amazon Glue, complete the following tasks:

- Specify `hudi` as a value for the `--dataLake-formats` job parameter. For more information, see [Using job parameters in Amazon Glue jobs](#).
- Create a key named `--conf` for your Amazon Glue job, and set it to the following value. Alternatively, you can set the following configuration using `SparkConf` in your script. These settings help Apache Spark correctly handle Hudi tables.

```
spark.serializer=org.apache.spark.serializer.KryoSerializer
```

- Lake Formation permission support for Hudi is enabled by default for Amazon Glue 4.0. No additional configuration is needed for reading/writing to Lake Formation-registered Hudi tables. To read a registered Hudi table, the Amazon Glue job IAM role must have the `SELECT` permission. To write to a registered Hudi table, the Amazon Glue job IAM role must have the `SUPER` permission. To learn more about managing Lake Formation permissions, see [Granting and revoking permissions on Data Catalog resources](#).

Using a different Hudi version

To use a version of Hudi that Amazon Glue doesn't support, specify your own Hudi JAR files using the `--extra-jars` job parameter. Do not include `hudi` as a value for the `--dataLake-formats` job parameter. If you use Amazon Glue 5.0 or above, you must set `--user-jars-first true` job parameter.

Example: Write a Hudi table to Amazon S3 and register it in the Amazon Glue Data Catalog

This example script demonstrates how to write a Hudi table to Amazon S3 and register the table to the Amazon Glue Data Catalog. The example uses the Hudi [Hive Sync tool](#) to register the table.

Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the Amazon Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [Using job parameters in Amazon Glue jobs](#).

Python

```
# Example: Create a Hudi table from a DataFrame
# and register the table to Glue Data Catalog

additional_options={
    "hoodie.table.name": "<your_table_name>",
    "hoodie.database.name": "<your_database_name>",
    "hoodie.datasource.write.storage.type": "COPY_ON_WRITE",
    "hoodie.datasource.write.operation": "upsert",
    "hoodie.datasource.write.recordkey.field": "<your_recordkey_field>",
    "hoodie.datasource.write.precombine.field": "<your_precombine_field>",
    "hoodie.datasource.write.partitionpath.field": "<your_partitionkey_field>",
    "hoodie.datasource.write.hive_style_partitioning": "true",
    "hoodie.datasource.hive_sync.enable": "true",
    "hoodie.datasource.hive_sync.database": "<your_database_name>",
    "hoodie.datasource.hive_sync.table": "<your_table_name>",
    "hoodie.datasource.hive_sync.partition_fields": "<your_partitionkey_field>",
    "hoodie.datasource.hive_sync.partition_extractor_class":
"org.apache.hudi.hive.MultiPartKeyValueExtractor",
    "hoodie.datasource.hive_sync.use_jdbc": "false",
    "hoodie.datasource.hive_sync.mode": "hms",
    "path": "s3://<s3Path/>"
}

dataFrame.write.format("hudi") \
    .options(**additional_options) \
    .mode("overwrite") \
    .save()
```

Scala

```
// Example: Example: Create a Hudi table from a DataFrame
// and register the table to Glue Data Catalog

val additionalOptions = Map(
    "hoodie.table.name" -> "<your_table_name>",
    "hoodie.database.name" -> "<your_database_name>",
    "hoodie.datasource.write.storage.type" -> "COPY_ON_WRITE",
    "hoodie.datasource.write.operation" -> "upsert",
    "hoodie.datasource.write.recordkey.field" -> "<your_recordkey_field>",
    "hoodie.datasource.write.precombine.field" -> "<your_precombine_field>",
    "hoodie.datasource.write.partitionpath.field" -> "<your_partitionkey_field>",
```

```

"hoodie.datasource.write.hive_style_partitioning" -> "true",
"hoodie.datasource.hive_sync.enable" -> "true",
"hoodie.datasource.hive_sync.database" -> "<your_database_name>",
"hoodie.datasource.hive_sync.table" -> "<your_table_name>",
"hoodie.datasource.hive_sync.partition_fields" -> "<your_partitionkey_field>",
"hoodie.datasource.hive_sync.partition_extractor_class" ->
"org.apache.hudi.hive.MultiPartKeyValueExtractor",
"hoodie.datasource.hive_sync.use_jdbc" -> "false",
"hoodie.datasource.hive_sync.mode" -> "hms",
"path" -> "s3://<s3Path/>")

dataFrame.write.format("hudi")
  .options(additionalOptions)
  .mode("append")
  .save()

```

Example: Read a Hudi table from Amazon S3 using the Amazon Glue Data Catalog

This example reads the Hudi table that you created in the [Example: Write a Hudi table to Amazon S3 and register it in the Amazon Glue Data Catalog](#) from Amazon S3.

Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the Amazon Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [Using job parameters in Amazon Glue jobs](#).

Python

For this example, use the [GlueContext.create_data_frame.from_catalog\(\)](#) method.

```

# Example: Read a Hudi table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

dataFrame = glueContext.create_data_frame.from_catalog(

```

```
    database = "<your_database_name>",  
    table_name = "<your_table_name>"  
  )
```

Scala

For this example, use the [getCatalogSource](#) method.

```
// Example: Read a Hudi table from Glue Data Catalog  
  
import com.amazonaws.services.glue.GlueContext  
import org.apache.spark.SparkContext  
  
object GlueApp {  
  def main(sysArgs: Array[String]): Unit = {  
    val spark: SparkContext = new SparkContext()  
    val glueContext: GlueContext = new GlueContext(spark)  
  
    val dataframe = glueContext.getCatalogSource(  
      database = "<your_database_name>",  
      tableName = "<your_table_name>"  
    ).getDataFrame()  
  }  
}
```

Example: Update and insert a DataFrame into a Hudi table in Amazon S3

This example uses the Amazon Glue Data Catalog to insert a DataFrame into the Hudi table that you created in [Example: Write a Hudi table to Amazon S3 and register it in the Amazon Glue Data Catalog](#).

Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the Amazon Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [Using job parameters in Amazon Glue jobs](#).

Python

For this example, use the [GlueContext.write_data_frame_from_catalog\(\)](#) method.

```
# Example: Upsert a Hudi table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

glueContext.write_data_frame.from_catalog(
    frame = dataframe,
    database = "<your_database_name>",
    table_name = "<your_table_name>",
    additional_options={
        "hoodie.table.name": "<your_table_name>",
        "hoodie.database.name": "<your_database_name>",
        "hoodie.datasource.write.storage.type": "COPY_ON_WRITE",
        "hoodie.datasource.write.operation": "upsert",
        "hoodie.datasource.write.recordkey.field": "<your_recordkey_field>",
        "hoodie.datasource.write.precombine.field": "<your_precombine_field>",
        "hoodie.datasource.write.partitionpath.field": "<your_partitionkey_field>",
        "hoodie.datasource.write.hive_style_partitioning": "true",
        "hoodie.datasource.hive_sync.enable": "true",
        "hoodie.datasource.hive_sync.database": "<your_database_name>",
        "hoodie.datasource.hive_sync.table": "<your_table_name>",
        "hoodie.datasource.hive_sync.partition_fields": "<your_partitionkey_field>",
        "hoodie.datasource.hive_sync.partition_extractor_class":
"org.apache.hudi.hive.MultiPartKeysValueExtractor",
        "hoodie.datasource.hive_sync.use_jdbc": "false",
        "hoodie.datasource.hive_sync.mode": "hms"
    }
)
```

Scala

For this example, use the [getCatalogSink](#) method.

```
// Example: Upsert a Hudi table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext

object GlueApp {
```

```

def main(sysArgs: Array[String]): Unit = {
  val spark: SparkContext = new SparkContext()
  val glueContext: GlueContext = new GlueContext(spark)
  glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
    additionalOptions = JsonOptions(Map(
      "hoodie.table.name" -> "<your_table_name>",
      "hoodie.database.name" -> "<your_database_name>",
      "hoodie.datasource.write.storage.type" -> "COPY_ON_WRITE",
      "hoodie.datasource.write.operation" -> "upsert",
      "hoodie.datasource.write.recordkey.field" -> "<your_recordkey_field>",
      "hoodie.datasource.write.precombine.field" -> "<your_precombine_field>",
      "hoodie.datasource.write.partitionpath.field" ->
"<your_partitionkey_field>",
      "hoodie.datasource.write.hive_style_partitioning" -> "true",
      "hoodie.datasource.hive_sync.enable" -> "true",
      "hoodie.datasource.hive_sync.database" -> "<your_database_name>",
      "hoodie.datasource.hive_sync.table" -> "<your_table_name>",
      "hoodie.datasource.hive_sync.partition_fields" ->
"<your_partitionkey_field>",
      "hoodie.datasource.hive_sync.partition_extractor_class" ->
"org.apache.hudi.hive.MultiPartKeyValueExtractor",
      "hoodie.datasource.hive_sync.use_jdbc" -> "false",
      "hoodie.datasource.hive_sync.mode" -> "hms"
    )))
  .writeDataFrame(dataFrame, glueContext)
}
}

```

Example: Read a Hudi table from Amazon S3 using Spark

This example reads a Hudi table from Amazon S3 using the Spark DataFrame API.

Python

```

# Example: Read a Hudi table from S3 using a Spark DataFrame

dataFrame = spark.read.format("hudi").load("s3://<s3path/>")

```

Scala

```

// Example: Read a Hudi table from S3 using a Spark DataFrame

```

```
val dataframe = spark.read.format("hudi").load("s3://<s3path/>")
```

Example: Write a Hudi table to Amazon S3 using Spark

This example writes a Hudi table to Amazon S3 using Spark.

Python

```
# Example: Write a Hudi table to S3 using a Spark DataFrame

dataframe.write.format("hudi") \
    .options(**additional_options) \
    .mode("overwrite") \
    .save("s3://<s3Path/>")
```

Scala

```
// Example: Write a Hudi table to S3 using a Spark DataFrame

dataframe.write.format("hudi")
    .options(additionalOptions)
    .mode("overwrite")
    .save("s3://<s3path/>")
```

Example: Read and write Hudi table with Lake Formation permission control

This example reads and writes a Hudi table with Lake Formation permission control.

1. Create a Hudi table and register it in Lake Formation.
 - a. To enable Lake Formation permission control, you'll first need to register the table Amazon S3 path on Lake Formation. For more information, see [Registering an Amazon S3 location](#). You can register it either from the Lake Formation console or by using the Amazon CLI:

```
aws lakeformation register-resource --resource-arn arn:aws:s3:::<s3-bucket>/<s3-
folder> --use-service-linked-role --region <REGION>
```

Once you register an Amazon S3 location, any Amazon Glue table pointing to the location (or any of its child locations) will return the value for the `IsRegisteredWithLakeFormation` parameter as true in the `GetTable` call.

- b. Create a Hudi table that points to the registered Amazon S3 path through the Spark dataframe API:

```
hoodie_options = {
    'hoodie.table.name': table_name,
    'hoodie.database.name': database_name,
    'hoodie.datasource.write.storage.type': 'COPY_ON_WRITE',
    'hoodie.datasource.write.recordkey.field': 'product_id',
    'hoodie.datasource.write.table.name': table_name,
    'hoodie.datasource.write.operation': 'upsert',
    'hoodie.datasource.write.precombine.field': 'updated_at',
    'hoodie.datasource.write.hive_style_partitioning': 'true',
    'hoodie.upsert.shuffle.parallelism': 2,
    'hoodie.insert.shuffle.parallelism': 2,
    'path': <S3_TABLE_LOCATION>,
    'hoodie.datasource.hive_sync.enable': 'true',
    'hoodie.datasource.hive_sync.database': database_name,
    'hoodie.datasource.hive_sync.table': table_name,
    'hoodie.datasource.hive_sync.use_jdbc': 'false',
    'hoodie.datasource.hive_sync.mode': 'hms'
}

df_products.write.format("hudi") \
    .options(**hoodie_options) \
    .mode("overwrite") \
    .save()
```

2. Grant Lake Formation permission to the Amazon Glue job IAM role. You can either grant permissions from the Lake Formation console, or using the Amazon CLI. For more information, see [Granting table permissions using the Lake Formation console and the named resource method](#)
3. Read the Hudi table registered in Lake Formation. The code is same as reading a non-registered Hudi table. Note that the Amazon Glue job IAM role needs to have the SELECT permission for the read to succeed.

```
val dataframe = glueContext.getCatalogSource(
    database = "<your_database_name>",
    tableName = "<your_table_name>"
).getDataFrame()
```

4. Write to a Hudi table registered in Lake Formation. The code is same as writing to a non-registered Hudi table. Note that the Amazon Glue job IAM role needs to have the SUPER permission for the write to succeed.

```
glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
    additionalOptions = JsonOptions(Map(
      "hoodie.table.name" -> "<your_table_name>",
      "hoodie.database.name" -> "<your_database_name>",
      "hoodie.datasource.write.storage.type" -> "COPY_ON_WRITE",
      "hoodie.datasource.write.operation" -> "<write_operation>",
      "hoodie.datasource.write.recordkey.field" -> "<your_recordkey_field>",
      "hoodie.datasource.write.precombine.field" -> "<your_precombine_field>",
      "hoodie.datasource.write.partitionpath.field" -> "<your_partitionkey_field>",
      "hoodie.datasource.write.hive_style_partitioning" -> "true",
      "hoodie.datasource.hive_sync.enable" -> "true",
      "hoodie.datasource.hive_sync.database" -> "<your_database_name>",
      "hoodie.datasource.hive_sync.table" -> "<your_table_name>",
      "hoodie.datasource.hive_sync.partition_fields" ->
"<your_partitionkey_field>",
      "hoodie.datasource.hive_sync.partition_extractor_class" ->
"org.apache.hudi.hive.MultiPartKeyValueExtractor",
      "hoodie.datasource.hive_sync.use_jdbc" -> "false",
      "hoodie.datasource.hive_sync.mode" -> "hms"
    )))
.writeDataFrame(dataFrame, glueContext)
```

Using the Delta Lake framework in Amazon Glue

Amazon Glue 3.0 and later supports the Linux Foundation Delta Lake framework. Delta Lake is an open-source data lake storage framework that helps you perform ACID transactions, scale metadata handling, and unify streaming and batch data processing. This topic covers available features for using your data in Amazon Glue when you transport or store your data in a Delta Lake table. To learn more about Delta Lake, see the official [Delta Lake documentation](#).

You can use Amazon Glue to perform read and write operations on Delta Lake tables in Amazon S3, or work with Delta Lake tables using the Amazon Glue Data Catalog. Additional operations such as insert, update, and [Table batch reads and writes](#) are also supported. When you use Delta Lake tables, you also have the option to use methods from the Delta Lake Python library such as `DeltaTable.forPath`. For more information about the Delta Lake Python library, see Delta Lake's Python documentation.

The following table lists the version of Delta Lake included in each Amazon Glue version.

| Amazon Glue version | Supported Delta Lake version |
|---------------------|------------------------------|
| 5.1 | 3.3.2 |
| 5.0 | 3.3.0 |
| 4.0 | 2.1.0 |
| 3.0 | 1.0.0 |

To learn more about the data lake frameworks that Amazon Glue supports, see [Using data lake frameworks with Amazon Glue ETL jobs](#).

Enabling Delta Lake for Amazon Glue

To enable Delta Lake for Amazon Glue, complete the following tasks:

- Specify `delta` as a value for the `--dataLake-formats` job parameter. For more information, see [Using job parameters in Amazon Glue jobs](#).
- Create a key named `--conf` for your Amazon Glue job, and set it to the following value. Alternatively, you can set the following configuration using `SparkConf` in your script. These settings help Apache Spark correctly handle Delta Lake tables.

```
spark.sql.extensions=io.delta.sql.DeltaSparkSessionExtension --conf
spark.sql.catalog.spark_catalog=org.apache.spark.sql.delta.catalog.DeltaCatalog --
conf
spark.delta.logStore.class=org.apache.spark.sql.delta.storage.S3SingleDriverLogStore
```

- Lake Formation permission support for Delta tables is enabled by default for Amazon Glue 4.0. No additional configuration is needed for reading/writing to Lake Formation-registered Delta tables. To read a registered Delta table, the Amazon Glue job IAM role must have the `SELECT` permission. To write to a registered Delta table, the Amazon Glue job IAM role must have the `SUPER` permission. To learn more about managing Lake Formation permissions, see [Granting and revoking permissions on Data Catalog resources](#).

Using a different Delta Lake version

To use a version of Delta lake that Amazon Glue doesn't support, specify your own Delta Lake JAR files using the `--extra-jars` job parameter. Do not include `delta` as a value for the `--datalake-formats` job parameter. If you use Amazon Glue 5.0 or above, you must set `--user-jars-first true` job parameter. To use the Delta Lake Python library in this case, you must specify the library JAR files using the `--extra-py-files` job parameter. The Python library comes packaged in the Delta Lake JAR files.

Example: Write a Delta Lake table to Amazon S3 and register it to the Amazon Glue Data Catalog

The following Amazon Glue ETL script demonstrates how to write a Delta Lake table to Amazon S3 and register the table to the Amazon Glue Data Catalog.

Python

```
# Example: Create a Delta Lake table from a DataFrame
# and register the table to Glue Data Catalog

additional_options = {
    "path": "s3://<s3Path>"
}
dataFrame.write \
    .format("delta") \
    .options(**additional_options) \
    .mode("append") \
    .partitionBy("<your_partitionkey_field>") \
    .saveAsTable("<your_database_name>.<your_table_name>")
```

Scala

```
// Example: Example: Create a Delta Lake table from a DataFrame
// and register the table to Glue Data Catalog

val additional_options = Map(
    "path" -> "s3://<s3Path>"
)
dataFrame.write.format("delta")
    .options(additional_options)
    .mode("append")
    .partitionBy("<your_partitionkey_field>")
    .saveAsTable("<your_database_name>.<your_table_name>")
```

Example: Read a Delta Lake table from Amazon S3 using the Amazon Glue Data Catalog

The following Amazon Glue ETL script reads the Delta Lake table that you created in [Example: Write a Delta Lake table to Amazon S3 and register it to the Amazon Glue Data Catalog](#).

Python

For this example, use the [create_data_frame_from_catalog](#) method.

```
# Example: Read a Delta Lake table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

df = glueContext.create_data_frame_from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Scala

For this example, use the [getCatalogSource](#) method.

```
// Example: Read a Delta Lake table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val df = glueContext.getCatalogSource("<your_database_name>",
"<your_table_name>",
      additionalOptions = additionalOptions)
      .getDataFrame()
  }
}
```

Example: Insert a DataFrame into a Delta Lake table in Amazon S3 using the Amazon Glue Data Catalog

This example inserts data into the Delta Lake table that you created in [Example: Write a Delta Lake table to Amazon S3 and register it to the Amazon Glue Data Catalog](#).

Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the Amazon Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [Using job parameters in Amazon Glue jobs](#).

Python

For this example, use the [write_data_frame.from_catalog](#) method.

```
# Example: Insert into a Delta Lake table in S3 using Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Scala

For this example, use the [getCatalogSink](#) method.

```
// Example: Insert into a Delta Lake table in S3 using Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext
```

```
object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
      additionalOptions = additionalOptions)
      .writeDataFrame(dataFrame, glueContext)
  }
}
```

Example: Read a Delta Lake table from Amazon S3 using the Spark API

This example reads a Delta Lake table from Amazon S3 using the Spark API.

Python

```
# Example: Read a Delta Lake table from S3 using a Spark DataFrame

dataFrame = spark.read.format("delta").load("s3://<s3path/>")
```

Scala

```
// Example: Read a Delta Lake table from S3 using a Spark DataFrame

val dataFrame = spark.read.format("delta").load("s3://<s3path/>")
```

Example: Write a Delta Lake table to Amazon S3 using Spark

This example writes a Delta Lake table to Amazon S3 using Spark.

Python

```
# Example: Write a Delta Lake table to S3 using a Spark DataFrame

dataFrame.write.format("delta") \
  .options(**additional_options) \
  .mode("overwrite") \
  .partitionBy("<your_partitionkey_field>") \
  .save("s3://<s3Path>")
```

Scala

```
// Example: Write a Delta Lake table to S3 using a Spark DataFrame

dataFrame.write.format("delta")
  .options(additionalOptions)
  .mode("overwrite")
  .partitionBy("<your_partitionkey_field>")
  .save("s3://<s3path/>")
```

Example: Read and write Delta Lake table with Lake Formation permission control

This example reads and writes a Delta Lake table with Lake Formation permission control.

1. Create a Delta table and register it in Lake Formation

- a. To enable Lake Formation permission control, you'll first need to register the table Amazon S3 path on Lake Formation. For more information, see [Registering an Amazon S3 location](#). You can register it either from the Lake Formation console or by using the Amazon CLI:

```
aws lakeformation register-resource --resource-arn arn:aws:s3:::<s3-bucket>/<s3-
folder> --use-service-linked-role --region <REGION>
```

Once you register an Amazon S3 location, any Amazon Glue table pointing to the location (or any of its child locations) will return the value for the `IsRegisteredWithLakeFormation` parameter as true in the `GetTable` call.

- b. Create a Delta table that points to the registered Amazon S3 path through Spark:

Note

The following are Python examples.

```
dataFrame.write \
  .format("delta") \
  .mode("overwrite") \
  .partitionBy("<your_partitionkey_field>") \
  .save("s3://<the_s3_path>")
```

After the data has been written to Amazon S3, use the Amazon Glue crawler to create a new Delta catalog table. For more information, see [Introducing native Delta Lake table support with Amazon Glue crawlers](#).

You can also create the table manually through the Amazon Glue CreateTable API.

2. Grant Lake Formation permission to the Amazon Glue job IAM role. You can either grant permissions from the Lake Formation console, or using the Amazon CLI. For more information, see [Granting table permissions using the Lake Formation console and the named resource method](#)
3. Read the Delta table registered in Lake Formation. The code is same as reading a non-registered Delta table. Note that the Amazon Glue job IAM role needs to have the SELECT permission for the read to succeed.

```
# Example: Read a Delta Lake table from Glue Data Catalog

df = glueContext.create_data_frame.from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

4. Write to a Delta table registered in Lake Formation. The code is same as writing to a non-registered Delta table. Note that the Amazon Glue job IAM role needs to have the SUPER permission for the write to succeed.

By default Amazon Glue uses Append as saveMode. You can change it by setting the saveMode option in additional_options. For information about saveMode support in Delta tables, see [Write to a table](#).

```
glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Using the Iceberg framework in Amazon Glue

Amazon Glue 3.0 and later supports the Apache Iceberg framework for data lakes. Iceberg provides a high-performance table format that works just like a SQL table. This topic covers available features for using your data in Amazon Glue when you transport or store your data in an Iceberg table. To learn more about Iceberg, see the official [Apache Iceberg documentation](#).

You can use Amazon Glue to perform read and write operations on Iceberg tables in Amazon S3, or work with Iceberg tables using the Amazon Glue Data Catalog. Additional operations including insert and all [Spark Queries](#) [Spark Writes](#) are also supported. Update is not supported for Iceberg tables.

Note

ALTER TABLE ... RENAME TO is not available for Apache Iceberg 0.13.1 for Amazon Glue 3.0.

The following table lists the version of Iceberg included in each Amazon Glue version.

| Amazon Glue version | Supported Iceberg version |
|---------------------|---------------------------|
| 5.1 | 1.10.0 |
| 5.0 | 1.7.1 |
| 4.0 | 1.0.0 |
| 3.0 | 0.13.1 |

To learn more about the data lake frameworks that Amazon Glue supports, see [Using data lake frameworks with Amazon Glue ETL jobs](#).

Enabling the Iceberg framework

To enable Iceberg for Amazon Glue, complete the following tasks:

- Specify `iceberg` as a value for the `--datalake-formats` job parameter. For more information, see [Using job parameters in Amazon Glue jobs](#).

- Create a key named `--conf` for your Amazon Glue job, and set it to the following value. Alternatively, you can set the following configuration using `SparkConf` in your script. These settings help Apache Spark correctly handle Iceberg tables.

```
spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
--conf spark.sql.catalog.glue_catalog=org.apache.iceberg.spark.SparkCatalog
--conf spark.sql.catalog.glue_catalog.warehouse=s3://<your-warehouse-dir>/
--conf spark.sql.catalog.glue_catalog.catalog-impl=org.apache.iceberg.aws.glue.GlueCatalog
--conf spark.sql.catalog.glue_catalog.io-impl=org.apache.iceberg.aws.s3.S3FileIO
```

If you are reading or writing to Iceberg tables that are registered with Lake Formation, follow the guidance in [the section called “Lake Formation for FGAC”](#) in Amazon Glue 5.0 and later. In Amazon Glue 4.0, add the following configuration to enable Lake Formation support.

```
--conf spark.sql.catalog.glue_catalog.glue.lakeformation-enabled=true
--conf spark.sql.catalog.glue_catalog.glue.id=<table-catalog-id>
```

If you use Amazon Glue 3.0 with Iceberg 0.13.1, you must set the following additional configurations to use Amazon DynamoDB lock manager to ensure atomic transaction. Amazon Glue 4.0 or later uses optimistic locking by default. For more information, see [Iceberg Amazon Integrations](#) in the official Apache Iceberg documentation.

```
--conf spark.sql.catalog.glue_catalog.lock-impl=org.apache.iceberg.aws.glue.DynamoLockManager
--conf spark.sql.catalog.glue_catalog.lock.table=<your-dynamodb-table-name>
```

Using a different Iceberg version

To use a version of Iceberg that Amazon Glue doesn't support, specify your own Iceberg JAR files using the `--extra-jars` job parameter. Do not include `iceberg` as a value for the `--datalake-formats` parameter. If you use Amazon Glue 5.0 or above, you must set `--user-jars-first true` job parameter.

Enabling encryption for Iceberg tables

Note

Iceberg tables have their own mechanisms to enable server-side encryption. You should enable this configuration in addition to Amazon Glue's security configuration.

To enable server-side encryption on Iceberg tables, review the guidance from the [Iceberg documentation](#).

Add Spark configuration for Iceberg cross region

To add additional spark configuration for Iceberg cross-region table access with the Amazon Glue Data Catalog and Amazon Lake Formation, follow the steps below:

1. Create a [Multi-region access point](#).
2. Set the following Spark properties:

```
-----
--conf spark.sql.catalog.my_catalog.s3.use-arn-region-enabled=true \
--conf spark.sql.catalog.{CATALOG}.s3.access-points.bucket1",
"arn:aws:s3::<account-id>:accesspoint/<mrp-id>.mrp \
--conf spark.sql.catalog.{CATALOG}.s3.access-points.bucket2",
"arn:aws:s3::<account-id>:accesspoint/<mrp-id>.mrp
-----
```

Example: Write an Iceberg table to Amazon S3 and register it to the Amazon Glue Data Catalog

This example script demonstrates how to write an Iceberg table to Amazon S3. The example uses [Iceberg Amazon Integrations](#) to register the table to the Amazon Glue Data Catalog.

Python

```
# Example: Create an Iceberg table from a DataFrame
# and register the table to Glue Data Catalog

dataFrame.createOrReplaceTempView("tmp_<your_table_name>")

query = f"""
CREATE TABLE glue_catalog.<your_database_name>.<your_table_name>
USING iceberg
```

```
TBLPROPERTIES ("format-version"="2")
AS SELECT * FROM tmp_<your_table_name>
"""
spark.sql(query)
```

Scala

```
// Example: Example: Create an Iceberg table from a DataFrame
// and register the table to Glue Data Catalog

dataFrame.createOrReplaceTempView("tmp_<your_table_name>")

val query = """CREATE TABLE glue_catalog.<your_database_name>.<your_table_name>
USING iceberg
TBLPROPERTIES ("format-version"="2")
AS SELECT * FROM tmp_<your_table_name>
"""
spark.sql(query)
```

Alternatively, you can write an Iceberg table to Amazon S3 and the Data Catalog using Spark methods.

Prerequisites: You will need to provision a catalog for the Iceberg library to use. When using the Amazon Glue Data Catalog, Amazon Glue makes this straightforward. The Amazon Glue Data Catalog is pre-configured for use by the Spark libraries as `glue_catalog`. Data Catalog tables are identified by a *databaseName* and a *tableName*. For more information about the Amazon Glue Data Catalog, see [Data discovery and cataloging](#).

If you are not using the Amazon Glue Data Catalog, you will need to provision a catalog through the Spark APIs. For more information, see [Spark Configuration](#) in the Iceberg documentation.

This example writes an Iceberg table to Amazon S3 and the Data Catalog using Spark.

Python

```
# Example: Write an Iceberg table to S3 on the Glue Data Catalog

# Create (equivalent to CREATE TABLE AS SELECT)
dataFrame.writeTo("glue_catalog.<databaseName>.<tableName>") \
    .tableProperty("format-version", "2") \
    .create()
```

```
# Append (equivalent to INSERT INTO)
dataFrame.writeTo("glue_catalog.databaseName.tableName") \
    .tableProperty("format-version", "2") \
    .append()
```

Scala

```
// Example: Write an Iceberg table to S3 on the Glue Data Catalog

// Create (equivalent to CREATE TABLE AS SELECT)
dataFrame.writeTo("glue_catalog.databaseName.tableName")
    .tableProperty("format-version", "2")
    .create()

// Append (equivalent to INSERT INTO)
dataFrame.writeTo("glue_catalog.databaseName.tableName")
    .tableProperty("format-version", "2")
    .append()
```

Example: Read an Iceberg table from Amazon S3 using the Amazon Glue Data Catalog

This example reads the Iceberg table that you created in [Example: Write an Iceberg table to Amazon S3 and register it to the Amazon Glue Data Catalog](#).

Python

For this example, use the [GlueContext.create_data_frame.from_catalog\(\)](#) method.

```
# Example: Read an Iceberg table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

df = glueContext.create_data_frame.from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Scala

For this example, use the [getCatalogSource](#) method.

```
// Example: Read an Iceberg table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val df = glueContext.getCatalogSource("<your_database_name>",
"<your_table_name>",
    additionalOptions = additionalOptions)
    .getDataFrame()
  }
}
```

Example: Insert a DataFrame into an Iceberg table in Amazon S3 using the Amazon Glue Data Catalog

This example inserts data into the Iceberg table that you created in [Example: Write an Iceberg table to Amazon S3 and register it to the Amazon Glue Data Catalog](#).

Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the Amazon Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [Using job parameters in Amazon Glue jobs](#).

Python

For this example, use the [GlueContext.write_data_frame_from_catalog\(\)](#) method.

```
# Example: Insert into an Iceberg table from Glue Data Catalog

from awsglue.context import GlueContext
```

```
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Scala

For this example, use the [getCatalogSink](#) method.

```
// Example: Insert into an Iceberg table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
      additionalOptions = additionalOptions)
      .writeDataFrame(dataFrame, glueContext)
  }
}
```

Example: Read an Iceberg table from Amazon S3 using Spark

Prerequisites: You will need to provision a catalog for the Iceberg library to use. When using the Amazon Glue Data Catalog, Amazon Glue makes this straightforward. The Amazon Glue Data Catalog is pre-configured for use by the Spark libraries as `glue_catalog`. Data Catalog tables are identified by a *databaseName* and a *tableName*. For more information about the Amazon Glue Data Catalog, see [Data discovery and cataloging](#).

If you are not using the Amazon Glue Data Catalog, you will need to provision a catalog through the Spark APIs. For more information, see [Spark Configuration](#) in the Iceberg documentation.

This example reads an Iceberg table in Amazon S3 from the Data Catalog using Spark.

Python

```
# Example: Read an Iceberg table on S3 as a DataFrame from the Glue Data Catalog  
dataFrame = spark.read.format("iceberg").load("glue_catalog.databaseName.tableName")
```

Scala

```
// Example: Read an Iceberg table on S3 as a DataFrame from the Glue Data Catalog  
val dataFrame =  
  spark.read.format("iceberg").load("glue_catalog.databaseName.tableName")
```

Example: Read and write Iceberg table with Lake Formation permission control

This example reads and writes an Iceberg table with Lake Formation permission control.

Note

This example works only in Amazon Glue 4.0. In Amazon Glue 5.0 and later, follow the guidance in [the section called "Lake Formation for FGAC"](#).

1. Create an Iceberg table and register it in Lake Formation:

- a. To enable Lake Formation permission control, you'll first need to register the table Amazon S3 path on Lake Formation. For more information, see [Registering an Amazon S3 location](#). You can register it either from the Lake Formation console or by using the Amazon CLI:

```
aws lakeformation register-resource --resource-arn arn:aws:s3:::<s3-bucket>/<s3-  
folder> --use-service-linked-role --region <REGION>
```

Once you register an Amazon S3 location, any Amazon Glue table pointing to the location (or any of its child locations) will return the value for the `IsRegisteredWithLakeFormation` parameter as true in the `GetTable` call.

- b. Create an Iceberg table that points to the registered path through Spark SQL:

Note

The following are Python examples.

```
dataFrame.createOrReplaceTempView("tmp_<your_table_name>")

query = f"""
CREATE TABLE glue_catalog.<your_database_name>.<your_table_name>
USING iceberg
AS SELECT * FROM tmp_<your_table_name>
"""
spark.sql(query)
```

You can also create the table manually through Amazon Glue CreateTable API. For more information, see [Creating Apache Iceberg tables](#).

Note

The UpdateTable API does not currently support Iceberg table format as an input to the operation.

2. Grant Lake Formation permission to the job IAM role. You can either grant permissions from the Lake Formation console, or using the Amazon CLI. For more information, see: <https://docs.aws.amazon.com/lake-formation/latest/dg/granting-table-permissions.html>
3. Read an Iceberg table registered with Lake Formation. The code is same as reading a non-registered Iceberg table. Note that your Amazon Glue job IAM role needs to have the SELECT permission for the read to succeed.

```
# Example: Read an Iceberg table from the Amazon Glue Data Catalog
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

df = glueContext.create_data_frame.from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
```

```
additional_options=additional_options
)
```

4. Write to an Iceberg table registered with Lake Formation. The code is same as writing to a non-registered Iceberg table. Note that your Amazon Glue job IAM role needs to have the SUPER permission for the write to succeed.

```
glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Shared configuration reference

You can use the following `format_options` values with any format type.

- `attachFilename` — A string in the appropriate format to be used as a column name. If you provide this option, the name of the source file for the record will be appended to the record. The parameter value will be used as the column name.
- `attachTimestamp` — A string in the appropriate format to be used as a column name. If you provide this option, the modification time of the source file for the record will be appended to the record. The parameter value will be used as the column name.

Amazon Glue Data Catalog support for Spark SQL jobs

The Amazon Glue Data Catalog is an Apache Hive metastore-compatible catalog. You can configure your Amazon Glue jobs and development endpoints to use the Data Catalog as an external Apache Hive metastore. You can then directly run Apache Spark SQL queries against the tables stored in the Data Catalog. Amazon Glue dynamic frames integrate with the Data Catalog by default. However, with this feature, Spark SQL jobs can start using the Data Catalog as an external Hive metastore.

This feature requires network access to the Amazon Glue API endpoint. For Amazon Glue jobs with connections located in private subnets, you must configure either a VPC endpoint or NAT gateway to provide the network access. For information about configuring a VPC endpoint, see [Setting up](#)

[network access to data stores](#). To create a NAT gateway, see [NAT Gateways](#) in the *Amazon VPC User Guide*.

You can configure Amazon Glue jobs and development endpoints by adding the "--enable-glue-catalog": "" argument to job arguments and development endpoint arguments respectively. Passing this argument sets certain configurations in Spark that enable it to access the Data Catalog as an external Hive metastore. It also [enables Hive support](#) in the SparkSession object created in the Amazon Glue job or development endpoint.

To enable the Data Catalog access, check the **Use Amazon Glue Data Catalog as the Hive metastore** check box in the **Catalog options** group on the **Add job** or **Add endpoint** page on the console. Note that the IAM role used for the job or development endpoint should have `glue:CreateDatabase` permissions. A database called "default" is created in the Data Catalog if it does not exist.

Lets look at an example of how you can use this feature in your Spark SQL jobs. The following example assumes that you have crawled the US legislators dataset available at `s3://awsglue-datasets/examples/us-legislators`.

To serialize/deserialize data from the tables defined in the Amazon Glue Data Catalog, Spark SQL needs the [Hive SerDe](#) class for the format defined in the Amazon Glue Data Catalog in the classpath of the spark job.

SerDes for certain common formats are distributed by Amazon Glue. The following are the Amazon S3 links for these:

- [JSON](#)
- [XML](#)
- [Grok](#)

Add the JSON SerDe as an [extra JAR to the development endpoint](#). For jobs, you can add the SerDe using the `--extra-jars` argument in the arguments field. For more information, see [Using job parameters in Amazon Glue jobs](#).

Here is an example input JSON to create a development endpoint with the Data Catalog enabled for Spark SQL.

```
{
```

```

"EndpointName": "Name",
"RoleArn": "role_ARN",
"PublicKey": "public_key_contents",
"NumberOfNodes": 2,
"Arguments": {
  "--enable-glue-datacatalog": ""
},
"ExtraJarsS3Path": "s3://crawler-public/json/serde/json-serde.jar"
}

```

Now query the tables created from the US legislators dataset using Spark SQL.

```

>>> spark.sql("use legislators")
DataFrame[]
>>> spark.sql("show tables").show()
+-----+-----+-----+
| database|      tableName|isTemporary|
+-----+-----+-----+
|legislators|      areas_json|      false|
|legislators|  countries_json|      false|
|legislators|      events_json|      false|
|legislators|  memberships_json|      false|
|legislators|  organizations_json|      false|
|legislators|      persons_json|      false|
+-----+-----+-----+
>>> spark.sql("describe memberships_json").show()
+-----+-----+-----+
|      col_name|data_type|      comment|
+-----+-----+-----+
|      area_id|  string|from deserializer|
|  on_behalf_of_id|  string|from deserializer|
|  organization_id|  string|from deserializer|
|      role|  string|from deserializer|
|      person_id|  string|from deserializer|
|legislative_perio...|  string|from deserializer|
|      start_date|  string|from deserializer|
|      end_date|  string|from deserializer|
+-----+-----+-----+

```

If the SerDe class for the format is not available in the job's classpath, you will see an error similar to the following.

```
>>> spark.sql("describe memberships_json").show()
```

```
Caused by: MetaException(message:java.lang.ClassNotFoundException Class
org.openx.data.jsonserde.JsonSerDe not found)
    at
org.apache.hadoop.hive.metastore.MetaStoreUtils.getDeserializer(MetaStoreUtils.java:399)
    at
org.apache.hadoop.hive.ql.metadata.Table.getDeserializerFromMetaStore(Table.java:276)
    ... 64 more
```

To view only the distinct `organization_ids` from the `memberships` table, run the following SQL query.

```
>>> spark.sql("select distinct organization_id from memberships_json").show()
+-----+
| organization_id|
+-----+
|d56acebe-8fdc-47b...|
|8fa6c3d2-71dc-478...|
+-----+
```

If you need to do the same with dynamic frames, run the following.

```
>>> memberships = glueContext.create_dynamic_frame.from_catalog(database="legislators",
    table_name="memberships_json")
>>> memberships.toDF().createOrReplaceTempView("memberships")
>>> spark.sql("select distinct organization_id from memberships").show()
+-----+
| organization_id|
+-----+
|d56acebe-8fdc-47b...|
|8fa6c3d2-71dc-478...|
+-----+
```

While `DynamicFrames` are optimized for ETL operations, enabling Spark SQL to access the Data Catalog directly provides a concise way to run complex SQL statements or port existing applications.

Using job bookmarks

Amazon Glue for Spark uses job bookmarks to track data that has already been processed. For a summary of the job bookmarks feature and what it supports, see [the section called “Tracking processed data using job bookmarks”](#). When programming a Amazon Glue job with bookmarks, you have access to flexibility unavailable in visual jobs.

- When reading from JDBC, you can specify the column(s) to use as bookmark keys in your Amazon Glue script.
- You can chose which `transformation_ctx` to apply to each method call.

Always call `job.init` in the beginning of the script and the `job.commit` in the end of the script with appropriately configured parameters. These two functions initialize the bookmark service and update the state change to the service. Bookmarks won't work without calling them.

Specify bookmark keys

For JDBC workflows, the bookmark keeps track of which rows your job has read by comparing the values of key fields to a bookmarked value. This is not necessary or applicable for Amazon S3 workflows. When writing a Amazon Glue script without the visual editor, you can specify which column to track with bookmarks. You can also specify multiple columns. Gaps in the sequence of values are permitted when specifying user-defined bookmark keys.

Warning

If user-defined bookmarks keys are used, they must each be strictly monotonically increasing or decreasing. When selecting additional fields for a compound key, fields for concepts like "minor versions" or "revision numbers" do not meet this criteria, since their values are reused throughout your dataset.

You can specify `jobBookmarkKeys` and `jobBookmarkKeysSortOrder` in the following ways:

- `create_dynamic_frame.from_catalog` — Use `additional_options`.
- `create_dynamic_frame.from_options` — Use `connection_options`.

Transformation context

Many of the Amazon Glue PySpark dynamic frame methods include an optional parameter named `transformation_ctx`, which is a unique identifier for the ETL operator instance. The `transformation_ctx` parameter is used to identify state information within a job bookmark for the given operator. Specifically, Amazon Glue uses `transformation_ctx` to index the key to the bookmark state.

Warning

The `transformation_ctx` serves as the key to search the bookmark state for a specific source in your script. For the bookmark to work properly, you should always keep the source and the associated `transformation_ctx` consistent. Changing the source property or renaming the `transformation_ctx` may make the previous bookmark invalid and the time stamp based filtering may not yield the correct result.

For job bookmarks to work properly, enable the job bookmark parameter and set the `transformation_ctx` parameter. If you don't pass in the `transformation_ctx` parameter, then job bookmarks are not enabled for a dynamic frame or a table used in the method. For example, if you have an ETL job that reads and joins two Amazon S3 sources, you might choose to pass the `transformation_ctx` parameter only to those methods that you want to enable bookmarks. If you reset the job bookmark for a job, it resets all transformations that are associated with the job regardless of the `transformation_ctx` used.

For more information about the `DynamicFrameReader` class, see [DynamicFrameReader class](#). For more information about PySpark extensions, see [Amazon Glue PySpark extensions reference](#).

Examples

Example

The following is an example of a generated script for an Amazon S3 data source. The portions of the script that are required for using job bookmarks are shown in italics. For more information about these elements see the [GlueContext class](#) API, and the [DynamicFrameWriter class](#) API.

```
# Sample Script
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
```

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ['JOB_NAME'])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

datasource0 = glueContext.create_dynamic_frame.from_catalog(
    database = "database",
    table_name = "relatedqueries_csv",
    transformation_ctx = "datasource0"
)

applymapping1 = ApplyMapping.apply(
    frame = datasource0,
    mappings = [("col0", "string", "name", "string"), ("col1", "string", "number",
"string")],
    transformation_ctx = "applymapping1"
)

datasink2 = glueContext.write_dynamic_frame.from_options(
    frame = applymapping1,
    connection_type = "s3",
    connection_options = {"path": "s3://input_path"},
    format = "json",
    transformation_ctx = "datasink2"
)

job.commit()
```

Example

The following is an example of a generated script for a JDBC source. The source table is an employee table with the empno column as the primary key. Although by default the job uses a sequential primary key as the bookmark key if no bookmark key is specified, because empno is not necessarily sequential—there could be gaps in the values—it does not qualify as a default bookmark key. Therefore, the script explicitly designates empno as the bookmark key. That portion of the code is shown in italics.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

datasource0 = glueContext.create_dynamic_frame.from_catalog(
    database = "hr",
    table_name = "emp",
    transformation_ctx = "datasource0",
    additional_options = {"jobBookmarkKeys":["empno"],"jobBookmarkKeysSortOrder":"asc"}
)

applymapping1 = ApplyMapping.apply(
    frame = datasource0,
    mappings = [("ename", "string", "ename", "string"), ("hrly_rate", "decimal(38,0)",
"hrly_rate", "decimal(38,0)"), ("comm", "decimal(7,2)", "comm", "decimal(7,2)"),
("hiredate", "timestamp", "hiredate", "timestamp"), ("empno", "decimal(5,0)", "empno",
"decimal(5,0)"), ("mgr", "decimal(5,0)", "mgr", "decimal(5,0)"), ("photo", "string",
"photo", "string"), ("job", "string", "job", "string"), ("deptno", "decimal(3,0)",
"deptno", "decimal(3,0)"), ("ssn", "decimal(9,0)", "ssn", "decimal(9,0)"), ("sal",
"decimal(7,2)", "sal", "decimal(7,2)"]],
    transformation_ctx = "applymapping1"
)

datasink2 = glueContext.write_dynamic_frame.from_options(
    frame = applymapping1,
    connection_type = "s3",
    connection_options = {"path": "s3://hr/employees"},
    format = "csv",
    transformation_ctx = "datasink2"
)

job.commit()
```

Using Sensitive Data Detection outside Amazon Glue Studio

Amazon Glue Studio allows you to detect sensitive data, however, you can also use the Sensitive Data Detection functionality outside of Amazon Glue Studio.

For a full list of managed sensitive data types, see [Managed data types](#).

Detecting Sensitive Data Detection using Amazon Managed PII types

Amazon Glue provides two APIs in a Amazon Glue ETL job. These are `detect()` and `classifyColumns()`:

```
detect(frame: DynamicFrame,
       entityTypesToDetect: Seq[String],
       outputColumnName: String = "DetectedEntities",
       detectionSensitivity: String = "LOW"): DynamicFrame

detect(frame: DynamicFrame,
       detectionParameters: JsonOptions,
       outputColumnName: String = "DetectedEntities",
       detectionSensitivity: String = "LOW"): DynamicFrame

classifyColumns(frame: DynamicFrame,
               entityTypesToDetect: Seq[String],
               sampleFraction: Double = 0.1,
               thresholdFraction: Double = 0.1,
               detectionSensitivity: String = "LOW")
```

You can use the `detect()` API to identify Amazon Managed PII types and custom entity types. A new column is automatically created with the detection result. The `classifyColumns()` API returns a map where keys are column names and values are list of detected entity types. `SampleFraction` indicates the fraction of the data to sample when scanning for PII entities whereas `ThresholdFraction` indicates the fraction of the data that must be met in order for a column to be identified as PII data.

Row-level detection

In the example, the job is performing the following actions using the `detect()` and `classifyColumns()` APIs:

- reading data from an Amazon S3 bucket and turns it into a dynamicFrame
- detecting instances of "Email" and "Credit Card" in the dynamicFrame
- returning a dynamicFrame with original values plus one column which encompasses detection result for each row
- writing the returned dynamicFrame in another Amazon S3 path

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame=
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar": "\"",
"withHeader": true, "separator": ","}"""), connectionType="s3", format="csv",
options=JsonOptions("""{"paths": ["s3://pathToSource"], "recurse": true}"""),
transformationContext="AmazonS3_node1650160158526").getDynamicFrame()

    val frameWithDetectedPII = EntityDetector.detect(frame, Seq("EMAIL",
"CREDIT_CARD"))

    glueContext.getSinkWithFormat(connectionType="s3",
options=JsonOptions("""{"path": "s3://pathToOutput/", "partitionKeys": []}"""),
transformationContext="someCtx",
format="json").writeDynamicFrame(frameWithDetectedPII)

    Job.commit()
  }
}
```

Row-level detection with fine-grained actions

In the example, the job is performing the following actions using the `detect()` APIs:

- reading data from an Amazon S3 bucket and turns it into a `dynamicFrame`
- detecting sensitive data types for “USA_PTIN”, “ BANK_ACCOUNT”, “USA_SSN”, “USA_PASSPORT_NUMBER” , and “PHONE_NUMBER” in the `dynamicFrame`
- returning a `dynamicFrame` with modified masked values plus one column which encompasses detection result for each row
- writing the returned `dynamicFrame` in another Amazon S3 path

In contrast with the above `detect()` API, this uses fine-grained actions for entity types to detect. For more information, see [Detection parameters for using detect\(\)](#).

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame =
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar": "\"",
"withHeader": true, "separator": ","}"""), connectionType="s3", format="csv",
options=JsonOptions("""{"paths": ["s3://pathToSource"], "recurse": true}"""),
transformationContext="AmazonS3_node_source").getDynamicFrame()

    val detectionParameters = JsonOptions(
      """
      {
```

```

        "USA_DRIVING_LICENSE": [{
            "action": "PARTIAL_REDACT",
            "sourceColumns": ["Driving License"],
            "actionOptions": {
                "matchPattern": "[0-9]",
                "redactChar": "*"
            }
        }],
        "BANK_ACCOUNT": [{

                "numRightCharsToExclude": 0,
                "redactChar": "*"
            }
        }
    ]
}
"""
)

```

```

val frameWithDetectedPII = EntityDetector.detect(frame, detectionParameters,
"DetectedEntities", "HIGH")

```

```

glueContext.getSinkWithFormat(connectionType="s3", options=JsonOptions("""{"path":
"s3://pathToOutput/", "partitionKeys": []}"""),
transformationContext="AmazonS3_node_target",
format="json").writeDynamicFrame(frameWithDetectedPII)

```

```

Job.commit()
}

```

```
}
```

Column-level detection

In the example, the job is performing the following actions using the `classifyColumns()` APIs:

- reading data from an Amazon S3 bucket and turns it into a `dynamicFrame`
- detecting instances of "Email" and "Credit Card" in the `dynamicFrame`
- set parameters to sample 100% of the column, mark an entity as detected if it is in 10% of cells, and have "LOW" sensitivity
- returns a map where keys are column names and values are list of detected entity types
- writing the returned `dynamicFrame` in another Amazon S3 path

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.DynamicFrame
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame =
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar":
"\\"", "withHeader": true, "separator": ",", "optimizePerformance": false}"""),
connectionType="s3", format="csv", options=JsonOptions("""{"paths": ["s3://
pathToSource"], "recurse": true}"""), transformationContext="frame").getDynamicFrame()

    import glueContext.sparkSession.implicits._

    val detectedDataFrame = EntityDetector.classifyColumns(
```

```

    frame,
    entityTypeToDetect = Seq("CREDIT_CARD", "PHONE_NUMBER"),
    sampleFraction = 1.0,
    thresholdFraction = 0.1,
    detectionSensitivity = "LOW"
  )
  val detectedDF = (detectedDataFrame).toSeq.toDF("columnName", "entityTypes")
  val DetectSensitiveData_node = DynamicFrame(detectedDF, glueContext)

  glueContext.getSinkWithFormat(connectionType="s3", options=JsonOptions("""{"path":
"s3://pathToOutput", "partitionKeys": []}"""), transformationContext="someCtx",
format="json").writeDynamicFrame(DetectSensitiveData_node)

  Job.commit()
}
}

```

Detecting Sensitive Data Detection using Amazon CustomEntityType PII types

You can define custom entities through Amazon Studio. However, to use this feature out of Amazon Studio, you have to first define the custom entity types and then add the defined custom entity types to the list of `entityTypesToDetect`.

If you have specific sensitive data types in your data (such as 'Employee Id'), you can create custom entities by calling the `CreateCustomEntityType()` API. The following example defines the custom entity type 'EMPLOYEE_ID' to the `CreateCustomEntityType()` API with the request parameters:

```

{
  "name": "EMPLOYEE_ID",
  "regexString": "\\d{4}-\\d{3}",
  "contextWords": ["employee"]
}

```

Then, modify the job to use the new custom sensitive data type by adding the custom entity type (EMPLOYEE_ID) to the `EntityDetector()` API:

```

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame=
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar": "\"",
"withHeader": true, "separator": ","}"""), connectionType="s3", format="csv",
options=JsonOptions("""{"paths": ["s3://pathToSource"], "recurse": true}"""),
transformationContext="AmazonS3_node1650160158526").getDynamicFrame()

    val frameWithDetectedPII = EntityDetector.detect(frame, Seq("EMAIL",
"CREDIT_CARD", "EMPLOYEE_ID"))

    glueContext.getSinkWithFormat(connectionType="s3",
options=JsonOptions("""{"path": "s3://pathToOutput/", "partitionKeys": []}"""),
transformationContext="someCtx",
format="json").writeDynamicFrame(frameWithDetectedPII)

    Job.commit()
  }
}

```

Note

If a custom sensitive data type is defined with the same name as an existing managed entity type, then the custom sensitive data type will take precedent and overwrite the managed entity type's logic.

Detection parameters for using detect()

This method is used for detecting entities in a `DynamicFrame`. It returns a new `DataFrame` with original values and an additional column `outputColumnName` that has PII detection metadata. Custom masking can be done after this `DynamicFrame` is returned within the Amazon Glue script, or the `detect()` with fine-grained actions API can be used instead.

```
detect(frame: DynamicFrame,
       entityTypesToDetect: Seq[String],
       outputColumnName: String = "DetectedEntities",
       detectionSensitivity: String = "LOW"): DynamicFrame
```

Parameters:

- **frame** – (type: `DynamicFrame`) The input `DynamicFrame` containing the data to be processed.
- **entityTypesToDetect** – (type: `[Seq[String]]`) List of entity types to detect. Can be either `Managed Entity Types` or `Custom Entity Types`.
- **outputColumnName** – (type: `String`, default: `"DetectedEntities"`) The name of the column where detected entities will be stored. If not provided, the default column name is `"DetectedEntities"`.
- **detectionSensitivity** – (type: `String`, options: `"LOW"` or `"HIGH"`, default: `"LOW"`) Specifies the sensitivity of the detection process. Valid options are `"LOW"` or `"HIGH"`. If not provided, the default sensitivity is set to `"LOW"`.

outputColumnName settings:

The name of the column where detected entities will be stored. If not provided, the default column name is `"DetectedEntities"`. For each row in the output column, the supplementary column includes a map of the column name to the detected entity metadata with the following key-value pairs:

- **entityType** – The detected entity type.
- **start** – The starting position of the detected entity in the original data.
- **end** – The ending position of the detected entity in the original data.
- **actionUsed** – The action performed on the detected entity (e.g., `"DETECT," "REDACT," "PARTIAL_REDACT," "SHA256_HASH"`).

Example:

```
{
  "DetectedEntities":{
    "SSN Col":[
      {
        "entityType":"USA_SSN",
        "actionUsed":"DETECT",
        "start":4,
        "end":15
      }
    ],
    "Random Data col":[
      {
        "entityType":"BANK_ACCOUNT",
        "actionUsed":"PARTIAL_REDACT",
        "start":4,
        "end":13
      },
      {
        "entityType":"IP_ADDRESS",
        "actionUsed":"REDACT",
        "start":4,
        "end":13
      }
    ]
  }
}
```

Detection Parameters for detect() with fine grained actions

This method is used for detecting entities in a `DynamicFrame` using specified parameters. It returns a new `DataFrame` with original values replaced with masked sensitive data and an additional column `outputColumnName` that has PII detection metadata.

```
detect(frame: DynamicFrame,
        detectionParameters: JsonOptions,
        outputColumnName: String = "DetectedEntities",
        detectionSensitivity: String = "LOW"): DynamicFrame
```

Parameters:

- **frame** – (type: `DynamicFrame`): The input `DynamicFrame` containing the data to be processed.
- **detectionParameters** – (type: `JsonOptions`): JSON options specifying parameters for the detection process.
- **outputColumnName** – (type: `String`, default: "DetectedEntities"): The name of the column where detected entities will be stored. If not provided, the default column name is "DetectedEntities".
- **detectionSensitivity** – (type: `String`, options: "LOW" or "HIGH", default: "LOW"): Specifies the sensitivity of the detection process. Valid options are "LOW" or "HIGH". If not provided, the default sensitivity is set to "LOW".

detectionParameters settings

If no settings are included, default values will be used.

- **action** – (type: `String`, options: "DETECT", "REDACT", "PARTIAL_REDACT", "SHA256_HASH") Specifies the action to be performed on the entity. Required. Note that actions that perform masking (all but "DETECT") can only perform one action per column. This is a preventative measure for masking coalesced entities.
- **sourceColumns** – (type: `List[String]`, default: ["*"]) List of source column names to perform detection on for the entity. Defaults to ["*"] if not present. Raises `IllegalArgumentException` if an invalid column name is used.
- **sourceColumnsToExclude** – (type: `List[String]`) List of source column names to to perform detection on for the entity. Use either `sourceColumns` or `sourceColumnsToExclude`. Raises `IllegalArgumentException` if an invalid column name is used.
- **actionOptions** – Additional options based on the specified action:
 - For "DETECT" and "SHA256_HASH", no options are allowed.
 - For "REDACT":
 - **redactText** – (type: `String`, default: "*****") Text to replace the detected entity.
 - For "PARTIAL_REDACT":
 - **redactChar** – (type: `String`, default: "*") Character to replace each detected character in the entity.
 - **matchPattern** – (type: `String`) Regex pattern for partial redaction. Cannot be combined with `numLeftCharsToExclude` or `numRightCharsToExclude`.

- **numLeftCharsToExclude** – (type: `String`, `integer`) Number of left characters to exclude. Cannot be combined with `matchPattern`, but can be used with `numRightCharsToExclude`.
- **numRightCharsToExclude** – (type: `String`, `integer`) Number of right characters to exclude. Cannot be combined with `matchPattern`, but can be used with `numRightCharsToExclude`.

`outputColumnName` settings

[See `outputColumnName` settings](#)

Detection Parameters for `classifyColumns()`

This method is used for detecting entities in a `DynamicFrame`. It returns a map where keys are column names and values are list of detected entity types. Custom masking can be done after this is returned within the Amazon Glue script.

```
classifyColumns(frame: DynamicFrame,  
               entityTypesToDetect: Seq[String],  
               sampleFraction: Double = 0.1,  
               thresholdFraction: Double = 0.1,  
               detectionSensitivity: String = "LOW")
```

Parameters:

- **frame** – (type: `DynamicFrame`) The input `DynamicFrame` containing the data to be processed.
- **entityTypesToDetect** – (type: `Seq[String]`) List of entity types to detect. Can be either Managed Entity Types or Custom Entity Types.
- **sampleFraction** – (type: `Double`, default: 10%) The fraction of the data to sample when scanning for PII entities.
- **thresholdFraction** – (type: `Double`, default: 10%): The fraction of the data that must be met in order for a column to be identified as PII data.
- **detectionSensitivity** – (type: `String`, options: "LOW" or "HIGH", default: "LOW") Specifies the sensitivity of the detection process. Valid options are "LOW" or "HIGH". If not provided, the default sensitivity is set to "LOW".

Managed Sensitive Data Types

Global entities

| Data Type | Category | Description |
|-------------|-----------|-------------------------|
| PERSON_NAME | Universal | The name of the person. |
| EMAIL | Personal | The email address. |
| IP_ADDRESS | Computer | The IP address |
| MAC_ADDRESS | Personal | The MAC address. |

US data types

| Data Type | Description |
|---------------------|---|
| BANK_ACCOUNT | The bank account number. Not specific to a country or region, however, only US and Canadian account formats are detected. |
| CREDIT_CARD | The credit card number. |
| PHONE_NUMBER | The phone number. Not specific to a country or region, however, only US and Canadian phone numbers are detected at this time. |
| USA_ATIN | The US Adoption Taxpayer Identification Number issued by the Internal Revenue Service. |
| USA_CPT_CODE | The CPT Code (US specific). |
| USA_DEA_NUMBER | The DEA number (US specific). |
| USA_DRIVING_LICENSE | The driver license number (US specific). |
| USA_HCPCS_CODE | The HCPCS code (US specific). |

| Data Type | Description |
|-------------------------------------|---|
| USA_HEALTH_INSURANCE_CLAIM_NUMBER | Health Insurance Claim Number (US specific). |
| USA_ITIN | The ITIN (for US persons or entities). |
| USA_MEDICARE_BENEFICIARY_IDENTIFIER | Medicare Beneficiary Identifier (US specific). |
| USA_NATIONAL_DRUG_CODE | The NDC code (US specific). |
| USA_NATIONAL_PROVIDER_IDENTIFIER | The National Provider Identifier number (US specific). |
| USA_PASSPORT_NUMBER | The passport number (for US persons). |
| USA_PTIN | The US Preparer Tax Identification Number issued by the Internal Revenue Service. |
| USA_SSN | The social security number (for US persons). |

Argentina data types

| Data Type | Description |
|-------------------------------------|--|
| ARGENTINA_TAX_IDENTIFICATION_NUMBER | Argentina Tax Identification Number. Also known as CUIT or CUIL. |

Australian data types

| Data Type | Description |
|---------------------------|---|
| AUSTRALIA_BUSINESS_NUMBER | Australia Business Number (ABN). A unique identifier issued by the Australian Business Register (ABR) to identify businesses to the government and community. |

| Data Type | Description |
|---------------------------|---|
| AUSTRALIA_COMPANY_NUMBER | Australia Company Number (ACN). Unique identifier issued by the Australian Securities and Investments Commission. |
| AUSTRALIA_DRIVING_LICENSE | A driver's license number for Australia. |
| AUSTRALIA_MEDICARE_NUMBER | Australian Medicare Number. Personal identifier issued by the Australian Health Insurance Commission. |
| AUSTRALIA_PASSPORT_NUMBER | Australian passport number. |
| AUSTRALIA_TAX_FILE_NUMBER | Australia Tax File Number (TFN). Issued by the Australian Taxation Office (ATO) to taxpayers (individual, company, etc) for tax dealings. |

Austria data types

| Data Type | Description |
|-----------------------------------|---|
| AUSTRIA_DRIVING_LICENSE | The driver license number (Austria specific). |
| AUSTRIA_PASSPORT_NUMBER | The passport number (Austria specific). |
| AUSTRIA_SSN | The social security number (for Austria persons). |
| AUSTRIA_TAX_IDENTIFICATION_NUMBER | Tax identification number (Austria specific). |
| AUSTRIA_VALUE_ADDED_TAX | Value-Added Tax (Austria specific). |

Balkans data types

| Data Type | Description |
|---|--|
| BOSNIA_UNIQUE_MASTER_CITIZEN_NUMBER | Unique master citizen number (JMBG) for Bosnia-Herzegovina citizens. |
| KOSOVO_UNIQUE_MASTER_CITIZEN_NUMBER | Unique master citizen number (JMBG) for Kosovo. |
| MACEDONIA_UNIQUE_MASTER_CITIZEN_NUMBER | Unique master citizen number for Macedonia. |
| MONTENEGRO_UNIQUE_MASTER_CITIZEN_NUMBER | Unique master citizen number (JMBG) for Montenegro. |
| SERBIA_UNIQUE_MASTER_CITIZEN_NUMBER | Unique master citizen number (JMBG) for Serbia. |
| SERBIA_VALUE_ADDED_TAX | Value-Added Tax (Serbia specific). |
| VOJVODINA_UNIQUE_MASTER_CITIZEN_NUMBER | Unique master citizen number (JMBG) for Vojvodina. |

Belgium data types

| Data Type | Description |
|--|---|
| BELGIUM_DRIVING_LICENSE | The driver license number (Belgium specific). |
| BELGIUM_NATIONAL_IDENTIFICATION_NUMBER | The Belgian National Number (BNN). |
| BELGIUM_PASSPORT_NUMBER | The passport number (Belgium specific). |
| BELGIUM_TAX_IDENTIFICATION_NUMBER | Tax identification number (Belgium specific). |
| BELGIUM_VALUE_ADDED_TAX | Value-Added Tax (Belgium specific). |

Brazil data types

| Data Type | Description |
|---|--|
| BRAZIL_BANK_ACCOUNT | The bank account number (Brazil specific). |
| BRAZIL_NATIONAL_IDENTIFICATION_NUMBER | The national identifier (Brazil specific). |
| BRAZIL_NATIONAL_REGISTRY_OF_LEGAL_ENTITIES_NUMBER | The identification number issued to companies (Brazil specific), also known as the CNPJ. |
| BRAZIL_NATURAL_PERSON_REGISTRY_NUMBER | Natural Person Registry Number, also known as CPF. |

Bulgaria data types

| Data Type | Description |
|-------------------------------|---|
| BULGARIA_DRIVING_LICENSE | The driver license number (Bulgaria specific). |
| BULGARIA_UNIFORM_CIVIL_NUMBER | Unified Civil Number (EGN) that serves as a national identification number. |
| BULGARIA_VALUE_ADDED_TAX | Value-Added Tax (Bulgaria specific). |

Canada data types

| Data Type | Description |
|--|--|
| CANADA_DRIVING_LICENSE | The driver license number (Canada specific). |
| CANADA_GOVERNMENT_IDENTIFICATION_CARD_NUMBER | The national identifier (Canada specific). |
| CANADA_PASSPORT_NUMBER | The passport number (Canada specific). |
| CANADA_PERMANENT_RESIDENCE_NUMBER | Permanent residence number (PR Card number). |

| Data Type | Description |
|--------------------------------|--|
| CANADA_PERSONAL_HEALTH_NUMBER | The unique identifier for healthcare (PHN number). |
| CANADA_SOCIAL_INSURANCE_NUMBER | The social insurance number (SIN) in Canada. |

Chile data types

| Data Type | Description |
|--------------------------------------|--|
| CHILE_DRIVING_LICENSE | The driver license number (Chile specific). |
| CHILE_NATIONAL_IDENTIFICATION_NUMBER | The Chile national identifier, also known as RUT or RUN. |

Colombia data types

| Data Type | Description |
|---|--|
| COLOMBIA_PERSONAL_IDENTIFICATION_NUMBER | Unique identifier assigned to Colombians at birth. |
| COLOMBIA_TAX_IDENTIFICATION_NUMBER | Tax identification number (Colombia specific). |

Croatia data types

| Data Type | Description |
|-------------------------|---|
| CROATIA_DRIVING_LICENSE | The driver license number (Croatia specific). |
| CROATIA_IDENTITY_NUMBER | The national identifier (Croatia specific). |
| CROATIA_PASSPORT_NUMBER | The passport number (Croatia specific). |

| Data Type | Description |
|--|---------------------------------------|
| CROATIA_PERSONAL_IDENTIFICATION_NUMBER | The personal identifier number (OIB). |

Cyprus data types

| Data Type | Description |
|---------------------------------------|--|
| CYPRUS_DRIVING_LICENSE | The driver license number (Cyprus specific). |
| CYPRUS_NATIONAL_IDENTIFICATION_NUMBER | The Cypriot identity card. |
| CYPRUS_PASSPORT_NUMBER | The passport number (Cyprus specific). |
| CYPRUS_TAX_IDENTIFICATION_NUMBER | Tax identification number (Cyprus specific). |
| CYPRUS_VALUE_ADDED_TAX | Value-Added Tax (Cyprus specific). |

Czechia data types

| Data Type | Description |
|--|--|
| CZECHIA_DRIVING_LICENSE | The driver license number (Czechia specific). |
| CZECHIA_PERSONAL_IDENTIFICATION_NUMBER | The personal identifier number (Czechia specific). |
| CZECHIA_VALUE_ADDED_TAX | Value-Added Tax (Czechia specific). |

Denmark data types

| Data Type | Description |
|-------------------------|---|
| DENMARK_DRIVING_LICENSE | The driver license number (Denmark specific). |

| Data Type | Description |
|--|--|
| DENMARK_PERSONAL_IDENTIFICATION_NUMBER | The personal identifier number (Denmark specific). |
| DENMARK_TAX_IDENTIFICATION_NUMBER | Tax identification number (Denmark specific). |
| DENMARK_VALUE_ADDED_TAX | Value-Added Tax (Denmark specific). |

Estonia data types

| Data Type | Description |
|--------------------------------------|--|
| ESTONIA_DRIVING_LICENSE | The driver license number (Estonia specific). |
| ESTONIA_PASSPORT_NUMBER | The passport number (Estonia specific). |
| ESTONIA_PERSONAL_IDENTIFICATION_CODE | The personal identifier number (Estonia specific). |
| ESTONIA_VALUE_ADDED_TAX | Value-Added Tax (Estonia specific). |

Finland data types

| Data Type | Description |
|--|--|
| FINLAND_DRIVING_LICENSE | The driver license number (Finland specific). |
| FINLAND_HEALTH_INSURANCE_NUMBER | The health insurance number (Finland specific) |
| FINLAND_NATIONAL_IDENTIFICATION_NUMBER | The national identifier number (Finland specific). |
| FINLAND_PASSPORT_NUMBER | The passport number (Finland specific). |
| FINLAND_VALUE_ADDED_TAX | Value-Added Tax (Finland specific). |

France data types

| Data Type | Description |
|---------------------------------------|--|
| FRANCE_BANK_ACCOUNT | The bank account number (France specific). |
| FRANCE_DRIVING_LICENSE | The driver license number (France specific). |
| FRANCE_HEALTH_INSURANCE_NUMBER | France health insurance number. |
| FRANCE_INSEE_CODE | France social security, SSN, or NIR number. |
| FRANCE_NATIONAL_IDENTIFICATION_NUMBER | France national identifier number (CNI). |
| FRANCE_PASSPORT_NUMBER | The passport number (France specific). |
| FRANCE_TAX_IDENTIFICATION_NUMBER | Tax identification number (France specific). |
| FRANCE_VALUE_ADDED_TAX | Value-Added Tax (France specific). |

Germany data types

| Data Type | Description |
|--|--|
| GERMANY_BANK_ACCOUNT | The bank account number (Germany specific). |
| GERMANY_DRIVING_LICENSE | The driver license number (Germany specific). |
| GERMANY_PASSPORT_NUMBER | The passport number (Germany specific). |
| GERMANY_PERSONAL_IDENTIFICATION_NUMBER | The personal identification number (Germany specific). |
| GERMANY_TAX_IDENTIFICATION_NUMBER | Tax identification number (Germany specific). |
| GERMANY_VALUE_ADDED_TAX | Value-Added Tax (Germany specific). |

Greece data types

| Data Type | Description |
|----------------------------------|--|
| GREECE_DRIVING_LICENSE | The driver license number (Greece specific). |
| GREECE_PASSPORT_NUMBER | The passport number (Greece specific). |
| GREECE_SSN | The social security number (for Greece persons). |
| GREECE_TAX_IDENTIFICATION_NUMBER | Tax identification number (Greece specific). |
| GREECE_VALUE_ADDED_TAX | Value-Added Tax (Greece specific). |

Hungary data types

| Data Type | Description |
|-----------------------------------|---|
| HUNGARY_DRIVING_LICENSE | The driver license number (Hungary specific). |
| HUNGARY_PASSPORT_NUMBER | The passport number (Hungary specific). |
| HUNGARY_SSN | The social security number (for Hungary persons). |
| HUNGARY_TAX_IDENTIFICATION_NUMBER | Tax identification number (Hungary specific). |
| HUNGARY_VALUE_ADDED_TAX | Value-Added Tax (Hungary specific). |

Iceland data types

| Data Type | Description |

|-----------------------|--|
| SPAIN_BANK_ACCOUNT | The bank account number (Spain specific). |
| SPAIN_DNI | The national identity card (Documento Nacional de Identidad) of Spain. |
| SPAIN_DRIVING_LICENSE | The driver license number (Spain specific). |
| SPAIN_NIE | The foreigner identity number (Spain specific), also known as the NIE. |
| SPAIN_NIF | Tax identification number (Spain specific), also known as the NIF. |
| SPAIN_PASSPORT_NUMBER | The passport number (Spain specific). |
| SPAIN_SSN | The social security number (for Spain persons). |
| SPAIN_VALUE_ADDED_TAX | Value-Added Tax (Spain specific). |

Sri Lanka data types

| Data Type | Description |
|--|---|
| SRI_LANKA_NATIONAL_IDENTIFICATION_NUMBER | The national identifier (Sri Lanka specific). |

Sweden data types

| Data Type | Description |
|---------------------------------------|---|
| SWEDEN_DRIVING_LICENSE | The driver license number (Sweden specific). |
| SWEDEN_PASSPORT_NUMBER | The passport number (Sweden specific). |
| SWEDEN_PERSONAL_IDENTIFICATION_NUMBER | The national identifier number (Sweden specific). |

| Data Type | Description |
|----------------------------------|--|
| SWEDEN_TAX_IDENTIFICATION_NUMBER | Sweden tax identification number (personnummer). |
| SWEDEN_VALUE_ADDED_TAX | Value-Added Tax (Sweden specific). |

Switzerland data types

| Data Type | Description |
|-------------------------------------|---|
| SWITZERLAND_AHV | The social security number for Swiss persons (AHV). |
| SWITZERLAND_HEALTH_INSURANCE_NUMBER | Swiss health insurance number. |
| SWITZERLAND_PASSPORT_NUMBER | The passport number (Switzerland specific). |
| SWITZERLAND_VALUE_ADDED_TAX | Value-Added Tax (Switzerland specific). |

Thailand data types

| Data Type | Description |
|---|---|
| THAILAND_PASSPORT_NUMBER | The passport number (Thailand specific). |
| THAILAND_PERSONAL_IDENTIFICATION_NUMBER | The personal identifier number (Thailand specific). |

Turkey data types

| Data Type | Description |
|---------------------------------------|---|
| TURKEY_NATIONAL_IDENTIFICATION_NUMBER | The national identifier number (Turkey specific). |

| Data Type | Description |
|------------------------|--|
| TURKEY_PASSPORT_NUMBER | The passport number (Turkey specific). |
| TURKEY_VALUE_ADDED_TAX | Value-Added Tax (Turkey specific). |

Ukraine data types

| Data Type | Description |
|--|---|
| UKRAINE_INDIVIDUAL_IDENTIFICATION_NUMBER | The unique identifier (Ukraine specific). |
| UKRAINE_PASSPORT_NUMBER_DOMESTIC | The domestic passport number (Ukraine specific). |
| UKRAINE_PASSPORT_NUMBER_INTERNATIONAL | The international passport number (Ukraine specific). |

United Arab Emirates (UAE) data types

| Data Type | Description |
|--------------------------------------|--|
| UNITED_ARAB_EMIRATES_PERSONAL_NUMBER | The personal identifier number (UAE specific). |

UK data types

| Data Type | Description |
|-------------------|---|
| UK_BANK_ACCOUNT | United Kingdom (UK) bank account. |
| UK_BANK_SORT_CODE | United Kingdom (UK) bank sort code. Sort codes are bank codes used to route money transfers between banks within their respective |

| Data Type | Description |
|-------------------------------------|--|
| | e countries via their respective clearance organizations. |
| UK_DRIVING_LICENSE | The driver's license number for the United Kingdom of Great Britain and Northern Ireland (UK specific) |
| UK_ELECTORAL_ROLL_NUMBER | The Electoral Roll Number (ERN) is the identification number issued to an individual for UK election registration. The format of this number is specified by the UK Government Standards of the UK Cabinet Office. |
| UK_NATIONAL_HEALTH_SERVICE_NUMBER | The National Health Service (NHS) number is the unique number allocated to a registered user of public health services in the United Kingdom. |
| UK_NATIONAL_INSURANCE_NUMBER | The National Insurance number (NINO) is a number used in the United Kingdom (UK) to identify an individual for the national insurance program or social security system. The number is sometimes referred to as NI No or NINO. |
| UK_PASSPORT_NUMBER | United Kingdom (UK) passport number. |
| UK_UNIQUE_TAXPAYER_REFERENCE_NUMBER | The United Kingdom (UK) Unique Taxpayer Reference (UTR) number. An identifier used by the UK government to manage the taxation system. |

| Data Type | Description |
|--------------------|---|
| UK_VALUE_ADDED_TAX | VAT is a consumption tax that is borne by the end consumer. VAT is paid for each transaction in the manufacturing and distribution process. For the United Kingdom, the VAT number is issued by the VAT office for the region in which the business is established. |
| UK_PHONE_NUMBER | United Kingdom (UK) phone number. |

Venezuela data types

| Data Type | Description |
|--|--|
| VENEZUELA_DRIVING_LICENSE | The driver license number (Venezuela specific). |
| VENEZUELA_NATIONAL_IDENTIFICATION_NUMBER | The national identifier number (Venezuela specific). |
| VENEZUELA_VALUE_ADDED_TAX | Value-Added Tax (Venezuela specific). |

Using fine-grained sensitive data detection

Note

Fine-grained actions is only available in Amazon Glue 3.0 and 4.0. This includes the Amazon Glue Studio experience. The persistent audit log changes are also not available in 2.0. All Amazon Glue Studio 3.0 and 4.0 visual jobs will have a script created that automatically uses fine-grained actions APIs.

The Detect Sensitive Data transform provides the ability to detect, mask, or remove entities that you define, or are pre-defined by Amazon Glue. Fine-grained actions further allows you to apply a specific action per entity. Additional benefits include:

- Improved performance as actions are being applied as soon data is detected.

- The option to include or exclude specific columns.
- The ability to use partial masking. This allows you to mask detected sensitive data entities partially, rather than masking the entire string. Both simple params with offsets and regex are supported.

The following are code snippets of sensitive data detection APIs and fine-grained actions used in the sample jobs referenced in the next section.

Detect API – fine-grained actions use the new `detectionParameters` parameter:

```
def detect(  
  frame: DynamicFrame,  
  detectionParameters: JsonOptions,  
  outputColumnName: String = "DetectedEntities",  
  detectionSensitivity: String = "LOW"  
): DynamicFrame = {}
```

Using Sensitive Data Detection APIs with fine-grained actions

Sensitive data detection APIs using **detect** analyzes the data given, determines if the rows or columns are Sensitive Data Entity Types, and will run actions specified by the user for each Entity type.

Using the detect API with fine-grained actions

Use the **detect** API and specify the `outputColumnName` and `detectionParameters`.

```
object GlueApp {  
  def main(sysArgs: Array[String]) {  
  
    val spark: SparkContext = new SparkContext()  
    val glueContext: GlueContext = new GlueContext(spark)  
  
    // @params: [JOB_NAME]  
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)  
    Job.init(args("JOB_NAME"), glueContext, args.asJava)  
  
    // Script generated for node S3 bucket. Creates DataFrame from data stored in  
    S3.
```

```

    val S3bucket_node1 =
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar":
"\\"", "withHeader": true, "separator": ",", "optimizePerformance": false}"""),
connectionType="s3", format="csv", options=JsonOptions("""{"paths":
["s3://189657479688-ddevansh-pii-test-bucket/tiny_pii.csv"], "recurse": true}"""),
transformationContext="S3bucket_node1").getDynamicFrame()

    // Script generated for node Detect Sensitive Data. Will run detect API for the
DataFrame
    // detectionParameter contains information on which EntityType are being
detected
    // and what actions are being applied to them when detected.
val DetectSensitiveData_node2 = EntityDetector.detect(
    frame = S3bucket_node1,
    detectionParameters = JsonOptions(
        """
        {
            "PHONE_NUMBER": [
                {
                    "action": "PARTIAL_REDACT",
                    "actionOptions": {
                        "numLeftCharsToExclude": "3",
                        "numRightCharsToExclude": "4",
                        "redactChar": "#"
                    },
                    "sourceColumnsToExclude": [ "Passport No", "DL NO#" ]
                }
            ],
            "USA_PASSPORT_NUMBER": [
                {
                    "action": "SHA256_HASH",
                    "sourceColumns": [ "Passport No" ]
                }
            ],
            "USA_DRIVING_LICENSE": [
                {
                    "action": "REDACT",
                    "actionOptions": {
                        "redactText": "USA_DL"
                    },
                    "sourceColumns": [ "DL NO#" ]
                }
            ]
        }
        """
    )
)

```

```
        }
        ""
    ),
    outputColumnName = "DetectedEntities"
)

// Script generated for node S3 bucket. Store Results of detect to S3 location
val S3bucket_node3 = glueContext.getSinkWithFormat(connectionType="s3",
options=JsonOptions("""{"path": "s3://amzn-s3-demo-bucket/test-output/",
"partitionKeys": []}"""), transformationContext="S3bucket_node3",
format="json").writeDynamicFrame(DetectSensitiveData_node2)

Job.commit()
}
```

The above script will create a DataFrame from a location in Amazon S3 and then it will run the detect API. Since the detect API requires the field `detectionParameters` (a map of the entity name to a list all of the action settings to be used for that entity) is represented by Amazon Glue's `JsonOptions` object, it will also allow us to extend the functionality of the API.

For each action specified per entity, enter a list of all column names to which to apply the entity/action combination. This allows you to customize the entities to detect for every column in your dataset and skip entities that you know are not in a specific column. This also allows your jobs to be more performant by not performing unnecessary detection calls those entities and allows you to perform actions unique to each column and entity combination.

Taking a closer look at the `detectionParameters`, there are three entity types in the sample job. These are `Phone Number`, `USA_PASSPORT_NUMBER`, and `USA_DRIVING_LICENSE`. For each of these entity types Amazon Glue will run different actions which are either `PARTIAL_REDACT`, `SHA256_HASH`, `REDACT`, and `DETECT`. Each of the Entity Types also have `sourceColumns` to apply to and/or `sourceColumnsToExclude` if detected.

Note

Only one edit-in-place action (`PARTIAL_REDACT`, `SHA256_HASH`, or `REDACT`) can be used per column but the `DETECT` action can be used with any of these actions.

The `detectionParameters` field has the below layout:

```

ENTITY_NAME -> List[Actions]
{
  "ENTITY_NAME": [{
    Action, // required
    ColumnSpecs,
    ActionOptionsMap
  }],
  "ENTITY_NAME2": [{
    ...
  }]
}

```

The types of actions and actionOptions are listed below:

```

DETECT
{
  # Required
  "action": "DETECT",
  # Optional, depending on action chosen
  "actionOptions": {
    // There are no actionOptions for DETECT
  },
  # 1 of below required, both can also used
  "sourceColumns": [
    "COL_1", "COL_2", ..., "COL_N"
  ],
  "sourceColumnsToExclude": [
    "COL_5"
  ]
}

SHA256_HASH
{
  # Required
  "action": "SHA256_HASH",
  # Required or optional, depending on action chosen
  "actionOptions": {
    // There are no actionOptions for SHA256_HASH
  },

  # 1 of below required, both can also used

```

```
    "sourceColumns": [
      "COL_1", "COL_2", ..., "COL_N"
    ],
    "sourceColumnsToExclude": [
      "COL_5"
    ]
  }
```

REDACT

```
{
  # Required
  "action": "REDACT",
  # Required or optional, depending on action chosen
  "actionOptions": {
    // The text that is being replaced
    "redactText": "USA_DL"
  },

  # 1 of below required, both can also used
  "sourceColumns": [
    "COL_1", "COL_2", ..., "COL_N"
  ],
  "sourceColumnsToExclude": [
    "COL_5"
  ]
}
```

PARTIAL_REDACT

```
{
  # Required
  "action": "PARTIAL_REDACT",
  # Required or optional, depending on action chosen
  "actionOptions": {
    // number of characters to not redact from the left side
    "numLeftCharsToExclude": "3",
    // number of characters to not redact from the right side
    "numRightCharsToExclude": "4",
    // the partial redact will be made with this redacted character
    "redactChar": "#",
    // regex pattern for partial redaction
    "matchPattern": "[0-9]"
  },

  # 1 of below required, both can also used
```

```

"sourceColumns": [
  "COL_1", "COL_2", ..., "COL_N"
],
"sourceColumnsToExclude": [
  "COL_5"
]
}

```

Once the script runs, results are output to the given Amazon S3 location. You can view your data in Amazon S3 but with the selected entity types being sensitized based on the selected action. In the case, we would have a rows that would have that looked like this:

```

{
  "Name": "Colby Schuster",
  "Address": "39041 Antonietta Vista, South Rodgerside, Nebraska 24151",
  "Car Owned": "Fiat",
  "Email": "Kitty46@gmail.com",
  "Company": "O'Reilly Group",
  "Job Title": "Dynamic Functionality Facilitator",
  "ITIN": "991-22-2906",
  "Username": "Cassandre.Kub43",
  "SSN": "914-22-2906",
  "DOB": "2020-08-27",
  "Phone Number": "1-2#####1718",
  "Bank Account No": "69741187",
  "Credit Card Number": "6441-6289-6867-2162-2711",
  "Passport No": "94f311e93a623c72ccb6fc46cf5f5b0265ccb42c517498a0f27fd4c43b47111e",
  "DL NO#": "USA_DL"
}

```

In the above script, the Phone Number was partially redacted with #. The Passport No was changed into a SHA256 hash. The DL NO# was detected as a USA driver license number and was redacted to "USA_DL" just like it was stated in the detectionParameters.

Note

The classifyColumns API is not available for use with fine-grained actions due to the nature of the API. This API performs column sampling (adjustable by the user but has default

values) to perform detection more quickly. Fine-grained actions require iterating over every value for this reason.

Persistent Audit Log

A new feature introduced with fine-grained actions (but also available when using the normal APIs) is the presence of a persistent audit log. Currently, running the detect API adds an additional column (defaults to `DetectedEntities` but customizable through the `outputColumnName` parameter with PII detection metadata. This now has an "actionUsed" metadata key, which is one of `DETECT`, `PARTIAL_REDACT`, `SHA256_HASH`, `REDACT`.

```
"DetectedEntities": {
  "Credit Card Number": [
    {
      "entityType": "CREDIT_CARD",
      "actionUsed": "DETECT",
      "start": 0,
      "end": 19
    }
  ],
  "Phone Number": [
    {
      "entityType": "PHONE_NUMBER",
      "actionUsed": "REDACT",
      "start": 0,
      "end": 14
    }
  ]
}
```

Even customers using APIs without fine-grained actions such as `detect(entityTypesToDetect, outputColumnName)` will see this persistent audit log in the resulting dataframe.

Customers using APIs with fine-grained actions will see all of the actions, regardless of if they are redacted or not. Example:

```

+-----+-----+
+-----+-----+
+
| Credit Card Number | Phone Number |
+-----+-----+
+-----+-----+
+
| 622126741306XXXX | +12#####7890 | {"Credit Card Number":
[{"entityType":"CREDIT_CARD","actionUsed":"PARTIAL_REDACT","start":0,"end":16}], "Phone
Number":
[{"entityType":"PHONE_NUMBER","actionUsed":"PARTIAL_REDACT","start":0,"end":12}]} |
| 6221 2674 1306 XXXX | +12#####7890 | {"Credit Card Number":
[{"entityType":"CREDIT_CARD","actionUsed":"PARTIAL_REDACT","start":0,"end":19}], "Phone
Number":
[{"entityType":"PHONE_NUMBER","actionUsed":"PARTIAL_REDACT","start":0,"end":14}]} |
| 6221-2674-1306-XXXX | 22#####7890 | {"Credit Card Number":
[{"entityType":"CREDIT_CARD","actionUsed":"PARTIAL_REDACT","start":0,"end":19}], "Phone
Number":
[{"entityType":"PHONE_NUMBER","actionUsed":"PARTIAL_REDACT","start":0,"end":14}]} |
+-----+-----+
+-----+-----+
+

```

If you do not want to see the **DetectedEntities** column, you can simply drop the additional column in a custom script.

Amazon Glue Visual Job API

Amazon Glue provides an API that allows customers to create data integration jobs using the Amazon Glue API from a JSON object that represents a visual step workflow. Customers can then use the visual editor in Amazon Glue Studio to work with these jobs.

For more information on Visual Job API data types, see [Visual Job API](#).

Topics

- [API design and CRUD APIs](#)
- [Getting started](#)
- [Visual job limitations](#)

API design and CRUD APIs

The `CreateJob` and `UpdateJob` [APIs](#) now support an additional optional parameter, `codegenConfigurationNodes`. Providing a non-empty JSON structure for this field will result in the DAG being registered in Amazon Glue Studio for the created job and the associated code being generated. A null value or empty string for this field on job create will be ignored.

Updates to the `codegenConfigurationNodes` field will be done through the `UpdateJob` Amazon Glue API in a similar way as `CreateJob`. The entire field should be specified in `UpdateJob` where the DAG has been changed as desired. A null value provided will be ignored and no update to the DAG would be performed. An empty structure or string will cause the `codegenConfigurationNodes` to be set as empty and any previous DAG removed. The `GetJob` API will return a DAG if one exists. The `DeleteJob` API will also delete any associated DAG.

Getting started

To create a job, use the [CreateJob action](#). The `CreateJob` request input will have an additional field 'codegenConfigurationNodes' where you can get specify the DAG object in JSON.

Things to keep in mind:

- The 'codegenConfigurationNodes' field is a map of nodeId to node.
- Each node begins with a key identifying what kind of node it is.
- There can only be one key specified since a node can only be of one type.
- The input field contains the parent nodes of the current node.

The following is a JSON representation of a **CreateJob** input.

```
{
  "node-1": {
    "S3CatalogSource": {
      "Table": "csvFormattedTable",
      "PartitionPredicate": "",
      "Name": "S3 bucket",
      "AdditionalOptions": {},
      "Database": "myDatabase"
    }
  },
  "node-3": {
    "S3DirectTarget": {
```

```
    "Inputs": ["node-2"],
    "PartitionKeys": [],
    "Compression": "none",
    "Format": "json",
    "SchemaChangePolicy": { "EnableUpdateCatalog": false },
    "Path": "",
    "Name": "S3 bucket"
  }
},
"node-2": {
  "ApplyMapping": {
    "Inputs": ["node-1"],
    "Name": "ApplyMapping",
    "Mapping": [
      {
        "FromType": "long",
        "ToType": "long",
        "Dropped": false,
        "ToKey": "myheader1",
        "FromPath": ["myheader1"]
      },
      {
        "FromType": "long",
        "ToType": "long",
        "Dropped": false,
        "ToKey": "myheader2",
        "FromPath": ["myheader2"]
      },
      {
        "FromType": "long",
        "ToType": "long",
        "Dropped": false,
        "ToKey": "myheader3",
        "FromPath": ["myheader3"]
      }
    ]
  }
}
```

Updating and getting jobs

Since *UpdateJob* will also have a 'codegenConfigurationNodes' field, the input format will be the same. See [UpdateJob](#) Action.

The *GetJob* action will return a 'codegenConfigurationNodes' field in the same format as well. See [GetJob](#) Action.

Visual job limitations

Since the 'codegenConfigurationNodes' parameter has been added to existing APIs, any limitations in those APIs will be inherited. In addition, the codegenConfigurationNodes and some nodes will be limited in size. See [Job Structure](#) for more information.

Programming Ray scripts

Amazon Glue makes it easy to write and run Ray scripts. This section describes the supported Ray capabilities that are available in Amazon Glue for Ray. You program Ray scripts in Python.

Your custom script must be compatible with the version of Ray that's defined by the `Runtime` field in your job definition. For more information about `Runtime` in the Jobs API, see [the section called "Jobs"](#). For information about each runtime environment, see [the section called "Supported Ray runtime environments"](#).

- [Connecting to data in Ray jobs](#)

Tutorial: Writing an ETL script in Amazon Glue for Ray

Ray gives you the ability to write and scale distributed tasks natively in Python. Amazon Glue for Ray offers serverless Ray environments that you can access from both jobs and interactive sessions (Ray interactive sessions are in preview). The Amazon Glue job system provides a consistent way to manage and run your tasks—on a schedule, from a trigger, or from the Amazon Glue console.

Combining these Amazon Glue tools creates a powerful toolchain that you can use for extract, transform, and load (ETL) workloads, a popular use case for Amazon Glue. In this tutorial, you will learn the basics of putting together this solution.

We also support using Amazon Glue for Spark for your ETL workloads. For a tutorial on writing a Amazon Glue for Spark script, see [the section called “Tutorial: Writing a Spark script”](#). For more information about available engines, see [the section called “Amazon Glue for Spark and Amazon Glue for Ray”](#). Ray is capable of addressing many different kinds of tasks in analytics, machine learning (ML), and application development.

In this tutorial, you will extract, transform, and load a CSV dataset that is hosted in Amazon Simple Storage Service (Amazon S3). You will begin with the New York City Taxi and Limousine Commission (TLC) Trip Record Data Dataset, which is stored in a public Amazon S3 bucket. For more information about this dataset, see the [Registry of Open Data on Amazon](#).

You will transform your data with predefined transforms that are available in the Ray Data library. Ray Data is a dataset preparation library designed by Ray and included by default in Amazon Glue for Ray environments. For more information about libraries included by default, see [the section called “Modules provided with Ray jobs”](#). You will then write your transformed data to an Amazon S3 bucket that you control.

Prerequisites – For this tutorial, you need an Amazon account with access to Amazon Glue and Amazon S3.

Step 1: Create a bucket in Amazon S3 to hold your output data

You will need an Amazon S3 bucket that you control to serve as a sink for data created in this tutorial. You can create this bucket with the following procedure.

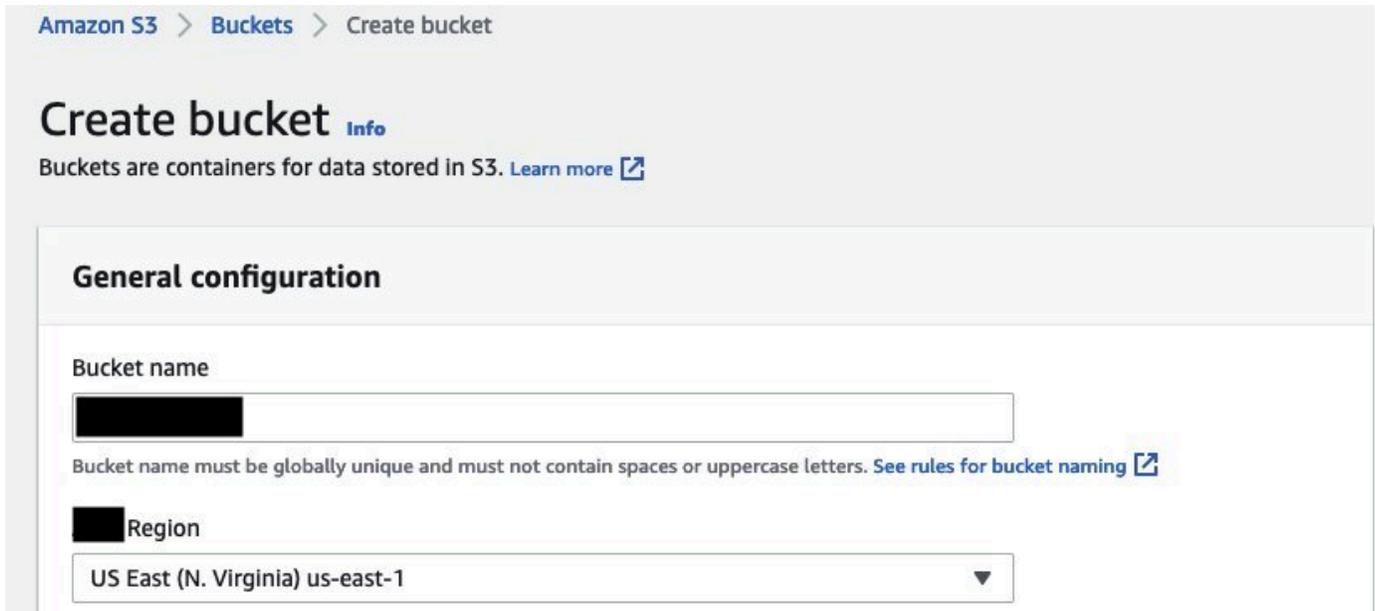

Note

If you want to write your data to an existing bucket that you control, you can skip this step. Take note of *yourBucketName*, the existing bucket's name, to use in later steps.

To create a bucket for your Ray job output

- Create a bucket by following the steps in [Creating a bucket](#) in the *Amazon S3 User Guide*.
 - When choosing a bucket name, take note of *yourBucketName*, which you will refer to in later steps.
 - For other configuration, the suggested settings provided in the Amazon S3 console should work fine in this tutorial.

As an example, the bucket creation dialog box might look like this in the Amazon S3 console.

The screenshot shows the 'Create bucket' dialog box in the Amazon S3 console. The breadcrumb navigation at the top reads 'Amazon S3 > Buckets > Create bucket'. The main heading is 'Create bucket' with an 'Info' link. Below the heading is a descriptive sentence: 'Buckets are containers for data stored in S3. Learn more' with an external link icon. The 'General configuration' section contains two fields: 'Bucket name' with a text input field (the content is redacted with a black box) and a note stating 'Bucket name must be globally unique and must not contain spaces or uppercase letters. See rules for bucket naming' with an external link icon; and 'Region' with a dropdown menu currently set to 'US East (N. Virginia) us-east-1'.

Step 2: Create an IAM role and policy for your Ray job

Your job will need an Amazon Identity and Access Management (IAM) role with the following:

- Permissions granted by the `AWSGlueServiceRole` managed policy. These are the basic permissions that are necessary to run an Amazon Glue job.
- Read access level permissions for the `nyc-t1c/*` Amazon S3 resource.
- Write access level permissions for the `yourBucketName/*` Amazon S3 resource.
- A trust relationship that allows the `glue.amazonaws.com` principal to assume the role.

You can create this role with the following procedure.

To create an IAM role for your Amazon Glue for Ray job

Note

You can create an IAM role by following many different procedures. For more information or options about how to provision IAM resources, see the [Amazon Identity and Access Management documentation](#).

1. Create a policy that defines the previously outlined Amazon S3 permissions by following the steps in [Creating IAM policies \(console\) with the visual editor](#) in the *IAM User Guide*.
 - When selecting a service, choose Amazon S3.
 - When selecting permissions for your policy, attach the following sets of actions for the following resources (mentioned previously):
 - Read access level permissions for the `nyc-tlc/*` Amazon S3 resource.
 - Write access level permissions for the `yourBucketName/*` Amazon S3 resource.
 - When selecting the policy name, take note of *YourPolicyName*, which you will refer to in a later step.
2. Create a role for your Amazon Glue for Ray job by following the steps in [Creating a role for an Amazon service \(console\)](#) in the *IAM User Guide*.
 - When selecting a trusted Amazon service entity, choose Glue. This will automatically populate the necessary trust relationship for your job.
 - When selecting policies for the permissions policy, attach the following policies:
 - `AWSGlueServiceRole`
 - *YourPolicyName*
 - When selecting the role name, take note of *YourRoleName*, which you will refer to in later steps.

Step 3: Create and run an Amazon Glue for Ray job

In this step, you create an Amazon Glue job using the Amazon Web Services Management Console, provide it with a sample script, and run the job. When you create a job, it creates a place in the console for you to store, configure, and edit your Ray script. For more information about creating jobs, see [the section called "Signing in to the console"](#).

In this tutorial, we address the following ETL scenario: you would like to read the January 2022 records from the New York City TLC Trip Record dataset, add a new column (`tip_rate`) to the dataset by combining data in existing columns, then remove a number of columns that aren't relevant to your current analysis, and then you would like to write the results to *yourBucketName*. The following Ray script performs these steps:

```
import ray
import pandas
```

```

from ray import data

ray.init('auto')

ds = ray.data.read_csv("s3://nyc-tlc/opendata_repo/opendata_webconvert/yellow/
yellow_tripdata_2022-01.csv")

# Add the given new column to the dataset and show the sample record after adding a new
column
ds = ds.add_column( "tip_rate", lambda df: df["tip_amount"] / df["total_amount"])

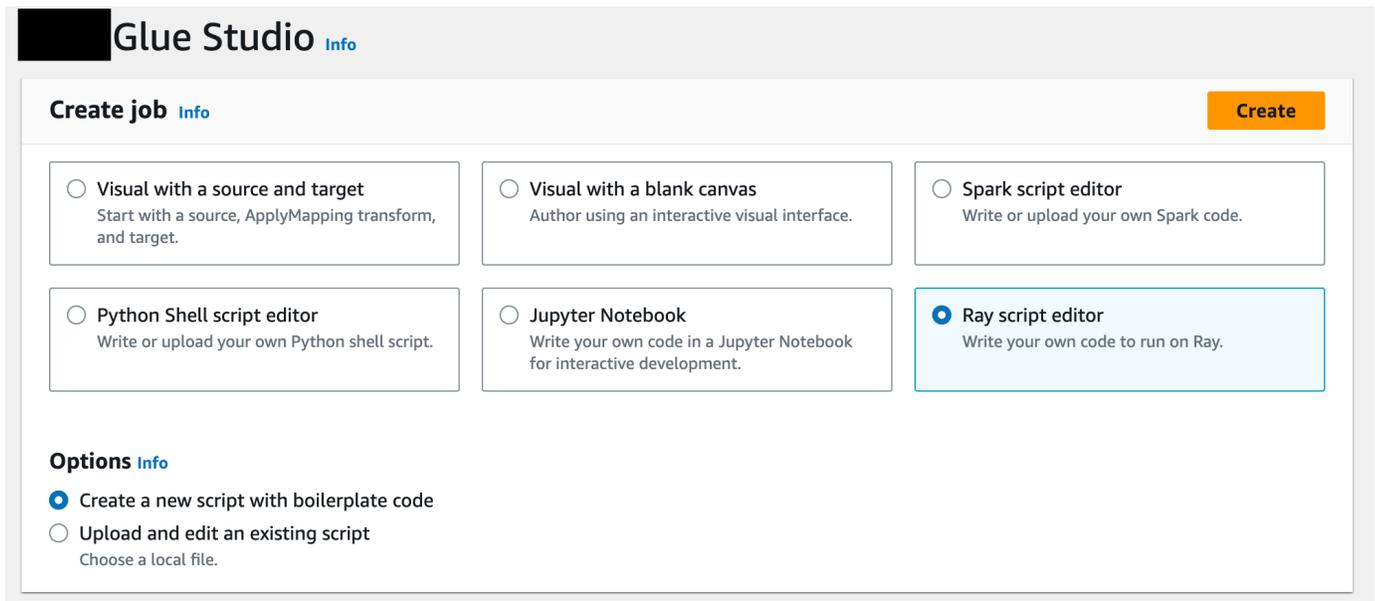

# Dropping few columns from the underlying Dataset
ds = ds.drop_columns(["payment_type", "fare_amount", "extra", "tolls_amount",
"improvement_surcharge"])

ds.write_parquet("s3://yourBucketName/ray/tutorial/output/")

```

To create and run an Amazon Glue for Ray job

1. In the Amazon Web Services Management Console, navigate to the Amazon Glue landing page.
2. In the side navigation pane, choose **ETL Jobs**.
3. In **Create job**, choose **Ray script editor**, and then choose **Create**, as in the following illustration.

4. Paste the full text of the script into the **Script** pane, and replace any existing text.

5. Navigate to **Job details** and set the **IAM Role** property to *YourRoleName*.
6. Choose **Save**, and then choose **Run**.

Step 4: Inspect your output

After running your Amazon Glue job, you should validate that the output matches the expectations of this scenario. You can do so with the following procedure.

To validate whether your Ray job ran successfully

1. On the job details page, navigate to **Runs**.
2. After a few minutes, you should see a run with a **Run status** of **Succeeded**.
3. Navigate to the Amazon S3 console at <https://console.amazonaws.cn/s3/> and inspect *yourBucketName*. You should see files written to your output bucket.
4. Read the Parquet files and verify their contents. You can do this with your existing tools. If you don't have a process for validating Parquet files, you can do this in the Amazon Glue console with an Amazon Glue interactive session, using either Spark or Ray (in preview).

In an interactive session, you have access to Ray Data, Spark, or pandas libraries, which are provided by default (based on your choice of engine). To verify your file contents, you can use common inspection methods that are available in those libraries—methods like `count`, `schema`, and `show`. For more information about interactive sessions in the console, see [Using notebooks with Amazon Glue Studio and Amazon Glue](#).

Because you have confirmed that files have been written to the bucket, you can say with relative certainty that if your output has problems, they are not related to IAM configuration. Configure your session with *yourRoleName* to have access to the relevant files.

If you don't see the expected outcomes, examine the troubleshooting content in this guide to identify and remediate the source of the error. You can find the troubleshooting content in the [Troubleshooting Amazon Glue](#) chapter. For specific errors that are related to Ray jobs, see [the section called "Troubleshooting Ray errors"](#) in the troubleshooting chapter.

Next steps

You have now seen and performed an ETL process using Amazon Glue for Ray from end to end. You can use the following resources to understand what tools Amazon Glue for Ray provides to transform and interpret your data at scale.

- For more information about Ray's task model, see [the section called “Using Ray Core and Ray Data in Amazon Glue for Ray”](#). For more experience in using Ray tasks, follow the examples in the Ray Core documentation. See [Ray Core: Ray Tutorials and Examples \(2.4.0\)](#) in the Ray documentation.
- For guidance about available data management libraries in Amazon Glue for Ray, see [the section called “Connecting to data”](#). For more experience using Ray Data to transform and write datasets, follow the examples in the Ray Data documentation. See [Ray Data: Examples \(2.4.0\)](#).
- For more information about configuring Amazon Glue for Ray jobs, see [the section called “Working with Ray jobs”](#).
- For more information about writing Amazon Glue for Ray scripts, continue reading the documentation in this section.

Using Ray Core and Ray Data in Amazon Glue for Ray

Ray is a framework for scaling up Python scripts by distributing work across a cluster. You can use Ray as a solution to many sorts of problems, so Ray provides libraries to optimize certain tasks. In Amazon Glue, we focus on using Ray to transform large datasets. Amazon Glue offers support for Ray Data and parts of Ray Core to facilitate this task.

What is Ray Core?

The first step of building a distributed application is identifying and defining work that can be performed concurrently. Ray Core contains the parts of Ray that you use to define tasks that can be performed concurrently. Ray provides reference and quick start information that you can use to learn the tools they provide. For more information, see [What is Ray Core?](#) and [Ray Core Quick Start](#). For more information about effectively defining concurrent tasks in Ray, see [Tips for first-time users](#).

Ray tasks and actors

In Amazon Glue for Ray documentation, we might refer to *tasks* and *actors*, which are core concepts in Ray.

Ray uses Python functions and classes as the building blocks of a distributed computing system. Much like when Python functions and variables become "methods" and "attributes" when used in a class, functions become "tasks" and classes become "actors" when they're used in Ray to send code to workers. You can identify functions and classes that might be used by Ray by the `@ray.remote` annotation.

Tasks and actors are configurable, they have a lifecycle, and they take up compute resources throughout their life. Code that throws errors can be traced back to a task or actor when you're finding the root cause of problems. Thus, these terms might come up when you're learning how to configure, monitor, or debug Amazon Glue for Ray jobs.

To begin learning how to effectively use tasks and actors to build a distributed application, see [Key Concepts](#) in the Ray docs.

Ray Core in Amazon Glue for Ray

Amazon Glue for Ray environments manage cluster formation and scaling, as well as collecting and visualizing logs. Because we manage these concerns, we consequently limit access to and support for the APIs in Ray Core that would be used to address these concerns in an open-source cluster.

In the managed Ray2.4 runtime environment, we do not support:

- [Ray Core CLI](#)
- [Ray State CLI](#)
- `ray.util.metrics` Prometheus metric utility methods:
 - [Counter](#)
 - [Gauge](#)
 - [Histogram](#)
- Other debugging tools:
 - [ray.util.pdb.set_trace](#)
 - [ray.util.inspect_serializability](#)
 - [ray.timeline](#)

What is Ray Data?

When you're connecting to data sources and destinations, handling datasets, and initiating common transforms, Ray Data is a straightforward methodology for using Ray to solve problems

transforming Ray datasets. For more information about using Ray Data, see [Ray Datasets: Distributed Data Preprocessing](#).

You can use Ray Data or other tools to access your data. For more information on accessing your data in Ray, see [the section called "Connecting to data"](#).

Ray Data in Amazon Glue for Ray

Ray Data is supported and provided by default in the managed Ray2.4 runtime environment. For more information about provided modules, see [the section called "Modules provided with Ray jobs"](#).

Providing files and Python libraries to Ray jobs

This section provides information that you need for using Python libraries with Amazon Glue Ray jobs. You can use certain common libraries included by default in all Ray jobs. You can also provide your own Python libraries to your Ray job.

Modules provided with Ray jobs

You can perform data integration workflows in a Ray job with the following provided packages. These packages are available by default in Ray jobs.

Amazon Glue version 4.0

In Amazon Glue 4.0, the Ray (Ray2.4 runtime) environment provides the following packages:

- boto3 == 1.26.133
- ray == 2.4.0
- pyarrow == 11.0.0
- pandas == 1.5.3
- numpy == 1.24.3
- fsspec == 2023.4.0

This list includes all packages that would be installed with `ray[data] == 2.4.0`. Ray Data is supported out of box.

Providing files to your Ray job

You can provide files to your Ray job with the `--working-dir` parameter. Provide this parameter with a path to a `.zip` file hosted on Amazon S3. Within the `.zip` file, your files must be contained in a single top-level directory. No other files should be at the top level.

Your files will be distributed to each Ray node before your script begins to run. Consider how this might impact the disk space that's available to each Ray node. Available disk space is determined by the `WorkerType` set in the job configuration. If you want to provide your job data at scale, this mechanism is not the right solution. For more information on providing data to your job, see [the section called "Connecting to data"](#).

Your files will be accessible as if the directory was provided to Ray through the `working_dir` parameter. For example, to read a file named `sample.txt` in your `.zip` file's top-level directory, you could call:

```
@ray.remote
def do_work():
    f = open("sample.txt", "r")
    print(f.read())
```

For more information about `working_dir`, see the [Ray documentation](#). This feature behaves similarly to Ray's native capabilities.

Additional Python modules for Ray jobs

Additional modules from PyPI

Ray jobs use the Python Package Installer (`pip3`) to install additional modules to be used by a Ray script. You can use the `--pip-install` parameter with a list of comma-separated Python modules to add a new module or change the version of an existing module.

For example, to update or add a new `scikit-learn` module, use the following key-value pair:

```
"--pip-install", "scikit-learn==0.21.3"
```

If you have custom modules or custom patches, you can distribute your own libraries from Amazon S3 with the `--s3-py-modules` parameter. Before uploading your distribution, it might need to be repackaged and rebuilt. Follow the guidelines in [the section called "Including Python code in Ray jobs"](#).

Custom distributions from Amazon S3

Custom distributions should adhere to Ray packaging guidelines for dependencies. You can find out how to build these distributions in the following section. For more information about how Ray sets up dependencies, see [Environment Dependencies](#) in the Ray documentation.

To include a custom distributable after assessing its contents, upload your distributable to a bucket available to the job's IAM role. Specify the Amazon S3 path to a Python zip archive in your parameter configuration. If you're providing multiple distributables, separate them by comma. For example:

```
"--s3-py-modules", "s3://s3bucket/pythonPackage.zip"
```

Limitations

Ray jobs do not support compiling native code in the job environment. You can be limited by this if your Python dependencies transitively depend on native, compiled code. Ray jobs can run provided binaries, but they must be compiled for Linux on ARM64. This means you might be able to use the contents of `aarch64manylinux` wheels. You can provide your native dependencies in a compiled form by repackaging a wheel to Ray standards. Typically, this means removing `dist-info` folders so that there is only one folder at the root at the archive.

You cannot upgrade the version of `ray` or `ray[data]` using this parameter. In order to use a new version of Ray, you will need to change the runtime field on your job, after we have released support for it. For more information about supported Ray versions, see [the section called "Amazon Glue versions"](#).

Including Python code in Ray jobs

The Python Software Foundation offers standardized behaviors for packaging Python files for use across different runtimes. Ray introduces limitations to packaging standards that you should be aware of. Amazon Glue does not specify packaging standards beyond those specified to Ray. The following instructions provide standard guidance on packaging simple Python packages.

Package your files in a `.zip` archive. A directory should be at the root of the archive. **There should be no other files at the root level of the archive, or this may lead to unexpected behavior.** The root directory is the package, and its name is used to refer to your Python code when importing it.

If you provide a distribution in this form to a Ray job with `--s3-py-modules`, you will be able to import Python code from your package in your Ray script.

Your package can provide a single Python module with some Python files, or you can package together many modules. When repackaging dependencies, such as libraries from PyPI, **check for hidden files and metadata directories** inside of those packages.

Warning

Certain OS behaviors make it difficult to properly follow these packaging instructions.

- OSX may add hidden files such as `__MACOSX` to your zip file at the top level.
- Windows may add your files to a folder inside the zip automatically, unintentionally creating a nested folder.

The following procedures assume you are interacting with your files in Amazon Linux 2 or a similar OS that provides a distribution of the Info-ZIP `zip` and `zipinfo` utilities. We recommend using these tools to prevent unexpected behaviors.

To package Python files for use in Ray

1. Create a temporary directory with your package name, then confirm your working directory is its parent directory. You can do this with the following commands:

```
cd parent_directory
mkdir temp_dir
```

2. Copy your files into the temporary directory, then confirm your directory structure. The contents of this directory will be directly accessed as your Python module. You can do this with the following command:

```
ls -AR temp_dir
# my_file_1.py
# my_file_2.py
```

3. Compress your temporary folder using `zip`. You can do this with the following commands:

```
zip -r zip_file.zip temp_dir
```

4. Confirm your file is properly packaged. `zip_file.zip` should now be found in your working directory. You can inspect it with the following command:

```
zipinfo -1 zip_file.zip
# temp_dir/
# temp_dir/my_file_1.py
# temp_dir/my_file_2.py
```

To repackage a Python package for use in Ray.

1. Create a temporary directory with your package name, then confirm your working directory is its parent directory. You can do this with the following commands:

```
cd parent_directory
mkdir temp_dir
```

2. Decompress your package and copy the contents into your temporary directory. Remove files related to your previous packaging standard, leaving only the contents of the module. Confirm your file structure looks correct with the following command:

```
ls -AR temp_dir
# my_module
# my_module/__init__.py
# my_module/my_file_1.py
# my_module/my_submodule/__init__.py
# my_module/my_submodule/my_file_2.py
# my_module/my_submodule/my_file_3.py
```

3. Compress your temporary folder using zip. You can do this with the following commands:

```
zip -r zip_file.zip temp_dir
```

4. Confirm your file is properly packaged. *zip_file*.zip should now be found in your working directory. You can inspect it with the following command:

```
zipinfo -1 zip_file.zip
# temp_dir/my_module/
# temp_dir/my_module/__init__.py
# temp_dir/my_module/my_file_1.py
# temp_dir/my_module/my_submodule/
# temp_dir/my_module/my_submodule/__init__.py
# temp_dir/my_module/my_submodule/my_file_2.py
```

```
# temp_dir/my_module/my_submodule/my_file_3.py
```

Connecting to data in Ray jobs

Amazon Glue Ray jobs can use a broad array of Python packages that are designed for you to quickly integrate data. We provide a minimal set of dependencies in order to not clutter your environment. For more information about what is included by default, see [the section called “Modules provided with Ray jobs”](#).

Note

Amazon Glue extract, transform, and load (ETL) provides the DynamicFrame abstraction to streamline ETL workflows where you resolve schema differences between rows in your dataset. Amazon Glue ETL provides additional features—job bookmarks and grouping input files. We don't currently provide corresponding features in Ray jobs.

Amazon Glue for Spark provides direct support for connecting to certain data formats, sources and sinks. In Ray, Amazon SDK for pandas and current third-party libraries substantively cover that need. You will need to consult those libraries to understand what capabilities are available.

Amazon Glue for Ray integration with Amazon VPC is not currently available. Resources in Amazon VPC will not be accessible without a public route. For more information about using Amazon Glue with Amazon VPC, see [the section called “Configuring interface VPC endpoints \(Amazon PrivateLink\) for Amazon Glue”](#).

Common libraries for working with data in Ray

Ray Data – Ray Data provides methods to handle common data formats, sources and sinks. For more information about supported formats and sources in Ray Data, see [Input/Output](#) in the Ray Data documentation. Ray Data is an opinionated library, rather than a general-purpose library, for handling datasets.

Ray provides certain guidance around use cases where Ray Data might be the best solution for your job. For more information, see [Ray use cases](#) in the Ray documentation.

Amazon SDK for pandas (awswrangler) – Amazon SDK for pandas is an Amazon product that delivers clean, tested solutions for reading from and writing to Amazon services when your

transformations manage data with pandas DataFrames. For more information about supported formats and sources in the Amazon SDK for pandas, see the [API Reference](#) in the Amazon SDK for pandas documentation.

For examples of how to read and write data with the Amazon SDK for pandas, see [Quick Start](#) in the Amazon SDK for pandas documentation. The Amazon SDK for pandas doesn't provide transforms for your data. It only provides support for reading and writing from sources.

Modin – Modin is a Python library that implements common pandas operations in a distributable way. For more information about Modin, see the [Modin documentation](#). Modin itself doesn't provide support for reading and writing from sources. It provides distributed implementations of common transforms. Modin is supported by the Amazon SDK for pandas.

When you run Modin and the Amazon SDK for pandas together in a Ray environment, you can perform common ETL tasks with performant results. For more information about using Modin with the Amazon SDK for pandas, see [At scale](#) in the Amazon SDK for pandas documentation.

Other frameworks – For more information about frameworks that Ray supports, see [The Ray Ecosystem](#) in the Ray documentation. We don't provide support for other frameworks in Amazon Glue for Ray.

Connecting to data through the Data Catalog

Managing your data through the Data Catalog in conjunction with Ray jobs is supported with the Amazon SDK for pandas. For more information, see [Glue Catalog](#) on the Amazon SDK for pandas website.

Using this service with an Amazon SDK

Amazon software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

Amazon Glue API

This section describes data types and primitives used by Amazon Glue SDKs and Tools. There are three general ways to interact with Amazon Glue programmatically outside of the Amazon Web Services Management Console, each with its own documentation:

- Language SDK libraries allow you to access Amazon Web Services resources from common programming languages. Find more information at [Tools to Build on Amazon Web Services](#).
- The Amazon CLI allows you to access Amazon Web Services resources from the command line. Find more information at [Amazon CLI Command Reference](#).
- Amazon CloudFormation allows you to define a set of Amazon Web Services resources to be provisioned together consistently. Find more information at [Amazon CloudFormation: Amazon Glue resource type reference](#).

This section documents shared primitives independently of these SDKs and Tools. Tools use the [Amazon Glue Web API Reference](#) to communicate with Amazon Web Services.

Security APIs in Amazon Glue

The Security API describes the security data types, and the API related to security in Amazon Glue.

Data types

- [DataCatalogEncryptionSettings structure](#)
- [EncryptionAtRest structure](#)
- [ConnectionPasswordEncryption structure](#)
- [EncryptionConfiguration structure](#)
- [S3Encryption structure](#)
- [CloudWatchEncryption structure](#)
- [JobBookmarksEncryption structure](#)
- [SecurityConfiguration structure](#)
- [GluePolicy structure](#)
- [DataQualityEncryption structure](#)

DataCatalogEncryptionSettings structure

Contains configuration information for maintaining Data Catalog security.

Fields

- `EncryptionAtRest` – An [EncryptionAtRest](#) object.

Specifies the encryption-at-rest configuration for the Data Catalog.

- `ConnectionPasswordEncryption` – A [ConnectionPasswordEncryption](#) object.

When connection password protection is enabled, the Data Catalog uses a customer-provided key to encrypt the password as part of `CreateConnection` or `UpdateConnection` and store it in the `ENCRYPTED_PASSWORD` field in the connection properties. You can enable catalog encryption or only password encryption.

EncryptionAtRest structure

Specifies the encryption-at-rest configuration for the Data Catalog.

Fields

- `CatalogEncryptionMode` – *Required:* UTF-8 string (valid values: `DISABLED` | `SSE-KMS="SSEKMS"` | `SSE-KMS-WITH-SERVICE-ROLE="SSEKMSWITHSERVICEROLE"`).

The encryption-at-rest mode for encrypting Data Catalog data.

- `SseAwsKmsKeyId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Amazon KMS key to use for encryption at rest.

- `CatalogEncryptionServiceRole` – UTF-8 string, matching the [Custom string pattern #53](#).

The role that Amazon Glue assumes to encrypt and decrypt the Data Catalog objects on the caller's behalf.

ConnectionPasswordEncryption structure

The data structure used by the Data Catalog to encrypt the password as part of `CreateConnection` or `UpdateConnection` and store it in the `ENCRYPTED_PASSWORD` field in the connection properties. You can enable catalog encryption or only password encryption.

When a `CreationConnection` request arrives containing a password, the Data Catalog first encrypts the password using your Amazon KMS key. It then encrypts the whole connection object again if catalog encryption is also enabled.

This encryption requires that you set Amazon KMS key permissions to enable or restrict access on the password key according to your security requirements. For example, you might want only administrators to have decrypt permission on the password key.

Fields

- `ReturnConnectionPasswordEncrypted` – *Required*: Boolean.

When the `ReturnConnectionPasswordEncrypted` flag is set to "true", passwords remain encrypted in the responses of `GetConnection` and `GetConnections`. This encryption takes effect independently from catalog encryption.

- `AwsKmsKeyId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

An Amazon KMS key that is used to encrypt the connection password.

If connection password protection is enabled, the caller of `CreateConnection` and `UpdateConnection` needs at least `kms:Encrypt` permission on the specified Amazon KMS key, to encrypt passwords before storing them in the Data Catalog.

You can set the decrypt permission to enable or restrict access on the password key according to your security requirements.

EncryptionConfiguration structure

Specifies an encryption configuration.

Fields

- `S3Encryption` – An array of [S3Encryption](#) objects.

The encryption configuration for Amazon Simple Storage Service (Amazon S3) data.

- `CloudWatchEncryption` – A [CloudWatchEncryption](#) object.

The encryption configuration for Amazon CloudWatch.

- `JobBookmarksEncryption` – A [JobBookmarksEncryption](#) object.

The encryption configuration for job bookmarks.

- `DataQualityEncryption` – A [DataQualityEncryption](#) object.

The encryption configuration for Amazon Glue Data Quality assets.

S3Encryption structure

Specifies how Amazon Simple Storage Service (Amazon S3) data should be encrypted.

Fields

- `S3EncryptionMode` – UTF-8 string (valid values: `DISABLED` | `SSE-KMS="SSEKMS"` | `SSE-S3="SSES3"`).

The encryption mode to use for Amazon S3 data.

- `KmsKeyArn` – UTF-8 string, matching the [Custom string pattern #42](#).

The Amazon Resource Name (ARN) of the KMS key to be used to encrypt the data.

CloudWatchEncryption structure

Specifies how Amazon CloudWatch data should be encrypted.

Fields

- `CloudWatchEncryptionMode` – UTF-8 string (valid values: `DISABLED` | `SSE-KMS="SSEKMS"`).

The encryption mode to use for CloudWatch data.

- `KmsKeyArn` – UTF-8 string, matching the [Custom string pattern #42](#).

The Amazon Resource Name (ARN) of the KMS key to be used to encrypt the data.

JobBookmarksEncryption structure

Specifies how job bookmark data should be encrypted.

Fields

- `JobBookmarksEncryptionMode` – UTF-8 string (valid values: DISABLED | CSE-KMS="CSEKMS").

The encryption mode to use for job bookmarks data.

- `KmsKeyArn` – UTF-8 string, matching the [Custom string pattern #42](#).

The Amazon Resource Name (ARN) of the KMS key to be used to encrypt the data.

SecurityConfiguration structure

Specifies a security configuration.

Fields

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the security configuration.

- `CreatedTimeStamp` – Timestamp.

The time at which this security configuration was created.

- `EncryptionConfiguration` – An [EncryptionConfiguration](#) object.

The encryption configuration associated with this security configuration.

GluePolicy structure

A structure for returning a resource policy.

Fields

- `PolicyInJson` – UTF-8 string, at least 2 bytes long.

Contains the requested policy document, in JSON format.

- `PolicyHash` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Contains the hash value associated with this policy.

- `CreateTime` – Timestamp.

The date and time at which the policy was created.

- `UpdateTime` – Timestamp.

The date and time at which the policy was last updated.

DataQualityEncryption structure

Specifies how Data Quality assets in your account should be encrypted.

Fields

- `DataQualityEncryptionMode` – UTF-8 string (valid values: DISABLED | SSE-KMS="SSEKMS").

The encryption mode to use for encrypting Data Quality assets. These assets include data quality rulesets, results, statistics, anomaly detection models and observations.

Valid values are SSEKMS for encryption using a customer-managed KMS key, or DISABLED.

- `KmsKeyArn` – UTF-8 string, matching the [Custom string pattern #42](#).

The Amazon Resource Name (ARN) of the KMS key to be used to encrypt the data.

Operations

- [GetDataCatalogEncryptionSettings](#) action (Python: `get_data_catalog_encryption_settings`)
- [PutDataCatalogEncryptionSettings](#) action (Python: `put_data_catalog_encryption_settings`)
- [PutResourcePolicy](#) action (Python: `put_resource_policy`)
- [GetResourcePolicy](#) action (Python: `get_resource_policy`)
- [DeleteResourcePolicy](#) action (Python: `delete_resource_policy`)
- [CreateSecurityConfiguration](#) action (Python: `create_security_configuration`)
- [DeleteSecurityConfiguration](#) action (Python: `delete_security_configuration`)
- [GetSecurityConfiguration](#) action (Python: `get_security_configuration`)
- [GetSecurityConfigurations](#) action (Python: `get_security_configurations`)

- [GetResourcePolicies action \(Python: get_resource_policies\)](#)

GetDataCatalogEncryptionSettings action (Python: get_data_catalog_encryption_settings)

Retrieves the security configuration for a specified catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog to retrieve the security configuration for. If none is provided, the Amazon account ID is used by default.

Response

- `DataCatalogEncryptionSettings` – A [DataCatalogEncryptionSettings](#) object.

The requested security configuration.

Errors

- `InternalServiceException`
- `InvalidInputException`
- `OperationTimeoutException`

PutDataCatalogEncryptionSettings action (Python: put_data_catalog_encryption_settings)

Sets the security configuration for a specified catalog. After the configuration has been set, the specified encryption is applied to every catalog write thereafter.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog to set the security configuration for. If none is provided, the Amazon account ID is used by default.

- `DataCatalogEncryptionSettings` – *Required:* A [DataCatalogEncryptionSettings](#) object.

The security configuration to set.

Response

- *No Response parameters.*

Errors

- `InternalServerErrorException`
- `InvalidInputException`
- `OperationTimeoutException`

PutResourcePolicy action (Python: `put_resource_policy`)

Sets the Data Catalog resource policy for access control.

Request

- `PolicyInJson` – *Required:* UTF-8 string, at least 2 bytes long.

Contains the policy document to set, in JSON format.

- `ResourceArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #50](#).

Do not use. For internal use only.

- `PolicyHashCondition` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The hash value returned when the previous policy was set using `PutResourcePolicy`. Its purpose is to prevent concurrent modifications of a policy. Do not use this parameter if no previous policy has been set.

- `PolicyExistsCondition` – UTF-8 string (valid values: `MUST_EXIST` | `NOT_EXIST` | `NONE`).

A value of `MUST_EXIST` is used to update a policy. A value of `NOT_EXIST` is used to create a new policy. If a value of `NONE` or a null value is used, the call does not depend on the existence of a policy.

- `EnableHybrid` – UTF-8 string (valid values: `TRUE` | `FALSE`).

If `'TRUE'`, indicates that you are using both methods to grant cross-account access to Data Catalog resources:

- By directly updating the resource policy with `PutResourcePolicy`
- By using the **Grant permissions** command on the Amazon Web Services Management Console.

Must be set to `'TRUE'` if you have already used the Management Console to grant cross-account access, otherwise the call fails. Default is `'FALSE'`.

Response

- `PolicyHash` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A hash of the policy that has just been set. This must be included in a subsequent call that overwrites or updates this policy.

Errors

- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `ConditionCheckFailureException`

GetResourcePolicy action (Python: `get_resource_policy`)

Retrieves a specified resource policy.

Request

- `ResourceArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #50](#).

The ARN of the Amazon Glue resource for which to retrieve the resource policy. If not supplied, the Data Catalog resource policy is returned. Use `GetResourcePolicies` to view all existing resource policies. For more information see [Specifying Amazon Glue Resource ARNs](#).

Response

- `PolicyInJson` – UTF-8 string, at least 2 bytes long.

Contains the requested policy document, in JSON format.

- `PolicyHash` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Contains the hash value associated with this policy.

- `CreateTime` – Timestamp.

The date and time at which the policy was created.

- `UpdateTime` – Timestamp.

The date and time at which the policy was last updated.

Errors

- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

DeleteResourcePolicy action (Python: `delete_resource_policy`)

Deletes a specified policy.

Request

- `PolicyHashCondition` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The hash value returned when this policy was set.

- `ResourceArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #50](#).

The ARN of the Amazon Glue resource for the resource policy to be deleted.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `ConditionCheckFailureException`

CreateSecurityConfiguration action (Python: `create_security_configuration`)

Creates a new security configuration. A security configuration is a set of security properties that can be used by Amazon Glue. You can use a security configuration to encrypt data at rest. For information about using security configurations in Amazon Glue, see [Encrypting Data Written by Crawlers, Jobs, and Development Endpoints](#).

Request

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name for the new security configuration.

- `EncryptionConfiguration` – *Required:* An [EncryptionConfiguration](#) object.

The encryption configuration for the new security configuration.

Response

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name assigned to the new security configuration.

- `CreatedTimestamp` – Timestamp.

The time at which the new security configuration was created.

Errors

- `AlreadyExistsException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`

DeleteSecurityConfiguration action (Python: `delete_security_configuration`)

Deletes a specified security configuration.

Request

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the security configuration to delete.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

GetSecurityConfiguration action (Python: `get_security_configuration`)

Retrieves a specified security configuration.

Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the security configuration to retrieve.

Response

- SecurityConfiguration – A [SecurityConfiguration](#) object.

The requested security configuration.

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

GetSecurityConfigurations action (Python: `get_security_configurations`)

Retrieves a list of all security configurations.

Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

Response

- `SecurityConfigurations` – An array of [SecurityConfiguration](#) objects.

A list of security configurations.

- `NextToken` – UTF-8 string.

A continuation token, if there are more security configurations to return.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

GetResourcePolicies action (Python: `get_resource_policies`)

Retrieves the resource policies set on individual resources by Amazon Resource Access Manager during cross-account permission grants. Also retrieves the Data Catalog resource policy.

If you enabled metadata encryption in Data Catalog settings, and you do not have permission on the Amazon KMS key, the operation can't return the Data Catalog resource policy.

Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

Response

- `GetResourcePoliciesResponseList` – An array of [GluePolicy](#) objects.

A list of the individual resource policies and the account-level resource policy.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list does not contain the last resource policy available.

Errors

- `InternalServerErrorException`
- `OperationTimeoutException`
- `InvalidInputException`
- `GlueEncryptionException`

Catalog objects API

The Catalog objects API describes the data types and API related to working with catalogs in Amazon Glue.

Topics

- [Catalogs API](#)
- [Database API](#)
- [Table API](#)
- [Partition API](#)
- [Connections API](#)
- [User-defined Function API](#)
- [Importing an Athena catalog to Amazon Glue](#)

Catalogs API

The Catalogs API describes the APIs for creating, deleting, locating, updating, and listing catalogs.

Data types

- [Catalog structure](#)
- [CatalogInput structure](#)
- [TargetRedshiftCatalog structure](#)
- [CatalogProperties structure](#)
- [CatalogPropertiesOutput structure](#)
- [DataLakeAccessProperties structure](#)
- [IcebergOptimizationProperties structure](#)
- [DataLakeAccessPropertiesOutput structure](#)
- [IcebergOptimizationPropertiesOutput structure](#)
- [FederatedCatalog structure](#)

Catalog structure

The catalog object represents a logical grouping of databases in the Amazon Glue Data Catalog or a federated source. You can now create a Redshift-federated catalog or a catalog containing resource links to Redshift databases in another account or region.

Fields

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog. To grant access to the default catalog, this field should not be provided.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 64 bytes long, matching the [Custom string pattern #25](#).

The name of the catalog. Cannot be the same as the account ID.

- `ResourceArn` – UTF-8 string.

The Amazon Resource Name (ARN) assigned to the catalog resource.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

Description string, not more than 2048 bytes long, matching the URI address multi-line string pattern. A description of the catalog.

- **Parameters** – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

A map array of key-value pairs that define parameters and properties of the catalog.

- **CreateTime** – Timestamp.

The time at which the catalog was created.

- **UpdateTime** – Timestamp.

The time at which the catalog was last updated.

- **TargetRedshiftCatalog** – A [TargetRedshiftCatalog](#) object.

A TargetRedshiftCatalog object that describes a target catalog for database resource linking.

- **FederatedCatalog** – A [FederatedCatalog](#) object.

A FederatedCatalog object that points to an entity outside the Amazon Glue Data Catalog.

- **CatalogProperties** – A [CatalogPropertiesOutput](#) object.

A CatalogProperties object that specifies data lake access properties and other custom properties.

- **CreateTableDefaultPermissions** – An array of [PrincipalPermissions](#) objects.

An array of PrincipalPermissions objects. Creates a set of default permissions on the table(s) for principals. Used by Amazon Lake Formation. Not used in the normal course of Amazon Glue operations.

- **CreateDatabaseDefaultPermissions** – An array of [PrincipalPermissions](#) objects.

An array of `PrincipalPermissions` objects. Creates a set of default permissions on the database(s) for principals. Used by Amazon Lake Formation. Not used in the normal course of Amazon Glue operations.

- `AllowFullTableExternalDataAccess` – UTF-8 string (valid values: `True` | `False`).

Allows third-party engines to access data in Amazon S3 locations that are registered with Lake Formation.

CatalogInput structure

A structure that describes catalog properties.

Fields

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

Description string, not more than 2048 bytes long, matching the URI address multi-line string pattern. A description of the catalog.

- `FederatedCatalog` – A [FederatedCatalog](#) object.

A `FederatedCatalog` object. A `FederatedCatalog` structure that references an entity outside the Amazon Glue Data Catalog, for example a Redshift database.

- `Parameters` – A map array of key-value pairs.

Each key is a `Key` string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

A map array of key-value pairs that define the parameters and properties of the catalog.

- `TargetRedshiftCatalog` – A [TargetRedshiftCatalog](#) object.

A `TargetRedshiftCatalog` object that describes a target catalog for resource linking.

- `CatalogProperties` – A [CatalogProperties](#) object.

A `CatalogProperties` object that specifies data lake access properties and other custom properties.

- `CreateTableDefaultPermissions` – An array of [PrincipalPermissions](#) objects.

An array of `PrincipalPermissions` objects. Creates a set of default permissions on the table(s) for principals. Used by Amazon Lake Formation. Typically should be explicitly set as an empty list.

- `CreateDatabaseDefaultPermissions` – An array of [PrincipalPermissions](#) objects.

An array of `PrincipalPermissions` objects. Creates a set of default permissions on the database(s) for principals. Used by Amazon Lake Formation. Typically should be explicitly set as an empty list.

- `AllowFullTableExternalDataAccess` – UTF-8 string (valid values: True | False).

Allows third-party engines to access data in Amazon S3 locations that are registered with Lake Formation.

TargetRedshiftCatalog structure

A structure that describes a target catalog for resource linking.

Fields

- `CatalogArn` – *Required:* UTF-8 string.

The Amazon Resource Name (ARN) of the catalog resource.

CatalogProperties structure

A structure that specifies data lake access properties and other custom properties.

Fields

- `DataLakeAccessProperties` – A [DataLakeAccessProperties](#) object.

A `DataLakeAccessProperties` object that specifies properties to configure data lake access for your catalog resource in the Amazon Glue Data Catalog.

- `IcebergOptimizationProperties` – An [IcebergOptimizationProperties](#) object.

A structure that specifies Iceberg table optimization properties for the catalog. This includes configuration for compaction, retention, and orphan file deletion operations that can be applied to Iceberg tables in this catalog.

- `CustomProperties` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

Additional key-value properties for the catalog, such as column statistics optimizations.

CatalogPropertiesOutput structure

Property attributes that include configuration properties for the catalog resource.

Fields

- `DataLakeAccessProperties` – A [DataLakeAccessPropertiesOutput](#) object.

A `DataLakeAccessProperties` object with input properties to configure data lake access for your catalog resource in the Amazon Glue Data Catalog.

- `IcebergOptimizationProperties` – An [IcebergOptimizationPropertiesOutput](#) object.

An `IcebergOptimizationPropertiesOutput` object that specifies Iceberg table optimization settings for the catalog, including configurations for compaction, retention, and orphan file deletion operations.

- `CustomProperties` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

Additional key-value properties for the catalog, such as column statistics optimizations.

DataLakeAccessProperties structure

Input properties to configure data lake access for your catalog resource in the Amazon Glue Data Catalog.

Fields

- `DataLakeAccess` – Boolean.

Turns on or off data lake access for Apache Spark applications that access Amazon Redshift databases in the Data Catalog from any non-Redshift engine, such as Amazon Athena, Amazon EMR, or Amazon Glue ETL.

- `DataTransferRole` – UTF-8 string, matching the [Custom string pattern #53](#).

A role that will be assumed by Amazon Glue for transferring data into/out of the staging bucket during a query.

- `KmsKey` – UTF-8 string.

An encryption key that will be used for the staging bucket that will be created along with the catalog.

- `CatalogType` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies a federated catalog type for the native catalog resource. The currently supported type is `aws:redshift`.

IcebergOptimizationProperties structure

A structure that specifies Iceberg table optimization properties for the catalog, including configurations for compaction, retention, and orphan file deletion operations.

Fields

- `RoleArn` – UTF-8 string, matching the [Custom string pattern #53](#).

The Amazon Resource Name (ARN) of the IAM role that will be assumed to perform Iceberg table optimization operations.

- `Compaction` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

A map of key-value pairs that specify configuration parameters for Iceberg table compaction operations, which optimize the layout of data files to improve query performance.

- `Retention` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

A map of key-value pairs that specify configuration parameters for Iceberg table retention operations, which manage the lifecycle of table snapshots to control storage costs.

- `OrphanFileDeletion` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

A map of key-value pairs that specify configuration parameters for Iceberg orphan file deletion operations, which identify and remove files that are no longer referenced by the table metadata.

DataLakeAccessPropertiesOutput structure

The output properties of the data lake access configuration for your catalog resource in the Amazon Glue Data Catalog.

Fields

- `DataLakeAccess` – Boolean.

Turns on or off data lake access for Apache Spark applications that access Amazon Redshift databases in the Data Catalog.

- `DataTransferRole` – UTF-8 string, matching the [Custom string pattern #53](#).

A role that will be assumed by Amazon Glue for transferring data into/out of the staging bucket during a query.

- `KmsKey` – UTF-8 string.

An encryption key that will be used for the staging bucket that will be created along with the catalog.

- `ManagedWorkgroupName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The managed Redshift Serverless compute name that is created for your catalog resource.

- `ManagedWorkgroupStatus` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The managed Redshift Serverless compute status.

- `RedshiftDatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The default Redshift database resource name in the managed compute.

- `StatusMessage` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A message that gives more detailed information about the managed workgroup status.

- `CatalogType` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies a federated catalog type for the native catalog resource. The currently supported type is `aws:redshift`.

IcebergOptimizationPropertiesOutput structure

A structure that contains the output properties of Iceberg table optimization configuration for your catalog resource in the Amazon Glue Data Catalog.

Fields

- `RoleArn` – UTF-8 string, matching the [Custom string pattern #53](#).

The Amazon Resource Name (ARN) of the IAM role that is used to perform Iceberg table optimization operations.

- `Compaction` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

A map of key-value pairs that specify configuration parameters for Iceberg table compaction operations, which optimize the layout of data files to improve query performance.

- `Retention` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

A map of key-value pairs that specify configuration parameters for Iceberg table retention operations, which manage the lifecycle of table snapshots to control storage costs.

- `OrphanFileDeletion` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

A map of key-value pairs that specify configuration parameters for Iceberg orphan file deletion operations, which identify and remove files that are no longer referenced by the table metadata.

- `LastUpdatedTime` – Timestamp.

The timestamp when the Iceberg optimization properties were last updated.

FederatedCatalog structure

A catalog that points to an entity outside the Amazon Glue Data Catalog.

Fields

- **Identifier** – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

A unique identifier for the federated catalog.

- **ConnectionName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to an external data source, for example a Redshift-federated catalog.

- **ConnectionType** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The type of connection used to access the federated catalog, specifying the protocol or method for connection to the external data source.

Operations

- [CreateCatalog action \(Python: create_catalog\)](#)
- [UpdateCatalog action \(Python: update_catalog\)](#)
- [DeleteCatalog action \(Python: delete_catalog\)](#)
- [GetCatalog action \(Python: get_catalog\)](#)
- [GetCatalogs action \(Python: get_catalogs\)](#)

CreateCatalog action (Python: create_catalog)

Creates a new catalog in the Amazon Glue Data Catalog.

Request

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 64 bytes long, matching the [Custom string pattern #25](#).

The name of the catalog to create.

- **CatalogInput** – *Required:* A [CatalogInput](#) object.

A [CatalogInput](#) object that defines the metadata for the catalog.

- Tags – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

A map array of key-value pairs, not more than 50 pairs. Each key is a UTF-8 string, not less than 1 or more than 128 bytes long. Each value is a UTF-8 string, not more than 256 bytes long. The tags you assign to the catalog.

Response

- *No Response parameters.*

Errors

- `InvalidInputException`
- `AlreadyExistsException`
- `ResourceNumberLimitExceededException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `ConcurrentModificationException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `FederatedResourceAlreadyExistsException`
- `FederationSourceException`

UpdateCatalog action (Python: `update_catalog`)

Updates an existing catalog's properties in the Amazon Glue Data Catalog.

Request

- `CatalogId` – *Required:* Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog.

- `CatalogInput` – *Required:* A [CatalogInput](#) object.

A `CatalogInput` object specifying the new properties of an existing catalog.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `ConcurrentModificationException`
- `AccessDeniedException`
- `FederationSourceException`

DeleteCatalog action (Python: `delete_catalog`)

Removes the specified catalog from the Amazon Glue Data Catalog.

After completing this operation, you no longer have access to the databases, tables (and all table versions and partitions that might belong to the tables) and the user-defined functions in the deleted catalog. Amazon Glue deletes these "orphaned" resources asynchronously in a timely manner, at the discretion of the service.

To ensure the immediate deletion of all related resources before calling the `DeleteCatalog` operation, use `DeleteTableVersion` (or `BatchDeleteTableVersion`), `DeletePartition` (or `BatchDeletePartition`), `DeleteTable` (or `BatchDeleteTable`), `DeleteUserDefinedFunction` and `DeleteDatabase` to delete any resources that belong to the catalog.

Request

- `CatalogId` – *Required*: Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `ConcurrentModificationException`
- `AccessDeniedException`
- `FederationSourceException`

GetCatalog action (Python: `get_catalog`)

The name of the Catalog to retrieve. This should be all lowercase.

Request

- `CatalogId` – *Required*: Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the parent catalog in which the catalog resides. If none is provided, the Amazon Account Number is used by default.

Response

- `Catalog` – A [Catalog](#) object.

A Catalog object. The definition of the specified catalog in the Amazon Glue Data Catalog.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `FederationSourceException`
- `FederationSourceRetryableException`

GetCatalogs action (Python: `get_catalogs`)

Retrieves all catalogs defined in a catalog in the Amazon Glue Data Catalog. For a Redshift-federated catalog use case, this operation returns the list of catalogs mapped to Redshift databases in the Redshift namespace catalog.

Request

- `ParentCatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the parent catalog in which the catalog resides. If none is provided, the Amazon Account Number is used by default.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of catalogs to return in one response.

- `Recursive` – Boolean.

Whether to list all catalogs across the catalog hierarchy, starting from the `ParentCatalogId`. Defaults to `false`. When `true`, all catalog objects in the `ParentCatalogId` hierarchy are enumerated in the response.

- `IncludeRoot` – Boolean.

Whether to list the default catalog in the account and region in the response. Defaults to `false`. When `true` and `ParentCatalogId = NULL | Amazon Account ID`, all catalogs and the default catalog are enumerated in the response.

When the `ParentCatalogId` is not equal to null, and this attribute is passed as `false` or `true`, an `InvalidInputException` is thrown.

Response

- `CatalogList` – *Required*: An array of [Catalog](#) objects.

An array of `Catalog` objects. A list of `Catalog` objects from the specified parent catalog.

- `NextToken` – UTF-8 string.

A continuation token for paginating the returned list of tokens, returned if the current segment of the list is not the last.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `FederationSourceException`
- `FederationSourceRetryableException`

Database API

The Database API describes database data types, and includes the API for creating, deleting, locating, updating, and listing databases.

Data types

- [Database structure](#)
- [DatabaseInput structure](#)
- [PrincipalPermissions structure](#)
- [DataLakePrincipal structure](#)
- [DatabaseIdentifier structure](#)
- [FederatedDatabase structure](#)

Database structure

The Database object represents a logical grouping of tables that might reside in a Hive metastore or an RDBMS.

Fields

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database. For Hive compatibility, this is folded to lowercase when it is stored.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the database.

- **LocationUri** – Uniform resource identifier (uri), not less than 1 or more than 1024 bytes long, matching the [URI address multi-line string pattern](#).

The location of the database (for example, an HDFS path).

- **Parameters** – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define parameters and properties of the database.

- `CreateTime` – Timestamp.

The time at which the metadata database was created in the catalog.

- `CreateTableDefaultPermissions` – An array of [PrincipalPermissions](#) objects.

Creates a set of default permissions on the table for principals. Used by Amazon Lake Formation. Not used in the normal course of Amazon Glue operations.

- `TargetDatabase` – A [DatabaseIdentifier](#) object.

A `DatabaseIdentifier` structure that describes a target database for resource linking.

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides.

- `FederatedDatabase` – A [FederatedDatabase](#) object.

A `FederatedDatabase` structure that references an entity outside the Amazon Glue Data Catalog.

DatabaseInput structure

The structure used to create or update a database.

Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database. For Hive compatibility, this is folded to lowercase when it is stored.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the database.

- `LocationUri` – Uniform resource identifier (uri), not less than 1 or more than 1024 bytes long, matching the [URI address multi-line string pattern](#).

The location of the database (for example, an HDFS path).

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define parameters and properties of the database.

These key-value pairs define parameters and properties of the database.

- `CreateTableDefaultPermissions` – An array of [PrincipalPermissions](#) objects.

Creates a set of default permissions on the table for principals. Used by Amazon Lake Formation. Not used in the normal course of Amazon Glue operations.

- `TargetDatabase` – A [DatabaseIdentifier](#) object.

A `DatabaseIdentifier` structure that describes a target database for resource linking.

- `FederatedDatabase` – A [FederatedDatabase](#) object.

A `FederatedDatabase` structure that references an entity outside the Amazon Glue Data Catalog.

PrincipalPermissions structure

Permissions granted to a principal.

Fields

- `Principal` – A [DataLakePrincipal](#) object.

The principal who is granted permissions.

- `Permissions` – An array of UTF-8 strings.

The permissions that are granted to the principal.

DataLakePrincipal structure

The Amazon Lake Formation principal.

Fields

- `DataLakePrincipalIdentifier` – UTF-8 string, not less than 1 or more than 255 bytes long.

An identifier for the Amazon Lake Formation principal.

DatabasIdentifier structure

A structure that describes a target database for resource linking.

Fields

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides.

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database.

- `Region` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Region of the target database.

FederatedDatabase structure

A database that points to an entity outside the Amazon Glue Data Catalog.

Fields

- `Identifier` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

A unique identifier for the federated database.

- **ConnectionName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to the external metastore.

- **ConnectionType** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The type of connection used to access the federated database, such as JDBC, ODBC, or other supported connection protocols.

Operations

- [CreateDatabase action \(Python: create_database\)](#)
- [UpdateDatabase action \(Python: update_database\)](#)
- [DeleteDatabase action \(Python: delete_database\)](#)
- [GetDatabase action \(Python: get_database\)](#)
- [GetDatabases action \(Python: get_databases\)](#)

CreateDatabase action (Python: create_database)

Creates a new database in a Data Catalog.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which to create the database. If none is provided, the Amazon account ID is used by default.

- **DatabaseInput** – *Required:* A [DatabaseInput](#) object.

The metadata for the database.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags you assign to the database.

Response

- *No Response parameters.*

Errors

- `InvalidInputException`
- `AlreadyExistsException`
- `ResourceNumberLimitExceededException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `ConcurrentModificationException`
- `FederatedResourceAlreadyExistsException`
- `FederationSourceException`
- `FederationSourceRetryableException`

UpdateDatabase action (Python: `update_database`)

Updates an existing database definition in a Data Catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the metadata database resides. If none is provided, the Amazon account ID is used by default.

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database to update in the catalog. For Hive compatibility, this is folded to lowercase.

- DatabaseInput – *Required:* A [DatabaseInput](#) object.

A DatabaseInput object specifying the new definition of the metadata database in the catalog.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException
- ConcurrentModificationException
- FederationSourceException
- FederationSourceRetryableException
- AlreadyExistsException

DeleteDatabase action (Python: delete_database)

Removes a specified database from a Data Catalog.

Note

After completing this operation, you no longer have access to the tables (and all table versions and partitions that might belong to the tables) and the user-defined functions in the deleted database. Amazon Glue deletes these "orphaned" resources asynchronously in a timely manner, at the discretion of the service.

To ensure the immediate deletion of all related resources, before calling DeleteDatabase, use DeleteTableVersion or BatchDeleteTableVersion, DeletePartition or BatchDeletePartition, DeleteUserDefinedFunction, and DeleteTable or BatchDeleteTable, to delete any resources that belong to the database.

Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides. If none is provided, the Amazon account ID is used by default.

- `name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database to delete. For Hive compatibility, this must be all lowercase.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ConcurrentModificationException`
- `FederationSourceException`
- `FederationSourceRetryableException`

GetDatabase action (Python: `get_database`)

Retrieves the definition of a specified database.

Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides. If none is provided, the Amazon account ID is used by default.

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database to retrieve. For Hive compatibility, this should be all lowercase.

Response

- Database – A [Database](#) object.

The definition of the specified database in the Data Catalog.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `FederationSourceException`
- `FederationSourceRetryableException`

GetDatabases action (Python: `get_databases`)

Retrieves all databases defined in a given Data Catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog from which to retrieve Databases. If none is provided, the Amazon account ID is used by default.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

- `MaxResults` – Number (integer), not less than 1 or more than 100.

The maximum number of databases to return in one response.

- `ResourceShareType` – UTF-8 string (valid values: FOREIGN | ALL | FEDERATED).

Allows you to specify that you want to list the databases shared with your account. The allowable values are FEDERATED, FOREIGN or ALL.

- If set to FEDERATED, will list the federated databases (referencing an external entity) shared with your account.
- If set to FOREIGN, will list the databases shared with your account.
- If set to ALL, will list the databases shared with your account, as well as the databases in your local account.
- `AttributesToGet` – An array of UTF-8 strings.

Specifies the database fields returned by the `GetDatabases` call. This parameter doesn't accept an empty list. The request must include the `NAME`.

Response

- `DatabaseList` – *Required:* An array of [Database](#) objects.

A list of Database objects from the specified catalog.

- `NextToken` – UTF-8 string.

A continuation token for paginating the returned list of tokens, returned if the current segment of the list is not the last.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `EntityNotFoundException`
- `FederationSourceException`
- `FederationSourceRetryableException`

Table API

The Table API describes data types and operations associated with tables.

Data types

- [Table structure](#)
- [TableInput structure](#)
- [FederatedTable structure](#)
- [Column structure](#)
- [StorageDescriptor structure](#)
- [SchemaReference structure](#)
- [SerDeInfo structure](#)

- [AuditContext structure](#)

Table structure

Represents a collection of related data organized in columns and rows.

Fields

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The table name. For Hive compatibility, this must be entirely lowercase.

- **DatabaseName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table metadata resides. For Hive compatibility, this must be all lowercase.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the table.

- **Owner** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The owner of the table.

- `CreateTime` – Timestamp.

The time when the table definition was created in the Data Catalog.

- `UpdateTime` – Timestamp.

The last time that the table was updated.

- `LastAccessTime` – Timestamp.

The last time that the table was accessed. This is usually taken from HDFS, and might not be reliable.

- `LastAnalyzedTime` – Timestamp.

The last time that column statistics were computed for this table.

- `Retention` – Number (integer), not more than None.

The retention time for this table.

- `StorageDescriptor` – A [StorageDescriptor](#) object.

A storage descriptor containing information about the physical storage of this table.

- `PartitionKeys` – An array of [Column](#) objects.

A list of columns by which the table is partitioned. Only primitive types are supported as partition keys.

When you create a table used by Amazon Athena, and you do not specify any `partitionKeys`, you must at least set the value of `partitionKeys` to an empty list. For example:

```
"PartitionKeys": []
```

- `ViewOriginalText` – UTF-8 string, not more than 409600 bytes long.

Included for Apache Hive compatibility. Not used in the normal course of Amazon Glue operations. If the table is a `VIRTUAL_VIEW`, certain Athena configuration encoded in base64.

- `ViewExpandedText` – UTF-8 string, not more than 409600 bytes long.

Included for Apache Hive compatibility. Not used in the normal course of Amazon Glue operations.

- `TableType` – UTF-8 string, not more than 255 bytes long.

The type of this table. Amazon Glue will create tables with the `EXTERNAL_TABLE` type. Other services, such as Athena, may create tables with additional table types.

Amazon Glue related table types:

`EXTERNAL_TABLE`

Hive compatible attribute - indicates a non-Hive managed table.

`GOVERNED`

Used by Amazon Lake Formation. The Amazon Glue Data Catalog understands `GOVERNED`.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define properties associated with the table.

- `CreatedBy` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The person or entity who created the table.

- `IsRegisteredWithLakeFormation` – Boolean.

Indicates whether the table has been registered with Amazon Lake Formation.

- `TargetTable` – A [TableIdentifier](#) object.

A `TableIdentifier` structure that describes a target table for resource linking.

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the table resides.

- `VersionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the table version.

- `FederatedTable` – A [FederatedTable](#) object.

A FederatedTable structure that references an entity outside the Amazon Glue Data Catalog.

- ViewDefinition – A [ViewDefinition](#) object.

A structure that contains all the information that defines the view, including the dialect or dialects for the view, and the query.

- IsMultiDialectView – Boolean.

Specifies whether the view supports the SQL dialects of one or more different query engines and can therefore be read by those engines.

TableInput structure

A structure used to define a table.

Fields

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The table name. For Hive compatibility, this is folded to lowercase when it is stored.

- Description – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the table.

- Owner – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The table owner. Included for Apache Hive compatibility. Not used in the normal course of Amazon Glue operations.

- LastAccessTime – Timestamp.

The last time that the table was accessed.

- LastAnalyzedTime – Timestamp.

The last time that column statistics were computed for this table.

- Retention – Number (integer), not more than None.

The retention time for this table.

- `StorageDescriptor` – A [StorageDescriptor](#) object.

A storage descriptor containing information about the physical storage of this table.

- `PartitionKeys` – An array of [Column](#) objects.

A list of columns by which the table is partitioned. Only primitive types are supported as partition keys.

When you create a table used by Amazon Athena, and you do not specify any `partitionKeys`, you must at least set the value of `partitionKeys` to an empty list. For example:

```
"PartitionKeys": []
```

- `ViewOriginalText` – UTF-8 string, not more than 409600 bytes long.

Included for Apache Hive compatibility. Not used in the normal course of Amazon Glue operations. If the table is a `VIRTUAL_VIEW`, certain Athena configuration encoded in base64.

- `ViewExpandedText` – UTF-8 string, not more than 409600 bytes long.

Included for Apache Hive compatibility. Not used in the normal course of Amazon Glue operations.

- `TableType` – UTF-8 string, not more than 255 bytes long.

The type of this table. Amazon Glue will create tables with the `EXTERNAL_TABLE` type. Other services, such as Athena, may create tables with additional table types.

Amazon Glue related table types:

`EXTERNAL_TABLE`

Hive compatible attribute - indicates a non-Hive managed table.

`GOVERNED`

Used by Amazon Lake Formation. The Amazon Glue Data Catalog understands `GOVERNED`.

- `Parameters` – A map array of key-value pairs.

Each key is a `Key` string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define properties associated with the table.

- `TargetTable` – A [TableIdentifier](#) object.

A `TableIdentifier` structure that describes a target table for resource linking.

- `ViewDefinition` – A [ViewDefinitionInput](#) object.

A structure that contains all the information that defines the view, including the dialect or dialects for the view, and the query.

FederatedTable structure

A table that points to an entity outside the Amazon Glue Data Catalog.

Fields

- `Identifier` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

A unique identifier for the federated table.

- `DatabaseIdentifier` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

A unique identifier for the federated database.

- `ConnectionName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to the external metastore.

- `ConnectionType` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The type of connection used to access the federated table, specifying the protocol or method for connecting to the external data source.

Column structure

A column in a `Table`.

Fields

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the Column.

- **Type** – UTF-8 string, not more than 131072 bytes long, matching the [Single-line string pattern](#).

The data type of the Column.

- **Comment** – Comment string, not more than 255 bytes long, matching the [Single-line string pattern](#).

A free-form text comment.

- **Parameters** – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define properties associated with the column.

StorageDescriptor structure

Describes the physical storage of table data.

Fields

- **Columns** – An array of [Column](#) objects.

A list of the Columns in the table.

- **Location** – Location string, not more than 2056 bytes long, matching the [URI address multi-line string pattern](#).

The physical location of the table. By default, this takes the form of the warehouse location, followed by the database location in the warehouse, followed by the table name.

- **AdditionalLocations** – An array of UTF-8 strings.

A list of locations that point to the path where a Delta table is located.

- `InputFormat` – Format string, not more than 128 bytes long, matching the [Single-line string pattern](#).

The input format: `SequenceFileInputFormat` (binary), or `TextInputFormat`, or a custom format.

- `OutputFormat` – Format string, not more than 128 bytes long, matching the [Single-line string pattern](#).

The output format: `SequenceFileOutputFormat` (binary), or `IgnoreKeyTextOutputFormat`, or a custom format.

- `Compressed` – Boolean.

`True` if the data in the table is compressed, or `False` if not.

- `NumberOfBuckets` – Number (integer).

Must be specified if the table contains any dimension columns.

- `SerdeInfo` – A [SerDeInfo](#) object.

The serialization/deserialization (SerDe) information.

- `BucketColumns` – An array of UTF-8 strings.

A list of reducer grouping columns, clustering columns, and bucketing columns in the table.

- `SortColumns` – An array of [Order](#) objects.

A list specifying the sort order of each bucket in the table.

- `Parameters` – A map array of key-value pairs.

Each key is a `Key` string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

The user-supplied properties in key-value form.

- `SkewedInfo` – A [SkewedInfo](#) object.

The information about values that appear frequently in a column (skewed values).

- `StoredAsSubDirectories` – Boolean.

True if the table data is stored in subdirectories, or False if not.

- SchemaReference – A [SchemaReference](#) object.

An object that references a schema stored in the Amazon Glue Schema Registry.

When creating a table, you can pass an empty list of columns for the schema, and instead use a schema reference.

SchemaReference structure

An object that references a schema stored in the Amazon Glue Schema Registry.

Fields

- SchemaId – A [SchemaId](#) object.

A structure that contains schema identity fields. Either this or the SchemaVersionId has to be provided.

- SchemaVersionId – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #45](#).

The unique ID assigned to a version of the schema. Either this or the SchemaId has to be provided.

- SchemaVersionNumber – Number (long), not less than 1 or more than 100000.

The version number of the schema.

SerDeInfo structure

Information about a serialization/deserialization program (SerDe) that serves as an extractor and loader.

Fields

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the SerDe.

- `SerializationLibrary` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Usually the class that implements the SerDe. An example is `org.apache.hadoop.hive.serde2.columnar.ColumnarSerDe`.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define initialization parameters for the SerDe.

Order structure

Specifies the sort order of a sorted column.

Fields

- `Column` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the column.

- `SortOrder` – *Required*: Number (integer), not more than 1.

Indicates that the column is sorted in ascending order (`= 1`), or in descending order (`= 0`).

SkewedInfo structure

Specifies skewed values in a table. Skewed values are those that occur with very high frequency.

Fields

- `SkewedColumnNames` – An array of UTF-8 strings.

A list of names of columns that contain skewed values.

- `SkewedColumnValues` – An array of UTF-8 strings.

A list of values that appear so frequently as to be considered skewed.

- `SkewedColumnValueLocationMaps` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A mapping of skewed values to the columns that contain them.

TableVersion structure

Specifies a version of a table.

Fields

- `Table` – A [Table](#) object.

The table in question.

- `VersionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID value that identifies this table version. A `VersionId` is a string representation of an integer. Each version is incremented by 1.

TableError structure

An error record for table operations.

Fields

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this must be entirely lowercase.

- `ErrorDetail` – An [ErrorDetail](#) object.

The details about the error.

TableVersionError structure

An error record for table-version operations.

Fields

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table in question.

- `VersionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID value of the version in question. A `VersionID` is a string representation of an integer. Each version is incremented by 1.

- `ErrorDetail` – An [ErrorDetail](#) object.

The details about the error.

SortCriterion structure

Specifies a field to sort by and a sort order.

Fields

- `FieldName` – Value string, not less than 1 or more than 1024 bytes long.

The name of the field on which to sort.

- `Sort` – UTF-8 string (valid values: `ASC="ASCENDING" | DESC="DESCENDING"`).

An ascending or descending sort.

TableIdentifier structure

A structure that describes a target table for resource linking.

Fields

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the table resides.

- DatabaseName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database that contains the target table.

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the target table.

- Region – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Region of the target table.

KeySchemaElement structure

A partition key pair consisting of a name and a type.

Fields

- Name – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of a partition key.

- Type – *Required:* UTF-8 string, not more than 131072 bytes long, matching the [Single-line string pattern](#).

The type of a partition key.

PartitionIndex structure

A structure for a partition index.

Fields

- Keys – *Required:* An array of UTF-8 strings, at least 1 string.

The keys for the partition index.

- IndexName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partition index.

PartitionIndexDescriptor structure

A descriptor for a partition index in a table.

Fields

- **IndexName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partition index.

- **Keys** – *Required:* An array of [KeySchemaElement](#) objects, at least 1 structure.

A list of one or more keys, as KeySchemaElement structures, for the partition index.

- **IndexStatus** – *Required:* UTF-8 string (valid values: CREATING | ACTIVE | DELETING | FAILED).

The status of the partition index.

The possible statuses are:

- **CREATING:** The index is being created. When an index is in a CREATING state, the index or its table cannot be deleted.
- **ACTIVE:** The index creation succeeds.
- **FAILED:** The index creation fails.
- **DELETING:** The index is deleted from the list of indexes.
- **BackfillErrors** – An array of [BackfillError](#) objects.

A list of errors that can occur when registering partition indexes for an existing table.

BackfillError structure

A list of errors that can occur when registering partition indexes for an existing table.

These errors give the details about why an index registration failed and provide a limited number of partitions in the response, so that you can fix the partitions at fault and try registering the index again. The most common set of errors that can occur are categorized as follows:

- **EncryptedPartitionError:** The partitions are encrypted.

- **InvalidPartitionTypeDataError:** The partition value doesn't match the data type for that partition column.
- **MissingPartitionValueError:** The partitions are encrypted.
- **UnsupportedPartitionCharacterError:** Characters inside the partition value are not supported. For example: U+0000 , U+0001, U+0002.
- **InternalError:** Any error which does not belong to other error codes.

Fields

- **Code** – UTF-8 string (valid values: ENCRYPTED_PARTITION_ERROR | INTERNAL_ERROR | INVALID_PARTITION_TYPE_DATA_ERROR | MISSING_PARTITION_VALUE_ERROR | UNSUPPORTED_PARTITION_CHARACTER_ERROR).

The error code for an error that occurred when registering partition indexes for an existing table.

- **Partitions** – An array of [PartitionValueList](#) objects.

A list of a limited number of partitions in the response.

IcebergInput structure

A structure that defines an Apache Iceberg metadata table to create in the catalog.

Fields

- **MetadataOperation** – *Required:* UTF-8 string (valid values: CREATE).

A required metadata operation. Can only be set to CREATE.

- **Version** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The table version for the Iceberg table. Defaults to 2.

- **CreateIcebergTableInput** – A [CreateIcebergTableInput](#) object.

The configuration parameters required to create a new Iceberg table in the Amazon Glue Data Catalog, including table properties and metadata specifications.

OpenTableFormatInput structure

A structure representing an open format table.

Fields

- `IcebergInput` – An [IcebergInput](#) object.

Specifies an `IcebergInput` structure that defines an Apache Iceberg metadata table.

ViewDefinition structure

A structure containing details for representations.

Fields

- `IsProtected` – Boolean.

You can set this flag as true to instruct the engine not to push user-provided operations into the logical plan of the view during query planning. However, setting this flag does not guarantee that the engine will comply. Refer to the engine's documentation to understand the guarantees provided, if any.

- `Definer` – UTF-8 string, not less than 20 or more than 2048 bytes long, matching the [Single-line string pattern](#).

The definer of a view in SQL.

- `SubObjects` – An array of UTF-8 strings, not more than 10 strings.

A list of table Amazon Resource Names (ARNs).

- `Representations` – An array of [ViewRepresentation](#) objects, not less than 1 or more than 1000 structures.

A list of representations.

ViewDefinitionInput structure

A structure containing details for creating or updating an Amazon Glue view.

Fields

- `IsProtected` – Boolean.

You can set this flag as true to instruct the engine not to push user-provided operations into the logical plan of the view during query planning. However, setting this flag does not guarantee that the engine will comply. Refer to the engine's documentation to understand the guarantees provided, if any.

- `Definer` – UTF-8 string, not less than 20 or more than 2048 bytes long, matching the [Single-line string pattern](#).

The definer of a view in SQL.

- `Representations` – An array of [ViewRepresentationInput](#) objects, not less than 1 or more than 10 structures.

A list of structures that contains the dialect of the view, and the query that defines the view.

- `SubObjects` – An array of UTF-8 strings, not more than 10 strings.

A list of base table ARNs that make up the view.

ViewRepresentation structure

A structure that contains the dialect of the view, and the query that defines the view.

Fields

- `Dialect` – UTF-8 string (valid values: REDSHIFT | ATHENA | SPARK).

The dialect of the query engine.

- `DialectVersion` – UTF-8 string, not less than 1 or more than 255 bytes long.

The version of the dialect of the query engine. For example, 3.0.0.

- `ViewOriginalText` – UTF-8 string, not more than 409600 bytes long.

The SELECT query provided by the customer during CREATE VIEW DDL. This SQL is not used during a query on a view (`ViewExpandedText` is used instead). `ViewOriginalText` is used for cases like SHOW CREATE VIEW where users want to see the original DDL command that created the view.

- `ViewExpandedText` – UTF-8 string, not more than 409600 bytes long.

The expanded SQL for the view. This SQL is used by engines while processing a query on a view. Engines may perform operations during view creation to transform `ViewOriginalText` to `ViewExpandedText`. For example:

- Fully qualified identifiers: `SELECT * from table1 -> SELECT * from db1.table1`
- `ValidationConnection` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to be used to validate the specific representation of the view.

- `IsStale` – Boolean.

Dialects marked as stale are no longer valid and must be updated before they can be queried in their respective query engines.

ViewRepresentationInput structure

A structure containing details of a representation to update or create a Lake Formation view.

Fields

- `Dialect` – UTF-8 string (valid values: REDSHIFT | ATHENA | SPARK).

A parameter that specifies the engine type of a specific representation.

- `DialectVersion` – UTF-8 string, not less than 1 or more than 255 bytes long.

A parameter that specifies the version of the engine of a specific representation.

- `ViewOriginalText` – UTF-8 string, not more than 409600 bytes long.

A string that represents the original SQL query that describes the view.

- `ValidationConnection` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to be used to validate the specific representation of the view.

- `ViewExpandedText` – UTF-8 string, not more than 409600 bytes long.

A string that represents the SQL query that describes the view with expanded resource ARNs

UpdateOpenTableFormatInput structure

Input parameters for updating open table format tables in Amazon GlueData Catalog, serving as a wrapper for format-specific update operations such as Apache Iceberg.

Fields

- UpdateIcebergInput – An [UpdateIcebergInput](#) object.

Apache Iceberg-specific update parameters that define the table modifications to be applied, including schema changes, partition specifications, and table properties.

UpdateIcebergInput structure

Input parameters specific to updating Apache Iceberg tables in Amazon Glue Data Catalog, containing the update operations to be applied to an existing Iceberg table.

Fields

- UpdateIcebergTableInput – *Required:* An [UpdateIcebergTableInput](#) object.

The specific update operations to be applied to the Iceberg table, containing a list of updates that define the new state of the table including schema, partitions, and properties.

CreateIcebergTableInput structure

The configuration parameters required to create a new Iceberg table in the Amazon Glue Data Catalog, including table properties and metadata specifications.

Fields

- Location – *Required:* Location string, not more than 2056 bytes long, matching the [URI address multi-line string pattern](#).

The S3 location where the Iceberg table data will be stored.

- Schema – *Required:* An [IcebergSchema](#) object.

The schema definition that specifies the structure, field types, and metadata for the Iceberg table.

- `PartitionSpec` – An [IcebergPartitionSpec](#) object.

The partitioning specification that defines how the Iceberg table data will be organized and partitioned for optimal query performance.

- `WriteOrder` – An [IcebergSortOrder](#) object.

The sort order specification that defines how data should be ordered within each partition to optimize query performance.

- `Properties` –

Key-value pairs of additional table properties and configuration settings for the Iceberg table.

UpdateIcebergTableInput structure

Contains the update operations to be applied to an existing Iceberg table in Amazon Glue Data Catalog, defining the new state of the table metadata.

Fields

- `Updates` – *Required:* An array of [IcebergTableUpdate](#) objects.

The list of table update operations that specify the changes to be made to the Iceberg table, including schema modifications, partition specifications, and table properties.

IcebergSortOrder structure

Defines the sort order specification for an Iceberg table, determining how data should be ordered within partitions to optimize query performance.

Fields

- `OrderId` – *Required:* Number (integer).

The unique identifier for this sort order specification within the Iceberg table's metadata.

- `Fields` – *Required:* An array of [IcebergSortField](#) objects.

The list of fields and their sort directions that define the ordering criteria for the Iceberg table data.

IcebergSortField structure

Defines a single field within an Iceberg sort order specification, including the source field, transformation, sort direction, and null value ordering.

Fields

- **SourceId** – *Required:* Number (integer).

The identifier of the source field from the table schema that this sort field is based on.

- **Transform** – *Required:* UTF-8 string.

The transformation function applied to the source field before sorting, such as identity, bucket, or truncate.

- **Direction** – *Required:* UTF-8 string (valid values: asc="ASC" | desc="DESC").

The sort direction for this field, either ascending or descending.

- **NullOrder** – *Required:* UTF-8 string (valid values: nulls-first="NULLS_FIRST" | nulls-last="NULLS_LAST").

The ordering behavior for null values in this field, specifying whether nulls should appear first or last in the sort order.

IcebergPartitionSpec structure

Defines the partitioning specification for an Iceberg table, determining how table data will be organized and partitioned for optimal query performance.

Fields

- **Fields** – *Required:* An array of [IcebergPartitionField](#) objects.

The list of partition fields that define how the table data should be partitioned, including source fields and their transformations.

- **SpecId** – Number (integer).

The unique identifier for this partition specification within the Iceberg table's metadata history.

IcebergPartitionField structure

Defines a single partition field within an Iceberg partition specification, including the source field, transformation function, partition name, and unique identifier.

Fields

- `SourceId` – *Required*: Number (integer).

The identifier of the source field from the table schema that this partition field is based on.

- `Transform` – *Required*: UTF-8 string.

The transformation function applied to the source field to create the partition, such as identity, bucket, truncate, year, month, day, or hour.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 1024 bytes long, matching the [Single-line string pattern](#).

The name of the partition field as it will appear in the partitioned table structure.

- `FieldId` – Number (integer).

The unique identifier assigned to this partition field within the Iceberg table's partition specification.

IcebergSchema structure

Defines the schema structure for an Iceberg table, including field definitions, data types, and schema metadata.

Fields

- `SchemaId` – Number (integer).

The unique identifier for this schema version within the Iceberg table's schema evolution history.

- `IdentifierFieldIds` – An array of signed 32-bit integers.

The list of field identifiers that uniquely identify records in the table, used for row-level operations and deduplication.

- `Type` – UTF-8 string (valid values: `struct="STRUCT"`).

The root type of the schema structure, typically "struct" for Iceberg table schemas.

- **Fields** – *Required*: An array of [IcebergStructField](#) objects.

The list of field definitions that make up the table schema, including field names, types, and metadata.

IcebergStructField structure

Defines a single field within an Iceberg table schema, including its identifier, name, data type, nullability, and documentation.

Fields

- **Id** – *Required*: Number (integer).

The unique identifier assigned to this field within the Iceberg table schema, used for schema evolution and field tracking.

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 1024 bytes long, matching the [Single-line string pattern](#).

The name of the field as it appears in the table schema and query operations.

- **Type** – *Required*: An empty-structure named IcebergDocument.

The data type definition for this field, specifying the structure and format of the data it contains.

- **Required** – *Required*: Boolean.

Indicates whether this field is required (non-nullable) or optional (nullable) in the table schema.

- **Doc** – Comment string, not more than 255 bytes long, matching the [Single-line string pattern](#).

Optional documentation or description text that provides additional context about the purpose and usage of this field.

IcebergTableUpdate structure

Defines a complete set of updates to be applied to an Iceberg table, including schema changes, partitioning modifications, sort order adjustments, location updates, and property changes.

Fields

- **Schema** – *Required*: An [IcebergSchema](#) object.

The updated schema definition for the Iceberg table, specifying any changes to field structure, data types, or schema metadata.

- `PartitionSpec` – An [IcebergPartitionSpec](#) object.

The updated partitioning specification that defines how the table data should be reorganized and partitioned.

- `SortOrder` – An [IcebergSortOrder](#) object.

The updated sort order specification that defines how data should be ordered within partitions for optimal query performance.

- `Location` – *Required*: Location string, not more than 2056 bytes long, matching the [URI address multi-line string pattern](#).

The updated S3 location where the Iceberg table data will be stored.

- `Properties` –

Updated key-value pairs of table properties and configuration settings for the Iceberg table.

AuditContext structure

A structure containing the Lake Formation audit context.

Fields

- `AdditionalAuditContext` – UTF-8 string, not more than 2048 bytes long.

A string containing the additional audit context information.

- `RequestedColumns` – An array of UTF-8 strings.

The requested columns for audit.

- `AllColumnsRequested` – Boolean.

All columns request for audit.

Operations

- [CreateTable action \(Python: `create_table`\)](#)

- [UpdateTable action \(Python: update_table\)](#)
- [DeleteTable action \(Python: delete_table\)](#)
- [BatchDeleteTable action \(Python: batch_delete_table\)](#)
- [GetTable action \(Python: get_table\)](#)
- [GetTables action \(Python: get_tables\)](#)
- [GetTableVersion action \(Python: get_table_version\)](#)
- [GetTableVersions action \(Python: get_table_versions\)](#)
- [DeleteTableVersion action \(Python: delete_table_version\)](#)
- [BatchDeleteTableVersion action \(Python: batch_delete_table_version\)](#)
- [SearchTables action \(Python: search_tables\)](#)
- [GetPartitionIndexes action \(Python: get_partition_indexes\)](#)
- [CreatePartitionIndex action \(Python: create_partition_index\)](#)
- [DeletePartitionIndex action \(Python: delete_partition_index\)](#)
- [GetColumnStatisticsForTable action \(Python: get_column_statistics_for_table\)](#)
- [UpdateColumnStatisticsForTable action \(Python: update_column_statistics_for_table\)](#)
- [DeleteColumnStatisticsForTable action \(Python: delete_column_statistics_for_table\)](#)

CreateTable action (Python: create_table)

Creates a new table definition in the Data Catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which to create the `Table`. If none is supplied, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog database in which to create the new table. For Hive compatibility, this name is entirely lowercase.

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier for the table within the specified database that will be created in the Amazon Glue Data Catalog.

- TableInput – A [TableInput](#) object.

The TableInput object that defines the metadata table to create in the catalog.

- PartitionIndexes – An array of [PartitionIndex](#) objects, not more than 3 structures.

A list of partition indexes, PartitionIndex structures, to create in the table.

- TransactionId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #44](#).

The ID of the transaction.

- OpenTableFormatInput – An [OpenTableFormatInput](#) object.

Specifies an OpenTableFormatInput structure when creating an open format table.

Response

- *No Response parameters.*

Errors

- AlreadyExistsException
- InvalidInputException
- EntityNotFoundException
- ResourceNumberLimitExceededException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException
- ConcurrentModificationException
- ResourceNotReadyException
- FederationSourceException

- `FederationSourceRetryableException`

UpdateTable action (Python: `update_table`)

Updates a metadata table in the Data Catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier for the table within the specified database that will be created in the Amazon Glue Data Catalog.

- `TableInput` – A [TableInput](#) object.

An updated `TableInput` object to define the metadata table in the catalog.

- `SkipArchive` – Boolean.

By default, `UpdateTable` always creates an archived version of the table before updating it. However, if `skipArchive` is set to true, `UpdateTable` does not create the archived version.

- `TransactionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #44](#).

The transaction ID at which to update the table contents.

- `VersionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The version ID at which to update the table contents.

- `ViewUpdateAction` – UTF-8 string (valid values: ADD | REPLACE | ADD_OR_REPLACE | DROP).

The operation to be performed when updating the view.

- `Force` – Boolean.

A flag that can be set to true to ignore matching storage descriptor and subobject matching requirements.

- `UpdateOpenTableFormatInput` – An [UpdateOpenTableFormatInput](#) object.

Input parameters for updating open table format tables in Amazon GlueData Catalog, serving as a wrapper for format-specific update operations such as Apache Iceberg.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ConcurrentModificationException`
- `ResourceNumberLimitExceededException`
- `GlueEncryptionException`
- `ResourceNotReadyException`
- `FederationSourceException`
- `FederationSourceRetryableException`
- `AlreadyExistsException`

DeleteTable action (Python: `delete_table`)

Removes a table definition from the Data Catalog.

Note

After completing this operation, you no longer have access to the table versions and partitions that belong to the deleted table. Amazon Glue deletes these "orphaned" resources asynchronously in a timely manner, at the discretion of the service.

To ensure the immediate deletion of all related resources, before calling `DeleteTable`, use `DeleteTableVersion` or `BatchDeleteTableVersion`, and `DeletePartition` or `BatchDeletePartition`, to delete any resources that belong to the table.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table to be deleted. For Hive compatibility, this name is entirely lowercase.

- `TransactionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #44](#).

The transaction ID at which to delete the table contents.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ConcurrentModificationException`
- `ResourceNotReadyException`
- `FederationSourceException`
- `FederationSourceRetryableException`

BatchDeleteTable action (Python: `batch_delete_table`)

Deletes multiple tables at once.

Note

After completing this operation, you no longer have access to the table versions and partitions that belong to the deleted table. Amazon Glue deletes these "orphaned" resources asynchronously in a timely manner, at the discretion of the service.

To ensure the immediate deletion of all related resources, before calling `BatchDeleteTable`, use `DeleteTableVersion` or `BatchDeleteTableVersion`, and `DeletePartition` or `BatchDeletePartition`, to delete any resources that belong to the table.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the tables to delete reside. For Hive compatibility, this name is entirely lowercase.

- `TablesToDelete` – *Required*: An array of UTF-8 strings, not more than 100 strings.

A list of the table to delete.

- `TransactionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #44](#).

The transaction ID at which to delete the table contents.

Response

- `Errors` – An array of [TableError](#) objects.

A list of errors encountered in attempting to delete the specified tables.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `ResourceNotReadyException`

GetTable action (Python: `get_table`)

Retrieves the Table definition in a Data Catalog for a specified table.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table for which to retrieve the definition. For Hive compatibility, this name is entirely lowercase.

- TransactionId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #44](#).

The transaction ID at which to read the table contents.

- QueryAsOfTime – Timestamp.

The time as of when to read the table contents. If not set, the most recent transaction commit time will be used. Cannot be specified along with TransactionId.

- AuditContext – An [AuditContext](#) object.

A structure containing the Lake Formation [audit context](#).

- IncludeStatusDetails – Boolean.

Specifies whether to include status details related to a request to create or update an Amazon Glue Data Catalog view.

Response

- Table – A [Table](#) object.

The Table object that defines the specified table.

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

- ResourceNotReadyException
- FederationSourceException
- FederationSourceRetryableException

GetTables action (Python: get_tables)

Retrieves the definitions of some or all of the tables in a given Database.

Request

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the Amazon account ID is used by default.

- DatabaseName – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog whose tables to list. For Hive compatibility, this name is entirely lowercase.

- Expression – UTF-8 string, not more than 2048 bytes long, matching the [Single-line string pattern](#).

A regular expression pattern. If present, only those tables whose names match the pattern are returned.

- NextToken – UTF-8 string.

A continuation token, included if this is a continuation call.

- MaxResults – Number (integer), not less than 1 or more than 100.

The maximum number of tables to return in a single response.

- TransactionId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #44](#).

The transaction ID at which to read the table contents.

- QueryAsOfTime – Timestamp.

The time as of when to read the table contents. If not set, the most recent transaction commit time will be used. Cannot be specified along with `TransactionId`.

- `AuditContext` – An [AuditContext](#) object.

A structure containing the Lake Formation [audit context](#).

- `IncludeStatusDetails` – Boolean.

Specifies whether to include status details related to a request to create or update an Amazon Glue Data Catalog view.

- `AttributesToGet` – An array of UTF-8 strings.

Specifies the table fields returned by the `GetTables` call. This parameter doesn't accept an empty list. The request must include `NAME`.

The following are the valid combinations of values:

- `NAME` - Names of all tables in the database.
- `NAME, TABLE_TYPE` - Names of all tables and the table types.

Response

- `TableList` – An array of [Table](#) objects.

A list of the requested `Table` objects.

- `NextToken` – UTF-8 string.

A continuation token, present if the current list segment is not the last.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `GlueEncryptionException`
- `FederationSourceException`

- `FederationSourceRetryableException`

GetTableVersion action (Python: `get_table_version`)

Retrieves a specified version of a table.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this name is entirely lowercase.

- `VersionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID value of the table version to be retrieved. A `VersionID` is a string representation of an integer. Each version is incremented by 1.

Response

- `TableVersion` – A [TableVersion](#) object.

The requested table version.

Errors

- `EntityNotFoundException`
- `InvalidInputException`

- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

GetTableVersions action (Python: `get_table_versions`)

Retrieves a list of strings that identify available versions of a specified table.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this name is entirely lowercase.

- `NextToken` – UTF-8 string.

A continuation token, if this is not the first call.

- `MaxResults` – Number (integer), not less than 1 or more than 100.

The maximum number of table versions to return in one response.

Response

- `TableVersions` – An array of [TableVersion](#) objects.

A list of strings identifying available versions of the specified table.

- `NextToken` – UTF-8 string.

A continuation token, if the list of available versions does not include the last one.

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

DeleteTableVersion action (Python: delete_table_version)

Deletes a specified version of a table.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the Amazon account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this name is entirely lowercase.

- **VersionId** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the table version to be deleted. A VersionID is a string representation of an integer. Each version is incremented by 1.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

BatchDeleteTableVersion action (Python: batch_delete_table_version)

Deletes a specified batch of versions of a table.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the Amazon account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this name is entirely lowercase.

- **VersionIds** – *Required:* An array of UTF-8 strings, not more than 100 strings.

A list of the IDs of versions to be deleted. A `VersionId` is a string representation of an integer. Each version is incremented by 1.

Response

- **Errors** – An array of [TableVersionError](#) objects.

A list of errors encountered while trying to delete the specified table versions.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

SearchTables action (Python: `search_tables`)

Searches a set of tables based on properties in the table metadata as well as on the parent database. You can search against text or filter conditions.

You can only get tables that you have access to based on the security policies defined in Lake Formation. You need at least a read-only access to the table for it to be returned. If you do not have access to all the columns in the table, these columns will not be searched against when returning the list of tables back to you. If you have access to the columns but not the data in the columns, those columns and the associated metadata for those columns will be included in the search.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique identifier, consisting of *account_id*.

- **NextToken** – UTF-8 string.

A continuation token, included if this is a continuation call.

- **Filters** – An array of [PropertyPredicate](#) objects.

A list of key-value pairs, and a comparator used to filter the search results. Returns all entities matching the predicate.

The `Comparator` member of the `PropertyPredicate` struct is used only for time fields, and can be omitted for other field types. Also, when comparing string values, such as when `Key=Name`, a fuzzy match algorithm is used. The `Key` field (for example, the value of the `Name` field) is split on certain punctuation characters, for example, `-`, `:`, `#`, etc. into tokens. Then each token is exact-match compared with the `Value` member of `PropertyPredicate`. For example, if `Key=Name` and `Value=link`, tables named `customer-link` and `xx-link-yy` are returned, but `xxlinkyy` is not returned.

- `SearchText` – Value string, not less than 1 or more than 1024 bytes long.

A string used for a text search.

Specifying a value in quotes filters based on an exact match to the value.

- `SortCriteria` – An array of [SortCriterion](#) objects, not more than 1 structures.

A list of criteria for sorting the results by a field name, in an ascending or descending order.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of tables to return in a single response.

- `ResourceShareType` – UTF-8 string (valid values: `FOREIGN` | `ALL` | `FEDERATED`).

Allows you to specify that you want to search the tables shared with your account. The allowable values are `FOREIGN` or `ALL`.

- If set to `FOREIGN`, will search the tables shared with your account.
- If set to `ALL`, will search the tables shared with your account, as well as the tables in your local account.
- `IncludeStatusDetails` – Boolean.

Specifies whether to include status details related to a request to create or update an Amazon Glue Data Catalog view.

Response

- `NextToken` – UTF-8 string.

A continuation token, present if the current list segment is not the last.

- `TableList` – An array of [Table](#) objects.

A list of the requested Table objects. The SearchTables response returns only the tables that you have access to.

Errors

- InternalServiceException
- InvalidInputException
- OperationTimeoutException

GetPartitionIndexes action (Python: get_partition_indexes)

Retrieves the partition indexes associated with a table.

Request

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID where the table resides.

- DatabaseName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a database from which you want to retrieve partition indexes.

- TableName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a table for which you want to retrieve the partition indexes.

- NextToken – UTF-8 string.

A continuation token, included if this is a continuation call.

Response

- PartitionIndexDescriptorList – An array of [PartitionIndexDescriptor](#) objects.

A list of index descriptors.

- NextToken – UTF-8 string.

A continuation token, present if the current list segment is not the last.

Errors

- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `EntityNotFoundException`
- `ConflictException`

CreatePartitionIndex action (Python: `create_partition_index`)

Creates a specified partition index in an existing table.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID where the table resides.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a database in which you want to create a partition index.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a table in which you want to create a partition index.

- `PartitionIndex` – *Required:* A [PartitionIndex](#) object.

Specifies a `PartitionIndex` structure to create a partition index in an existing table.

Response

- *No Response parameters.*

Errors

- AlreadyExistsException
- InvalidInputException
- EntityNotFoundException
- ResourceNumberLimitExceededException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

DeletePartitionIndex action (Python: delete_partition_index)

Deletes a specified partition index from an existing table.

Request

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID where the table resides.

- DatabaseName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a database from which you want to delete a partition index.

- TableName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a table from which you want to delete a partition index.

- IndexName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partition index to be deleted.

Response

- *No Response parameters.*

Errors

- `InternalServerErrorException`
- `OperationTimeoutException`
- `InvalidInputException`
- `EntityNotFoundException`
- `ConflictException`
- `GlueEncryptionException`

GetColumnStatisticsForTable action (Python: `get_column_statistics_for_table`)

Retrieves table statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is `GetTable`.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the Amazon account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `ColumnNames` – *Required:* An array of UTF-8 strings, not more than 100 strings.

A list of the column names.

Response

- `ColumnStatisticsList` – An array of [ColumnStatistics](#) objects.

List of ColumnStatistics.

- Errors – An array of [ColumnError](#) objects.

List of ColumnStatistics that failed to be retrieved.

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

UpdateColumnStatisticsForTable action (Python: `update_column_statistics_for_table`)

Creates or updates table statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is `UpdateTable`.

Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the Amazon account ID is used by default.

- `databaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `tableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `ColumnStatisticsList` – *Required:* An array of [ColumnStatistics](#) objects, not more than 25 structures.

A list of the column statistics.

Response

- `Errors` – An array of [ColumnStatisticsError](#) objects.

List of `ColumnStatisticsErrors`.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

DeleteColumnStatisticsForTable action (Python: `delete_column_statistics_for_table`)

Retrieves table statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is `DeleteTable`.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the Amazon account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `ColumnName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the column.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

Partition API

The Partition API describes data types and operations used to work with partitions.

Data types

- [Partition structure](#)
- [PartitionInput structure](#)
- [PartitionSpecWithSharedStorageDescriptor structure](#)
- [PartitionListComposingSpec structure](#)
- [PartitionSpecProxy structure](#)
- [PartitionValueList structure](#)
- [Segment structure](#)
- [PartitionError structure](#)

- [BatchUpdatePartitionFailureEntry structure](#)
- [BatchUpdatePartitionRequestEntry structure](#)
- [StorageDescriptor structure](#)
- [SchemaReference structure](#)
- [SerDeInfo structure](#)
- [SkewedInfo structure](#)

Partition structure

Represents a slice of table data.

Fields

- `Values` – An array of UTF-8 strings.

The values of the partition.

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which to create the partition.

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database table in which to create the partition.

- `CreationTime` – Timestamp.

The time at which the partition was created.

- `LastAccessTime` – Timestamp.

The last time at which the partition was accessed.

- `StorageDescriptor` – A [StorageDescriptor](#) object.

Provides information about the physical location where the partition is stored.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define partition parameters.

- `LastAnalyzedTime` – Timestamp.

The last time at which column statistics were computed for this partition.

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the partition resides.

PartitionInput structure

The structure used to create and update a partition.

Fields

- `Values` – An array of UTF-8 strings.

The values of the partition. Although this parameter is not required by the SDK, you must specify this parameter for a valid input.

The values for the keys for the new partition must be passed as an array of String objects that must be ordered in the same order as the partition keys appearing in the Amazon S3 prefix. Otherwise Amazon Glue will add the values to the wrong keys.

- `LastAccessTime` – Timestamp.

The last time at which the partition was accessed.

- `StorageDescriptor` – A [StorageDescriptor](#) object.

Provides information about the physical location where the partition is stored.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define partition parameters.

- `LastAnalyzedTime` – Timestamp.

The last time at which column statistics were computed for this partition.

PartitionSpecWithSharedStorageDescriptor structure

A partition specification for partitions that share a physical location.

Fields

- `StorageDescriptor` – A [StorageDescriptor](#) object.

The shared physical storage information.

- `Partitions` – An array of [Partition](#) objects.

A list of the partitions that share this physical location.

PartitionListComposingSpec structure

Lists the related partitions.

Fields

- `Partitions` – An array of [Partition](#) objects.

A list of the partitions in the composing specification.

PartitionSpecProxy structure

Provides a root path to specified partitions.

Fields

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog database in which the partitions reside.

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table that contains the partitions.

- `RootPath` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The root path of the proxy for addressing the partitions.

- `PartitionSpecWithSharedSD` – A [PartitionSpecWithSharedStorageDescriptor](#) object.

A specification of partitions that share the same physical storage location.

- `PartitionListComposingSpec` – A [PartitionListComposingSpec](#) object.

Specifies a list of partitions.

PartitionValueList structure

Contains a list of values defining partitions.

Fields

- `Values` – *Required*: An array of UTF-8 strings.

The list of values.

Segment structure

Defines a non-overlapping region of a table's partitions, allowing multiple requests to be run in parallel.

Fields

- `SegmentNumber` – *Required*: Number (integer), not more than None.

The zero-based index number of the segment. For example, if the total number of segments is 4, `SegmentNumber` values range from 0 through 3.

- `TotalSegments` – *Required*: Number (integer), not less than 1 or more than 10.

The total number of segments.

PartitionError structure

Contains information about a partition error.

Fields

- `PartitionValues` – An array of UTF-8 strings.

The values that define the partition.

- `ErrorDetail` – An [ErrorDetail](#) object.

The details about the partition error.

BatchUpdatePartitionFailureEntry structure

Contains information about a batch update partition error.

Fields

- `PartitionValueList` – An array of UTF-8 strings, not more than 100 strings.

A list of values defining the partitions.

- `ErrorDetail` – An [ErrorDetail](#) object.

The details about the batch update partition error.

BatchUpdatePartitionRequestEntry structure

A structure that contains the values and structure used to update a partition.

Fields

- `PartitionValueList` – *Required:* An array of UTF-8 strings, not more than 100 strings.

A list of values defining the partitions.

- `PartitionInput` – *Required:* A [PartitionInput](#) object.

The structure used to update a partition.

StorageDescriptor structure

Describes the physical storage of table data.

Fields

- **Columns** – An array of [Column](#) objects.

A list of the Columns in the table.

- **Location** – Location string, not more than 2056 bytes long, matching the [URI address multi-line string pattern](#).

The physical location of the table. By default, this takes the form of the warehouse location, followed by the database location in the warehouse, followed by the table name.

- **AdditionalLocations** – An array of UTF-8 strings.

A list of locations that point to the path where a Delta table is located.

- **InputFormat** – Format string, not more than 128 bytes long, matching the [Single-line string pattern](#).

The input format: `SequenceFileInputFormat` (binary), or `TextInputFormat`, or a custom format.

- **OutputFormat** – Format string, not more than 128 bytes long, matching the [Single-line string pattern](#).

The output format: `SequenceFileOutputFormat` (binary), or `IgnoreKeyTextOutputFormat`, or a custom format.

- **Compressed** – Boolean.

True if the data in the table is compressed, or False if not.

- **NumberOfBuckets** – Number (integer).

Must be specified if the table contains any dimension columns.

- **SerdeInfo** – A [SerDeInfo](#) object.

The serialization/deserialization (SerDe) information.

- **BucketColumns** – An array of UTF-8 strings.

A list of reducer grouping columns, clustering columns, and bucketing columns in the table.

- `SortColumns` – An array of [Order](#) objects.

A list specifying the sort order of each bucket in the table.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

The user-supplied properties in key-value form.

- `SkewedInfo` – A [SkewedInfo](#) object.

The information about values that appear frequently in a column (skewed values).

- `StoredAsSubDirectories` – Boolean.

True if the table data is stored in subdirectories, or False if not.

- `SchemaReference` – A [SchemaReference](#) object.

An object that references a schema stored in the Amazon Glue Schema Registry.

When creating a table, you can pass an empty list of columns for the schema, and instead use a schema reference.

SchemaReference structure

An object that references a schema stored in the Amazon Glue Schema Registry.

Fields

- `SchemaId` – A [Schemaid](#) object.

A structure that contains schema identity fields. Either this or the `SchemaVersionId` has to be provided.

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #45](#).

The unique ID assigned to a version of the schema. Either this or the `SchemaId` has to be provided.

- `SchemaVersionNumber` – Number (long), not less than 1 or more than 100000.

The version number of the schema.

SerdeInfo structure

Information about a serialization/deserialization program (SerDe) that serves as an extractor and loader.

Fields

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the SerDe.

- `SerializationLibrary` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Usually the class that implements the SerDe. An example is `org.apache.hadoop.hive.serde2.columnar.ColumnarSerDe`.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define initialization parameters for the SerDe.

SkewedInfo structure

Specifies skewed values in a table. Skewed values are those that occur with very high frequency.

Fields

- `SkewedColumnNames` – An array of UTF-8 strings.

A list of names of columns that contain skewed values.

- `SkewedColumnValues` – An array of UTF-8 strings.

A list of values that appear so frequently as to be considered skewed.

- `SkewedColumnValueLocationMaps` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A mapping of skewed values to the columns that contain them.

Operations

- [CreatePartition action \(Python: `create_partition`\)](#)
- [BatchCreatePartition action \(Python: `batch_create_partition`\)](#)
- [UpdatePartition action \(Python: `update_partition`\)](#)
- [DeletePartition action \(Python: `delete_partition`\)](#)
- [BatchDeletePartition action \(Python: `batch_delete_partition`\)](#)
- [GetPartition action \(Python: `get_partition`\)](#)
- [GetPartitions action \(Python: `get_partitions`\)](#)
- [BatchGetPartition action \(Python: `batch_get_partition`\)](#)
- [BatchUpdatePartition action \(Python: `batch_update_partition`\)](#)
- [GetColumnStatisticsForPartition action \(Python: `get_column_statistics_for_partition`\)](#)
- [UpdateColumnStatisticsForPartition action \(Python: `update_column_statistics_for_partition`\)](#)
- [DeleteColumnStatisticsForPartition action \(Python: `delete_column_statistics_for_partition`\)](#)

CreatePartition action (Python: `create_partition`)

Creates a new partition.

Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Amazon account ID of the catalog in which the partition is to be created.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata database in which the partition is to be created.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata table in which the partition is to be created.

- **PartitionInput** – *Required:* A [PartitionInput](#) object.

A [PartitionInput](#) structure defining the partition to be created.

Response

- *No Response parameters.*

Errors

- `InvalidInputException`
- `AlreadyExistsException`
- `ResourceNumberLimitExceededException`
- `InternalServiceException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `GlueEncryptionException`

BatchCreatePartition action (Python: `batch_create_partition`)

Creates one or more partitions in a batch operation.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog in which the partition is to be created. Currently, this should be the Amazon account ID.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata database in which the partition is to be created.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata table in which the partition is to be created.

- **PartitionInputList** – *Required:* An array of [PartitionInput](#) objects, not more than 100 structures.

A list of [PartitionInput](#) structures that define the partitions to be created.

Response

- **Errors** – An array of [PartitionError](#) objects.

The errors encountered when trying to create the requested partitions.

Errors

- `InvalidInputException`
- `AlreadyExistsException`
- `ResourceNumberLimitExceededException`
- `InternalServiceException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `GlueEncryptionException`

UpdatePartition action (Python: `update_partition`)

Updates a partition.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partition to be updated resides. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table in question resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table in which the partition to be updated is located.

- `PartitionValueList` – *Required*: An array of UTF-8 strings, not more than 100 strings.

List of partition key values that define the partition to update.

- `PartitionInput` – *Required*: A [PartitionInput](#) object.

The new partition object to update the partition to.

The `Values` property can't be changed. If you want to change the partition key values for a partition, delete and recreate the partition.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

DeletePartition action (Python: `delete_partition`)

Deletes a specified partition.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partition to be deleted resides. If none is provided, the Amazon account ID is used by default.

- **DatabaseName** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table in question resides.

- **TableName** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table that contains the partition to be deleted.

- **PartitionValues** – *Required*: An array of UTF-8 strings.

The values that define the partition.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

BatchDeletePartition action (Python: `batch_delete_partition`)

Deletes one or more partitions in a batch operation.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partition to be deleted resides. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table in question resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table that contains the partitions to be deleted.

- `PartitionsToDelete` – *Required*: An array of [PartitionValueList](#) objects, not more than 25 structures.

A list of `PartitionInput` structures that define the partitions to be deleted.

Response

- `Errors` – An array of [PartitionError](#) objects.

The errors encountered when trying to delete the requested partitions.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

GetPartition action (Python: `get_partition`)

Retrieves information about a specified partition.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partition in question resides. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partition resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partition's table.

- `PartitionValues` – *Required*: An array of UTF-8 strings.

The values that define the partition.

Response

- `Partition` – A [Partition](#) object.

The requested information, in the form of a `Partition` object.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `FederationSourceException`
- `FederationSourceRetryableException`

GetPartitions action (Python: `get_partitions`)

Retrieves information about the partitions in a table.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `Expression` – Predicate string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

An expression that filters the partitions to be returned.

The expression uses SQL syntax similar to the SQL WHERE filter clause. The SQL statement parser [JSQParser](#) parses the expression.

Operators: The following are the operators that you can use in the `Expression` API call:

=

Checks whether the values of the two operands are equal; if yes, then the condition becomes true.

Example: Assume 'variable a' holds 10 and 'variable b' holds 20.

(a = b) is not true.

< >

Checks whether the values of two operands are equal; if the values are not equal, then the condition becomes true.

Example: (a < > b) is true.

>

Checks whether the value of the left operand is greater than the value of the right operand; if yes, then the condition becomes true.

Example: (a > b) is not true.

<

Checks whether the value of the left operand is less than the value of the right operand; if yes, then the condition becomes true.

Example: (a < b) is true.

>=

Checks whether the value of the left operand is greater than or equal to the value of the right operand; if yes, then the condition becomes true.

Example: (a >= b) is not true.

<=

Checks whether the value of the left operand is less than or equal to the value of the right operand; if yes, then the condition becomes true.

Example: (a <= b) is true.

AND, OR, IN, BETWEEN, LIKE, NOT, IS NULL

Logical operators.

Supported Partition Key Types: The following are the supported partition keys.

- string
- date
- timestamp
- int
- bigint
- long
- tinyint

- decimal

If an type is encountered that is not valid, an exception is thrown.

The following list shows the valid operators on each type. When you define a crawler, the `partitionKey` type is created as a `STRING`, to be compatible with the catalog partitions.

Sample API Call:

Example

The table `twitter_partition` has three partitions:

```
year = 2015
  year = 2016
  year = 2017
```

Example

Get partition year equal to 2015

```
aws glue get-partitions --database-name dbname --table-name twitter_partition
  --expression "year=*'2015'"
```

Example

Get partition year between 2016 and 2018 (exclusive)

```
aws glue get-partitions --database-name dbname --table-name twitter_partition
  --expression "year>'2016' AND year<'2018'"
```

Example

Get partition year between 2015 and 2018 (inclusive). The following API calls are equivalent to each other:

```
aws glue get-partitions --database-name dbname --table-name twitter_partition
  --expression "year>='2015' AND year<='2018'"
```

```
aws glue get-partitions --database-name dbname --table-name
twitter_partition
--expression "year BETWEEN 2015 AND 2018"

aws glue get-partitions --database-name dbname --table-name
twitter_partition
--expression "year IN (2015,2016,2017,2018)"
```

Example

A wildcard partition filter, where the following call output is partition year=2017. A regular expression is not supported in LIKE.

```
aws glue get-partitions --database-name dbname --table-name twitter_partition
--expression "year LIKE '%7'"
```

- NextToken – UTF-8 string.

A continuation token, if this is not the first call to retrieve these partitions.

- Segment – A [Segment](#) object.

The segment of the table's partitions to scan in this request.

- MaxResults – Number (integer), not less than 1 or more than 1000.

The maximum number of partitions to return in a single response.

- ExcludeColumnSchema – Boolean.

When true, specifies not returning the partition column schema. Useful when you are interested only in other partition attributes such as partition values or location. This approach avoids the problem of a large response by not returning duplicate data.

- TransactionId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #44](#).

The transaction ID at which to read the partition contents.

- QueryAsOfTime – Timestamp.

The time as of when to read the partition contents. If not set, the most recent transaction commit time will be used. Cannot be specified along with TransactionId.

Response

- **Partitions** – An array of [Partition](#) objects.

A list of requested partitions.

- **NextToken** – UTF-8 string.

A continuation token, if the returned list of partitions does not include the last one.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `GlueEncryptionException`
- `InvalidStateException`
- `ResourceNotReadyException`
- `FederationSourceException`
- `FederationSourceRetryableException`

BatchGetPartition action (Python: `batch_get_partition`)

Retrieves partitions in a batch request.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the Amazon account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- **PartitionsToGet** – *Required:* An array of [PartitionValueList](#) objects, not more than 1000 structures.

A list of partition values identifying the partitions to retrieve.

Response

- **Partitions** – An array of [Partition](#) objects.

A list of the requested partitions.

- **UnprocessedKeys** – An array of [PartitionValueList](#) objects, not more than 1000 structures.

A list of the partition values in the request for which partitions were not returned.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `InternalServiceException`
- `GlueEncryptionException`
- `InvalidStateException`
- `FederationSourceException`
- `FederationSourceRetryableException`

BatchUpdatePartition action (Python: `batch_update_partition`)

Updates one or more partitions in a batch operation.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog in which the partition is to be updated. Currently, this should be the Amazon account ID.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata database in which the partition is to be updated.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata table in which the partition is to be updated.

- `Entries` – *Required*: An array of [BatchUpdatePartitionRequestEntry](#) objects, not less than 1 or more than 100 structures.

A list of up to 100 `BatchUpdatePartitionRequestEntry` objects to update.

Response

- `Errors` – An array of [BatchUpdatePartitionFailureEntry](#) objects.

The errors encountered when trying to update the requested partitions. A list of `BatchUpdatePartitionFailureEntry` objects.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `InternalServiceException`
- `GlueEncryptionException`

GetColumnStatisticsForPartition action (Python: `get_column_statistics_for_partition`)

Retrieves partition statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is `GetPartition`.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the Amazon account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `PartitionValues` – *Required:* An array of UTF-8 strings.

A list of partition values identifying the partition.

- `ColumnNames` – *Required:* An array of UTF-8 strings, not more than 100 strings.

A list of the column names.

Response

- `ColumnStatisticsList` – An array of [ColumnStatistics](#) objects.

List of `ColumnStatistics` that failed to be retrieved.

- `Errors` – An array of [ColumnError](#) objects.

Error occurred during retrieving column statistics data.

Errors

- `EntityNotFoundException`
- `InvalidInputException`

- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

UpdateColumnStatisticsForPartition action (Python: `update_column_statistics_for_partition`)

Creates or updates partition statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is `UpdatePartition`.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the Amazon account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `PartitionValues` – *Required:* An array of UTF-8 strings.

A list of partition values identifying the partition.

- `ColumnStatisticsList` – *Required:* An array of [ColumnStatistics](#) objects, not more than 25 structures.

A list of the column statistics.

Response

- `Errors` – An array of [ColumnStatisticsError](#) objects.

Error occurred during updating column statistics data.

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

DeleteColumnStatisticsForPartition action (Python: `delete_column_statistics_for_partition`)

Delete the partition column statistics of a column.

The Identity and Access Management (IAM) permission required for this operation is `DeletePartition`.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `PartitionValues` – *Required*: An array of UTF-8 strings.

A list of partition values identifying the partition.

- `ColumnName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the column.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

Connections API

The Connections API describes the data types and API related to working with connections in Amazon Glue.

Topics

- [Connection API](#)
- [Connection Types API](#)
- [Connection Metadata and Preview API](#)

Connection API

The Connection API describes Amazon Glue connection data types, and the API for creating, deleting, updating, and listing connections.

Data types

- [Connection structure](#)

- [ConnectionInput structure](#)
- [TestConnectionInput structure](#)
- [PhysicalConnectionRequirements structure](#)
- [GetConnectionsFilter structure](#)
- [AuthenticationConfiguration structure](#)
- [AuthenticationConfigurationInput structure](#)
- [OAuth2Properties structure](#)
- [OAuth2PropertiesInput structure](#)
- [OAuth2ClientApplication structure](#)
- [AuthorizationCodeProperties structure](#)
- [BasicAuthenticationCredentials structure](#)
- [OAuth2Credentials structure](#)

Connection structure

Defines a connection to a data source.

Fields

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection definition.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The description of the connection.

- **ConnectionType** – UTF-8 string (valid values: JDBC | SFTP | MONGODB | KAFKA | NETWORK | MARKETPLACE | CUSTOM | SALESFORCE | VIEW_VALIDATION_REDSHIFT | VIEW_VALIDATION_ATHENA | GOOGLEADS | GOOGLESHEETS | GOOGLEANALYTICS4 | SERVICENOW | MARKETO | SAPODATA | ZENDESK | JIRACLOUD | NETSUITEERP | HUBSPOT | FACEBOOKADS | INSTAGRAMADS | ZOHOCRIM | SALESFORCEPARDOT | SALESFORCEMARKETINGCLOUD | ADOBEANALYTICS | SLACK | LINKEDIN | MIXPANEL | ASANA | STRIPE | SMARTSHEET | DATADOG | WOOCOMMERCE | INTERCOM | SNAPCHATADS | PAYPAL

| QUICKBOOKS | FACEBOOKPAGEINSIGHTS | FRESHDESK | TWILIO | DOCUSIGNMONITOR
 | FRESHSALES | ZOOM | GOOGLESEARCHCONSOLE | SALESFORCECOMMERCECLOUD |
 SAPCONCUR | DYNATRACE | MICROSOFTDYNAMIC365FINANCEANDOPS | MICROSOFTTEAMS |
 BLACKBAUDRAISEREDGENXT | MAILCHIMP | GITLAB | PENDO | PRODUCTBOARD | CIRCLECI |
 PIPEDIVE | SENDGRID | AZURECOSMOS | AZURESQL | BIGQUERY | BLACKBAUD | CLOUDERAHIVE
 | CLOUDERAIMPALA | CLOUDWATCH | CLOUDWATCHMETRICS | CMDDB | DATALAKEGEN2 | DB2 |
 DB2AS400 | DOCUMENTDB | DOMO | DYNAMODB | GOOGLECLOUDSTORAGE | HBASE | KUSTOMER |
 MICROSOFTDYNAMICS365CRM | MONDAY | MYSQL | OKTA | OPENSEARCH | ORACLE | PIPEDRIVE
 | POSTGRESQL | SAPHANA | SQLSERVER | SYNAPSE | TERADATA | TERADATANOS | TIMESTREAM |
 TPCDS | VERTICA).

The type of the connection. Currently, SFTP is not supported.

- **MatchCriteria** – An array of UTF-8 strings, not more than 10 strings.

A list of criteria that can be used in selecting this connection.

- **ConnectionProperties** – A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string (valid values: HOST | PORT | USERNAME="USER_NAME" | PASSWORD
 | ENCRYPTED_PASSWORD | JDBC_DRIVER_JAR_URI | JDBC_DRIVER_CLASS_NAME
 | JDBC_ENGINE | JDBC_ENGINE_VERSION | CONFIG_FILES | INSTANCE_ID
 | JDBC_CONNECTION_URL | JDBC_ENFORCE_SSL | CUSTOM_JDBC_CERT |
 SKIP_CUSTOM_JDBC_CERT_VALIDATION | CUSTOM_JDBC_CERT_STRING |
 CONNECTION_URL | KAFKA_BOOTSTRAP_SERVERS | KAFKA_SSL_ENABLED
 | KAFKA_CUSTOM_CERT | KAFKA_SKIP_CUSTOM_CERT_VALIDATION |
 KAFKA_CLIENT_KEYSTORE | KAFKA_CLIENT_KEYSTORE_PASSWORD |
 KAFKA_CLIENT_KEY_PASSWORD | ENCRYPTED_KAFKA_CLIENT_KEYSTORE_PASSWORD
 | ENCRYPTED_KAFKA_CLIENT_KEY_PASSWORD | KAFKA_SASL_MECHANISM
 | KAFKA_SASL_PLAIN_USERNAME | KAFKA_SASL_PLAIN_PASSWORD |
 ENCRYPTED_KAFKA_SASL_PLAIN_PASSWORD | KAFKA_SASL_SCRAM_USERNAME
 | KAFKA_SASL_SCRAM_PASSWORD | KAFKA_SASL_SCRAM_SECRETS_ARN |
 ENCRYPTED_KAFKA_SASL_SCRAM_PASSWORD | KAFKA_SASL_GSSAPI_KEYTAB
 | KAFKA_SASL_GSSAPI_KRB5_CONF | KAFKA_SASL_GSSAPI_SERVICE |
 KAFKA_SASL_GSSAPI_PRINCIPAL | SECRET_ID | CONNECTOR_URL | CONNECTOR_TYPE
 | CONNECTOR_CLASS_NAME | ENDPOINT | ENDPOINT_TYPE | ROLE_ARN | REGION |
 WORKGROUP_NAME | CLUSTER_IDENTIFIER | DATABASE).

Each value is a Value string, not less than 1 or more than 1024 bytes long.

These key-value pairs define parameters for the connection when using the version 1 Connection schema:

- **HOST** - The host URI: either the fully qualified domain name (FQDN) or the IPv4 address of the database host.
- **PORT** - The port number, between 1024 and 65535, of the port on which the database host is listening for database connections.
- **USER_NAME** - The name under which to log in to the database. The value string for **USER_NAME** is "USERNAME".
- **PASSWORD** - A password, if one is used, for the user name.
- **ENCRYPTED_PASSWORD** - When you enable connection password protection by setting `ConnectionPasswordEncryption` in the Data Catalog encryption settings, this field stores the encrypted password.
- **JDBC_DRIVER_JAR_URI** - The Amazon Simple Storage Service (Amazon S3) path of the JAR file that contains the JDBC driver to use.
- **JDBC_DRIVER_CLASS_NAME** - The class name of the JDBC driver to use.
- **JDBC_ENGINE** - The name of the JDBC engine to use.
- **JDBC_ENGINE_VERSION** - The version of the JDBC engine to use.
- **CONFIG_FILES** - (Reserved for future use.)
- **INSTANCE_ID** - The instance ID to use.
- **JDBC_CONNECTION_URL** - The URL for connecting to a JDBC data source.
- **JDBC_ENFORCE_SSL** - A case-insensitive Boolean string (true, false) specifying whether Secure Sockets Layer (SSL) with hostname matching is enforced for the JDBC connection on the client. The default is false.
- **CUSTOM_JDBC_CERT** - An Amazon S3 location specifying the customer's root certificate. Amazon Glue uses this root certificate to validate the customer's certificate when connecting to the customer database. Amazon Glue only handles X.509 certificates. The certificate provided must be DER-encoded and supplied in Base64 encoding PEM format.
- **SKIP_CUSTOM_JDBC_CERT_VALIDATION** - By default, this is `false`. Amazon Glue validates the Signature algorithm and Subject Public Key Algorithm for the customer certificate. The only permitted algorithms for the Signature algorithm are `SHA256withRSA`, `SHA384withRSA` or `SHA512withRSA`. For the Subject Public Key Algorithm, the key length must be at least 2048. You can set the value of this property to `true` to skip Amazon Glue's validation of the customer certificate.

- **CUSTOM_JDBC_CERT_STRING** - A custom JDBC certificate string which is used for domain match or distinguished name match to prevent a man-in-the-middle attack. In Oracle database, this is used as the `SSL_SERVER_CERT_DN`; in Microsoft SQL Server, this is used as the `hostNameInCertificate`.
- **CONNECTION_URL** - The URL for connecting to a general (non-JDBC) data source.
- **SECRET_ID** - The secret ID used for the secret manager of credentials.
- **CONNECTOR_URL** - The connector URL for a **MARKETPLACE** or **CUSTOM** connection.
- **CONNECTOR_TYPE** - The connector type for a **MARKETPLACE** or **CUSTOM** connection.
- **CONNECTOR_CLASS_NAME** - The connector class name for a **MARKETPLACE** or **CUSTOM** connection.
- **KAFKA_BOOTSTRAP_SERVERS** - A comma-separated list of host and port pairs that are the addresses of the Apache Kafka brokers in a Kafka cluster to which a Kafka client will connect to and bootstrap itself.
- **KAFKA_SSL_ENABLED** - Whether to enable or disable SSL on an Apache Kafka connection. Default value is "true".
- **KAFKA_CUSTOM_CERT** - The Amazon S3 URL for the private CA cert file (.pem format). The default is an empty string.
- **KAFKA_SKIP_CUSTOM_CERT_VALIDATION** - Whether to skip the validation of the CA cert file or not. Amazon Glue validates for three algorithms: `SHA256withRSA`, `SHA384withRSA` and `SHA512withRSA`. Default value is "false".
- **KAFKA_CLIENT_KEYSTORE** - The Amazon S3 location of the client keystore file for Kafka client side authentication (Optional).
- **KAFKA_CLIENT_KEYSTORE_PASSWORD** - The password to access the provided keystore (Optional).
- **KAFKA_CLIENT_KEY_PASSWORD** - A keystore can consist of multiple keys, so this is the password to access the client key to be used with the Kafka server side key (Optional).
- **ENCRYPTED_KAFKA_CLIENT_KEYSTORE_PASSWORD** - The encrypted version of the Kafka client keystore password (if the user has the Amazon Glue encrypt passwords setting selected).
- **ENCRYPTED_KAFKA_CLIENT_KEY_PASSWORD** - The encrypted version of the Kafka client key password (if the user has the Amazon Glue encrypt passwords setting selected).
- **KAFKA_SASL_MECHANISM** - "SCRAM-SHA-512", "GSSAPI", "AWS_MSK_IAM", or "PLAIN". These are the supported [SASL Mechanisms](#).

- `KAFKA_SASL_PLAIN_USERNAME` - A plaintext username used to authenticate with the "PLAIN" mechanism.
- `KAFKA_SASL_PLAIN_PASSWORD` - A plaintext password used to authenticate with the "PLAIN" mechanism.
- `ENCRYPTED_KAFKA_SASL_PLAIN_PASSWORD` - The encrypted version of the Kafka SASL PLAIN password (if the user has the Amazon Glue encrypt passwords setting selected).
- `KAFKA_SASL_SCRAM_USERNAME` - A plaintext username used to authenticate with the "SCRAM-SHA-512" mechanism.
- `KAFKA_SASL_SCRAM_PASSWORD` - A plaintext password used to authenticate with the "SCRAM-SHA-512" mechanism.
- `ENCRYPTED_KAFKA_SASL_SCRAM_PASSWORD` - The encrypted version of the Kafka SASL SCRAM password (if the user has the Amazon Glue encrypt passwords setting selected).
- `KAFKA_SASL_SCRAM_SECRETS_ARN` - The Amazon Resource Name of a secret in Amazon Secrets Manager.
- `KAFKA_SASL_GSSAPI_KEYTAB` - The S3 location of a Kerberos keytab file. A keytab stores long-term keys for one or more principals. For more information, see [MIT Kerberos Documentation: Keytab](#).
- `KAFKA_SASL_GSSAPI_KRB5_CONF` - The S3 location of a Kerberos `krb5.conf` file. A `krb5.conf` stores Kerberos configuration information, such as the location of the KDC server. For more information, see [MIT Kerberos Documentation: krb5.conf](#).
- `KAFKA_SASL_GSSAPI_SERVICE` - The Kerberos service name, as set with `sasl.kerberos.service.name` in your [Kafka Configuration](#).
- `KAFKA_SASL_GSSAPI_PRINCIPAL` - The name of the Kerberos principal used by Amazon Glue. For more information, see [Kafka Documentation: Configuring Kafka Brokers](#).
- `ROLE_ARN` - The role to be used for running queries.
- `REGION` - The Amazon Region where queries will be run.
- `WORKGROUP_NAME` - The name of an Amazon Redshift serverless workgroup or Amazon Athena workgroup in which queries will run.
- `CLUSTER_IDENTIFIER` - The cluster identifier of an Amazon Redshift cluster in which queries will run.
- `DATABASE` - The Amazon Redshift database that you are connecting to.
- `SparkProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 2048 bytes long.

Connection properties specific to the Spark compute environment.

- `AthenaProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 2048 bytes long.

Connection properties specific to the Athena compute environment.

- `PythonProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 2048 bytes long.

Connection properties specific to the Python compute environment.

- `PhysicalConnectionRequirements` – A [PhysicalConnectionRequirements](#) object.

The physical connection requirements, such as virtual private cloud (VPC) and SecurityGroup, that are needed to make this connection successfully.

- `CreationTime` – Timestamp.

The timestamp of the time that this connection definition was created.

- `LastUpdatedTime` – Timestamp.

The timestamp of the last time the connection definition was updated.

- `LastUpdatedBy` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The user, group, or role that last updated this connection definition.

- `Status` – UTF-8 string (valid values: READY | IN_PROGRESS | FAILED).

The status of the connection. Can be one of: READY, IN_PROGRESS, or FAILED.

- `StatusReason` – UTF-8 string, not less than 1 or more than 16384 bytes long.

The reason for the connection status.

- `LastConnectionValidationTime` – Timestamp.

A timestamp of the time this connection was last validated.

- `AuthenticationConfiguration` – An [AuthenticationConfiguration](#) object.

The authentication properties of the connection.

- `ConnectionSchemaVersion` – Number (integer), not less than 1 or more than 2.

The version of the connection schema for this connection. Version 2 supports properties for specific compute environments.

- `CompatibleComputeEnvironments` – An array of UTF-8 strings.

A list of compute environments compatible with the connection.

ConnectionInput structure

A structure that is used to specify a connection to create or update.

Fields

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The description of the connection.

- `ConnectionType` – *Required:* UTF-8 string (valid values: JDBC | SFTP | MONGODB | KAFKA | NETWORK | MARKETPLACE | CUSTOM | SALESFORCE | VIEW_VALIDATION_REDSHIFT | VIEW_VALIDATION_ATHENA | GOOGLEADS | GOOGLESHEETS | GOOGLLEANALYTICS4 | SERVICENOW | MARKETO | SAPODATA | ZENDESK | JIRACLOUD | NETSUITEERP | HUBSPOT | FACEBOOKADS | INSTAGRAMADS | ZOHOCRIM | SALESFORCEPARDOT | SALESFORCEMARKETINGCLOUD | ADOBEANALYTICS | SLACK | LINKEDIN | MIXPANEL | ASANA | STRIPE | SMARTSHEET | DATADOG | WOOCOMMERCE | INTERCOM | SNAPCHATADS | PAYPAL | QUICKBOOKS | FACEBOOKPAGEINSIGHTS | FRESHDESK | TWILIO | DOCUSIGNMONITOR | FRESHSALES | ZOOM | GOOGLESEARCHCONSOLE | SALESFORCECOMMERCECLOUD | SAPCONCUR | DYNATRACE | MICROSOFTDYNAMIC365FINANCEANDOPS | MICROSOFTTEAMS |

BLACKBAUDRAISEREDGENXT | MAILCHIMP | GITLAB | PENDO | PRODUCTBOARD | CIRCLECI | PIPEDIVE | SENDGRID | AZURECOSMOS | AZURESQL | BIGQUERY | BLACKBAUD | CLOUDERAHIVE | CLOUDERAIMPALA | CLOUDWATCH | CLOUDWATCHMETRICS | CMDDB | DATALAKEGEN2 | DB2 | DB2AS400 | DOCUMENTDB | DOMO | DYNAMODB | GOOGLECLOUDSTORAGE | HBASE | KUSTOMER | MICROSOFTDYNAMICS365CRM | MONDAY | MYSQL | OKTA | OPENSEARCH | ORACLE | PIPEDRIVE | POSTGRESQL | SAPHANA | SQLSERVER | SYNAPSE | TERADATA | TERADATANOS | TIMESTREAM | TPCDS | VERTICA).

The type of the connection. Currently, these types are supported:

- JDBC - Designates a connection to a database through Java Database Connectivity (JDBC).

JDBC Connections use the following ConnectionParameters.

- Required: All of (HOST, PORT, JDBC_ENGINE) or JDBC_CONNECTION_URL.
- Required: All of (USERNAME, PASSWORD) or SECRET_ID.
- Optional: JDBC_ENFORCE_SSL, CUSTOM_JDBC_CERT, CUSTOM_JDBC_CERT_STRING, SKIP_CUSTOM_JDBC_CERT_VALIDATION. These parameters are used to configure SSL with JDBC.
- KAFKA - Designates a connection to an Apache Kafka streaming platform.

KAFKA Connections use the following ConnectionParameters.

- Required: KAFKA_BOOTSTRAP_SERVERS.
- Optional: KAFKA_SSL_ENABLED, KAFKA_CUSTOM_CERT, KAFKA_SKIP_CUSTOM_CERT_VALIDATION. These parameters are used to configure SSL with KAFKA.
- Optional: KAFKA_CLIENT_KEYSTORE, KAFKA_CLIENT_KEYSTORE_PASSWORD, KAFKA_CLIENT_KEY_PASSWORD, ENCRYPTED_KAFKA_CLIENT_KEYSTORE_PASSWORD, ENCRYPTED_KAFKA_CLIENT_KEY_PASSWORD. These parameters are used to configure TLS client configuration with SSL in KAFKA.
- Optional: KAFKA_SASL_MECHANISM. Can be specified as SCRAM-SHA-512, GSSAPI, or AWS_MSK_IAM.
- Optional: KAFKA_SASL_SCRAM_USERNAME, KAFKA_SASL_SCRAM_PASSWORD, ENCRYPTED_KAFKA_SASL_SCRAM_PASSWORD. These parameters are used to configure SASL/SCRAM-SHA-512 authentication with KAFKA.

- **Optional:** KAFKA_SASL_GSSAPI_KEYTAB, KAFKA_SASL_GSSAPI_KRB5_CONF, KAFKA_SASL_GSSAPI_SERVICE, KAFKA_SASL_GSSAPI_PRINCIPAL. These parameters are used to configure SASL/GSSAPI authentication with KAFKA.
- **MONGODB** - Designates a connection to a MongoDB document database.

MONGODB Connections use the following ConnectionParameters.

- **Required:** CONNECTION_URL.
- **Required:** All of (USERNAME, PASSWORD) or SECRET_ID.
- **VIEW_VALIDATION_REDSHIFT** - Designates a connection used for view validation by Amazon Redshift.
- **VIEW_VALIDATION_ATHENA** - Designates a connection used for view validation by Amazon Athena.
- **NETWORK** - Designates a network connection to a data source within an Amazon Virtual Private Cloud environment (Amazon VPC).

NETWORK Connections do not require ConnectionParameters. Instead, provide a PhysicalConnectionRequirements.

- **MARKETPLACE** - Uses configuration settings contained in a connector purchased from Amazon Web Services Marketplace to read from and write to data stores that are not natively supported by Amazon Glue.

MARKETPLACE Connections use the following ConnectionParameters.

- **Required:** CONNECTOR_TYPE, CONNECTOR_URL, CONNECTOR_CLASS_NAME, CONNECTION_URL.
- **Required for JDBC CONNECTOR_TYPE connections:** All of (USERNAME, PASSWORD) or SECRET_ID.
- **CUSTOM** - Uses configuration settings contained in a custom connector to read from and write to data stores that are not natively supported by Amazon Glue.

For more information on the connection parameters needed for a particular connector, see the documentation for the connector in [Adding an Amazon Glue connection](#) in the Amazon Glue User Guide.

SFTP is not supported.

For more information about how optional `ConnectionProperties` are used to configure features in Amazon Glue, consult [Amazon Glue connection properties](#).

For more information about how optional `ConnectionProperties` are used to configure features in Amazon Glue Studio, consult [Using connectors and connections](#).

- `MatchCriteria` – An array of UTF-8 strings, not more than 10 strings.

A list of criteria that can be used in selecting this connection.

- `ConnectionProperties` – *Required*: A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string (valid values: `HOST` | `PORT` | `USERNAME="USER_NAME"` | `PASSWORD` | `ENCRYPTED_PASSWORD` | `JDBC_DRIVER_JAR_URI` | `JDBC_DRIVER_CLASS_NAME` | `JDBC_ENGINE` | `JDBC_ENGINE_VERSION` | `CONFIG_FILES` | `INSTANCE_ID` | `JDBC_CONNECTION_URL` | `JDBC_ENFORCE_SSL` | `CUSTOM_JDBC_CERT` | `SKIP_CUSTOM_JDBC_CERT_VALIDATION` | `CUSTOM_JDBC_CERT_STRING` | `CONNECTION_URL` | `KAFKA_BOOTSTRAP_SERVERS` | `KAFKA_SSL_ENABLED` | `KAFKA_CUSTOM_CERT` | `KAFKA_SKIP_CUSTOM_CERT_VALIDATION` | `KAFKA_CLIENT_KEYSTORE` | `KAFKA_CLIENT_KEYSTORE_PASSWORD` | `KAFKA_CLIENT_KEY_PASSWORD` | `ENCRYPTED_KAFKA_CLIENT_KEYSTORE_PASSWORD` | `ENCRYPTED_KAFKA_CLIENT_KEY_PASSWORD` | `KAFKA_SASL_MECHANISM` | `KAFKA_SASL_PLAIN_USERNAME` | `KAFKA_SASL_PLAIN_PASSWORD` | `ENCRYPTED_KAFKA_SASL_PLAIN_PASSWORD` | `KAFKA_SASL_SCRAM_USERNAME` | `KAFKA_SASL_SCRAM_PASSWORD` | `KAFKA_SASL_SCRAM_SECRETS_ARN` | `ENCRYPTED_KAFKA_SASL_SCRAM_PASSWORD` | `KAFKA_SASL_GSSAPI_KEYTAB` | `KAFKA_SASL_GSSAPI_KRB5_CONF` | `KAFKA_SASL_GSSAPI_SERVICE` | `KAFKA_SASL_GSSAPI_PRINCIPAL` | `SECRET_ID` | `CONNECTOR_URL` | `CONNECTOR_TYPE` | `CONNECTOR_CLASS_NAME` | `ENDPOINT` | `ENDPOINT_TYPE` | `ROLE_ARN` | `REGION` | `WORKGROUP_NAME` | `CLUSTER_IDENTIFIER` | `DATABASE`).

Each value is a Value string, not less than 1 or more than 1024 bytes long.

These key-value pairs define parameters for the connection.

- `SparkProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 2048 bytes long.

Connection properties specific to the Spark compute environment.

- `AthenaProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 2048 bytes long.

Connection properties specific to the Athena compute environment.

- `PythonProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 2048 bytes long.

Connection properties specific to the Python compute environment.

- `PhysicalConnectionRequirements` – A [PhysicalConnectionRequirements](#) object.

The physical connection requirements, such as virtual private cloud (VPC) and SecurityGroup, that are needed to successfully make this connection.

- `AuthenticationConfiguration` – An [AuthenticationConfigurationInput](#) object.

The authentication properties of the connection.

- `ValidateCredentials` – Boolean.

A flag to validate the credentials during create connection. Default is true.

- `ValidateForComputeEnvironments` – An array of UTF-8 strings.

The compute environments that the specified connection properties are validated against.

TestConnectionInput structure

A structure that is used to specify testing a connection to a service.

Fields

- `ConnectionType` – *Required*: UTF-8 string (valid values: JDBC | SFTP | MONGODB | KAFKA | NETWORK | MARKETPLACE | CUSTOM | SALESFORCE | VIEW_VALIDATION_REDSHIFT | VIEW_VALIDATION_ATHENA | GOOGLESHEETS | GOOGLEANALYTICS4)

| SERVICENOW | MARKETO | SAPODATA | ZENDESK | JIRACLOUD | NETSUITEERP
 | HUBSPOT | FACEBOOKADS | INSTAGRAMADS | ZOHOCRIM | SALESFORCEPARDOT |
 SALESFORCEMARKETINGCLOUD | ADOBEANALYTICS | SLACK | LINKEDIN | MIXPANEL | ASANA
 | STRIPE | SMARTSHEET | DATADOG | WOOCOMMERCE | INTERCOM | SNAPCHATADS | PAYPAL
 | QUICKBOOKS | FACEBOOKPAGEINSIGHTS | FRESHDESK | TWILIO | DOCUSIGNMONITOR
 | FRESHSALES | ZOOM | GOOGLESEARCHCONSOLE | SALESFORCECOMMERCECLOUD |
 SAPCONCUR | DYNATRACE | MICROSOFTDYNAMIC365FINANCEANDOPS | MICROSOFTTEAMS |
 BLACKBAUDRAISEREDGENXT | MAILCHIMP | GITLAB | PENDO | PRODUCTBOARD | CIRCLECI |
 PIPEDIVE | SENDGRID | AZURECOSMOS | AZURESQL | BIGQUERY | BLACKBAUD | CLOUDERAHIVE
 | CLOUDERAIMPALA | CLOUDWATCH | CLOUDWATCHMETRICS | CMDDB | DATALAKEGEN2 | DB2 |
 DB2AS400 | DOCUMENTDB | DOMO | DYNAMODB | GOOGLECLOUDSTORAGE | HBASE | KUSTOMER |
 MICROSOFTDYNAMICS365CRM | MONDAY | MYSQL | OKTA | OPENSEARCH | ORACLE | PIPEDRIVE
 | POSTGRESQL | SAPHANA | SQLSERVER | SYNAPSE | TERADATA | TERADATANOS | TIMESTREAM |
 TPCDS | VERTICA).

The type of connection to test. This operation is only available for the JDBC or SALESFORCE connection types.

- **ConnectionProperties** – *Required*: A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string (valid values: HOST | PORT | USERNAME="USER_NAME" | PASSWORD | ENCRYPTED_PASSWORD | JDBC_DRIVER_JAR_URI | JDBC_DRIVER_CLASS_NAME | JDBC_ENGINE | JDBC_ENGINE_VERSION | CONFIG_FILES | INSTANCE_ID | JDBC_CONNECTION_URL | JDBC_ENFORCE_SSL | CUSTOM_JDBC_CERT | SKIP_CUSTOM_JDBC_CERT_VALIDATION | CUSTOM_JDBC_CERT_STRING | CONNECTION_URL | KAFKA_BOOTSTRAP_SERVERS | KAFKA_SSL_ENABLED | KAFKA_CUSTOM_CERT | KAFKA_SKIP_CUSTOM_CERT_VALIDATION | KAFKA_CLIENT_KEYSTORE | KAFKA_CLIENT_KEYSTORE_PASSWORD | KAFKA_CLIENT_KEY_PASSWORD | ENCRYPTED_KAFKA_CLIENT_KEYSTORE_PASSWORD | ENCRYPTED_KAFKA_CLIENT_KEY_PASSWORD | KAFKA_SASL_MECHANISM | KAFKA_SASL_PLAIN_USERNAME | KAFKA_SASL_PLAIN_PASSWORD | ENCRYPTED_KAFKA_SASL_PLAIN_PASSWORD | KAFKA_SASL_SCRAM_USERNAME | KAFKA_SASL_SCRAM_PASSWORD | KAFKA_SASL_SCRAM_SECRETS_ARN | ENCRYPTED_KAFKA_SASL_SCRAM_PASSWORD | KAFKA_SASL_GSSAPI_KEYTAB | KAFKA_SASL_GSSAPI_KRB5_CONF | KAFKA_SASL_GSSAPI_SERVICE | KAFKA_SASL_GSSAPI_PRINCIPAL | SECRET_ID | CONNECTOR_URL | CONNECTOR_TYPE | CONNECTOR_CLASS_NAME | ENDPOINT | ENDPOINT_TYPE | ROLE_ARN | REGION | WORKGROUP_NAME | CLUSTER_IDENTIFIER | DATABASE).

Each value is a Value string, not less than 1 or more than 1024 bytes long.

The key-value pairs that define parameters for the connection.

JDBC connections use the following connection properties:

- Required: All of (HOST, PORT, JDBC_ENGINE) or JDBC_CONNECTION_URL.
- Required: All of (USERNAME, PASSWORD) or SECRET_ID.
- Optional: JDBC_ENFORCE_SSL, CUSTOM_JDBC_CERT, CUSTOM_JDBC_CERT_STRING, SKIP_CUSTOM_JDBC_CERT_VALIDATION. These parameters are used to configure SSL with JDBC.

SALESFORCE connections require the AuthenticationConfiguration member to be configured.

- AuthenticationConfiguration – An [AuthenticationConfigurationInput](#) object.

A structure containing the authentication configuration in the TestConnection request. Required for a connection to Salesforce using OAuth authentication.

PhysicalConnectionRequirements structure

The OAuth client app in GetConnection response.

Fields

- SubnetId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The subnet ID used by the connection.

- SecurityGroupIdList – An array of UTF-8 strings, not more than 50 strings.

The security group ID list used by the connection.

- AvailabilityZone – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The connection's Availability Zone.

GetConnectionsFilter structure

Filters the connection definitions that are returned by the GetConnections API operation.

Fields

- **MatchCriteria** – An array of UTF-8 strings, not more than 10 strings.

A criteria string that must match the criteria recorded in the connection definition for that connection definition to be returned.

- **ConnectionType** – UTF-8 string (valid values: JDBC | SFTP | MONGODB | KAFKA | NETWORK | MARKETPLACE | CUSTOM | SALESFORCE | VIEW_VALIDATION_REDSHIFT | VIEW_VALIDATION_ATHENA | GOOGLEADS | GOOGLESHEETS | GOOGLLEANALYTICS4 | SERVICENOW | MARKETO | SAPODATA | ZENDESK | JIRACLOUD | NETSUITEERP | HUBSPOT | FACEBOOKADS | INSTAGRAMADS | ZOHOCRIM | SALESFORCEPARDOT | SALESFORCEMARKETINGCLOUD | ADOBEANALYTICS | SLACK | LINKEDIN | MIXPANEL | ASANA | STRIPE | SMARTSHEET | DATADOG | WOOCOMMERCE | INTERCOM | SNAPCHATADS | PAYPAL | QUICKBOOKS | FACEBOOKPAGEINSIGHTS | FRESHDESK | TWILIO | DOCUSIGNMONITOR | FRESHSALES | ZOOM | GOOGLESEARCHCONSOLE | SALESFORCECOMMERCECLOUD | SAPCONCUR | DYNATRACE | MICROSOFTDYNAMIC365FINANCEANDOPS | MICROSOFTTEAMS | BLACKBAUDRAISEREDGENXT | MAILCHIMP | GITLAB | PENDO | PRODUCTBOARD | CIRCLECI | PIPEDIVE | SENDGRID | AZURECOSMOS | AZURESQL | BIGQUERY | BLACKBAUD | CLOUDERAHIVE | CLOUDERAIMPALA | CLOUDWATCH | CLOUDWATCHMETRICS | CMDDB | DATALAKEGEN2 | DB2 | DB2AS400 | DOCUMENTDB | DOMO | DYNAMODB | GOOGLECLOUDSTORAGE | HBASE | KUSTOMER | MICROSOFTDYNAMICS365CRM | MONDAY | MYSQL | OKTA | OPENSEARCH | ORACLE | PIPEDRIVE | POSTGRESQL | SAPHANA | SQLSERVER | SYNAPSE | TERADATA | TERADATANOS | TIMESTREAM | TPCDS | VERTICA).

The type of connections to return. Currently, SFTP is not supported.

- **ConnectionSchemaVersion** – Number (integer), not less than 1 or more than 2.

Denotes if the connection was created with schema version 1 or 2.

AuthenticationConfiguration structure

A structure containing the authentication configuration.

Fields

- `AuthenticationType` – UTF-8 string (valid values: BASIC | OAUTH2 | CUSTOM | IAM).

A structure containing the authentication configuration.

- `SecretArn` – UTF-8 string, matching the [Custom string pattern #36](#).

The secret manager ARN to store credentials.

- `KmsKeyArn` – UTF-8 string, matching the [Custom string pattern #42](#).

The Amazon Resource Name (ARN) of the KMS key used to encrypt sensitive authentication information. This key is used to protect credentials and other sensitive data stored within the authentication configuration.

- `OAuth2Properties` – An [OAuth2Properties](#) object.

The properties for OAuth2 authentication.

AuthenticationConfigurationInput structure

A structure containing the authentication configuration in the CreateConnection request.

Fields

- `AuthenticationType` – UTF-8 string (valid values: BASIC | OAUTH2 | CUSTOM | IAM).

A structure containing the authentication configuration in the CreateConnection request.

- `OAuth2Properties` – An [OAuth2PropertiesInput](#) object.

The properties for OAuth2 authentication in the CreateConnection request.

- `SecretArn` – UTF-8 string, matching the [Custom string pattern #36](#).

The secret manager ARN to store credentials in the CreateConnection request.

- `KmsKeyArn` – UTF-8 string, matching the [Custom string pattern #42](#).

The ARN of the KMS key used to encrypt the connection. Only taken as input in the request and stored in the Secret Manager.

- `BasicAuthenticationCredentials` – A [BasicAuthenticationCredentials](#) object.

The credentials used when the authentication type is basic authentication.

- `CustomAuthenticationCredentials` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 2048 bytes long.

The credentials used when the authentication type is custom authentication.

OAuth2Properties structure

A structure containing properties for OAuth2 authentication.

Fields

- `OAuth2GrantType` – UTF-8 string (valid values: `AUTHORIZATION_CODE` | `CLIENT_CREDENTIALS` | `JWT_BEARER`).

The OAuth2 grant type. For example, `AUTHORIZATION_CODE`, `JWT_BEARER`, or `CLIENT_CREDENTIALS`.

- `OAuth2ClientApplication` – An [OAuth2ClientApplication](#) object.

The client application type. For example, `AWS_MANAGED` or `USER_MANAGED`.

- `TokenUrl` – UTF-8 string, not more than 256 bytes long, matching the [Custom string pattern #40](#).

The URL of the provider's authentication server, to exchange an authorization code for an access token.

- `TokenUrlParametersMap` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 512 bytes long.

A map of parameters that are added to the token GET request.

OAuth2PropertiesInput structure

A structure containing properties for OAuth2 in the `CreateConnection` request.

Fields

- `OAuth2GrantType` – UTF-8 string (valid values: `AUTHORIZATION_CODE` | `CLIENT_CREDENTIALS` | `JWT_BEARER`).

The OAuth2 grant type in the `CreateConnection` request. For example, `AUTHORIZATION_CODE`, `JWT_BEARER`, or `CLIENT_CREDENTIALS`.

- `OAuth2ClientApplication` – An [OAuth2ClientApplication](#) object.

The client application type in the `CreateConnection` request. For example, `AWS_MANAGED` or `USER_MANAGED`.

- `TokenUrl` – UTF-8 string, not more than 256 bytes long, matching the [Custom string pattern #40](#).

The URL of the provider's authentication server, to exchange an authorization code for an access token.

- `TokenUrlParametersMap` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 512 bytes long.

A map of parameters that are added to the token GET request.

- `AuthorizationCodeProperties` – An [AuthorizationCodeProperties](#) object.

The set of properties required for the the OAuth2 `AUTHORIZATION_CODE` grant type.

- `OAuth2Credentials` – An [OAuth2Credentials](#) object.

The credentials used when the authentication type is OAuth2 authentication.

OAuth2ClientApplication structure

The OAuth2 client app used for the connection.

Fields

- `UserManagedClientApplicationClientId` – UTF-8 string, not more than 2048 bytes long, matching the [Custom string pattern #37](#).

The client application `clientId` if the `ClientAppType` is `USER_MANAGED`.

- `AWSTManagedClientApplicationReference` – UTF-8 string, not more than 2048 bytes long, matching the [Custom string pattern #37](#).

The reference to the SaaS-side client app that is Amazon managed.

AuthorizationCodeProperties structure

The set of properties required for the the OAuth2 AUTHORIZATION_CODE grant type workflow.

Fields

- `AuthorizationCode` – UTF-8 string, not less than 1 or more than 4096 bytes long, matching the [Custom string pattern #37](#).

An authorization code to be used in the third leg of the AUTHORIZATION_CODE grant workflow. This is a single-use code which becomes invalid once exchanged for an access token, thus it is acceptable to have this value as a request parameter.

- `RedirectUri` – UTF-8 string, not more than 512 bytes long, matching the [Custom string pattern #41](#).

The redirect URI where the user gets redirected to by authorization server when issuing an authorization code. The URI is subsequently used when the authorization code is exchanged for an access token.

BasicAuthenticationCredentials structure

For supplying basic auth credentials when not providing a `SecretArn` value.

Fields

- `Username` – UTF-8 string, not more than 512 bytes long, matching the [Custom string pattern #37](#).

The username to connect to the data source.

- `Password` – UTF-8 string, not more than 512 bytes long, matching the [Custom string pattern #33](#).

The password to connect to the data source.

OAuth2Credentials structure

The credentials used when the authentication type is OAuth2 authentication.

Fields

- `UserManagedClientApplicationClientSecret` – UTF-8 string, not more than 512 bytes long, matching the [Custom string pattern #38](#).

The client application client secret if the client application is user managed.

- `AccessToken` – UTF-8 string, not more than 4096 bytes long, matching the [Custom string pattern #38](#).

The access token used when the authentication type is OAuth2.

- `RefreshToken` – UTF-8 string, not more than 4096 bytes long, matching the [Custom string pattern #38](#).

The refresh token used when the authentication type is OAuth2.

- `JwtToken` – UTF-8 string, not more than 8000 bytes long, matching the [Custom string pattern #39](#).

The JSON Web Token (JWT) used when the authentication type is OAuth2.

Operations

- [CreateConnection action \(Python: `create_connection`\)](#)
- [DeleteConnection action \(Python: `delete_connection`\)](#)
- [GetConnection action \(Python: `get_connection`\)](#)
- [GetConnections action \(Python: `get_connections`\)](#)
- [UpdateConnection action \(Python: `update_connection`\)](#)
- [TestConnection action \(Python: `test_connection`\)](#)
- [BatchDeleteConnection action \(Python: `batch_delete_connection`\)](#)

CreateConnection action (Python: `create_connection`)

Creates a connection definition in the Data Catalog.

Connections used for creating federated resources require the IAM `glue:PassConnection` permission.

Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which to create the connection. If none is provided, the Amazon account ID is used by default.

- `connectionInput` – *Required:* A [ConnectionInput](#) object.

A `ConnectionInput` object defining the connection to create.

- `tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags you assign to the connection.

Response

- `createConnectionStatus` – UTF-8 string (valid values: `READY` | `IN_PROGRESS` | `FAILED`).

The status of the connection creation request. The request can take some time for certain authentication types, for example when creating an OAuth connection with token exchange over VPC.

Errors

- `AlreadyExistsException`
- `InvalidInputException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `GlueEncryptionException`

DeleteConnection action (Python: delete_connection)

Deletes a connection from the Data Catalog.

Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connection resides. If none is provided, the Amazon account ID is used by default.

- `connectionName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to delete.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `OperationTimeoutException`

GetConnection action (Python: get_connection)

Retrieves a connection definition from the Data Catalog.

Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connection resides. If none is provided, the Amazon account ID is used by default.

- `name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection definition to retrieve.

- `HidePassword` – Boolean.

Allows you to retrieve the connection metadata without returning the password. For instance, the Amazon Glue console uses this flag to retrieve the connection, and does not display the password. Set this parameter when the caller might not have permission to use the Amazon KMS key to decrypt the password, but it does have permission to access the rest of the connection properties.

- `ApplyOverrideForComputeEnvironment` – UTF-8 string (valid values: SPARK | ATHENA | PYTHON).

For connections that may be used in multiple services, specifies returning properties for the specified compute environment.

Response

- `Connection` – A [Connection](#) object.

The requested connection definition.

Errors

- `EntityNotFoundException`
- `OperationTimeoutException`
- `InvalidInputException`
- `GlueEncryptionException`

GetConnections action (Python: `get_connections`)

Retrieves a list of connection definitions from the Data Catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connections reside. If none is provided, the Amazon account ID is used by default.

- **Filter** – A [GetConnectionsFilter](#) object.

A filter that controls which connections are returned.

- **HidePassword** – Boolean.

Allows you to retrieve the connection metadata without returning the password. For instance, the Amazon Glue console uses this flag to retrieve the connection, and does not display the password. Set this parameter when the caller might not have permission to use the Amazon KMS key to decrypt the password, but it does have permission to access the rest of the connection properties.

- **NextToken** – UTF-8 string.

A continuation token, if this is a continuation call.

- **MaxResults** – Number (integer), not less than 1 or more than 1000.

The maximum number of connections to return in one response.

Response

- **ConnectionList** – An array of [Connection](#) objects.

A list of requested connection definitions.

- **NextToken** – UTF-8 string.

A continuation token, if the list of connections returned does not include the last of the filtered connections.

Errors

- `EntityNotFoundException`
- `OperationTimeoutException`
- `InvalidInputException`
- `GlueEncryptionException`

UpdateConnection action (Python: update_connection)

Updates a connection definition in the Data Catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connection resides. If none is provided, the Amazon account ID is used by default.

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection definition to update.

- `ConnectionInput` – *Required:* A [ConnectionInput](#) object.

A `ConnectionInput` object that redefines the connection in question.

Response

- *No Response parameters.*

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `InvalidInputException`
- `GlueEncryptionException`

TestConnection action (Python: test_connection)

Tests a connection to a service to validate the service credentials that you provide.

You can either provide an existing connection name or a `TestConnectionInput` for testing a non-existing connection input. Providing both at the same time will cause an error.

If the action is successful, the service sends back an HTTP 200 response.

Request

- **ConnectionName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Optional. The name of the connection to test. If only name is provided, the operation will get the connection and use that for testing.

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID where the connection resides.

- **TestConnectionInput** – A [TestConnectionInput](#) object.

A structure that is used to specify testing a connection to a service.

Response

- *No Response parameters.*

Errors

- `InvalidInputException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `GlueEncryptionException`
- `FederationSourceException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `ConflictException`
- `InternalServiceException`

BatchDeleteConnection action (Python: `batch_delete_connection`)

Deletes a list of connection definitions from the Data Catalog.

Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connections reside. If none is provided, the Amazon account ID is used by default.

- `connectionNameList` – *Required:* An array of UTF-8 strings, not more than 25 strings.

A list of names of the connections to delete.

Response

- `succeeded` – An array of UTF-8 strings.

A list of names of the connection definitions that were successfully deleted.

- `errors` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a An [ErrorDetail](#) object.

A map of the names of connections that were not successfully deleted to error details.

Errors

- `InternalServiceException`
- `OperationTimeoutException`

Connection Types API

The Connection Type API describes Amazon Glue APIs related to describing connection types.

Connection management APIs

- [DescribeConnectionType](#) action (Python: `describe_connection_type`)
- [ListConnectionTypes](#) action (Python: `list_connection_types`)

- [ConnectionTypeBrief structure](#)
- [ConnectionTypeVariant structure](#)

DescribeConnectionType action (Python: `describe_connection_type`)

The `DescribeConnectionType` API provides full details of the supported options for a given connection type in Amazon Glue.

Request

- `ConnectionType` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection type to be described.

Response

- `ConnectionType` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection type.

- `Description` – UTF-8 string, not more than 1024 bytes long.

A description of the connection type.

- `Capabilities` – A [Capabilities](#) object.

The supported authentication types, data interface types (compute environments), and data operations of the connector.

- `ConnectionProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a [Property](#) object.

Connection properties which are common across compute environments.

- `ConnectionOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a A [Property](#) object.

Returns properties that can be set when creating a connection in the `ConnectionInput.ConnectionProperties`. `ConnectionOptions` defines parameters that can be set in a Spark ETL script in the connection options map passed to a dataframe.

- `AuthenticationConfiguration` – An [AuthConfiguration](#) object.

The type of authentication used for the connection.

- `ComputeEnvironmentConfigurations` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a A [ComputeEnvironmentConfiguration](#) object.

The compute environments that are supported by the connection.

- `PhysicalConnectionRequirements` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a A [Property](#) object.

Physical requirements for a connection, such as VPC, Subnet and Security Group specifications.

- `AthenaConnectionProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a A [Property](#) object.

Connection properties specific to the Athena compute environment.

- `PythonConnectionProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a A [Property](#) object.

Connection properties specific to the Python compute environment.

- `SparkConnectionProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a [Property](#) object.

Connection properties specific to the Spark compute environment.

Errors

- `ValidationException`
- `InvalidInputException`
- `InternalServiceException`

ListConnectionTypes action (Python: `list_connection_types`)

The `ListConnectionTypes` API provides a discovery mechanism to learn available connection types in Amazon Glue. The response contains a list of connection types with high-level details of what is supported for each connection type. The connection types listed are the set of supported options for the `ConnectionType` value in the `CreateConnection` API.

Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

- `NextToken` – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Custom string pattern #11](#).

A continuation token, if this is a continuation call.

Response

- `ConnectionTypes` – An array of [ConnectionTypeBrief](#) objects.

A list of `ConnectionTypeBrief` objects containing brief information about the supported connection types.

- `NextToken` – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Custom string pattern #11](#).

A continuation token, if the current list segment is not the last.

Errors

- `InternalServiceException`

ConnectionTypeBrief structure

Brief information about a supported connection type returned by the `ListConnectionTypes` API.

Fields

- `ConnectionType` – UTF-8 string (valid values: JDBC | SFTP | MONGODB | KAFKA | NETWORK | MARKETPLACE | CUSTOM | SALESFORCE | VIEW_VALIDATION_REDSHIFT | VIEW_VALIDATION_ATHENA | GOOGLEADS | GOOGLESHEETS | GOOGLLEANALYTICS4 | SERVICENOW | MARKETO | SAPODATA | ZENDESK | JIRACLOUD | NETSUITEERP | HUBSPOT | FACEBOOKADS | INSTAGRAMADS | ZOHOCRIM | SALESFORCEPARDOT | SALESFORCEMARKETINGCLOUD | ADOBEANALYTICS | SLACK | LINKEDIN | MIXPANEL | ASANA | STRIPE | SMARTSHEET | DATADOG | WOOCOMMERCE | INTERCOM | SNAPCHATADS | PAYPAL | QUICKBOOKS | FACEBOOKPAGEINSIGHTS | FRESHDESK | TWILIO | DOCUSIGNMONITOR | FRESHSALES | ZOOM | GOOGLESEARCHCONSOLE | SALESFORCECOMMERCECLOUD | SAPCONCUR | DYNATRACE | MICROSOFTDYNAMIC365FINANCEANDOPS | MICROSOFTTEAMS | BLACKBAUDRAISEREDGENXT | MAILCHIMP | GITLAB | PENDO | PRODUCTBOARD | CIRCLECI | PIPEDIVE | SENDGRID | AZURECOSMOS | AZURESQL | BIGQUERY | BLACKBAUD | CLOUDERAHIVE | CLOUDERAIMPALA | CLOUDWATCH | CLOUDWATCHMETRICS | CMDDB | DATALAKEGEN2 | DB2 | DB2AS400 | DOCUMENTDB | DOMO | DYNAMODB | GOOGLECLOUDSTORAGE | HBASE | KUSTOMER | MICROSOFTDYNAMICS365CRM | MONDAY | MYSQL | OKTA | OPENSEARCH | ORACLE | PIPEDRIVE | POSTGRESQL | SAPHANA | SQLSERVER | SYNAPSE | TERADATA | TERADATANOS | TIMESTREAM | TPCDS | VERTICA).

The name of the connection type.

- `DisplayName` – UTF-8 string, not less than 1 or more than 128 bytes long.

The human-readable name for the connection type that is displayed in the Amazon Glue console.

- `Vendor` – UTF-8 string, not less than 1 or more than 128 bytes long.

The name of the vendor or provider that created or maintains this connection type.

- `Description` – UTF-8 string, not more than 1024 bytes long.

A description of the connection type.

- **Categories** – .

A list of categories that this connection type belongs to. Categories help users filter and find appropriate connection types based on their use cases.

- **Capabilities** – A [Capabilities](#) object.

The supported authentication types, data interface types (compute environments), and data operations of the connector.

- **LogoUrl** – UTF-8 string.

The URL of the logo associated with a connection type.

- **ConnectionTypeVariants** – An array of [ConnectionTypeVariant](#) objects.

A list of variants available for this connection type. Different variants may provide specialized configurations for specific use cases or implementations of the same general connection type.

ConnectionTypeVariant structure

Represents a variant of a connection type in Amazon Glue Data Catalog. Connection type variants provide specific configurations and behaviors for different implementations of the same general connection type.

Fields

- **ConnectionTypeVariantName** – UTF-8 string, not less than 1 or more than 128 bytes long.

The unique identifier for the connection type variant. This name is used internally to identify the specific variant of a connection type.

- **DisplayName** – UTF-8 string, not less than 1 or more than 128 bytes long.

The human-readable name for the connection type variant that is displayed in the Amazon Glue console.

- **Description** – UTF-8 string, not more than 1024 bytes long.

A detailed description of the connection type variant, including its purpose, use cases, and any specific configuration requirements.

- `LogoUrl` – UTF-8 string.

The URL of the logo associated with a connection type variant.

datatypes

- [Validation structure](#)
- [AuthConfiguration structure](#)
- [Capabilities structure](#)
- [Property structure](#)
- [AllowedValue structure](#)
- [ComputeEnvironmentConfiguration structure](#)

Validation structure

Defines how a validation is performed on a connection property.

Fields

- `ValidationType` – *Required:* UTF-8 string (valid values: REGEX | RANGE).

The type of validation to be performed, such as REGEX.

- `Patterns` – .

A list of patterns that apply to the validation.

- `Description` – *Required:* UTF-8 string, not less than 1 or more than 1024 bytes long.

A description for the validation.

- `MaxLength` – Number (integer).

A maximum length for a string connection property.

- `Maximum` – Number (integer).

A maximum value when specifying a RANGE type of validation.

- `Minimum` – Number (integer).

A minimum value when specifying a RANGE type of validation.

AuthConfiguration structure

The authentication configuration for a connection returned by the DescribeConnectionType API.

Fields

- `AuthenticationType` – *Required:* A [Property](#) object.

The type of authentication for a connection.

- `SecretArn` – A [Property](#) object.

The Amazon Resource Name (ARN) for the Secrets Manager.

- `OAuth2Properties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a A [Property](#) object.

A map of key-value pairs for the OAuth2 properties. Each value is a a Property object.

- `BasicAuthenticationProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a A [Property](#) object.

A map of key-value pairs for the OAuth2 properties. Each value is a a Property object.

- `CustomAuthenticationProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a A [Property](#) object.

A map of key-value pairs for the custom authentication properties. Each value is a a Property object.

Capabilities structure

Specifies the supported authentication types returned by the DescribeConnectionType API.

Fields

- `SupportedAuthenticationTypes` – *Required:* An array of UTF-8 strings.

A list of supported authentication types.

- `SupportedDataOperations` – *Required:* An array of UTF-8 strings.

A list of supported data operations.

- `SupportedComputeEnvironments` – *Required:* An array of UTF-8 strings.

A list of supported compute environments.

Property structure

An object that defines a connection type for a compute environment.

Fields

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The name of the property.

- `Description` – *Required:* UTF-8 string, not more than 1024 bytes long.

A description of the property.

- `Required` – *Required:* Boolean.

Indicates whether the property is required.

- `PropertyTypes` – *Required:* An array of UTF-8 strings.

Describes the type of property.

- `AllowedValues` – An array of [AllowedValue](#) objects.

A list of `AllowedValue` objects representing the values allowed for the property.

- `DataOperationScopes` – An array of UTF-8 strings.

Indicates which data operations are applicable to the property.

AllowedValue structure

An object representing a value allowed for a property.

Fields

- **Description** – UTF-8 string, not more than 1024 bytes long.

A description of the allowed value.

- **Value** – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The value allowed for the property.

ComputeEnvironmentConfiguration structure

An object containing configuration for a compute environment (such as Spark, Python or Athena) returned by the DescribeConnectionType API.

Fields

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

A name for the compute environment configuration.

- **Description** – *Required:* UTF-8 string, not more than 1024 bytes long.

A description of the compute environment.

- **ComputeEnvironment** – *Required:* UTF-8 string (valid values: SPARK | ATHENA | PYTHON).

The type of compute environment.

- **SupportedAuthenticationTypes** – *Required:* An array of UTF-8 strings.

The supported authentication types for the compute environment.

- **ConnectionOptions** – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a [Property](#) object.

The parameters used as connection options for the compute environment.

- **ConnectionPropertyNameOverrides** – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 128 bytes long.

The connection property name overrides for the compute environment.

- `ConnectionOptionNameOverrides` – *Required*: A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 128 bytes long.

The connection option name overrides for the compute environment.

- `ConnectionPropertiesRequiredOverrides` – *Required*: .

The connection properties that are required as overrides for the compute environment.

- `PhysicalConnectionPropertiesRequired` – Boolean.

Indicates whether `PhysicalConnectionProperties` are required for the compute environment.

Connection Metadata and Preview API

The following connection APIs describe operations for describing connection metadata.

Data types

- [Entity structure](#)
- [Field structure](#)

Entity structure

An entity supported by a given `ConnectionType`.

Fields

- `EntityName` – UTF-8 string.

The name of the entity.

- `Label` – UTF-8 string.

Label used for the entity.

- `IsParentEntity` – Boolean.

A Boolean value which helps to determine whether there are sub objects that can be listed.

- `Description` – UTF-8 string.

A description of the entity.

- `Category` – UTF-8 string.

The type of entities that are present in the response. This value depends on the source connection. For example this is `SObjects` for Salesforce and databases or schemas or tables for sources like Amazon Redshift.

- `CustomProperties` –

An optional map of keys which may be returned for an entity by a connector.

Field structure

The `Field` object has information about the different properties associated with a field in the connector.

Fields

- `FieldName` – UTF-8 string.

A unique identifier for the field.

- `Label` – UTF-8 string.

A readable label used for the field.

- `Description` – UTF-8 string.

A description of the field.

- `FieldType` – UTF-8 string (valid values: `INT` | `SMALLINT` | `BIGINT` | `FLOAT` | `LONG` | `DATE` | `BOOLEAN` | `MAP` | `ARRAY` | `STRING` | `TIMESTAMP` | `DECIMAL` | `BYTE` | `SHORT` | `DOUBLE` | `STRUCT`).

The type of data in the field.

- `IsPrimaryKey` – Boolean.

Indicates whether this field can be used as a primary key for the given entity.

- `IsNullable` – Boolean.

Indicates whether this field can be nullable or not.

- `IsRetrievable` – Boolean.

Indicates whether this field can be added in the Select clause of a SQL query or whether it is retrievable or not.

- `IsFilterable` – Boolean.

Indicates whether this field can be used in a filter clause (WHERE clause) of a SQL statement when querying data.

- `IsPartitionable` – Boolean.

Indicates whether a given field can be used in partitioning the query made to SaaS.

- `IsCreateable` – Boolean.

Indicates whether this field can be created as part of a destination write.

- `IsUpdateable` – Boolean.

Indicates whether this field can be updated as part of a destination write.

- `IsUpsertable` – Boolean.

Indicates whether this field can be upserted as part of a destination write.

- `IsDefaultOnCreate` – Boolean.

Indicates whether this field is populated automatically when the object is created, such as a created at timestamp.

- `SupportedValues` – .

A list of supported values for the field.

- `SupportedFilterOperators` – An array of UTF-8 strings.

Indicates the supported filter operators for this field.

- `CustomProperties` –

Optional map of keys which may be returned.

Operations

- [ListEntities action \(Python: list_entities\)](#)
- [DescribeEntity action \(Python: describe_entity\)](#)
- [GetEntityRecords action \(Python: get_entity_records\)](#)

ListEntities action (Python: list_entities)

Returns the available entities supported by the connection type.

Request

- `ConnectionName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A name for the connection that has required credentials to query any connection type.

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID of the catalog that contains the connection. This can be null, By default, the Amazon Account ID is the catalog ID.

- `ParentEntityName` – UTF-8 string.

Name of the parent entity for which you want to list the children. This parameter takes a fully-qualified path of the entity in order to list the child entities.

- `NextToken` – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Custom string pattern #11](#).

A continuation token, included if this is a continuation call.

- `DataStoreApiVersion` – UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #23](#).

The API version of the SaaS connector.

Response

- `Entities` – An array of [Entity](#) objects.

A list of Entity objects.

- NextToken – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Custom string pattern #11](#).

A continuation token, present if the current segment is not the last.

Errors

- EntityNotFoundException
- OperationTimeoutException
- InvalidInputException
- GlueEncryptionException
- ValidationException
- FederationSourceException
- AccessDeniedException

DescribeEntity action (Python: describe_entity)

Provides details regarding the entity used with the connection type, with a description of the data model for each field in the selected entity.

The response includes all the fields which make up the entity.

Request

- ConnectionName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection that contains the connection type credentials.

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID of the catalog that contains the connection. This can be null, By default, the Amazon Account ID is the catalog ID.

- EntityName – *Required:* UTF-8 string.

The name of the entity that you want to describe from the connection type.

- NextToken – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Custom string pattern #11](#).

A continuation token, included if this is a continuation call.

- DataStoreApiVersion – UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #23](#).

The version of the API used for the data store.

Response

- Fields – An array of [Field](#) objects.

Describes the fields for that connector entity. This is the list of Field objects. Field is very similar to column in a database. The Field object has information about different properties associated with fields in the connector.

- NextToken – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Custom string pattern #11](#).

A continuation token, present if the current segment is not the last.

Errors

- EntityNotFoundException
- OperationTimeoutException
- InvalidInputException
- GlueEncryptionException
- ValidationException
- FederationSourceException
- AccessDeniedException

GetEntityRecords action (Python: `get_entity_records`)

This API is used to query preview data from a given connection type or from a native Amazon S3 based Amazon Glue Data Catalog.

Returns records as an array of JSON blobs. Each record is formatted using Jackson JsonNode based on the field type defined by the DescribeEntity API.

Spark connectors generate schemas according to the same data type mapping as in the DescribeEntity API. Spark connectors convert data to the appropriate data types matching the schema when returning rows.

Request

- **ConnectionName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection that contains the connection type credentials.

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID of the catalog that contains the connection. This can be null, By default, the Amazon Account ID is the catalog ID.

- **EntityName** – *Required*: UTF-8 string.

Name of the entity that we want to query the preview data from the given connection type.

- **NextToken** – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Custom string pattern #11](#).

A continuation token, included if this is a continuation call.

- **DataStoreApiVersion** – UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #23](#).

The API version of the SaaS connector.

- **ConnectionOptions** – A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #18](#).

Each value is a UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #17](#).

Connector options that are required to query the data.

- **FilterPredicate** – UTF-8 string, not less than 1 or more than 100000 bytes long.

A filter predicate that you can apply in the query request.

- **Limit** – *Required*: Number (long), not less than 1 or more than 1000.

Limits the number of records fetched with the request.

- **SelectedFields** – An array of UTF-8 strings, not less than 1 or more than 1000 strings.

List of fields that we want to fetch as part of preview data.

Response

- **Records** – An array of a structures.

A list of the requested objects.

- **NextToken** – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Custom string pattern #11](#).

A continuation token, present if the current segment is not the last.

Errors

- `EntityNotFoundException`
- `OperationTimeoutException`
- `InvalidInputException`
- `GlueEncryptionException`
- `ValidationException`
- `FederationSourceException`
- `AccessDeniedException`

User-defined Function API

The User-defined Function API describes Amazon Glue data types and operations used in working with functions.

Data types

- [UserDefinedFunction structure](#)

- [UserDefinedFunctionInput structure](#)

UserDefinedFunction structure

Represents the equivalent of a Hive user-defined function (UDF) definition.

Fields

- **FunctionName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function.

- **DatabaseName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database that contains the function.

- **ClassName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Java class that contains the function code.

- **OwnerName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The owner of the function.

- **OwnerType** – UTF-8 string (valid values: USER | ROLE | GROUP).

The owner type.

- **CreateTime** – Timestamp.

The time at which the function was created.

- **ResourceUris** – An array of [ResourceUri](#) objects, not more than 1000 structures.

The resource URIs for the function.

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the function resides.

UserDefinedFunctionInput structure

A structure used to create or update a user-defined function.

Fields

- **FunctionName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function.

- **ClassName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Java class that contains the function code.

- **OwnerName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The owner of the function.

- **OwnerType** – UTF-8 string (valid values: USER | ROLE | GROUP).

The owner type.

- **ResourceUris** – An array of [ResourceUri](#) objects, not more than 1000 structures.

The resource URIs for the function.

Operations

- [CreateUserDefinedFunction action \(Python: create_user_defined_function\)](#)
- [UpdateUserDefinedFunction action \(Python: update_user_defined_function\)](#)
- [DeleteUserDefinedFunction action \(Python: delete_user_defined_function\)](#)
- [GetUserDefinedFunction action \(Python: get_user_defined_function\)](#)
- [GetUserDefinedFunctions action \(Python: get_user_defined_functions\)](#)

CreateUserDefinedFunction action (Python: create_user_defined_function)

Creates a new function definition in the Data Catalog.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which to create the function. If none is provided, the Amazon account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which to create the function.

- **FunctionInput** – *Required:* An [UserDefinedFunctionInput](#) object.

A FunctionInput object that defines the function to create in the Data Catalog.

Response

- *No Response parameters.*

Errors

- AlreadyExistsException
- InvalidInputException
- InternalServiceException
- EntityNotFoundException
- OperationTimeoutException
- ResourceNumberLimitExceededException
- GlueEncryptionException

UpdateUserDefinedFunction action (Python: update_user_defined_function)

Updates an existing function definition in the Data Catalog.

Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the function to be updated is located. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the function to be updated is located.

- `FunctionName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function.

- `FunctionInput` – *Required*: An [UserDefinedFunctionInput](#) object.

A `FunctionInput` object that redefines the function in the Data Catalog.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

DeleteUserDefinedFunction action (Python: `delete_user_defined_function`)

Deletes an existing function definition from the Data Catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the function to be deleted is located. If none is supplied, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the function is located.

- `FunctionName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function definition to be deleted.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

GetUserDefinedFunction action (Python: `get_user_defined_function`)

Retrieves a specified function definition from the Data Catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the function to be retrieved is located. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the function is located.

- `FunctionName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function.

Response

- `UserDefinedFunction` – An [UserDefinedFunction](#) object.

The requested function definition.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

GetUserDefinedFunctions action (Python: `get_user_defined_functions`)

Retrieves multiple function definitions from the Data Catalog.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the functions to be retrieved are located. If none is provided, the Amazon account ID is used by default.

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the functions are located. If none is provided, functions from all the databases across the catalog will be returned.

- `Pattern` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

An optional function-name pattern string that filters the function definitions returned.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

- `MaxResults` – Number (integer), not less than 1 or more than 100.

The maximum number of functions to return in one response.

Response

- `UserDefinedFunctions` – An array of [UserDefinedFunction](#) objects.

A list of requested function definitions.

- `NextToken` – UTF-8 string.

A continuation token, if the list of functions returned does not include the last requested function.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `GlueEncryptionException`

Importing an Athena catalog to Amazon Glue

The Migration API describes Amazon Glue data types and operations having to do with migrating an Athena Data catalog to Amazon Glue.

Data types

- [CatalogImportStatus structure](#)

CatalogImportStatus structure

A structure containing migration status information.

Fields

- `ImportCompleted` – Boolean.

True if the migration has completed, or False otherwise.

- `ImportTime` – Timestamp.

The time that the migration was started.

- `ImportedBy` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the person who initiated the migration.

Operations

- [ImportCatalogToGlue action \(Python: `import_catalog_to_glue`\)](#)
- [GetCatalogImportStatus action \(Python: `get_catalog_import_status`\)](#)

ImportCatalogToGlue action (Python: `import_catalog_to_glue`)

Imports an existing Amazon Athena Data Catalog to Amazon Glue.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog to import. Currently, this should be the Amazon account ID.

Response

- *No Response parameters.*

Errors

- `InternalServiceException`
- `OperationTimeoutException`

GetCatalogImportStatus action (Python: `get_catalog_import_status`)

Retrieves the status of a migration operation.

Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog to migrate. Currently, this should be the Amazon account ID.

Response

- `ImportStatus` – A [CatalogImportStatus](#) object.

The status of the specified catalog migration.

Errors

- `InternalServiceException`
- `OperationTimeoutException`

Table optimizer API

The table optimizer API describes the Amazon Glue API for enabling compaction to improve read performance.

Data types

- [TableOptimizer](#) structure
- [TableOptimizerConfiguration](#) structure
- [TableOptimizerVpcConfiguration](#) structure

- [CompactionConfiguration structure](#)
- [IcebergCompactionConfiguration structure](#)
- [TableOptimizerRun structure](#)
- [BatchGetTableOptimizerEntry structure](#)
- [BatchTableOptimizer structure](#)
- [BatchGetTableOptimizerError structure](#)
- [RetentionConfiguration structure](#)
- [IcebergRetentionConfiguration structure](#)
- [OrphanFileDeletionConfiguration structure](#)
- [IcebergOrphanFileDeletionConfiguration structure](#)
- [CompactionMetrics structure](#)
- [RetentionMetrics structure](#)
- [OrphanFileDeletionMetrics structure](#)
- [IcebergCompactionMetrics structure](#)
- [IcebergRetentionMetrics structure](#)
- [IcebergOrphanFileDeletionMetrics structure](#)
- [RunMetrics structure](#)

TableOptimizer structure

Contains details about an optimizer associated with a table.

Fields

- `type` – UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer. The valid values are:

- `compaction`: for managing compaction with a table optimizer.
- `retention`: for managing the retention of snapshot with a table optimizer.
- `orphan_file_deletion`: for managing the deletion of orphan files with a table optimizer.
- `configuration` – A [TableOptimizerConfiguration](#) object.

A `TableOptimizerConfiguration` object that was specified when creating or updating a table optimizer.

- `lastRun` – A [TableOptimizerRun](#) object.

A `TableOptimizerRun` object representing the last run of the table optimizer.

- `configurationSource` – UTF-8 string (valid values: `catalog="CATALOG" | table="TABLE"`).

Specifies the source of the optimizer configuration. This indicates how the table optimizer was configured and which entity or service initiated the configuration.

TableOptimizerConfiguration structure

Contains details on the configuration of a table optimizer. You pass this configuration when creating or updating a table optimizer.

Fields

- `roleArn` – UTF-8 string, not less than 20 or more than 2048 bytes long, matching the [Single-line string pattern](#).

A role passed by the caller which gives the service permission to update the resources associated with the optimizer on the caller's behalf.

- `enabled` – Boolean.

Whether table optimization is enabled.

- `vpcConfiguration` – A [TableOptimizerVpcConfiguration](#) object.

A `TableOptimizerVpcConfiguration` object representing the VPC configuration for a table optimizer.

This configuration is necessary to perform optimization on tables that are in a customer VPC.

- `compactionConfiguration` – A [CompactionConfiguration](#) object.

The configuration for a compaction optimizer. This configuration defines how data files in your table will be compacted to improve query performance and reduce storage costs.

- `retentionConfiguration` – A [RetentionConfiguration](#) object.

The configuration for a snapshot retention optimizer.

- `orphanFileDeletionConfiguration` – An [OrphanFileDeletionConfiguration](#) object.

The configuration for an orphan file deletion optimizer.

TableOptimizerVpcConfiguration structure

An object that describes the VPC configuration for a table optimizer.

This configuration is necessary to perform optimization on tables that are in a customer VPC.

Fields

- `glueConnectionName` – UTF-8 string, at least 1 byte long.

The name of the Amazon Glue connection used for the VPC for the table optimizer.

CompactionConfiguration structure

The configuration for a compaction optimizer. This configuration defines how data files in your table will be compacted to improve query performance and reduce storage costs.

Fields

- `icebergConfiguration` – An [IcebergCompactionConfiguration](#) object.

The configuration for an Iceberg compaction optimizer.

IcebergCompactionConfiguration structure

The configuration for an Iceberg compaction optimizer. This configuration defines parameters for optimizing the layout of data files in Iceberg tables.

Fields

- `strategy` – UTF-8 string (valid values: `binpack="BINPACK" | sort="SORT" | z-order="ZORDER"`).

The strategy to use for compaction. Valid values are:

- `binpack`: Combines small files into larger files, typically targeting sizes over 100MB, while applying any pending deletes. This is the recommended compaction strategy for most use cases.
- `sort`: Organizes data based on specified columns which are sorted hierarchically during compaction, improving query performance for filtered operations. This strategy is recommended when your queries frequently filter on specific columns. To use this strategy, you must first define a sort order in your Iceberg table properties using the `sort_order` table property.
- `z-order`: Optimizes data organization by blending multiple attributes into a single scalar value that can be used for sorting, allowing efficient querying across multiple dimensions. This strategy is recommended when you need to query data across multiple dimensions simultaneously. To use this strategy, you must first define a sort order in your Iceberg table properties using the `sort_order` table property.

If an input is not provided, the default value 'binpack' will be used.

- `minInputFiles` – Number (integer).

The minimum number of data files that must be present in a partition before compaction will actually compact files. This parameter helps control when compaction is triggered, preventing unnecessary compaction operations on partitions with few files. If an input is not provided, the default value 100 will be used.

- `deleteFileThreshold` – Number (integer).

The minimum number of deletes that must be present in a data file to make it eligible for compaction. This parameter helps optimize compaction by focusing on files that contain a significant number of delete operations, which can improve query performance by removing deleted records. If an input is not provided, the default value 1 will be used.

TableOptimizerRun structure

Contains details for a table optimizer run.

Fields

- `eventType` – UTF-8 string (valid values: `starting="STARTING"` | `completed="COMPLETED"` | `failed="FAILED"` | `in_progress="IN_PROGRESS"`).

An event type representing the status of the table optimizer run.

- `startTimestamp` – Timestamp.

Represents the epoch timestamp at which the compaction job was started within Lake Formation.

- `endTimestamp` – Timestamp.

Represents the epoch timestamp at which the compaction job ended.

- `metrics` – A [RunMetrics](#) object.

A `RunMetrics` object containing metrics for the optimizer run.

This member is deprecated. See the individual metric members for compaction, retention, and orphan file deletion.

- `error` – UTF-8 string.

An error that occurred during the optimizer run.

- `compactionMetrics` – A [CompactionMetrics](#) object.

A `CompactionMetrics` object containing metrics for the optimizer run.

- `compactionStrategy` – UTF-8 string (valid values: `binpack="BINPACK" | sort="SORT" | z-order="ZORDER"`).

The strategy used for the compaction run. Indicates which algorithm was applied to determine how files were selected and combined during the compaction process. Valid values are:

- `binpack`: Combines small files into larger files, typically targeting sizes over 100MB, while applying any pending deletes. This is the recommended compaction strategy for most use cases.
- `sort`: Organizes data based on specified columns which are sorted hierarchically during compaction, improving query performance for filtered operations. This strategy is recommended when your queries frequently filter on specific columns. To use this strategy, you must first define a sort order in your Iceberg table properties using the `sort_order` table property.
- `z-order`: Optimizes data organization by blending multiple attributes into a single scalar value that can be used for sorting, allowing efficient querying across multiple dimensions. This strategy is recommended when you need to query data across multiple dimensions

simultaneously. To use this strategy, you must first define a sort order in your Iceberg table properties using the `sort_order` table property.

- `retentionMetrics` – A [RetentionMetrics](#) object.

A `RetentionMetrics` object containing metrics for the optimizer run.

- `orphanFileDeletionMetrics` – An [OrphanFileDeletionMetrics](#) object.

An `OrphanFileDeletionMetrics` object containing metrics for the optimizer run.

BatchGetTableOptimizerEntry structure

Represents a table optimizer to retrieve in the `BatchGetTableOptimizer` operation.

Fields

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `databaseName` – UTF-8 string, at least 1 byte long.

The name of the database in the catalog in which the table resides.

- `tableName` – UTF-8 string, at least 1 byte long.

The name of the table.

- `type` – UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

BatchTableOptimizer structure

Contains details for one of the table optimizers returned by the `BatchGetTableOptimizer` operation.

Fields

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `databaseName` – UTF-8 string, at least 1 byte long.

The name of the database in the catalog in which the table resides.

- `tableName` – UTF-8 string, at least 1 byte long.

The name of the table.

- `tableOptimizer` – A [TableOptimizer](#) object.

A `TableOptimizer` object that contains details on the configuration and last run of a table optimizer.

BatchGetTableOptimizerError structure

Contains details on one of the errors in the error list returned by the `BatchGetTableOptimizer` operation.

Fields

- `error` – An [ErrorDetail](#) object.

An `ErrorDetail` object containing code and message details about the error.

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `databaseName` – UTF-8 string, at least 1 byte long.

The name of the database in the catalog in which the table resides.

- `tableName` – UTF-8 string, at least 1 byte long.

The name of the table.

- `type` – UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

RetentionConfiguration structure

The configuration for a snapshot retention optimizer.

Fields

- `icebergConfiguration` – An [IcebergRetentionConfiguration](#) object.

The configuration for an Iceberg snapshot retention optimizer.

IcebergRetentionConfiguration structure

The configuration for an Iceberg snapshot retention optimizer.

Fields

- `snapshotRetentionPeriodInDays` – Number (integer).

The number of days to retain the Iceberg snapshots. If an input is not provided, the corresponding Iceberg table configuration field will be used or if not present, the default value 5 will be used.

- `numberOfSnapshotsToRetain` – Number (integer).

The number of Iceberg snapshots to retain within the retention period. If an input is not provided, the corresponding Iceberg table configuration field will be used or if not present, the default value 1 will be used.

- `cleanExpiredFiles` – Boolean.

If set to false, snapshots are only deleted from table metadata, and the underlying data and metadata files are not deleted.

- `runRateInHours` – Number (integer).

The interval in hours between retention job runs. This parameter controls how frequently the retention optimizer will run to clean up expired snapshots. The value must be between 3 and 168 hours (7 days). If an input is not provided, the default value 24 will be used.

OrphanFileDeletionConfiguration structure

The configuration for an orphan file deletion optimizer.

Fields

- `icebergConfiguration` – An [IcebergOrphanFileDeletionConfiguration](#) object.

The configuration for an Iceberg orphan file deletion optimizer.

IcebergOrphanFileDeletionConfiguration structure

The configuration for an Iceberg orphan file deletion optimizer.

Fields

- `orphanFileRetentionPeriodInDays` – Number (integer).

The number of days that orphan files should be retained before file deletion. If an input is not provided, the default value 3 will be used.

- `location` – UTF-8 string.

Specifies a directory in which to look for files (defaults to the table's location). You may choose a sub-directory rather than the top-level table location.

- `runRateInHours` – Number (integer).

The interval in hours between orphan file deletion job runs. This parameter controls how frequently the orphan file deletion optimizer will run to clean up orphan files. The value must be between 3 and 168 hours (7 days). If an input is not provided, the default value 24 will be used.

CompactionMetrics structure

A structure that contains compaction metrics for the optimizer run.

Fields

- `IcebergMetrics` – An [IcebergCompactionMetrics](#) object.

A structure containing the Iceberg compaction metrics for the optimizer run.

RetentionMetrics structure

A structure that contains retention metrics for the optimizer run.

Fields

- `IcebergMetrics` – An [IcebergRetentionMetrics](#) object.

A structure containing the Iceberg retention metrics for the optimizer run.

OrphanFileDeletionMetrics structure

A structure that contains orphan file deletion metrics for the optimizer run.

Fields

- `IcebergMetrics` – An [IcebergOrphanFileDeletionMetrics](#) object.

A structure containing the Iceberg orphan file deletion metrics for the optimizer run.

IcebergCompactionMetrics structure

Compaction metrics for Iceberg for the optimizer run.

Fields

- `DpuHours` – Number (double).

The number of DPU hours consumed by the job.

- `NumberOfDpus` – Number (Integer).

The number of DPUs consumed by the job, rounded up to the nearest whole number.

- `JobDurationInHour` – Number (double).

The duration of the job in hours.

IcebergRetentionMetrics structure

Snapshot retention metrics for Iceberg for the optimizer run.

Fields

- `DpuHours` – Number (double).

The number of DPU hours consumed by the job.

- `NumberOfDpus` – Number (Integer).

The number of DPUs consumed by the job, rounded up to the nearest whole number.

- `JobDurationInHour` – Number (double).

The duration of the job in hours.

IcebergOrphanFileDeletionMetrics structure

Orphan file deletion metrics for Iceberg for the optimizer run.

Fields

- `DpuHours` – Number (double).

The number of DPU hours consumed by the job.

- `NumberOfDpus` – Number (Integer).

The number of DPUs consumed by the job, rounded up to the nearest whole number.

- `JobDurationInHour` – Number (double).

The duration of the job in hours.

RunMetrics structure

Metrics for the optimizer run.

This structure is deprecated. See the individual metric members for compaction, retention, and orphan file deletion.

Fields

- `NumberOfBytesCompacted` – UTF-8 string.

The number of bytes removed by the compaction job run.

- `NumberOfFilesCompacted` – UTF-8 string.

The number of files removed by the compaction job run.

- `NumberOfDpus` – UTF-8 string.

The number of DPUs consumed by the job, rounded up to the nearest whole number.

- `JobDurationInHour` – UTF-8 string.

The duration of the job in hours.

Operations

- [GetTableOptimizer action \(Python: `get_table_optimizer`\)](#)
- [BatchGetTableOptimizer action \(Python: `batch_get_table_optimizer`\)](#)
- [ListTableOptimizerRuns action \(Python: `list_table_optimizer_runs`\)](#)
- [CreateTableOptimizer action \(Python: `create_table_optimizer`\)](#)
- [DeleteTableOptimizer action \(Python: `delete_table_optimizer`\)](#)
- [UpdateTableOptimizer action \(Python: `update_table_optimizer`\)](#)

GetTableOptimizer action (Python: `get_table_optimizer`)

Returns the configuration of all optimizers associated with a specified table.

Request

- `CatalogId` – *Required:* Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `Type` – *Required:* UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

Response

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `TableOptimizer` – A [TableOptimizer](#) object.

The optimizer associated with the specified table.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `AccessDeniedException`
- `InternalServiceException`
- `ThrottlingException`

BatchGetTableOptimizer action (Python: `batch_get_table_optimizer`)

Returns the configuration for the specified table optimizers.

Request

- `Entries` – *Required*: An array of [BatchGetTableOptimizerEntry](#) objects.

A list of `BatchGetTableOptimizerEntry` objects specifying the table optimizers to retrieve.

Response

- `TableOptimizers` – An array of [BatchTableOptimizer](#) objects.

A list of `BatchTableOptimizer` objects.

- `Failures` – An array of [BatchGetTableOptimizerError](#) objects.

A list of errors from the operation.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `AccessDeniedException`
- `InternalServiceException`
- `ThrottlingException`

ListTableOptimizerRuns action (Python: `list_table_optimizer_runs`)

Lists the history of previous optimizer runs for a specific table.

Request

- `CatalogId` – *Required:* Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `Type` – *Required:* UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

- `MaxResults` – Number (integer).

The maximum number of optimizer runs to return on each call.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

Response

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `NextToken` – UTF-8 string.

A continuation token for paginating the returned list of optimizer runs, returned if the current segment of the list is not the last.

- `TableOptimizerRuns` – An array of [TableOptimizerRun](#) objects.

A list of the optimizer runs associated with a table.

Errors

- `EntityNotFoundException`
- `AccessDeniedException`
- `InvalidInputException`
- `ValidationException`

- `InternalServiceException`
- `ThrottlingException`

CreateTableOptimizer action (Python: `create_table_optimizer`)

Creates a new table optimizer for a specific function.

Request

- `CatalogId` – *Required:* Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `Type` – *Required:* UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

- `TableOptimizerConfiguration` – *Required:* A [TableOptimizerConfiguration](#) object.

A `TableOptimizerConfiguration` object representing the configuration of a table optimizer.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `ValidationException`

- `InvalidInputException`
- `AccessDeniedException`
- `AlreadyExistsException`
- `InternalServiceException`
- `ThrottlingException`

DeleteTableOptimizer action (Python: `delete_table_optimizer`)

Deletes an optimizer and all associated metadata for a table. The optimization will no longer be performed on the table.

Request

- `CatalogId` – *Required*: Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `Type` – *Required*: UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`

- `InvalidInputException`
- `AccessDeniedException`
- `InternalServiceException`
- `ThrottlingException`

UpdateTableOptimizer action (Python: `update_table_optimizer`)

Updates the configuration for an existing table optimizer.

Request

- `CatalogId` – *Required:* Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `Type` – *Required:* UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

- `TableOptimizerConfiguration` – *Required:* A [TableOptimizerConfiguration](#) object.

A `TableOptimizerConfiguration` object representing the configuration of a table optimizer.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `AccessDeniedException`
- `ValidationException`
- `InternalServiceException`
- `ThrottlingException`
- `ConcurrentModificationException`

Crawlers and classifiers API

The Crawler and classifiers API describes the Amazon Glue crawler and classifier data types, and includes the API for creating, deleting, updating, and listing crawlers or classifiers.

Topics

- [Classifier API](#)
- [Crawler API](#)
- [Column statistics API](#)
- [Crawler scheduler API](#)

Classifier API

The Classifier API describes Amazon Glue classifier data types, and includes the API for creating, deleting, updating, and listing classifiers.

Data types

- [Classifier structure](#)
- [GrokClassifier structure](#)
- [XMLClassifier structure](#)
- [JsonClassifier structure](#)
- [CsvClassifier structure](#)
- [CreateGrokClassifierRequest structure](#)

- [UpdateGrokClassifierRequest structure](#)
- [CreateXMLClassifierRequest structure](#)
- [UpdateXMLClassifierRequest structure](#)
- [CreateJsonClassifierRequest structure](#)
- [UpdateJsonClassifierRequest structure](#)
- [CreateCsvClassifierRequest structure](#)
- [UpdateCsvClassifierRequest structure](#)

Classifier structure

Classifiers are triggered during a crawl task. A classifier checks whether a given file is in a format it can handle. If it is, the classifier creates a schema in the form of a `StructType` object that matches that data format.

You can use the standard classifiers that Amazon Glue provides, or you can write your own classifiers to best categorize your data sources and specify the appropriate schemas to use for them. A classifier can be a grok classifier, an XML classifier, a JSON classifier, or a custom CSV classifier, as specified in one of the fields in the `Classifier` object.

Fields

- `GrokClassifier` – A [GrokClassifier](#) object.

A classifier that uses grok.

- `XMLClassifier` – A [XMLClassifier](#) object.

A classifier for XML content.

- `JsonClassifier` – A [JsonClassifier](#) object.

A classifier for JSON content.

- `CsvClassifier` – A [CsvClassifier](#) object.

A classifier for comma-separated values (CSV).

GrokClassifier structure

A classifier that uses grok patterns.

Fields

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- **Classification** – *Required*: UTF-8 string.

An identifier of the data format that the classifier matches, such as Twitter, JSON, Omniture logs, and so on.

- **CreationTime** – Timestamp.

The time that this classifier was registered.

- **LastUpdated** – Timestamp.

The time that this classifier was last updated.

- **Version** – Number (long).

The version of this classifier.

- **GrokPattern** – *Required*: UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [A Logstash Grok string pattern](#).

The grok pattern applied to a data store by this classifier. For more information, see built-in patterns in [Writing Custom Classifiers](#).

- **CustomPatterns** – UTF-8 string, not more than 16000 bytes long, matching the [URI address multi-line string pattern](#).

Optional custom grok patterns defined by this classifier. For more information, see custom patterns in [Writing Custom Classifiers](#).

XMLClassifier structure

A classifier for XML content.

Fields

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- **Classification** – *Required*: UTF-8 string.

An identifier of the data format that the classifier matches.

- **CreationTime** – Timestamp.

The time that this classifier was registered.

- **LastUpdated** – Timestamp.

The time that this classifier was last updated.

- **Version** – Number (long).

The version of this classifier.

- **RowTag** – UTF-8 string.

The XML tag designating the element that contains each record in an XML document being parsed. This can't identify a self-closing element (closed by `</>`). An empty row element that contains only attributes can be parsed as long as it ends with a closing tag (for example, `<row item_a="A" item_b="B"></row>` is okay, but `<row item_a="A" item_b="B" />` is not).

JsonClassifier structure

A classifier for JSON content.

Fields

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- **CreationTime** – Timestamp.

The time that this classifier was registered.

- **LastUpdated** – Timestamp.

The time that this classifier was last updated.

- **Version** – Number (long).

The version of this classifier.

- `JsonPath` – *Required*: UTF-8 string.

A `JsonPath` string defining the JSON data for the classifier to classify. Amazon Glue supports a subset of `JsonPath`, as described in [Writing JsonPath Custom Classifiers](#).

CsvClassifier structure

A classifier for custom CSV content.

Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `CreationTime` – Timestamp.

The time that this classifier was registered.

- `LastUpdated` – Timestamp.

The time that this classifier was last updated.

- `Version` – Number (long).

The version of this classifier.

- `Delimiter` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #26](#).

A custom symbol to denote what separates each column entry in the row.

- `QuoteSymbol` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #26](#).

A custom symbol to denote what combines content into a single column value. It must be different from the column delimiter.

- `ContainsHeader` – UTF-8 string (valid values: UNKNOWN | PRESENT | ABSENT).

Indicates whether the CSV file contains a header.

- `Header` – An array of UTF-8 strings.

A list of strings representing column names.

- `DisableValueTrimming` – Boolean.

Specifies not to trim values before identifying the type of column values. The default value is `true`.

- `AllowSingleColumn` – Boolean.

Enables the processing of files that contain only one column.

- `CustomDatatypeConfigured` – Boolean.

Enables the custom datatype to be configured.

- `CustomDatatypes` – An array of UTF-8 strings.

A list of custom datatypes including "BINARY", "BOOLEAN", "DATE", "DECIMAL", "DOUBLE", "FLOAT", "INT", "LONG", "SHORT", "STRING", "TIMESTAMP".

- `Serde` – UTF-8 string (valid values: `OpenCSVSerDe` | `LazySimpleSerDe` | `None`).

Sets the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Valid values are `OpenCSVSerDe`, `LazySimpleSerDe`, and `None`. You can specify the `None` value when you want the crawler to do the detection.

CreateGrokClassifierRequest structure

Specifies a grok classifier for `CreateClassifier` to create.

Fields

- `Classification` – *Required*: UTF-8 string.

An identifier of the data format that the classifier matches, such as Twitter, JSON, Omniture logs, Amazon CloudWatch Logs, and so on.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the new classifier.

- `GrokPattern` – *Required*: UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [A Logstash Grok string pattern](#).

The grok pattern used by this classifier.

- `CustomPatterns` – UTF-8 string, not more than 16000 bytes long, matching the [URI address multi-line string pattern](#).

Optional custom grok patterns used by this classifier.

UpdateGrokClassifierRequest structure

Specifies a grok classifier to update when passed to `UpdateClassifier`.

Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `GrokClassifier`.

- `Classification` – UTF-8 string.

An identifier of the data format that the classifier matches, such as Twitter, JSON, Omniture logs, Amazon CloudWatch Logs, and so on.

- `GrokPattern` – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Logstash Grok string pattern](#).

The grok pattern used by this classifier.

- `CustomPatterns` – UTF-8 string, not more than 16000 bytes long, matching the [URI address multi-line string pattern](#).

Optional custom grok patterns used by this classifier.

CreateXMLClassifierRequest structure

Specifies an XML classifier for `CreateClassifier` to create.

Fields

- `Classification` – *Required*: UTF-8 string.

An identifier of the data format that the classifier matches.

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- RowTag – UTF-8 string.

The XML tag designating the element that contains each record in an XML document being parsed. This can't identify a self-closing element (closed by `</>`). An empty row element that contains only attributes can be parsed as long as it ends with a closing tag (for example, `<row item_a="A" item_b="B"></row>` is okay, but `<row item_a="A" item_b="B" />` is not).

UpdateXMLClassifierRequest structure

Specifies an XML classifier to be updated.

Fields

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- Classification – UTF-8 string.

An identifier of the data format that the classifier matches.

- RowTag – UTF-8 string.

The XML tag designating the element that contains each record in an XML document being parsed. This cannot identify a self-closing element (closed by `</>`). An empty row element that contains only attributes can be parsed as long as it ends with a closing tag (for example, `<row item_a="A" item_b="B"></row>` is okay, but `<row item_a="A" item_b="B" />` is not).

CreateJsonClassifierRequest structure

Specifies a JSON classifier for `CreateClassifier` to create.

Fields

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `JsonPath` – *Required*: UTF-8 string.

A `JsonPath` string defining the JSON data for the classifier to classify. Amazon Glue supports a subset of `JsonPath`, as described in [Writing JsonPath Custom Classifiers](#).

UpdateJsonClassifierRequest structure

Specifies a JSON classifier to be updated.

Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `JsonPath` – UTF-8 string.

A `JsonPath` string defining the JSON data for the classifier to classify. Amazon Glue supports a subset of `JsonPath`, as described in [Writing JsonPath Custom Classifiers](#).

CreateCsvClassifierRequest structure

Specifies a custom CSV classifier for `CreateClassifier` to create.

Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `Delimiter` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #26](#).

A custom symbol to denote what separates each column entry in the row.

- `QuoteSymbol` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #26](#).

A custom symbol to denote what combines content into a single column value. Must be different from the column delimiter.

- `ContainsHeader` – UTF-8 string (valid values: UNKNOWN | PRESENT | ABSENT).

Indicates whether the CSV file contains a header.

- `Header` – An array of UTF-8 strings.

A list of strings representing column names.

- `DisableValueTrimming` – Boolean.

Specifies not to trim values before identifying the type of column values. The default value is true.

- `AllowSingleColumn` – Boolean.

Enables the processing of files that contain only one column.

- `CustomDatatypeConfigured` – Boolean.

Enables the configuration of custom datatypes.

- `CustomDatatypes` – An array of UTF-8 strings.

Creates a list of supported custom datatypes.

- `Serde` – UTF-8 string (valid values: OpenCSVSerDe | LazySimpleSerDe | None).

Sets the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Valid values are `OpenCSVSerDe`, `LazySimpleSerDe`, and `None`. You can specify the `None` value when you want the crawler to do the detection.

UpdateCsvClassifierRequest structure

Specifies a custom CSV classifier to be updated.

Fields

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `Delimiter` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #26](#).

A custom symbol to denote what separates each column entry in the row.

- `QuoteSymbol` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #26](#).

A custom symbol to denote what combines content into a single column value. It must be different from the column delimiter.

- `ContainsHeader` – UTF-8 string (valid values: UNKNOWN | PRESENT | ABSENT).

Indicates whether the CSV file contains a header.

- `Header` – An array of UTF-8 strings.

A list of strings representing column names.

- `DisableValueTrimming` – Boolean.

Specifies not to trim values before identifying the type of column values. The default value is true.

- `AllowSingleColumn` – Boolean.

Enables the processing of files that contain only one column.

- `CustomDatatypeConfigured` – Boolean.

Specifies the configuration of custom datatypes.

- `CustomDatatypes` – An array of UTF-8 strings.

Specifies a list of supported custom datatypes.

- `Serde` – UTF-8 string (valid values: OpenCSVSerDe | LazySimpleSerDe | None).

Sets the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Valid values are `OpenCSVSerDe`, `LazySimpleSerDe`, and `None`. You can specify the `None` value when you want the crawler to do the detection.

Operations

- [CreateClassifier action \(Python: `create_classifier`\)](#)

- [DeleteClassifier action \(Python: delete_classifier\)](#)
- [GetClassifier action \(Python: get_classifier\)](#)
- [GetClassifiers action \(Python: get_classifiers\)](#)
- [UpdateClassifier action \(Python: update_classifier\)](#)

CreateClassifier action (Python: create_classifier)

Creates a classifier in the user's account. This can be a `GrokClassifier`, an `XMLClassifier`, a `JsonClassifier`, or a `CsvClassifier`, depending on which field of the request is present.

Request

- `GrokClassifier` – A [CreateGrokClassifierRequest](#) object.
A `GrokClassifier` object specifying the classifier to create.
- `XMLClassifier` – A [CreateXMLClassifierRequest](#) object.
An `XMLClassifier` object specifying the classifier to create.
- `JsonClassifier` – A [CreateJsonClassifierRequest](#) object.
A `JsonClassifier` object specifying the classifier to create.
- `CsvClassifier` – A [CreateCsvClassifierRequest](#) object.
A `CsvClassifier` object specifying the classifier to create.

Response

- *No Response parameters.*

Errors

- `AlreadyExistsException`
- `InvalidInputException`
- `OperationTimeoutException`

DeleteClassifier action (Python: delete_classifier)

Removes a classifier from the Data Catalog.

Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the classifier to remove.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- OperationTimeoutException

GetClassifier action (Python: get_classifier)

Retrieve a classifier by name.

Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the classifier to retrieve.

Response

- Classifier – A [Classifier](#) object.

The requested classifier.

Errors

- `EntityNotFoundException`
- `OperationTimeoutException`

GetClassifiers action (Python: `get_classifiers`)

Lists all classifier objects in the Data Catalog.

Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The size of the list to return (optional).

- `NextToken` – UTF-8 string.

An optional continuation token.

Response

- `Classifiers` – An array of [Classifier](#) objects.

The requested list of classifier objects.

- `NextToken` – UTF-8 string.

A continuation token.

Errors

- `OperationTimeoutException`

UpdateClassifier action (Python: `update_classifier`)

Modifies an existing classifier (a `GrokClassifier`, an `XMLClassifier`, a `JsonClassifier`, or a `CsvClassifier`, depending on which field is present).

Request

- `GrokClassifier` – An [UpdateGrokClassifierRequest](#) object.

A GrokClassifier object with updated fields.

- XMLClassifier – An [UpdateXMLClassifierRequest](#) object.

An XMLClassifier object with updated fields.

- JsonClassifier – An [UpdateJsonClassifierRequest](#) object.

A JsonClassifier object with updated fields.

- CsvClassifier – An [UpdateCsvClassifierRequest](#) object.

A CsvClassifier object with updated fields.

Response

- *No Response parameters.*

Errors

- InvalidInputException
- VersionMismatchException
- EntityNotFoundException
- OperationTimeoutException

Crawler API

The Crawler API describes Amazon Glue crawler data types, along with the API for creating, deleting, updating, and listing crawlers.

Data types

- [Crawler structure](#)
- [Schedule structure](#)
- [CrawlerTargets structure](#)
- [S3Target structure](#)
- [S3DeltaCatalogTarget structure](#)
- [S3DeltaDirectTarget structure](#)

- [JdbcTarget structure](#)
- [MongoDBTarget structure](#)
- [DynamoDBTarget structure](#)
- [DeltaTarget structure](#)
- [IcebergTarget structure](#)
- [HudiTarget structure](#)
- [CatalogTarget structure](#)
- [CrawlerMetrics structure](#)
- [CrawlerHistory structure](#)
- [CrawlsFilter structure](#)
- [SchemaChangePolicy structure](#)
- [LastCrawlInfo structure](#)
- [RecrawlPolicy structure](#)
- [LineageConfiguration structure](#)
- [LakeFormationConfiguration structure](#)

Crawler structure

Specifies a crawler program that examines a data source and uses classifiers to try to determine its schema. If successful, the crawler records metadata concerning the data source in the Amazon Glue Data Catalog.

Fields

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler.

- **Role** – UTF-8 string.

The Amazon Resource Name (ARN) of an IAM role that's used to access customer resources, such as Amazon Simple Storage Service (Amazon S3) data.

- **Targets** – A [CrawlerTargets](#) object.

A collection of targets to crawl.

- `DatabaseName` – UTF-8 string.

The name of the database in which the crawler's output is stored.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the crawler.

- `Classifiers` – An array of UTF-8 strings.

A list of UTF-8 strings that specify the custom classifiers that are associated with the crawler.

- `RecrawlPolicy` – A [RecrawlPolicy](#) object.

A policy that specifies whether to crawl the entire dataset again, or to crawl only folders that were added since the last crawler run.

- `SchemaChangePolicy` – A [SchemaChangePolicy](#) object.

The policy that specifies update and delete behaviors for the crawler.

- `LineageConfiguration` – A [LineageConfiguration](#) object.

A configuration that specifies whether data lineage is enabled for the crawler.

- `State` – UTF-8 string (valid values: READY | RUNNING | STOPPING).

Indicates whether the crawler is running, or whether a run is pending.

- `TablePrefix` – UTF-8 string, not more than 128 bytes long.

The prefix added to the names of tables that are created.

- `Schedule` – A [Schedule](#) object.

For scheduled crawlers, the schedule when the crawler runs.

- `CrawlElapsedTime` – Number (long).

If the crawler is running, contains the total time elapsed since the last crawl began.

- `CreationTime` – Timestamp.

The time that the crawler was created.

- `LastUpdated` – Timestamp.

The time that the crawler was last updated.

- `LastCrawl` – A [LastCrawlInfo](#) object.

The status of the last crawl, and potentially error information if an error occurred.

- `Version` – Number (long).

The version of the crawler.

- `Configuration` – UTF-8 string.

Crawler configuration information. This versioned JSON string allows users to specify aspects of a crawler's behavior. For more information, see [Setting crawler configuration options](#).

- `CrawlerSecurityConfiguration` – UTF-8 string, not more than 128 bytes long.

The name of the `SecurityConfiguration` structure to be used by this crawler.

- `LakeFormationConfiguration` – A [LakeFormationConfiguration](#) object.

Specifies whether the crawler should use Amazon Lake Formation credentials for the crawler instead of the IAM role credentials.

Schedule structure

A scheduling object using a cron statement to schedule an event.

Fields

- `ScheduleExpression` – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- `State` – UTF-8 string (valid values: SCHEDULED | NOT_SCHEDULED | TRANSITIONING).

The state of the schedule.

CrawlerTargets structure

Specifies data stores to crawl.

Fields

- **S3Targets** – An array of [S3Target](#) objects.
Specifies Amazon Simple Storage Service (Amazon S3) targets.
- **JdbcTargets** – An array of [JdbcTarget](#) objects.
Specifies JDBC targets.
- **MongoDBTargets** – An array of [MongoDBTarget](#) objects.
Specifies Amazon DocumentDB or MongoDB targets.
- **DynamoDBTargets** – An array of [DynamoDBTarget](#) objects.
Specifies Amazon DynamoDB targets.
- **CatalogTargets** – An array of [CatalogTarget](#) objects.
Specifies Amazon Glue Data Catalog targets.
- **DeltaTargets** – An array of [DeltaTarget](#) objects.
Specifies Delta data store targets.
- **IcebergTargets** – An array of [IcebergTarget](#) objects.
Specifies Apache Iceberg data store targets.
- **HudiTargets** – An array of [HudiTarget](#) objects.
Specifies Apache Hudi data store targets.

S3Target structure

Specifies a data store in Amazon Simple Storage Service (Amazon S3).

Fields

- **Path** – UTF-8 string.
The path to the Amazon S3 target.
- **Exclusions** – An array of UTF-8 strings.

A list of glob patterns used to exclude from the crawl. For more information, see [Catalog Tables with a Crawler](#).

- `ConnectionName` – UTF-8 string, not less than 1 or more than 2048 bytes long.

The name of a connection which allows a job or crawler to access data in Amazon S3 within an Amazon Virtual Private Cloud environment (Amazon VPC).

- `SampleSize` – Number (integer).

Sets the number of files in each leaf folder to be crawled when crawling sample files in a dataset. If not set, all the files are crawled. A valid value is an integer between 1 and 249.

- `EventQueueArn` – UTF-8 string.

A valid Amazon SQS ARN. For example, `arn:aws:sqs:region:account:sqs`.

- `DlqEventQueueArn` – UTF-8 string.

A valid Amazon dead-letter SQS ARN. For example, `arn:aws:sqs:region:account:deadLetterQueue`.

S3DeltaCatalogTarget structure

Specifies a target that writes to a Delta Lake data source in the Amazon Glue Data Catalog.

Fields

- `Name` – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- `Inputs` – *Required*: An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `PartitionKeys` – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- `Table` – *Required*: UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

- `Database` – *Required*: UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options for the connector.

- `SchemaChangePolicy` – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

- `AutoDataQuality` – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 Delta catalog target. When set to `true`, data quality checks are performed automatically during the write operation.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 Delta catalog target.

S3DeltaDirectTarget structure

Specifies a target that writes to a Delta Lake data source in Amazon S3.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `PartitionKeys` – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- `Path` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon S3 path of your Delta Lake data source to write to.

- **Compression** – *Required*: UTF-8 string (valid values: `uncompressed="UNCOMPRESSED" | snappy="SNAPPY"`).

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **NumberTargetPartitions** – UTF-8 string.

Specifies the number of target partitions for distributing Delta Lake dataset files across Amazon S3.

- **Format** – *Required*: UTF-8 string (valid values: `json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA" | iceberg="ICEBERG" | hyper="HYPER" | xml="XML"`).

Specifies the data output format for the target.

- **AdditionalOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options for the connector.

- **SchemaChangePolicy** – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

- **AutoDataQuality** – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 Delta direct target. When set to `true`, data quality checks are performed automatically during the write operation.

JdbcTarget structure

Specifies a JDBC data store to crawl.

Fields

- **ConnectionName** – UTF-8 string, not less than 1 or more than 2048 bytes long.

The name of the connection to use to connect to the JDBC target.

- **Path** – UTF-8 string.

The path of the JDBC target.

- `Exclusions` – An array of UTF-8 strings.

A list of glob patterns used to exclude from the crawl. For more information, see [Catalog Tables with a Crawler](#).

- `EnableAdditionalMetadata` – An array of UTF-8 strings.

Specify a value of `RAWTYPES` or `COMMENTS` to enable additional metadata in table responses. `RAWTYPES` provides the native-level datatype. `COMMENTS` provides comments associated with a column or table in the database.

If you do not need additional metadata, keep the field empty.

MongoDBTarget structure

Specifies an Amazon DocumentDB or MongoDB data store to crawl.

Fields

- `ConnectionName` – UTF-8 string, not less than 1 or more than 2048 bytes long.

The name of the connection to use to connect to the Amazon DocumentDB or MongoDB target.

- `Path` – UTF-8 string.

The path of the Amazon DocumentDB or MongoDB target (database/collection).

- `ScanAll` – Boolean.

Indicates whether to scan all the records, or to sample rows from the table. Scanning all the records can take a long time when the table is not a high throughput table.

A value of `true` means to scan all records, while a value of `false` means to sample the records. If no value is specified, the value defaults to `true`.

DynamoDBTarget structure

Specifies an Amazon DynamoDB table to crawl.

Fields

- `Path` – UTF-8 string.

The name of the DynamoDB table to crawl.

- `scanAll` – Boolean.

Indicates whether to scan all the records, or to sample rows from the table. Scanning all the records can take a long time when the table is not a high throughput table.

A value of `true` means to scan all records, while a value of `false` means to sample the records. If no value is specified, the value defaults to `true`.

- `scanRate` – Number (double).

The percentage of the configured read capacity units to use by the Amazon Glue crawler. Read capacity units is a term defined by DynamoDB, and is a numeric value that acts as rate limiter for the number of reads that can be performed on that table per second.

The valid values are null or a value between 0.1 to 1.5. A null value is used when user does not provide a value, and defaults to 0.5 of the configured Read Capacity Unit (for provisioned tables), or 0.25 of the max configured Read Capacity Unit (for tables using on-demand mode).

DeltaTarget structure

Specifies a Delta data store to crawl one or more Delta tables.

Fields

- `DeltaTables` – An array of UTF-8 strings.

A list of the Amazon S3 paths to the Delta tables.

- `ConnectionName` – UTF-8 string, not less than 1 or more than 2048 bytes long.

The name of the connection to use to connect to the Delta table target.

- `WriteManifest` – Boolean.

Specifies whether to write the manifest files to the Delta table path.

- `CreateNativeDeltaTable` – Boolean.

Specifies whether the crawler will create native tables, to allow integration with query engines that support querying of the Delta transaction log directly.

IcebergTarget structure

Specifies an Apache Iceberg data source where Iceberg tables are stored in Amazon S3.

Fields

- **Paths** – An array of UTF-8 strings.

One or more Amazon S3 paths that contains Iceberg metadata folders as `s3://bucket/prefix`.

- **ConnectionName** – UTF-8 string, not less than 1 or more than 2048 bytes long.

The name of the connection to use to connect to the Iceberg target.

- **Exclusions** – An array of UTF-8 strings.

A list of glob patterns used to exclude from the crawl. For more information, see [Catalog Tables with a Crawler](#).

- **MaximumTraversalDepth** – Number (integer).

The maximum depth of Amazon S3 paths that the crawler can traverse to discover the Iceberg metadata folder in your Amazon S3 path. Used to limit the crawler run time.

HudiTarget structure

Specifies an Apache Hudi data source.

Fields

- **Paths** – An array of UTF-8 strings.

An array of Amazon S3 location strings for Hudi, each indicating the root folder with which the metadata files for a Hudi table resides. The Hudi folder may be located in a child folder of the root folder.

The crawler will scan all folders underneath a path for a Hudi folder.

- **ConnectionName** – UTF-8 string, not less than 1 or more than 2048 bytes long.

The name of the connection to use to connect to the Hudi target. If your Hudi files are stored in buckets that require VPC authorization, you can set their connection properties here.

- **Exclusions** – An array of UTF-8 strings.

A list of glob patterns used to exclude from the crawl. For more information, see [Catalog Tables with a Crawler](#).

- **MaximumTraversalDepth** – Number (integer).

The maximum depth of Amazon S3 paths that the crawler can traverse to discover the Hudi metadata folder in your Amazon S3 path. Used to limit the crawler run time.

CatalogTarget structure

Specifies an Amazon Glue Data Catalog target.

Fields

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database to be synchronized.

- **Tables** – *Required:* An array of UTF-8 strings, at least 1 string.

A list of the tables to be synchronized.

- **ConnectionName** – UTF-8 string, not less than 1 or more than 2048 bytes long.

The name of the connection for an Amazon S3-backed Data Catalog table to be a target of the crawl when using a Catalog connection type paired with a NETWORK Connection type.

- **EventQueueArn** – UTF-8 string.

A valid Amazon SQS ARN. For example, `arn:aws:sqs:region:account:sqs`.

- **DLqEventQueueArn** – UTF-8 string.

A valid Amazon dead-letter SQS ARN. For example, `arn:aws:sqs:region:account:deadLetterQueue`.

CrawlerMetrics structure

Metrics for a specified crawler.

Fields

- `CrawlerName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler.

- `TimeLeftSeconds` – Number (double), not more than None.

The estimated time left to complete a running crawl.

- `StillEstimating` – Boolean.

True if the crawler is still estimating how long it will take to complete this run.

- `LastRuntimeSeconds` – Number (double), not more than None.

The duration of the crawler's most recent run, in seconds.

- `MedianRuntimeSeconds` – Number (double), not more than None.

The median duration of this crawler's runs, in seconds.

- `TablesCreated` – Number (integer), not more than None.

The number of tables created by this crawler.

- `TablesUpdated` – Number (integer), not more than None.

The number of tables updated by this crawler.

- `TablesDeleted` – Number (integer), not more than None.

The number of tables deleted by this crawler.

CrawlerHistory structure

Contains the information for a run of a crawler.

Fields

- `CrawlId` – UTF-8 string.

A UUID identifier for each crawl.

- State – UTF-8 string (valid values: RUNNING | COMPLETED | FAILED | STOPPED).

The state of the crawl.

- StartTime – Timestamp.

The date and time on which the crawl started.

- EndTime – Timestamp.

The date and time on which the crawl ended.

- Summary – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A run summary for the specific crawl in JSON. Contains the catalog tables and partitions that were added, updated, or deleted.

- ErrorMessage – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

If an error occurred, the error message associated with the crawl.

- LogGroup – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log group string pattern](#).

The log group associated with the crawl.

- LogStream – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log-stream string pattern](#).

The log stream associated with the crawl.

- MessagePrefix – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The prefix for a CloudWatch message about this crawl.

- DPUHour – Number (double), not more than None.

The number of data processing units (DPU) used in hours for the crawl.

CrawlsFilter structure

A list of fields, comparators and value that you can use to filter the crawler runs for a specified crawler.

Fields

- **FieldName** – UTF-8 string (valid values: CRAWL_ID | STATE | START_TIME | END_TIME | DPU_HOUR).

A key used to filter the crawler runs for a specified crawler. Valid values for each of the field names are:

- **CRAWL_ID**: A string representing the UUID identifier for a crawl.
- **STATE**: A string representing the state of the crawl.
- **START_TIME** and **END_TIME**: The epoch timestamp in milliseconds.
- **DPU_HOUR**: The number of data processing unit (DPU) hours used for the crawl.
- **FilterOperator** – UTF-8 string (valid values: GT | GE | LT | LE | EQ | NE).

A defined comparator that operates on the value. The available operators are:

- **GT**: Greater than.
- **GE**: Greater than or equal to.
- **LT**: Less than.
- **LE**: Less than or equal to.
- **EQ**: Equal to.
- **NE**: Not equal to.
- **FieldValue** – UTF-8 string.

The value provided for comparison on the crawl field.

SchemaChangePolicy structure

A policy that specifies update and deletion behaviors for the crawler.

Fields

- **UpdateBehavior** – UTF-8 string (valid values: LOG | UPDATE_IN_DATABASE).

The update behavior when the crawler finds a changed schema.

- `DeleteBehavior` – UTF-8 string (valid values: LOG | DELETE_FROM_DATABASE | DEPRECATE_IN_DATABASE).

The deletion behavior when the crawler finds a deleted object.

LastCrawlInfo structure

Status and error information about the most recent crawl.

Fields

- `Status` – UTF-8 string (valid values: SUCCEEDED | CANCELLED | FAILED).

Status of the last crawl.

- `ErrorMessage` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

If an error occurred, the error information about the last crawl.

- `LogGroup` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log group string pattern](#).

The log group for the last crawl.

- `LogStream` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log-stream string pattern](#).

The log stream for the last crawl.

- `MessagePrefix` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The prefix for a message about this crawl.

- `StartTime` – Timestamp.

The time at which the crawl started.

RecrawlPolicy structure

When crawling an Amazon S3 data source after the first crawl is complete, specifies whether to crawl the entire dataset again or to crawl only folders that were added since the last crawler run. For more information, see [Incremental Crawls in Amazon Glue](#) in the developer guide.

Fields

- `RecrawlBehavior` – UTF-8 string (valid values: `CRAWL_EVERYTHING` | `CRAWL_NEW_FOLDERS_ONLY` | `CRAWL_EVENT_MODE`).

Specifies whether to crawl the entire dataset again or to crawl only folders that were added since the last crawler run.

A value of `CRAWL_EVERYTHING` specifies crawling the entire dataset again.

A value of `CRAWL_NEW_FOLDERS_ONLY` specifies crawling only folders that were added since the last crawler run.

A value of `CRAWL_EVENT_MODE` specifies crawling only the changes identified by Amazon S3 events.

LineageConfiguration structure

Specifies data lineage configuration settings for the crawler.

Fields

- `CrawlerLineageSettings` – UTF-8 string (valid values: `ENABLE` | `DISABLE`).

Specifies whether data lineage is enabled for the crawler. Valid values are:

- `ENABLE`: enables data lineage for the crawler
- `DISABLE`: disables data lineage for the crawler

LakeFormationConfiguration structure

Specifies Amazon Lake Formation configuration settings for the crawler.

Fields

- `UseLakeFormationCredentials` – Boolean.

Specifies whether to use Amazon Lake Formation credentials for the crawler instead of the IAM role credentials.

- `AccountId` – UTF-8 string, not more than 12 bytes long.

Required for cross account crawls. For same account crawls as the target data, this can be left as null.

Operations

- [CreateCrawler action \(Python: `create_crawler`\)](#)
- [DeleteCrawler action \(Python: `delete_crawler`\)](#)
- [GetCrawler action \(Python: `get_crawler`\)](#)
- [GetCrawlers action \(Python: `get_crawlers`\)](#)
- [GetCrawlerMetrics action \(Python: `get_crawler_metrics`\)](#)
- [UpdateCrawler action \(Python: `update_crawler`\)](#)
- [StartCrawler action \(Python: `start_crawler`\)](#)
- [StopCrawler action \(Python: `stop_crawler`\)](#)
- [BatchGetCrawlers action \(Python: `batch_get_crawlers`\)](#)
- [ListCrawlers action \(Python: `list_crawlers`\)](#)
- [ListCrawls action \(Python: `list_crawls`\)](#)

CreateCrawler action (Python: `create_crawler`)

Creates a new crawler with specified targets, role, configuration, and optional schedule. At least one crawl target must be specified, in the `s3Targets` field, the `jdbcTargets` field, or the `DynamoDBTargets` field.

Request

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the new crawler.

- Role – *Required*: UTF-8 string.

The IAM role or Amazon Resource Name (ARN) of an IAM role used by the new crawler to access customer resources.

- DatabaseName – UTF-8 string.

The Amazon Glue database where results are written, such as: `arn:aws:daylight:us-east-1::database/sometable/*`.

- Description – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the new crawler.

- Targets – *Required*: A [CrawlerTargets](#) object.

A list of collection of targets to crawl.

- Schedule – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- Classifiers – An array of UTF-8 strings.

A list of custom classifiers that the user has registered. By default, all built-in classifiers are included in a crawl, but these custom classifiers always override the default classifiers for a given classification.

- TablePrefix – UTF-8 string, not more than 128 bytes long.

The table prefix used for catalog tables that are created.

- SchemaChangePolicy – A [SchemaChangePolicy](#) object.

The policy for the crawler's update and deletion behavior.

- RecrawlPolicy – A [RecrawlPolicy](#) object.

A policy that specifies whether to crawl the entire dataset again, or to crawl only folders that were added since the last crawler run.

- LineageConfiguration – A [LineageConfiguration](#) object.

Specifies data lineage configuration settings for the crawler.

- `LakeFormationConfiguration` – A [LakeFormationConfiguration](#) object.

Specifies Amazon Lake Formation configuration settings for the crawler.

- `Configuration` – UTF-8 string.

Crawler configuration information. This versioned JSON string allows users to specify aspects of a crawler's behavior. For more information, see [Setting crawler configuration options](#).

- `CrawlerSecurityConfiguration` – UTF-8 string, not more than 128 bytes long.

The name of the `SecurityConfiguration` structure to be used by this crawler.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to use with this crawler request. You may use tags to limit access to the crawler. For more information about tags in Amazon Glue, see [Amazon Tags in Amazon Glue](#) in the developer guide.

Response

- *No Response parameters.*

Errors

- `InvalidInputException`
- `AlreadyExistsException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`

DeleteCrawler action (Python: `delete_crawler`)

Removes a specified crawler from the Amazon Glue Data Catalog, unless the crawler state is `RUNNING`.

Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler to remove.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- CrawlerRunningException
- SchedulerTransitioningException
- OperationTimeoutException

GetCrawler action (Python: `get_crawler`)

Retrieves metadata for a specified crawler.

Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler to retrieve metadata for.

Response

- Crawler – A [Crawler](#) object.

The metadata for the specified crawler.

Errors

- EntityNotFoundException

- `OperationTimeoutException`

GetCrawlers action (Python: `get_crawlers`)

Retrieves metadata for all crawlers defined in the customer account.

Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The number of crawlers to return on each call.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

Response

- `Crawlers` – An array of [Crawler](#) objects.

A list of crawler metadata.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list has not reached the end of those defined in this customer account.

Errors

- `OperationTimeoutException`

GetCrawlerMetrics action (Python: `get_crawler_metrics`)

Retrieves metrics about specified crawlers.

Request

- `CrawlerNameList` – An array of UTF-8 strings, not more than 100 strings.

A list of the names of crawlers about which to retrieve metrics.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

- NextToken – UTF-8 string.

A continuation token, if this is a continuation call.

Response

- CrawlerMetricsList – An array of [CrawlerMetrics](#) objects.

A list of metrics for the specified crawler.

- NextToken – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

Errors

- OperationTimeoutException

UpdateCrawler action (Python: update_crawler)

Updates a crawler. If a crawler is running, you must stop it using StopCrawler before updating it.

Request

- Name – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the new crawler.

- Role – UTF-8 string.

The IAM role or Amazon Resource Name (ARN) of an IAM role that is used by the new crawler to access customer resources.

- DatabaseName – UTF-8 string.

The Amazon Glue database where results are stored, such as: arn:aws:daylight:us-east-1::database/sometable/*.

- **Description** – UTF-8 string, not more than 2048 bytes long, matching the [URI address multiline string pattern](#).

A description of the new crawler.

- **Targets** – A [CrawlerTargets](#) object.

A list of targets to crawl.

- **Schedule** – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- **Classifiers** – An array of UTF-8 strings.

A list of custom classifiers that the user has registered. By default, all built-in classifiers are included in a crawl, but these custom classifiers always override the default classifiers for a given classification.

- **TablePrefix** – UTF-8 string, not more than 128 bytes long.

The table prefix used for catalog tables that are created.

- **SchemaChangePolicy** – A [SchemaChangePolicy](#) object.

The policy for the crawler's update and deletion behavior.

- **RecrawlPolicy** – A [RecrawlPolicy](#) object.

A policy that specifies whether to crawl the entire dataset again, or to crawl only folders that were added since the last crawler run.

- **LineageConfiguration** – A [LineageConfiguration](#) object.

Specifies data lineage configuration settings for the crawler.

- **LakeFormationConfiguration** – A [LakeFormationConfiguration](#) object.

Specifies Amazon Lake Formation configuration settings for the crawler.

- **Configuration** – UTF-8 string.

Crawler configuration information. This versioned JSON string allows users to specify aspects of a crawler's behavior. For more information, see [Setting crawler configuration options](#).

- **CrawlerSecurityConfiguration** – UTF-8 string, not more than 128 bytes long.

The name of the `SecurityConfiguration` structure to be used by this crawler.

Response

- *No Response parameters.*

Errors

- `InvalidInputException`
- `VersionMismatchException`
- `EntityNotFoundException`
- `CrawlerRunningException`
- `OperationTimeoutException`

StartCrawler action (Python: `start_crawler`)

Starts a crawl using the specified crawler, regardless of what is scheduled. If the crawler is already running, returns a [CrawlerRunningException](#).

Request

- Name – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the crawler to start.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `CrawlerRunningException`
- `OperationTimeoutException`

StopCrawler action (Python: stop_crawler)

If the specified crawler is running, stops the crawl.

Request

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the crawler to stop.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- CrawlerNotRunningException
- CrawlerStoppingException
- OperationTimeoutException

BatchGetCrawlers action (Python: batch_get_crawlers)

Returns a list of resource metadata for a given list of crawler names. After calling the `ListCrawlers` operation, you can call this operation to access the data to which you have been granted permissions. This operation supports all IAM permissions, including permission conditions that uses tags.

Request

- **CrawlerNames** – *Required*: An array of UTF-8 strings, not more than 100 strings.

A list of crawler names, which might be the names returned from the `ListCrawlers` operation.

Response

- **Crawlers** – An array of [Crawler](#) objects.

A list of crawler definitions.

- `CrawlersNotFound` – An array of UTF-8 strings, not more than 100 strings.

A list of names of crawlers that were not found.

Errors

- `InvalidInputException`
- `OperationTimeoutException`

ListCrawlers action (Python: `list_crawlers`)

Retrieves the names of all crawler resources in this Amazon account, or the resources with the specified tag. This operation allows you to see which resources are available in your account, and their names.

This operation takes the optional `Tags` field, which you can use as a filter on the response so that tagged resources can be retrieved as a group. If you choose to use tags filtering, only resources with the tag are retrieved.

Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Specifies to return only these tagged resources.

Response

- `CrawlerNames` – An array of UTF-8 strings, not more than 100 strings.

The names of all crawlers in the account, or the crawlers with the specified tags.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

Errors

- `OperationTimeoutException`

ListCrawls action (Python: `list_crawls`)

Returns all the crawls of a specified crawler. Returns only the crawls that have occurred since the launch date of the crawler history feature, and only retains up to 12 months of crawls. Older crawls will not be returned.

You may use this API to:

- Retrieve all the crawls of a specified crawler.
- Retrieve all the crawls of a specified crawler within a limited count.
- Retrieve all the crawls of a specified crawler in a specific time range.
- Retrieve all the crawls of a specified crawler with a particular state, crawl ID, or DPU hour value.

Request

- `CrawlerName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler whose runs you want to retrieve.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return. The default is 20, and maximum is 100.

- `Filters` – An array of [CrawlsFilter](#) objects.

Filters the crawls by the criteria you specify in a list of `CrawlsFilter` objects.

- NextToken – UTF-8 string.

A continuation token, if this is a continuation call.

Response

- Crawls – An array of [CrawlerHistory](#) objects.

A list of CrawlerHistory objects representing the crawl runs that meet your criteria.

- NextToken – UTF-8 string.

A continuation token for paginating the returned list of tokens, returned if the current segment of the list is not the last.

Errors

- EntityNotFoundException
- OperationTimeoutException
- InvalidInputException

Column statistics API

The column statistics API describes Amazon Glue APIs for returning statistics on columns in a table.

Data types

- [ColumnStatisticsTaskRun structure](#)
- [ColumnStatisticsTaskSettings structure](#)
- [ExecutionAttempt structure](#)

ColumnStatisticsTaskRun structure

The object that shows the details of the column stats run.

Fields

- CustomerId – UTF-8 string, not more than 12 bytes long.

The Amazon account ID.

- `ColumnStatisticsTaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The identifier for the particular column statistics task run.

- `DatabaseName` – UTF-8 string.

The database where the table resides.

- `TableName` – UTF-8 string.

The name of the table for which column statistics is generated.

- `ColumnNameList` – An array of UTF-8 strings.

A list of the column names. If none is supplied, all column names for the table will be used by default.

- `CatalogID` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is supplied, the Amazon account ID is used by default.

- `Role` – UTF-8 string.

The IAM role that the service assumes to generate statistics.

- `SampleSize` – Number (double), not more than 100.

The percentage of rows used to generate statistics. If none is supplied, the entire table will be used to generate stats.

- `SecurityConfiguration` – UTF-8 string, not more than 128 bytes long.

Name of the security configuration that is used to encrypt CloudWatch logs for the column stats task run.

- `NumberOfWorkers` – Number (integer), at least 1.

The number of workers used to generate column statistics. The job is preconfigured to autoscale up to 25 instances.

- `WorkerType` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The type of workers being used for generating stats. The default is `g.1x`.

- `ComputationType` – UTF-8 string (valid values: `FULL` | `INCREMENTAL`).

The type of column statistics computation.

- `Status` – UTF-8 string (valid values: `STARTING` | `RUNNING` | `SUCCEEDED` | `FAILED` | `STOPPED`).

The status of the task run.

- `CreationTime` – Timestamp.

The time that this task was created.

- `LastUpdated` – Timestamp.

The last point in time when this task was modified.

- `StartTime` – Timestamp.

The start time of the task.

- `EndTime` – Timestamp.

The end time of the task.

- `ErrorMessage` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The error message for the job.

- `DPUSeconds` – Number (double), not more than None.

The calculated DPU usage in seconds for all autoscaled workers.

ColumnStatisticsTaskSettings structure

The settings for a column statistics task.

Fields

- `DatabaseName` – UTF-8 string.

The name of the database where the table resides.

- `TableName` – UTF-8 string.

The name of the table for which to generate column statistics.

- `Schedule` – A [Schedule](#) object.

A schedule for running the column statistics, specified in CRON syntax.

- `ColumnNameList` – An array of UTF-8 strings.

A list of column names for which to run statistics.

- `CatalogID` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides.

- `Role` – UTF-8 string.

The role used for running the column statistics.

- `SampleSize` – Number (double), not more than 100.

The percentage of data to sample.

- `SecurityConfiguration` – UTF-8 string, not more than 128 bytes long.

Name of the security configuration that is used to encrypt CloudWatch logs.

- `ScheduleType` – UTF-8 string (valid values: CRON | AUTO).

The type of schedule for a column statistics task. Possible values may be CRON or AUTO.

- `SettingSource` – UTF-8 string (valid values: CATALOG | TABLE).

The source of setting the column statistics task. Possible values may be CATALOG or TABLE.

- `LastExecutionAttempt` – An [ExecutionAttempt](#) object.

The last `ExecutionAttempt` for the column statistics task run.

ExecutionAttempt structure

A run attempt for a column statistics task run.

Fields

- `Status` – UTF-8 string (valid values: FAILED | STARTED).

The status of the last column statistics task run.

- `ColumnStatisticsTaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A task run ID for the last column statistics task run.

- `ExecutionTimestamp` – Timestamp.

A timestamp when the last column statistics task run occurred.

- `ErrorMessage` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

An error message associated with the last column statistics task run.

Operations

- [StartColumnStatisticsTaskRun](#) action (Python: `start_column_statistics_task_run`)
- [GetColumnStatisticsTaskRun](#) action (Python: `get_column_statistics_task_run`)
- [GetColumnStatisticsTaskRuns](#) action (Python: `get_column_statistics_task_runs`)
- [ListColumnStatisticsTaskRuns](#) action (Python: `list_column_statistics_task_runs`)
- [StopColumnStatisticsTaskRun](#) action (Python: `stop_column_statistics_task_run`)
- [CreateColumnStatisticsTaskSettings](#) action (Python: `create_column_statistics_task_settings`)
- [UpdateColumnStatisticsTaskSettings](#) action (Python: `update_column_statistics_task_settings`)
- [GetColumnStatisticsTaskSettings](#) action (Python: `get_column_statistics_task_settings`)
- [DeleteColumnStatisticsTaskSettings](#) action (Python: `delete_column_statistics_task_settings`)
- [StartColumnStatisticsTaskRunSchedule](#) action (Python: `start_column_statistics_task_run_schedule`)
- [StopColumnStatisticsTaskRunSchedule](#) action (Python: `stop_column_statistics_task_run_schedule`)

StartColumnStatisticsTaskRun action (Python: `start_column_statistics_task_run`)

Starts a column statistics task run, for a specified table and columns.

Request

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table to generate statistics.

- `ColumnNameList` – An array of UTF-8 strings.

A list of the column names to generate statistics. If none is supplied, all column names for the table will be used by default.

- `Role` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The IAM role that the service assumes to generate statistics.

- `SampleSize` – Number (double), not more than 100.

The percentage of rows used to generate statistics. If none is supplied, the entire table will be used to generate stats.

- `CatalogID` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table reside. If none is supplied, the Amazon account ID is used by default.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the security configuration that is used to encrypt CloudWatch logs for the column stats task run.

Response

- `ColumnStatisticsTaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The identifier for the column statistics task run.

Errors

- `AccessDeniedException`
- `EntityNotFoundException`
- `ColumnStatisticsTaskRunningException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `InvalidInputException`

GetColumnStatisticsTaskRun action (Python: `get_column_statistics_task_run`)

Get the associated metadata/information for a task run, given a task run ID.

Request

- `ColumnStatisticsTaskRunId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The identifier for the particular column statistics task run.

Response

- `ColumnStatisticsTaskRun` – A [ColumnStatisticsTaskRun](#) object.

A `ColumnStatisticsTaskRun` object representing the details of the column stats run.

Errors

- `EntityNotFoundException`
- `OperationTimeoutException`
- `InvalidInputException`

GetColumnStatisticsTaskRuns action (Python: `get_column_statistics_task_runs`)

Retrieves information about all runs associated with the specified table.

Request

- `DatabaseName` – *Required*: UTF-8 string.

The name of the database where the table resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of the response.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

Response

- `ColumnStatisticsTaskRuns` – An array of [ColumnStatisticsTaskRun](#) objects.

A list of column statistics task runs.

- `NextToken` – UTF-8 string.

A continuation token, if not all task runs have yet been returned.

Errors

- `OperationTimeoutException`

ListColumnStatisticsTaskRuns action (Python: `list_column_statistics_task_runs`)

List all task runs for a particular account.

Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of the response.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

Response

- `ColumnStatisticsTaskRunIds` – An array of UTF-8 strings, not more than 100 strings.

A list of column statistics task run IDs.

- `NextToken` – UTF-8 string.

A continuation token, if not all task run IDs have yet been returned.

Errors

- `OperationTimeoutException`

StopColumnStatisticsTaskRun action (Python: `stop_column_statistics_task_run`)

Stops a task run for the specified table.

Request

- `DatabaseName` – *Required:* UTF-8 string.

The name of the database where the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- ColumnStatisticsTaskNotRunningException
- ColumnStatisticsTaskStoppingException
- OperationTimeoutException

CreateColumnStatisticsTaskSettings action (Python: create_column_statistics_task_settings)

Creates settings for a column statistics task.

Request

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table for which to generate column statistics.

- `Role` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The role used for running the column statistics.

- `Schedule` – UTF-8 string.

A schedule for running the column statistics, specified in CRON syntax.

- `ColumnNameList` – An array of UTF-8 strings.

A list of column names for which to run statistics.

- `SampleSize` – Number (double), not more than 100.

The percentage of data to sample.

- `CatalogID` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the security configuration that is used to encrypt CloudWatch logs.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

A map of tags.

Response

- *No Response parameters.*

Errors

- `AlreadyExistsException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ColumnStatisticsTaskRunningException`

UpdateColumnStatisticsTaskSettings action (Python: `update_column_statistics_task_settings`)

Updates settings for a column statistics task.

Request

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table for which to generate column statistics.

- `Role` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The role used for running the column statistics.

- `Schedule` – UTF-8 string.

A schedule for running the column statistics, specified in CRON syntax.

- `ColumnNameList` – An array of UTF-8 strings.

A list of column names for which to run statistics.

- `SampleSize` – Number (double), not more than 100.

The percentage of data to sample.

- `CatalogID` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the security configuration that is used to encrypt CloudWatch logs.

Response

- *No Response parameters.*

Errors

- `AccessDeniedException`
- `EntityNotFoundException`
- `InvalidInputException`

- `VersionMismatchException`
- `OperationTimeoutException`

GetColumnStatisticsTaskSettings action (Python: `get_column_statistics_task_settings`)

Gets settings for a column statistics task.

Request

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table for which to retrieve column statistics.

Response

- `ColumnStatisticsTaskSettings` – A [ColumnStatisticsTaskSettings](#) object.

A `ColumnStatisticsTaskSettings` object representing the settings for the column statistics task.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`

DeleteColumnStatisticsTaskSettings action (Python: `delete_column_statistics_task_settings`)

Deletes settings for a column statistics task.

Request

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table for which to delete column statistics.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`

StartColumnStatisticsTaskRunSchedule action (Python: `start_column_statistics_task_run_schedule`)

Starts a column statistics task run schedule.

Request

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table for which to start a column statistic task run schedule.

Response

- *No Response parameters.*

Errors

- `AccessDeniedException`
- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`

StopColumnStatisticsTaskRunSchedule action (Python: `stop_column_statistics_task_run_schedule`)

Stops a column statistics task run schedule.

Request

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table for which to stop a column statistic task run schedule.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`

Exceptions

- [ColumnStatisticsTaskRunningException structure](#)
- [ColumnStatisticsTaskNotRunningException structure](#)
- [ColumnStatisticsTaskStoppingException structure](#)
- [ColumnStatisticsTaskAutoConcurrencyLimitException structure](#)
- [InvalidCatalogSettingException structure](#)

ColumnStatisticsTaskRunningException structure

An exception thrown when you try to start another job while running a column stats generation job.

Fields

- Message – UTF-8 string.

A message describing the problem.

ColumnStatisticsTaskNotRunningException structure

An exception thrown when you try to stop a task run when there is no task running.

Fields

- Message – UTF-8 string.

A message describing the problem.

ColumnStatisticsTaskStoppingException structure

An exception thrown when you try to stop a task run.

Fields

- Message – UTF-8 string.

A message describing the problem.

ColumnStatisticsTaskAutoConcurrencyLimitException structure

An exception thrown when you have already reached the limit of concurrent auto statistics jobs.

Fields

- `Message` – UTF-8 string.
A message describing the problem.

InvalidCatalogSettingException structure

An exception thrown when there is a problem with the catalog settings.

Fields

- `Message` – UTF-8 string.
A message describing the problem.

Crawler scheduler API

The Crawler scheduler API describes Amazon Glue crawler data types, along with the API for creating, deleting, updating, and listing crawlers.

Data types

- [Schedule structure](#)

Schedule structure

A scheduling object using a `cron` statement to schedule an event.

Fields

- `ScheduleExpression` – UTF-8 string.
A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- **State** – UTF-8 string (valid values: SCHEDULED | NOT_SCHEDULED | TRANSITIONING).

The state of the schedule.

Operations

- [UpdateCrawlerSchedule action \(Python: update_crawler_schedule\)](#)
- [StartCrawlerSchedule action \(Python: start_crawler_schedule\)](#)
- [StopCrawlerSchedule action \(Python: stop_crawler_schedule\)](#)

UpdateCrawlerSchedule action (Python: update_crawler_schedule)

Updates the schedule of a crawler using a cron expression.

Request

- **CrawlerName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler whose schedule to update.

- **Schedule** – UTF-8 string.

The updated cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- InvalidInputException
- VersionMismatchException
- SchedulerTransitioningException

- `OperationTimeoutException`

StartCrawlerSchedule action (Python: `start_crawler_schedule`)

Changes the schedule state of the specified crawler to `SCHEDULED`, unless the crawler is already running or the schedule state is already `SCHEDULED`.

Request

- `CrawlerName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the crawler to schedule.

Response

- *No Response parameters.*

Errors

- `EntityNotFoundException`
- `SchedulerRunningException`
- `SchedulerTransitioningException`
- `NoScheduleException`
- `OperationTimeoutException`

StopCrawlerSchedule action (Python: `stop_crawler_schedule`)

Sets the schedule state of the specified crawler to `NOT_SCHEDULED`, but does not stop the crawler if it is already running.

Request

- `CrawlerName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the crawler whose schedule state to set.

Response

- *No Response parameters.*

Errors

- EntityNotFoundException
- SchedulerNotRunningException
- SchedulerTransitioningException
- OperationTimeoutException

Autogenerating ETL Scripts API

The ETL script-generation API describes the datatypes and API for generating ETL scripts in Amazon Glue.

Data types

- [CodeGenNode structure](#)
- [CodeGenNodeArg structure](#)
- [CodeGenEdge structure](#)
- [Location structure](#)
- [CatalogEntry structure](#)
- [MappingEntry structure](#)

CodeGenNode structure

Represents a node in a directed acyclic graph (DAG)

Fields

- **Id** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Identifier string pattern](#).
A node identifier that is unique within the node's graph.
- **NodeType** – *Required:* UTF-8 string.

The type of node that this is.

- **Args** – *Required*: An array of [CodeGenNodeArg](#) objects, not more than 50 structures.

Properties of the node, in the form of name-value pairs.

- **LineNumber** – Number (integer).

The line number of the node.

CodeGenNodeArg structure

An argument or property of a node.

Fields

- **Name** – *Required*: UTF-8 string.

The name of the argument or property.

- **Value** – *Required*: UTF-8 string.

The value of the argument or property.

- **Param** – Boolean.

True if the value is used as a parameter.

CodeGenEdge structure

Represents a directional edge in a directed acyclic graph (DAG).

Fields

- **Source** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Identifier string pattern](#).

The ID of the node at which the edge starts.

- **Target** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Identifier string pattern](#).

The ID of the node at which the edge ends.

- `TargetParameter` – UTF-8 string.

The target of the edge.

Location structure

The location of resources.

Fields

- `Jdbc` – An array of [CodeGenNodeArg](#) objects, not more than 50 structures.

A JDBC location.

- `S3` – An array of [CodeGenNodeArg](#) objects, not more than 50 structures.

An Amazon Simple Storage Service (Amazon S3) location.

- `DynamoDB` – An array of [CodeGenNodeArg](#) objects, not more than 50 structures.

An Amazon DynamoDB table location.

CatalogEntry structure

Specifies a table definition in the Amazon Glue Data Catalog.

Fields

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in which the table metadata resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table in question.

MappingEntry structure

Defines a mapping.

Fields

- `SourceTable` – UTF-8 string.

The name of the source table.

- `SourcePath` – UTF-8 string.

The source path.

- `SourceType` – UTF-8 string.

The source type.

- `TargetTable` – UTF-8 string.

The target table.

- `TargetPath` – UTF-8 string.

The target path.

- `TargetType` – UTF-8 string.

The target type.

Operations

- [CreateScript action \(Python: `create_script`\)](#)
- [GetDataflowGraph action \(Python: `get_dataflow_graph`\)](#)
- [GetMapping action \(Python: `get_mapping`\)](#)
- [GetPlan action \(Python: `get_plan`\)](#)

CreateScript action (Python: `create_script`)

Transforms a directed acyclic graph (DAG) into code.

Request

- `DagNodes` – An array of [CodeGenNode](#) objects.

A list of the nodes in the DAG.

- `DagEdges` – An array of [CodeGenEdge](#) objects.

A list of the edges in the DAG.

- `Language` – UTF-8 string (valid values: PYTHON | SCALA).

The programming language of the resulting code from the DAG.

Response

- `PythonScript` – UTF-8 string.

The Python script generated from the DAG.

- `ScalaCode` – UTF-8 string.

The Scala code generated from the DAG.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

GetDataflowGraph action (Python: `get_dataflow_graph`)

Transforms a Python script into a directed acyclic graph (DAG).

Request

- `PythonScript` – UTF-8 string.

The Python script to transform.

Response

- `DagNodes` – An array of [CodeGenNode](#) objects.

A list of the nodes in the resulting DAG.

- `DagEdges` – An array of [CodeGenEdge](#) objects.

A list of the edges in the resulting DAG.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

GetMapping action (Python: `get_mapping`)

Creates mappings.

Request

- `Source` – *Required:* A [CatalogEntry](#) object.

Specifies the source table.

- `Sinks` – An array of [CatalogEntry](#) objects.

A list of target tables.

- `Location` – A [Location](#) object.

Parameters for the mapping.

Response

- `Mapping` – *Required:* An array of [MappingEntry](#) objects.

A list of mappings to the specified targets.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `EntityNotFoundException`

GetPlan action (Python: get_plan)

Gets code to perform a specified mapping.

Request

- **Mapping** – *Required:* An array of [MappingEntry](#) objects.

The list of mappings from a source table to target tables.

- **Source** – *Required:* A [CatalogEntry](#) object.

The source table.

- **Sinks** – An array of [CatalogEntry](#) objects.

The target tables.

- **Location** – A [Location](#) object.

The parameters for the mapping.

- **Language** – UTF-8 string (valid values: PYTHON | SCALA).

The programming language of the code to perform the mapping.

- **AdditionalPlanOptionsMap** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A map to hold additional optional key-value parameters.

Currently, these key-value pairs are supported:

- **inferSchema** — Specifies whether to set `inferSchema` to true or false for the default script generated by an Amazon Glue job. For example, to set `inferSchema` to true, pass the following key value pair:

```
--additional-plan-options-map '{"inferSchema":"true"}
```

Response

- **PythonScript** – UTF-8 string.

A Python script to perform the mapping.

- ScalaCode – UTF-8 string.

The Scala code to perform the mapping.

Errors

- InvalidInputException
- InternalServiceException
- OperationTimeoutException

Visual job API

The Visual job API allows you to create data integration jobs by using the Amazon Glue API from a JSON object that represents a visual configuration of a Amazon Glue job.

A list of CodeGenConfigurationNodes are provided to a create or update job API to register a DAG in Amazon Glue Studio for the created job and generate the associated code.

Data types

- [CodeGenConfigurationNode structure](#)
- [JDBCConectorOptions structure](#)
- [StreamingDataPreviewOptions structure](#)
- [AthenaConnectorSource structure](#)

CodeGenConfigurationNode structure

CodeGenConfigurationNode enumerates all valid Node types. One and only one of its member variables can be populated.

Fields

- AthenaConnectorSource – An [AthenaConnectorSource](#) object.
Specifies a connector to an Amazon Athena data source.
- JDBCConnectorSource – A [JDBCConnectorSource](#) object.
Specifies a connector to a JDBC data source.
- SparkConnectorSource – A [SparkConnectorSource](#) object.
Specifies a connector to an Apache Spark data source.
- CatalogSource – A [CatalogSource](#) object.
Specifies a data store in the Amazon Glue Data Catalog.
- RedshiftSource – A [RedshiftSource](#) object.

Specifies an Amazon Redshift data store.

- `S3CatalogSource` – A [S3CatalogSource](#) object.

Specifies an Amazon S3 data store in the Amazon Glue Data Catalog.

- `S3CsvSource` – A [S3CsvSource](#) object.

Specifies a command-separated value (CSV) data store stored in Amazon S3.

- `S3JsonSource` – A [S3JsonSource](#) object.

Specifies a JSON data store stored in Amazon S3.

- `S3ParquetSource` – A [S3ParquetSource](#) object.

Specifies an Apache Parquet data store stored in Amazon S3.

- `RelationalCatalogSource` – A [RelationalCatalogSource](#) object.

Specifies a relational catalog data store in the Amazon Glue Data Catalog.

- `DynamoDBCatalogSource` – A [DynamoDBCatalogSource](#) object.

Specifies a DynamoDBC Catalog data store in the Amazon Glue Data Catalog.

- `JDBCConnectorTarget` – A [JDBCConnectorTarget](#) object.

Specifies a data target that writes to Amazon S3 in Apache Parquet columnar storage.

- `SparkConnectorTarget` – A [SparkConnectorTarget](#) object.

Specifies a target that uses an Apache Spark connector.

- `CatalogTarget` – A [BasicCatalogTarget](#) object.

Specifies a target that uses a Amazon Glue Data Catalog table.

- `RedshiftTarget` – A [RedshiftTarget](#) object.

Specifies a target that uses Amazon Redshift.

- `S3CatalogTarget` – A [S3CatalogTarget](#) object.

Specifies a data target that writes to Amazon S3 using the Amazon Glue Data Catalog.

- `S3GlueParquetTarget` – A [S3GlueParquetTarget](#) object.

Specifies a data target that writes to Amazon S3 in Apache Parquet columnar storage.

- `S3DirectTarget` – A [S3DirectTarget](#) object.

Specifies a data target that writes to Amazon S3.

- `ApplyMapping` – An [ApplyMapping](#) object.

Specifies a transform that maps data property keys in the data source to data property keys in the data target. You can rename keys, modify the data types for keys, and choose which keys to drop from the dataset.

- `SelectFields` – A [SelectFields](#) object.

Specifies a transform that chooses the data property keys that you want to keep.

- `DropFields` – A [DropFields](#) object.

Specifies a transform that chooses the data property keys that you want to drop.

- `RenameField` – A [RenameField](#) object.

Specifies a transform that renames a single data property key.

- `Spigot` – A [Spigot](#) object.

Specifies a transform that writes samples of the data to an Amazon S3 bucket.

- `Join` – A [Join](#) object.

Specifies a transform that joins two datasets into one dataset using a comparison phrase on the specified data property keys. You can use inner, outer, left, right, left semi, and left anti joins.

- `SplitFields` – A [SplitFields](#) object.

Specifies a transform that splits data property keys into two `DynamicFrames`. The output is a collection of `DynamicFrames`: one with selected data property keys, and one with the remaining data property keys.

- `SelectFromCollection` – A [SelectFromCollection](#) object.

Specifies a transform that chooses one `DynamicFrame` from a collection of `DynamicFrames`. The output is the selected `DynamicFrame`.

- `FillMissingValues` – A [FillMissingValues](#) object.

Specifies a transform that locates records in the dataset that have missing values and adds a new field with a value determined by imputation. The input data set is used to train the machine learning model that determines what the missing value should be.

- **Filter** – A [Filter](#) object.

Specifies a transform that splits a dataset into two, based on a filter condition.

- **CustomCode** – A [CustomCode](#) object.

Specifies a transform that uses custom code you provide to perform the data transformation. The output is a collection of `DynamicFrames`.

- **SparkSQL** – A [SparkSQL](#) object.

Specifies a transform where you enter a SQL query using Spark SQL syntax to transform the data. The output is a single `DynamicFrame`.

- **DirectKinesisSource** – A [DirectKinesisSource](#) object.

Specifies a direct Amazon Kinesis data source.

- **DirectKafkaSource** – A [DirectKafkaSource](#) object.

Specifies an Apache Kafka data store.

- **CatalogKinesisSource** – A [CatalogKinesisSource](#) object.

Specifies a Kinesis data source in the Amazon Glue Data Catalog.

- **CatalogKafkaSource** – A [CatalogKafkaSource](#) object.

Specifies an Apache Kafka data store in the Data Catalog.

- **DropNullFields** – A [DropNullFields](#) object.

Specifies a transform that removes columns from the dataset if all values in the column are 'null'. By default, Amazon Glue Studio will recognize null objects, but some values such as empty strings, strings that are "null", -1 integers or other placeholders such as zeros, are not automatically recognized as nulls.

- **Merge** – A [Merge](#) object.

Specifies a transform that merges a `DynamicFrame` with a staging `DynamicFrame` based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not de-duplicated.

- **Union** – An [Union](#) object.

Specifies a transform that combines the rows from two or more datasets into a single result.

- **PIIDetection** – A [PIIDetection](#) object.

Specifies a transform that identifies, removes or masks PII data.

- Aggregate – An [Aggregate](#) object.

Specifies a transform that groups rows by chosen fields and computes the aggregated value by specified function.

- DropDuplicates – A [DropDuplicates](#) object.

Specifies a transform that removes rows of repeating data from a data set.

- GovernedCatalogTarget – A [GovernedCatalogTarget](#) object.

Specifies a data target that writes to a governed catalog.

- GovernedCatalogSource – A [GovernedCatalogSource](#) object.

Specifies a data source in a governed Data Catalog.

- MicrosoftSqlServerCatalogSource – A [MicrosoftSqlServerCatalogSource](#) object.

Specifies a Microsoft SQL server data source in the Amazon Glue Data Catalog.

- MySQLCatalogSource – A [MySQLCatalogSource](#) object.

Specifies a MySQL data source in the Amazon Glue Data Catalog.

- OracleSQLCatalogSource – An [OracleSQLCatalogSource](#) object.

Specifies an Oracle data source in the Amazon Glue Data Catalog.

- PostgreSQLCatalogSource – A [PostgreSQLCatalogSource](#) object.

Specifies a PostgreSQL data source in the Amazon Glue Data Catalog.

- MicrosoftSqlServerCatalogTarget – A [MicrosoftSqlServerCatalogTarget](#) object.

Specifies a target that uses Microsoft SQL.

- MySQLCatalogTarget – A [MySQLCatalogTarget](#) object.

Specifies a target that uses MySQL.

- OracleSQLCatalogTarget – An [OracleSQLCatalogTarget](#) object.

Specifies a target that uses Oracle SQL.

- PostgreSQLCatalogTarget – A [PostgreSQLCatalogTarget](#) object.

Specifies a target that uses Postgres SQL.

- Route – A [Route](#) object.

Specifies a route node that directs data to different output paths based on defined filtering conditions.

- DynamicTransform – A [DynamicTransform](#) object.

Specifies a custom visual transform created by a user.

- EvaluateDataQuality – An [EvaluateDataQuality](#) object.

Specifies your data quality evaluation criteria.

- S3CatalogHudiSource – A [S3CatalogHudiSource](#) object.

Specifies a Hudi data source that is registered in the Amazon Glue Data Catalog. The data source must be stored in Amazon S3.

- CatalogHudiSource – A [CatalogHudiSource](#) object.

Specifies a Hudi data source that is registered in the Amazon Glue Data Catalog.

- S3HudiSource – A [S3HudiSource](#) object.

Specifies a Hudi data source stored in Amazon S3.

- S3HudiCatalogTarget – A [S3HudiCatalogTarget](#) object.

Specifies a target that writes to a Hudi data source in the Amazon Glue Data Catalog.

- S3HudiDirectTarget – A [S3HudiDirectTarget](#) object.

Specifies a target that writes to a Hudi data source in Amazon S3.

- S3CatalogDeltaSource – A [S3CatalogDeltaSource](#) object.

Specifies a Delta Lake data source that is registered in the Amazon Glue Data Catalog. The data source must be stored in Amazon S3.

- CatalogDeltaSource – A [CatalogDeltaSource](#) object.

Specifies a Delta Lake data source that is registered in the Amazon Glue Data Catalog.

- S3DeltaSource – A [S3DeltaSource](#) object.

Specifies a Delta Lake data source stored in Amazon S3.

- `S3DeltaCatalogTarget` – A [S3DeltaCatalogTarget](#) object.
Specifies a target that writes to a Delta Lake data source in the Amazon Glue Data Catalog.
- `S3DeltaDirectTarget` – A [S3DeltaDirectTarget](#) object.
Specifies a target that writes to a Delta Lake data source in Amazon S3.
- `AmazonRedshiftSource` – An [AmazonRedshiftSource](#) object.
Specifies a target that writes to a data source in Amazon Redshift.
- `AmazonRedshiftTarget` – An [AmazonRedshiftTarget](#) object.
Specifies a target that writes to a data target in Amazon Redshift.
- `EvaluateDataQualityMultiFrame` – An [EvaluateDataQualityMultiFrame](#) object.
Specifies your data quality evaluation criteria. Allows multiple input data and returns a collection of Dynamic Frames.
- `Recipe` – A [Recipe](#) object.
Specifies a Amazon Glue DataBrew recipe node.
- `SnowflakeSource` – A [SnowflakeSource](#) object.
Specifies a Snowflake data source.
- `SnowflakeTarget` – A [SnowflakeTarget](#) object.
Specifies a target that writes to a Snowflake data source.
- `ConnectorDataSource` – A [ConnectorDataSource](#) object.
Specifies a source generated with standard connection options.
- `ConnectorDataTarget` – A [ConnectorDataTarget](#) object.
Specifies a target generated with standard connection options.
- `S3CatalogIcebergSource` – A [S3CatalogIcebergSource](#) object.
Specifies an Apache Iceberg data source that is registered in the Amazon Glue Data Catalog. The Iceberg data source must be stored in Amazon S3.
- `CatalogIcebergSource` – A [CatalogIcebergSource](#) object.
Specifies an Apache Iceberg data source that is registered in the Amazon Glue Data Catalog.

- `S3IcebergCatalogTarget` – A [S3IcebergCatalogTarget](#) object.

Specifies an Apache Iceberg catalog target that writes data to Amazon S3 and registers the table in the Amazon Glue Data Catalog.

- `S3IcebergDirectTarget` – A [S3IcebergDirectTarget](#) object.

Defines configuration parameters for writing data to Amazon S3 as an Apache Iceberg table.

- `S3ExcelSource` – A [S3ExcelSource](#) object.

Defines configuration parameters for reading Excel files from Amazon S3.

- `S3HyperDirectTarget` – A [S3HyperDirectTarget](#) object.

Defines configuration parameters for writing data to Amazon S3 using HyperDirect optimization.

- `DynamoDBELTConnectorSource` – A [DynamoDBELTConnectorSource](#) object.

Specifies a DynamoDB ELT connector source for extracting data from DynamoDB tables.

JDBCConnectorOptions structure

Additional connection options for the connector.

Fields

- `FilterPredicate` – UTF-8 string, matching the [Custom string pattern #61](#).

Extra condition clause to filter data from source. For example:

```
BillingCity='Mountain View'
```

When using a query instead of a table name, you should validate that the query works with the specified `filterPredicate`.

- `PartitionColumn` – UTF-8 string, matching the [Custom string pattern #61](#).

The name of an integer column that is used for partitioning. This option works only when it's included with `lowerBound`, `upperBound`, and `numPartitions`. This option works the same way as in the Spark SQL JDBC reader.

- `LowerBound` – Number (long), not more than None.

The minimum value of `partitionColumn` that is used to decide partition stride.

- `UpperBound` – Number (long), not more than None.

The maximum value of `partitionColumn` that is used to decide partition stride.

- `NumPartitions` – Number (long), not more than None.

The number of partitions. This value, along with `lowerBound` (inclusive) and `upperBound` (exclusive), form partition strides for generated `WHERE` clause expressions that are used to split the `partitionColumn`.

- `JobBookmarkKeys` – An array of UTF-8 strings.

The name of the job bookmark keys on which to sort.

- `JobBookmarkKeysSortOrder` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies an ascending or descending sort order.

- `DataTypeMapping` – A map array of key-value pairs.

Each key is a UTF-8 string (valid values: ARRAY | BIGINT | BINARY | BIT | BLOB | BOOLEAN | CHAR | CLOB | DATALINK | DATE | DECIMAL | DISTINCT | DOUBLE | FLOAT | INTEGER | JAVA_OBJECT | LONGNVARCHAR | LONGVARBINARY | LONGVARCHAR | NCHAR | NCLOB | NULL | NUMERIC | NVARCHAR | OTHER | REAL | REF | REF_CURSOR | ROWID | SMALLINT | SQLXML | STRUCT | TIME | TIME_WITH_TIMEZONE | TIMESTAMP | TIMESTAMP_WITH_TIMEZONE | TINYINT | VARBINARY | VARCHAR).

Each value is a UTF-8 string (valid values: DATE | STRING | TIMESTAMP | INT | FLOAT | LONG | BIGDECIMAL | BYTE | SHORT | DOUBLE).

Custom data type mapping that builds a mapping from a JDBC data type to an Amazon Glue data type. For example, the option `"dataTypeMapping": {"FLOAT": "STRING"}` maps data fields of JDBC type `FLOAT` into the Java `String` type by calling the `ResultSet.getString()` method of the driver, and uses it to build the Amazon Glue record. The `ResultSet` object is implemented by each driver, so the behavior is specific to the driver you use. Refer to the documentation for your JDBC driver to understand how the driver performs the conversions.

StreamingDataPreviewOptions structure

Specifies options related to data preview for viewing a sample of your data.

Fields

- `PollingTime` – Number (long), at least 10.

The polling time in milliseconds.

- `RecordPollingLimit` – Number (long), at least 1.

The limit to the number of records polled.

AthenaConnectorSource structure

Specifies a connector to an Amazon Athena data source.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- `ConnectionName` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the connection that is associated with the connector.

- `ConnectorName` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of a connector that assists with accessing the data store in Amazon Glue Studio.

- `ConnectionType` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The type of connection, such as `marketplace.athena` or `custom.athena`, designating a connection to an Amazon Athena data store.

- `ConnectionTable` – UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the data source.

- `SchemaName` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the Cloudwatch log group to read from. For example, `/aws-glue/jobs/output`.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the custom Athena source.

JDBCConnectorSource structure

Specifies a connector to a JDBC data source.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- **ConnectionName** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the connection that is associated with the connector.

- **ConnectorName** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of a connector that assists with accessing the data store in Amazon Glue Studio.

- **ConnectionType** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The type of connection, such as marketplace.jdbc or custom.jdbc, designating a connection to a JDBC data store.

- **AdditionalOptions** – A [JDBCConnectorOptions](#) object.

Additional connection options for the connector.

- **ConnectionTable** – UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the data source.

- **Query** – UTF-8 string, matching the [Custom string pattern #62](#).

The table or SQL query to get the data from. You can specify either `ConnectionTable` or `query`, but not both.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the custom JDBC source.

SparkConnectorSource structure

Specifies a connector to an Apache Spark data source.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- **ConnectionName** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the connection that is associated with the connector.

- **ConnectorName** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of a connector that assists with accessing the data store in Amazon Glue Studio.

- **ConnectionType** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The type of connection, such as marketplace.spark or custom.spark, designating a connection to an Apache Spark data store.

- **AdditionalOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Additional connection options for the connector.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies data schema for the custom spark source.

CatalogSource structure

Specifies a data store in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data store.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

- `PartitionPredicate` – UTF-8 string, matching the [Custom string pattern #61](#).

Partitions satisfying this predicate are deleted. Files within the retention period in these partitions are not deleted.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the catalog source.

MySQLCatalogSource structure

Specifies a MySQL data source in the Amazon Glue Data Catalog.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

PostgreSQLCatalogSource structure

Specifies a PostgreSQL data source in the Amazon Glue Data Catalog.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

OracleSQLCatalogSource structure

Specifies an Oracle data source in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

MicrosoftSQLServerCatalogSource structure

Specifies a Microsoft SQL server data source in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

CatalogKinesisSource structure

Specifies a Kinesis data source in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- **WindowSize** – Number (integer), not more than None.

The amount of time to spend processing each micro batch.

- **DetectSchema** – Boolean.

Whether to automatically determine the schema from the incoming data.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- **StreamingOptions** – A [KinesisStreamingSourceOptions](#) object.

Additional options for the Kinesis streaming data source.

- **DataPreviewOptions** – A [StreamingDataPreviewOptions](#) object.

Additional options for data preview.

DirectKinesisSource structure

Specifies a direct Amazon Kinesis data source.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- **WindowSize** – Number (integer), not more than None.

The amount of time to spend processing each micro batch.

- **DetectSchema** – Boolean.

Whether to automatically determine the schema from the incoming data.

- `StreamingOptions` – A [KinesisStreamingSourceOptions](#) object.

Additional options for the Kinesis streaming data source.

- `DataPreviewOptions` – A [StreamingDataPreviewOptions](#) object.

Additional options for data preview.

KinesisStreamingSourceOptions structure

Additional options for the Amazon Kinesis streaming data source.

Fields

- `EndpointUrl` – UTF-8 string, matching the [Custom string pattern #61](#).

The URL of the Kinesis endpoint.

- `StreamName` – UTF-8 string, matching the [Custom string pattern #61](#).

The name of the Kinesis data stream.

- `Classification` – UTF-8 string, matching the [Custom string pattern #61](#).

An optional classification.

- `Delimiter` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the delimiter character.

- `StartingPosition` – UTF-8 string (valid values: `latest="LATEST" | trim_horizon="TRIM_HORIZON" | earliest="EARLIEST" | timestamp="TIMESTAMP"`).

The starting position in the Kinesis data stream to read data from. The possible values are "latest", "trim_horizon", "earliest", or a timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where Z represents a UTC timezone offset with a +/-). For example: "2023-04-04T08:00:00-04:00". The default value is "latest".

Note: Using a value that is a timestamp string in UTC format for "startingPosition" is supported only for Amazon Glue version 4.0 or later.

- `MaxFetchTimeInMs` – Number (long), not more than None.

The maximum time spent for the job executor to read records for the current batch from the Kinesis data stream, specified in milliseconds (ms). Multiple `GetRecords` API calls may be made within this time. The default value is `1000`.

- `MaxFetchRecordsPerShard` – Number (long), not more than None.

The maximum number of records to fetch per shard in the Kinesis data stream per microbatch. Note: The client can exceed this limit if the streaming job has already read extra records from Kinesis (in the same `get-records` call). If `MaxFetchRecordsPerShard` needs to be strict then it needs to be a multiple of `MaxRecordPerRead`. The default value is `100000`.

- `MaxRecordPerRead` – Number (long), not more than None.

The maximum number of records to fetch from the Kinesis data stream in each `getRecords` operation. The default value is `10000`.

- `AddIdleTimeBetweenReads` – Boolean.

Adds a time delay between two consecutive `getRecords` operations. The default value is `"False"`. This option is only configurable for Amazon Glue version 2.0 and above.

- `IdleTimeBetweenReadsInMs` – Number (long), not more than None.

The minimum time delay between two consecutive `getRecords` operations, specified in ms. The default value is `1000`. This option is only configurable for Amazon Glue version 2.0 and above.

- `DescribeShardInterval` – Number (long), not more than None.

The minimum time interval between two `ListShards` API calls for your script to consider resharding. The default value is `1s`.

- `NumRetries` – Number (integer), not more than None.

The maximum number of retries for Kinesis Data Streams API requests. The default value is `3`.

- `RetryIntervalMs` – Number (long), not more than None.

The cool-off time period (specified in ms) before retrying the Kinesis Data Streams API call. The default value is `1000`.

- `MaxRetryIntervalMs` – Number (long), not more than None.

The maximum cool-off time period (specified in ms) between two retries of a Kinesis Data Streams API call. The default value is `10000`.

- `AvoidEmptyBatches` – Boolean.

Avoids creating an empty microbatch job by checking for unread data in the Kinesis data stream before the batch is started. The default value is "False".

- `StreamArn` – UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon Resource Name (ARN) of the Kinesis data stream.

- `RoleArn` – UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon Resource Name (ARN) of the role to assume using AWS Security Token Service (AWS STS). This role must have permissions for describe or read record operations for the Kinesis data stream. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSSessionName".

- `RoleSessionName` – UTF-8 string, matching the [Custom string pattern #61](#).

An identifier for the session assuming the role using AWS STS. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSRoleARN".

- `AddRecordTimestamp` – UTF-8 string, matching the [Custom string pattern #61](#).

When this option is set to 'true', the data output will contain an additional column named "__src_timestamp" that indicates the time when the corresponding record received by the stream. The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.

- `EmitConsumerLagMetrics` – UTF-8 string, matching the [Custom string pattern #61](#).

When this option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the stream and the time it arrives in Amazon Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.

- `StartingTimestamp` – UTF-8 string.

The timestamp of the record in the Kinesis data stream to start reading data from. The possible values are a timestamp string in UTC format of the pattern yyyy-mm-ddTHH:MM:SSZ (where Z represents a UTC timezone offset with a +/-). For example: "2023-04-04T08:00:00+08:00".

- `FanoutConsumerARN` – UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon Resource Name (ARN) of the Kinesis Data Streams enhanced fan-out consumer. When specified, enables enhanced fan-out for dedicated throughput and lower latency data consumption.

CatalogKafkaSource structure

Specifies an Apache Kafka data store in the Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data store.

- **WindowSize** – Number (integer), not more than None.

The amount of time to spend processing each micro batch.

- **DetectSchema** – Boolean.

Whether to automatically determine the schema from the incoming data.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- **StreamingOptions** – A [KafkaStreamingSourceOptions](#) object.

Specifies the streaming options.

- **DataPreviewOptions** – A [StreamingDataPreviewOptions](#) object.

Specifies options related to data preview for viewing a sample of your data.

DirectKafkaSource structure

Specifies an Apache Kafka data store.

Fields

- Name – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data store.

- StreamingOptions – A [KafkaStreamingSourceOptions](#) object.

Specifies the streaming options.

- WindowSize – Number (integer), not more than None.

The amount of time to spend processing each micro batch.

- DetectSchema – Boolean.

Whether to automatically determine the schema from the incoming data.

- DataPreviewOptions – A [StreamingDataPreviewOptions](#) object.

Specifies options related to data preview for viewing a sample of your data.

KafkaStreamingSourceOptions structure

Additional options for streaming.

Fields

- BootstrapServers – UTF-8 string, matching the [Custom string pattern #61](#).

A list of bootstrap server URLs, for example, as `b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094`. This option must be specified in the API call or defined in the table metadata in the Data Catalog.

- SecurityProtocol – UTF-8 string, matching the [Custom string pattern #61](#).

The protocol used to communicate with brokers. The possible values are "SSL" or "PLAINTEXT".

- ConnectionName – UTF-8 string, matching the [Custom string pattern #61](#).

The name of the connection.

- TopicName – UTF-8 string, matching the [Custom string pattern #61](#).

The topic name as specified in Apache Kafka. You must specify at least one of "topicName", "assign" or "subscribePattern".

- Assign – UTF-8 string, matching the [Custom string pattern #61](#).

The specific TopicPartitions to consume. You must specify at least one of "topicName", "assign" or "subscribePattern".

- SubscribePattern – UTF-8 string, matching the [Custom string pattern #61](#).

A Java regex string that identifies the topic list to subscribe to. You must specify at least one of "topicName", "assign" or "subscribePattern".

- Classification – UTF-8 string, matching the [Custom string pattern #61](#).

An optional classification.

- Delimiter – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the delimiter character.

- StartingOffsets – UTF-8 string, matching the [Custom string pattern #61](#).

The starting position in the Kafka topic to read data from. The possible values are "earliest" or "latest". The default value is "latest".

- EndingOffsets – UTF-8 string, matching the [Custom string pattern #61](#).

The end point when a batch query is ended. Possible values are either "latest" or a JSON string that specifies an ending offset for each TopicPartition.

- PollTimeoutMs – Number (long), not more than None.

The timeout in milliseconds to poll data from Kafka in Spark job executors. The default value is 512.

- NumRetries – Number (integer), not more than None.

The number of times to retry before failing to fetch Kafka offsets. The default value is 3.

- RetryIntervalMs – Number (long), not more than None.

The time in milliseconds to wait before retrying to fetch Kafka offsets. The default value is 10.

- MaxOffsetsPerTrigger – Number (long), not more than None.

The rate limit on the maximum number of offsets that are processed per trigger interval. The specified total number of offsets is proportionally split across `topicPartitions` of different volumes. The default value is null, which means that the consumer reads all offsets until the known latest offset.

- `MinPartitions` – Number (integer), not more than None.

The desired minimum number of partitions to read from Kafka. The default value is null, which means that the number of spark partitions is equal to the number of Kafka partitions.

- `IncludeHeaders` – Boolean.

Whether to include the Kafka headers. When the option is set to "true", the data output will contain an additional column named "glue_streaming_kafka_headers" with type `Array[Struct(key: String, value: String)]`. The default value is "false". This option is available in Amazon Glue version 3.0 or later only.

- `AddRecordTimestamp` – UTF-8 string, matching the [Custom string pattern #61](#).

When this option is set to 'true', the data output will contain an additional column named "`__src_timestamp`" that indicates the time when the corresponding record received by the topic. The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.

- `EmitConsumerLagMetrics` – UTF-8 string, matching the [Custom string pattern #61](#).

When this option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the topic and the time it arrives in Amazon Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.

- `StartingTimestamp` – UTF-8 string.

The timestamp of the record in the Kafka topic to start reading data from. The possible values are a timestamp string in UTC format of the pattern `yyyy-mm-ddTHH:MM:SSZ` (where Z represents a UTC timezone offset with a +/-). For example: "2023-04-04T08:00:00+08:00".

Only one of `StartingTimestamp` or `StartingOffsets` must be set.

RedshiftSource structure

Specifies an Amazon Redshift data store.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Amazon Redshift data store.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The database table to read from.

- **RedshiftTmpDir** – UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon S3 path where temporary data can be staged when copying out of the database.

- **TmpDirIAMRole** – UTF-8 string, matching the [Custom string pattern #61](#).

The IAM role with permissions.

AmazonRedshiftSource structure

Specifies an Amazon Redshift source.

Fields

- **Name** – UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Amazon Redshift source.

- **Data** – An [AmazonRedshiftNodeData](#) object.

Specifies the data of the Amazon Reshift source node.

AmazonRedshiftNodeData structure

Specifies an Amazon Redshift node.

Fields

- **AccessType** – UTF-8 string, matching the [Custom string pattern #60](#).

The access type for the Redshift connection. Can be a direct connection or catalog connections.

- `SourceType` – UTF-8 string, matching the [Custom string pattern #60](#).

The source type to specify whether a specific table is the source or a custom query.

- `Connection` – An [Option](#) object.

The Amazon Glue connection to the Redshift cluster.

- `Schema` – An [Option](#) object.

The Redshift schema name when working with a direct connection.

- `Table` – An [Option](#) object.

The Redshift table name when working with a direct connection.

- `CatalogDatabase` – An [Option](#) object.

The name of the Amazon Glue Data Catalog database when working with a data catalog.

- `CatalogTable` – An [Option](#) object.

The Amazon Glue Data Catalog table name when working with a data catalog.

- `CatalogRedshiftSchema` – UTF-8 string.

The Redshift schema name when working with a data catalog.

- `CatalogRedshiftTable` – UTF-8 string.

The database table to read from.

- `TempDir` – UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon S3 path where temporary data can be staged when copying out of the database.

- `IamRole` – An [Option](#) object.

Optional. The role name use when connection to S3. The IAM role ill default to the role on the job when left blank.

- `AdvancedOptions` – An array of [AmazonRedshiftAdvancedOption](#) objects.

Optional values when connecting to the Redshift cluster.

- `SampleQuery` – UTF-8 string.

The SQL used to fetch the data from a Redshift sources when the `SourceType` is 'query'.

- `PreAction` – UTF-8 string.

The SQL used before a MERGE or APPEND with upsert is run.

- `PostAction` – UTF-8 string.

The SQL used before a MERGE or APPEND with upsert is run.

- `Action` – UTF-8 string.

Specifies how writing to a Redshift cluster will occur.

- `TablePrefix` – UTF-8 string, matching the [Custom string pattern #60](#).

Specifies the prefix to a table.

- `Upsert` – Boolean.

The action used on Redshift sinks when doing an APPEND.

- `MergeAction` – UTF-8 string, matching the [Custom string pattern #60](#).

The action used when to determine how a MERGE in a Redshift sink will be handled.

- `MergeWhenMatched` – UTF-8 string, matching the [Custom string pattern #60](#).

The action used when to determine how a MERGE in a Redshift sink will be handled when an existing record matches a new record.

- `MergeWhenNotMatched` – UTF-8 string, matching the [Custom string pattern #60](#).

The action used when to determine how a MERGE in a Redshift sink will be handled when an existing record doesn't match a new record.

- `MergeClause` – UTF-8 string.

The SQL used in a custom merge to deal with matching records.

- `CrawlerConnection` – UTF-8 string.

Specifies the name of the connection that is associated with the catalog table used.

- `TableSchema` – An array of [Option](#) objects.

The array of schema output for a given node.

- `StagingTable` – UTF-8 string.

The name of the temporary staging table that is used when doing a MERGE or APPEND with upsert.

- `SelectedColumns` – An array of [Option](#) objects.

The list of column names used to determine a matching record when doing a MERGE or APPEND with upsert.

AmazonRedshiftAdvancedOption structure

Specifies an optional value when connecting to the Redshift cluster.

Fields

- `Key` – UTF-8 string.

The key for the additional connection option.

- `Value` – UTF-8 string.

The value for the additional connection option.

Option structure

Specifies an option value.

Fields

- `Value` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the value of the option.

- `Label` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the label of the option.

- `Description` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the description of the option.

S3CatalogSource structure

Specifies an Amazon S3 data store in the Amazon Glue Data Catalog.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data store.

- Database – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The database to read from.

- Table – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The database table to read from.

- PartitionPredicate – UTF-8 string, matching the [Custom string pattern #61](#).

Partitions satisfying this predicate are deleted. Files within the retention period in these partitions are not deleted. Set to "" – empty by default.

- AdditionalOptions – A [S3SourceAdditionalOptions](#) object.

Specifies additional connection options.

S3SourceAdditionalOptions structure

Specifies additional connection options for the Amazon S3 data store.

Fields

- BoundedSize – Number (long).

Sets the upper limit for the target size of the dataset in bytes that will be processed.

- BoundedFiles – Number (long).

Sets the upper limit for the target number of files that will be processed.

S3CsvSource structure

Specifies a command-separated value (CSV) data store stored in Amazon S3.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data store.

- **Paths** – *Required*: An array of UTF-8 strings.

A list of the Amazon S3 paths to read from.

- **CompressionType** – UTF-8 string (valid values: `gzip="GZIP" | bzip2="BZIP2"`).

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are `"gzip"` and `"bzip2"`.

- **Exclusions** – An array of UTF-8 strings.

A string containing a JSON list of Unix-style glob patterns to exclude. For example, `"[\"**\.pdf\"]"` excludes all PDF files.

- **GroupSize** – UTF-8 string, matching the [Custom string pattern #61](#).

The target group size in bytes. The default is computed based on the input data size and the size of your cluster. When there are fewer than 50,000 input files, `"groupFiles"` must be set to `"inPartition"` for this to take effect.

- **GroupFiles** – UTF-8 string, matching the [Custom string pattern #61](#).

Grouping files is turned on by default when the input contains more than 50,000 files. To turn on grouping with fewer than 50,000 files, set this parameter to `"inPartition"`. To disable grouping when there are more than 50,000 files, set this parameter to `"none"`.

- **Recurse** – Boolean.

If set to true, recursively reads files in all subdirectories under the specified paths.

- **MaxBand** – Number (integer), not more than None.

This option controls the duration in milliseconds after which the s3 listing is likely to be consistent. Files with modification timestamps falling within the last `maxBand` milliseconds are tracked specially when using `JobBookmarks` to account for Amazon S3 eventual consistency. Most users don't need to set this option. The default is 900000 milliseconds, or 15 minutes.

- **MaxFilesInBand** – Number (integer), not more than None.

This option specifies the maximum number of files to save from the last `maxBand` seconds. If this number is exceeded, extra files are skipped and only processed in the next job run.

- **AdditionalOptions** – A [S3DirectSourceAdditionalOptions](#) object.

Specifies additional connection options.

- `Separator` – *Required*: UTF-8 string (valid values: `comma="COMMA" | ctrlA="CTRLA" | pipe="PIPE" | semicolon="SEMICOLON" | tab="TAB"`).

Specifies the delimiter character. The default is a comma: `,`, but any other character can be specified.

- `Escaper` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies a character to use for escaping. This option is used only when reading CSV files. The default value is none. If enabled, the character which immediately follows is used as-is, except for a small set of well-known escapes (`\n`, `\r`, `\t`, and `\0`).

- `QuoteChar` – *Required*: UTF-8 string (valid values: `quote="QUOTE" | quillemet="QUILLET" | single_quote="SINGLE_QUOTE" | disabled="DISABLED"`).

Specifies the character to use for quoting. The default is a double quote: `'"`. Set this to `-1` to turn off quoting entirely.

- `Multiline` – Boolean.

A Boolean value that specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to `True` if any record spans multiple lines. The default value is `False`, which allows for more aggressive file-splitting during parsing.

- `WithHeader` – Boolean.

A Boolean value that specifies whether to treat the first line as a header. The default value is `False`.

- `WriteHeader` – Boolean.

A Boolean value that specifies whether to write the header to output. The default value is `True`.

- `SkipFirst` – Boolean.

A Boolean value that specifies whether to skip the first data line. The default value is `False`.

- `OptimizePerformance` – Boolean.

A Boolean value that specifies whether to use the advanced SIMD CSV reader along with Apache Arrow based columnar memory formats. Only available in Amazon Glue version 3.0.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 CSV source.

DirectJDBCSource structure

Specifies the direct JDBC source connection.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the JDBC source connection.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The database of the JDBC source connection.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The table of the JDBC source connection.

- `ConnectionName` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The connection name of the JDBC source.

- `ConnectionType` – *Required:* UTF-8 string (valid values: `sqlserver` | `mysql` | `oracle` | `postgresql` | `redshift`).

The connection type of the JDBC source.

- `RedshiftTmpDir` – UTF-8 string, matching the [Custom string pattern #61](#).

The temp directory of the JDBC Redshift source.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the direct JDBC source.

S3DirectSourceAdditionalOptions structure

Specifies additional connection options for the Amazon S3 data store.

Fields

- **BoundedSize** – Number (long).
Sets the upper limit for the target size of the dataset in bytes that will be processed.
- **BoundedFiles** – Number (long).
Sets the upper limit for the target number of files that will be processed.
- **EnableSamplePath** – Boolean.
Sets option to enable a sample path.
- **SamplePath** – UTF-8 string, matching the [Custom string pattern #61](#).
If enabled, specifies the sample path.

S3JsonSource structure

Specifies a JSON data store stored in Amazon S3.

Fields

- **Name** – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).
The name of the data store.
- **Paths** – *Required*: An array of UTF-8 strings.
A list of the Amazon S3 paths to read from.
- **CompressionType** – UTF-8 string (valid values: gzip="GZIP" | bzip2="BZIP2").
Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").
- **Exclusions** – An array of UTF-8 strings.
A string containing a JSON list of Unix-style glob patterns to exclude. For example, "[\ "**.pdf\""]" excludes all PDF files.
- **GroupSize** – UTF-8 string, matching the [Custom string pattern #61](#).

The target group size in bytes. The default is computed based on the input data size and the size of your cluster. When there are fewer than 50,000 input files, "groupFiles" must be set to "inPartition" for this to take effect.

- `GroupFiles` – UTF-8 string, matching the [Custom string pattern #61](#).

Grouping files is turned on by default when the input contains more than 50,000 files. To turn on grouping with fewer than 50,000 files, set this parameter to "inPartition". To disable grouping when there are more than 50,000 files, set this parameter to "none".

- `Recurse` – Boolean.

If set to true, recursively reads files in all subdirectories under the specified paths.

- `MaxBand` – Number (integer), not more than None.

This option controls the duration in milliseconds after which the s3 listing is likely to be consistent. Files with modification timestamps falling within the last maxBand milliseconds are tracked specially when using JobBookmarks to account for Amazon S3 eventual consistency. Most users don't need to set this option. The default is 900000 milliseconds, or 15 minutes.

- `MaxFilesInBand` – Number (integer), not more than None.

This option specifies the maximum number of files to save from the last maxBand seconds. If this number is exceeded, extra files are skipped and only processed in the next job run.

- `AdditionalOptions` – A [S3DirectSourceAdditionalOptions](#) object.

Specifies additional connection options.

- `JsonPath` – UTF-8 string, matching the [Custom string pattern #61](#).

A JsonPath string defining the JSON data.

- `Multiline` – Boolean.

A Boolean value that specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to True if any record spans multiple lines. The default value is False, which allows for more aggressive file-splitting during parsing.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 JSON source.

S3ParquetSource structure

Specifies an Apache Parquet data store stored in Amazon S3.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data store.

- **Paths** – *Required:* An array of UTF-8 strings.

A list of the Amazon S3 paths to read from.

- **CompressionType** – UTF-8 string (valid values: `snappy="SNAPPY"` | `lzo="LZO"` | `gzip="GZIP"` | `brotli="BROTLI"` | `lz4="LZ4"` | `uncompressed="UNCOMPRESSED"` | `none="NONE"`).

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **Exclusions** – An array of UTF-8 strings.

A string containing a JSON list of Unix-style glob patterns to exclude. For example, "[\ "**.pdf\""]" excludes all PDF files.

- **GroupSize** – UTF-8 string, matching the [Custom string pattern #61](#).

The target group size in bytes. The default is computed based on the input data size and the size of your cluster. When there are fewer than 50,000 input files, "groupFiles" must be set to "inPartition" for this to take effect.

- **GroupFiles** – UTF-8 string, matching the [Custom string pattern #61](#).

Grouping files is turned on by default when the input contains more than 50,000 files. To turn on grouping with fewer than 50,000 files, set this parameter to "inPartition". To disable grouping when there are more than 50,000 files, set this parameter to "none".

- **Recurse** – Boolean.

If set to true, recursively reads files in all subdirectories under the specified paths.

- **MaxBand** – Number (integer), not more than None.

This option controls the duration in milliseconds after which the s3 listing is likely to be consistent. Files with modification timestamps falling within the last maxBand milliseconds are tracked specially when using JobBookmarks to account for Amazon S3 eventual consistency. Most users don't need to set this option. The default is 900000 milliseconds, or 15 minutes.

- `MaxFilesInBand` – Number (integer), not more than None.

This option specifies the maximum number of files to save from the last maxBand seconds. If this number is exceeded, extra files are skipped and only processed in the next job run.

- `AdditionalOptions` – A [S3DirectSourceAdditionalOptions](#) object.

Specifies additional connection options.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 Parquet source.

S3DeltaSource structure

Specifies a Delta Lake data source stored in Amazon S3.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Delta Lake source.

- `Paths` – *Required:* An array of UTF-8 strings.

A list of the Amazon S3 paths to read from.

- `AdditionalDeltaOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options.

- `AdditionalOptions` – A [S3DirectSourceAdditionalOptions](#) object.

Specifies additional options for the connector.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the Delta Lake source.

S3CatalogDeltaSource structure

Specifies a Delta Lake data source that is registered in the Amazon Glue Data Catalog. The data source must be stored in Amazon S3.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Delta Lake data source.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

- **AdditionalDeltaOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the Delta Lake source.

CatalogDeltaSource structure

Specifies a Delta Lake data source that is registered in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Delta Lake data source.

- Database – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).
The name of the database to read from.
- Table – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).
The name of the table in the database to read from.
- AdditionalDeltaOptions – A map array of key-value pairs.
Each key is a UTF-8 string, matching the [Custom string pattern #61](#).
Each value is a UTF-8 string, matching the [Custom string pattern #61](#).
Specifies additional connection options.
- OutputSchemas – An array of [GlueSchema](#) objects.
Specifies the data schema for the Delta Lake source.

S3HudiSource structure

Specifies a Hudi data source stored in Amazon S3.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).
The name of the Hudi source.
- Paths – *Required:* An array of UTF-8 strings.
A list of the Amazon S3 paths to read from.
- AdditionalHudiOptions – A map array of key-value pairs.
Each key is a UTF-8 string, matching the [Custom string pattern #61](#).
Each value is a UTF-8 string, matching the [Custom string pattern #61](#).
Specifies additional connection options.
- AdditionalOptions – A [S3DirectSourceAdditionalOptions](#) object.
Specifies additional options for the connector.
- OutputSchemas – An array of [GlueSchema](#) objects.

Specifies the data schema for the Hudi source.

S3CatalogHudiSource structure

Specifies a Hudi data source that is registered in the Amazon Glue Data Catalog. The Hudi data source must be stored in Amazon S3.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Hudi data source.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

- **AdditionalHudiOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the Hudi source.

S3ExcelSource structure

Specifies an S3 Excel data source.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the S3 Excel data source.

- **Paths** – *Required*: An array of UTF-8 strings.

The S3 paths where the Excel files are located.

- **CompressionType** – UTF-8 string (valid values: snappy="SNAPPY" | lzo="LZO" | gzip="GZIP" | brotli="BROTLI" | lz4="LZ4" | uncompressed="UNCOMPRESSED" | none="NONE").

The compression format used for the Excel files.

- **Exclusions** – An array of UTF-8 strings.

Patterns to exclude specific files or paths from processing.

- **GroupSize** – UTF-8 string, matching the [Custom string pattern #61](#).

Defines the size of file groups for batch processing.

- **GroupFiles** – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies how files should be grouped for processing.

- **Recurse** – Boolean.

Indicates whether to recursively process subdirectories.

- **MaxBand** – Number (integer), not more than None.

The maximum number of processing bands to use.

- **MaxFilesInBand** – Number (integer), not more than None.

The maximum number of files to process in each band.

- **AdditionalOptions** – A [S3DirectSourceAdditionalOptions](#) object.

Additional configuration options for S3 direct source processing.

- **NumberRows** – Number (long).

The number of rows to process from each Excel file.

- **SkipFooter** – Number (integer), not more than None.

The number of rows to skip at the end of each Excel file.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

The Amazon Glue schemas to apply to the processed data.

CatalogHudiSource structure

Specifies a Hudi data source that is registered in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Hudi data source.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

- **AdditionalHudiOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the Hudi source.

DynamoDBCatalogSource structure

Specifies a DynamoDB data source in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

- `PitrEnabled` – Boolean.

Specifies whether Point-in-Time Recovery (PITR) is enabled for the DynamoDB table. When set to `true`, allows reading from a specific point in time. The default value is `false`.

- `AdditionalOptions` – A [DDBELTCatalogAdditionalOptions](#) object.

Specifies additional connection options for the DynamoDB data source.

RelationalCatalogSource structure

Specifies a Relational database data source in the Amazon Glue Data Catalog.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data source.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to read from.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

JDBCConnectorTarget structure

Specifies a data target that writes to Amazon S3 in Apache Parquet columnar storage.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `ConnectionName` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the connection that is associated with the connector.

- `ConnectionTable` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the data target.

- `ConnectorName` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of a connector that will be used.

- `ConnectionType` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The type of connection, such as `marketplace.jdbc` or `custom.jdbc`, designating a connection to a JDBC data target.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Additional connection options for the connector.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the JDBC target.

SparkConnectorTarget structure

Specifies a target that uses an Apache Spark connector.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `ConnectionName` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of a connection for an Apache Spark connector.

- `ConnectorName` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of an Apache Spark connector.

- `ConnectionType` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The type of connection, such as `marketplace.spark` or `custom.spark`, designating a connection to an Apache Spark data store.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Additional connection options for the connector.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the custom spark target.

BasicCatalogTarget structure

Specifies a target that uses a Amazon Glue Data Catalog table.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of your data target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `PartitionKeys` – An array of UTF-8 strings.

The partition keys used to distribute data across multiple partitions or shards based on a specific key or set of key.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The database that contains the table you want to use as the target. This database must already exist in the Data Catalog.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The table that defines the schema of your output data. This table must already exist in the Data Catalog.

MySQLCatalogTarget structure

Specifies a target that uses MySQL.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

PostgreSQLCatalogTarget structure

Specifies a target that uses Postgres SQL.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

OracleSQLCatalogTarget structure

Specifies a target that uses Oracle SQL.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

MicrosoftSQLServerCatalogTarget structure

Specifies a target that uses Microsoft SQL.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

RedshiftTarget structure

Specifies a target that uses Amazon Redshift.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

- **RedshiftTmpDir** – UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon S3 path where temporary data can be staged when copying out of the database.

- **TmpDirIAMRole** – UTF-8 string, matching the [Custom string pattern #61](#).

The IAM role with permissions.

- **UpsertRedshiftOptions** – An [UpsertRedshiftTargetOptions](#) object.

The set of options to configure an upsert operation when writing to a Redshift target.

AmazonRedshiftTarget structure

Specifies an Amazon Redshift target.

Fields

- **Name** – UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Amazon Redshift target.

- Data – An [AmazonRedshiftNodeData](#) object.

Specifies the data of the Amazon Redshift target node.

- Inputs – An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

UpsertRedshiftTargetOptions structure

The options to configure an upsert operation when writing to a Redshift target .

Fields

- TableLocation – UTF-8 string, matching the [Custom string pattern #61](#).

The physical location of the Redshift table.

- ConnectionName – UTF-8 string, matching the [Custom string pattern #61](#).

The name of the connection to use to write to Redshift.

- UpsertKeys – An array of UTF-8 strings.

The keys used to determine whether to perform an update or insert.

S3CatalogTarget structure

Specifies a data target that writes to Amazon S3 using the Amazon Glue Data Catalog.

Fields

- Name – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- Inputs – *Required*: An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- PartitionKeys – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- **SchemaChangePolicy** – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

- **AutoDataQuality** – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 catalog target.

When set to `true`, data quality checks are performed automatically during the write operation.

S3GlueParquetTarget structure

Specifies a data target that writes to Amazon S3 in Apache Parquet columnar storage.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Path** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

A single Amazon S3 path to write to.

- **Compression** – UTF-8 string (valid values: `snappy="SNAPPY"` | `lzo="LZO"` | `gzip="GZIP"` | `brotli="BROTLI"` | `lz4="LZ4"` | `uncompressed="UNCOMPRESSED"` | `none="NONE"`).

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- `NumberTargetPartitions` – UTF-8 string.

Specifies the number of target partitions for Parquet files when writing to Amazon S3 using Amazon Glue.

- `SchemaChangePolicy` – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

- `AutoDataQuality` – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 Amazon Glue Parquet target. When set to `true`, data quality checks are performed automatically during the write operation.

CatalogSchemaChangePolicy structure

A policy that specifies update behavior for the crawler.

Fields

- `EnableUpdateCatalog` – Boolean.

Whether to use the specified update behavior when the crawler finds a changed schema.

- `UpdateBehavior` – UTF-8 string (valid values: `UPDATE_IN_DATABASE` | `LOG`).

The update behavior when the crawler finds a changed schema.

S3DirectTarget structure

Specifies a data target that writes to Amazon S3.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `PartitionKeys` – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Path** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

A single Amazon S3 path to write to.

- **Compression** – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **NumberTargetPartitions** – UTF-8 string.

Specifies the number of target partitions when writing data directly to Amazon S3.

- **Format** – *Required:* UTF-8 string (valid values: json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA" | iceberg="ICEBERG" | hyper="HYPER" | xml="XML").

Specifies the data output format for the target.

- **SchemaChangePolicy** – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

- **AutoDataQuality** – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 direct target. When set to true, data quality checks are performed automatically during the write operation.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 direct target.

S3HudiCatalogTarget structure

Specifies a target that writes to a Hudi data source in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `PartitionKeys` – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- `AdditionalOptions` – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options for the connector.

- `SchemaChangePolicy` – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

- `AutoDataQuality` – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 Hudi catalog target.

When set to `true`, data quality checks are performed automatically during the write operation.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 Hudi catalog target.

S3HudiDirectTarget structure

Specifies a target that writes to a Hudi data source in Amazon S3.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Path** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon S3 path of your Hudi data source to write to.

- **Compression** – *Required:* UTF-8 string (valid values: `gzip="GZIP" | lzo="LZO" | uncompressed="UNCOMPRESSED" | snappy="SNAPPY"`).

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **NumberTargetPartitions** – UTF-8 string.

Specifies the number of target partitions for distributing Hudi dataset files across Amazon S3.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Format** – *Required:* UTF-8 string (valid values: `json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA" | iceberg="ICEBERG" | hyper="HYPER" | xml="XML"`).

Specifies the data output format for the target.

- **AdditionalOptions** – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options for the connector.

- **SchemaChangePolicy** – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

- **AutoDataQuality** – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 Hudi direct target. When set to `true`, data quality checks are performed automatically during the write operation.

S3DeltaCatalogTarget structure

Specifies a target that writes to a Delta Lake data source in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- **AdditionalOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options for the connector.

- **SchemaChangePolicy** – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

- **AutoDataQuality** – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 Delta catalog target. When set to `true`, data quality checks are performed automatically during the write operation.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 Delta catalog target.

S3DeltaDirectTarget structure

Specifies a target that writes to a Delta Lake data source in Amazon S3.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Path** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon S3 path of your Delta Lake data source to write to.

- **Compression** – *Required:* UTF-8 string (valid values: uncompressed="UNCOMPRESSED" | snappy="SNAPPY").

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **NumberTargetPartitions** – UTF-8 string.

Specifies the number of target partitions for distributing Delta Lake dataset files across Amazon S3.

- **Format** – *Required:* UTF-8 string (valid values: json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA" | iceberg="ICEBERG" | hyper="HYPER" | xml="XML").

Specifies the data output format for the target.

- **AdditionalOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options for the connector.

- `SchemaChangePolicy` – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

- `AutoDataQuality` – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 Delta direct target. When set to `true`, data quality checks are performed automatically during the write operation.

S3HyperDirectTarget structure

Specifies a HyperDirect data target that writes to Amazon S3.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The unique identifier for the HyperDirect target node.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

Specifies the input source for the HyperDirect target.

- `Format` – UTF-8 string (valid values: `json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA" | iceberg="ICEBERG" | hyper="HYPER" | xml="XML"`).

Specifies the data output format for the HyperDirect target.

- `PartitionKeys` – An array of UTF-8 strings.

Defines the partitioning strategy for the output data.

- `Path` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The S3 location where the output data will be written.

- `Compression` – UTF-8 string (valid values: `uncompressed="UNCOMPRESSED"`).

The compression type to apply to the output data.

- `SchemaChangePolicy` – A [DirectSchemaChangePolicy](#) object.

Defines how schema changes are handled during write operations.

- `AutoDataQuality` – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 Hyper direct target. When set to `true`, data quality checks are performed automatically during the write operation.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 Hyper direct target.

S3IcebergDirectTarget structure

Specifies a target that writes to an Iceberg data source in Amazon S3.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

Specifies the unique identifier for the Iceberg target node in your data pipeline.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

Defines the single input source that provides data to this Iceberg target.

- `PartitionKeys` – An array of UTF-8 strings.

Specifies the columns used to partition the Iceberg table data in S3.

- `Path` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

Defines the S3 location where the Iceberg table data will be stored.

- `Format` – *Required:* UTF-8 string (valid values: `json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA" | iceberg="ICEBERG" | hyper="HYPER" | xml="XML"`).

Specifies the file format used for storing Iceberg table data (e.g., Parquet, ORC).

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Provides additional configuration options for customizing the Iceberg table behavior.

- `SchemaChangePolicy` – A [DirectSchemaChangePolicy](#) object.

Defines how schema changes are handled when writing data to the Iceberg table.

- `Compression` – *Required*: UTF-8 string (valid values: `gzip="GZIP" | lzo="LZO" | uncompressed="UNCOMPRESSED" | snappy="SNAPPY"`).

Specifies the compression codec used for Iceberg table files in S3.

- `NumberTargetPartitions` – UTF-8 string.

Sets the number of target partitions for distributing Iceberg table files across S3.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 Iceberg direct target.

DirectSchemaChangePolicy structure

A policy that specifies update behavior for the crawler.

Fields

- `EnableUpdateCatalog` – Boolean.

Whether to use the specified update behavior when the crawler finds a changed schema.

- `UpdateBehavior` – UTF-8 string (valid values: `UPDATE_IN_DATABASE | LOG`).

The update behavior when the crawler finds a changed schema.

- `Table` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the table in the database that the schema change policy applies to.

- `Database` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the database that the schema change policy applies to.

ApplyMapping structure

Specifies a transform that maps data property keys in the data source to data property keys in the data target. You can rename keys, modify the data types for keys, and choose which keys to drop from the dataset.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- Mapping – *Required:* An array of [Mapping](#) objects.

Specifies the mapping of data property keys in the data source to data property keys in the data target.

Mapping structure

Specifies the mapping of data property keys.

Fields

- ToKey – UTF-8 string, matching the [Custom string pattern #61](#).

After the apply mapping, what the name of the column should be. Can be the same as FromPath.

- FromPath – An array of UTF-8 strings.

The table or column to be modified.

- FromType – UTF-8 string, matching the [Custom string pattern #61](#).

The type of the data to be modified.

- ToType – UTF-8 string, matching the [Custom string pattern #61](#).

The data type that the data is to be modified to.

- Dropped – Boolean.

If true, then the column is removed.

- Children – An array of [Mapping](#) objects.

Only applicable to nested data structures. If you want to change the parent structure, but also one of its children, you can fill out this data structure. It is also Mapping, but its FromPath will be the parent's FromPath plus the FromPath from this structure.

For the children part, suppose you have the structure:

```
{ "FromPath": "OuterStructure", "ToKey": "OuterStructure", "ToType":  
"Struct", "Dropped": false, "Children": [{ "FromPath": "inner", "ToKey":  
"inner", "ToType": "Double", "Dropped": false, }] }
```

You can specify a Mapping that looks like:

```
{ "FromPath": "OuterStructure", "ToKey": "OuterStructure", "ToType":  
"Struct", "Dropped": false, "Children": [{ "FromPath": "inner", "ToKey":  
"inner", "ToType": "Double", "Dropped": false, }] }
```

SelectFields structure

Specifies a transform that chooses the data property keys that you want to keep.

Fields

- Name – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- Inputs – *Required*: An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- Paths – *Required*: An array of UTF-8 strings.

A JSON path to a variable in the data structure.

DropFields structure

Specifies a transform that chooses the data property keys that you want to drop.

Fields

- Name – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- Paths – *Required:* An array of UTF-8 strings.

A JSON path to a variable in the data structure.

RenameField structure

Specifies a transform that renames a single data property key.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- SourcePath – *Required:* An array of UTF-8 strings.

A JSON path to a variable in the data structure for the source data.

- TargetPath – *Required:* An array of UTF-8 strings.

A JSON path to a variable in the data structure for the target data.

Spigot structure

Specifies a transform that writes samples of the data to an Amazon S3 bucket.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- **Path** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

A path in Amazon S3 where the transform will write a subset of records from the dataset to a JSON file in an Amazon S3 bucket.

- **Topk** – Number (integer), not more than 100.

Specifies a number of records to write starting from the beginning of the dataset.

- **Prob** – Number (double), not more than 1.

The probability (a decimal value with a maximum value of 1) of picking any given record. A value of 1 indicates that each row read from the dataset should be included in the sample output.

Join structure

Specifies a transform that joins two datasets into one dataset using a comparison phrase on the specified data property keys. You can use inner, outer, left, right, left semi, and left anti joins.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 2 or more than 2 strings.

The data inputs identified by their node names.

- **JoinType** – *Required:* UTF-8 string (valid values: equijoin="EQUIJOIN" | left="LEFT" | right="RIGHT" | outer="OUTER" | leftsemi="LEFT_SEMI" | leftanti="LEFT_ANTI").

Specifies the type of join to be performed on the datasets.

- **Columns** – *Required:* An array of [JoinColumn](#) objects, not less than 2 or more than 2 structures.

A list of the two columns to be joined.

JoinColumn structure

Specifies a column to be joined.

Fields

- **From** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The column to be joined.

- **Keys** – *Required:* An array of UTF-8 strings.

The key of the column to be joined.

SplitFields structure

Specifies a transform that splits data property keys into two `DynamicFrames`. The output is a collection of `DynamicFrames`: one with selected data property keys, and one with the remaining data property keys.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- **Paths** – *Required:* An array of UTF-8 strings.

A JSON path to a variable in the data structure.

SelectFromCollection structure

Specifies a transform that chooses one `DynamicFrame` from a collection of `DynamicFrames`. The output is the selected `DynamicFrame`.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- Index – *Required:* Number (integer), not more than None.

The index for the DynamicFrame to be selected.

FillMissingValues structure

Specifies a transform that locates records in the dataset that have missing values and adds a new field with a value determined by imputation. The input data set is used to train the machine learning model that determines what the missing value should be.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- ImputedPath – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

A JSON path to a variable in the data structure for the dataset that is imputed.

- FilledPath – UTF-8 string, matching the [Custom string pattern #61](#).

A JSON path to a variable in the data structure for the dataset that is filled.

Filter structure

Specifies a transform that splits a dataset into two, based on a filter condition.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- `LogicalOperator` – *Required:* UTF-8 string (valid values: AND | OR).

The operator used to filter rows by comparing the key value to a specified value.

- `Filters` – *Required:* An array of [FilterExpression](#) objects.

Specifies a filter expression.

FilterExpression structure

Specifies a filter expression.

Fields

- `Operation` – *Required:* UTF-8 string (valid values: EQ | LT | GT | LTE | GTE | REGEX | ISNULL).

The type of operation to perform in the expression.

- `Negated` – Boolean.

Whether the expression is to be negated.

- `Values` – *Required:* An array of [FilterValue](#) objects.

A list of filter values.

FilterValue structure

Represents a single entry in the list of values for a `FilterExpression`.

Fields

- `Type` – *Required:* UTF-8 string (valid values: COLUMNEXTRACTED | CONSTANT).

The type of filter value.

- `Value` – *Required:* An array of UTF-8 strings.

The value to be associated.

CustomCode structure

Specifies a transform that uses custom code you provide to perform the data transformation. The output is a collection of `DynamicFrames`.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, at least 1 string.

The data inputs identified by their node names.

- **Code** – *Required:* UTF-8 string, matching the [Custom string pattern #54](#).

The custom code that is used to perform the data transformation.

- **ClassName** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name defined for the custom code node class.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the custom code transform.

SparkSQL structure

Specifies a transform where you enter a SQL query using Spark SQL syntax to transform the data. The output is a single `DynamicFrame`.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, at least 1 string.

The data inputs identified by their node names. You can associate a table name with each input node to use in the SQL query. The name you choose must meet the Spark SQL naming restrictions.

- **SqlQuery** – *Required:* UTF-8 string, matching the [Custom string pattern #62](#).

A SQL query that must use Spark SQL syntax and return a single data set.

- `SqlAliases` – *Required*: An array of [SqlAlias](#) objects.

A list of aliases. An alias allows you to specify what name to use in the SQL for a given input. For example, you have a datasource named "MyDataSource". If you specify `From` as `MyDataSource`, and `Alias` as `SqlName`, then in your SQL you can do:

```
select * from SqlName
```

and that gets data from `MyDataSource`.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the SparkSQL transform.

SqlAlias structure

Represents a single entry in the list of values for `SqlAliases`.

Fields

- `From` – *Required*: UTF-8 string, matching the [Custom string pattern #60](#).

A table, or a column in a table.

- `Alias` – *Required*: UTF-8 string, matching the [Custom string pattern #61](#).

A temporary name given to a table, or a column in a table.

DropNullFields structure

Specifies a transform that removes columns from the dataset if all values in the column are 'null'. By default, Amazon Glue Studio will recognize null objects, but some values such as empty strings, strings that are "null", -1 integers or other placeholders such as zeros, are not automatically recognized as nulls.

Fields

- `Name` – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- **Inputs** – *Required*: An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- **NullCheckBoxList** – A [NullCheckBoxList](#) object.

A structure that represents whether certain values are recognized as null values for removal.

- **NullTextList** – An array of [NullValueField](#) objects, not more than 50 structures.

A structure that specifies a list of [NullValueField](#) structures that represent a custom null value such as zero or other value being used as a null placeholder unique to the dataset.

The `DropNullFields` transform removes custom null values only if both the value of the null placeholder and the datatype match the data.

NullCheckBoxList structure

Represents whether certain values are recognized as null values for removal.

Fields

- **IsEmpty** – Boolean.

Specifies that an empty string is considered as a null value.

- **IsNullString** – Boolean.

Specifies that a value spelling out the word 'null' is considered as a null value.

- **IsNegOne** – Boolean.

Specifies that an integer value of -1 is considered as a null value.

NullValueField structure

Represents a custom null value such as a zeros or other value being used as a null placeholder unique to the dataset.

Fields

- **Value** – *Required*: UTF-8 string, matching the [Custom string pattern #61](#).

The value of the null placeholder.

- **Datatype** – *Required:* A [Datatype](#) object.

The datatype of the value.

Datatype structure

A structure representing the datatype of the value.

Fields

- **Id** – *Required:* UTF-8 string, matching the [Custom string pattern #60](#).

The datatype of the value.

- **Label** – *Required:* UTF-8 string, matching the [Custom string pattern #60](#).

A label assigned to the datatype.

Merge structure

Specifies a transform that merges a `DynamicFrame` with a staging `DynamicFrame` based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not de-duplicated.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 2 or more than 2 strings.

The data inputs identified by their node names.

- **Source** – *Required:* UTF-8 string, matching the [Custom string pattern #60](#).

The source `DynamicFrame` that will be merged with a staging `DynamicFrame`.

- **PrimaryKeys** – *Required:* An array of UTF-8 strings.

The list of primary key fields to match records from the source and staging dynamic frames.

Union structure

Specifies a transform that combines the rows from two or more datasets into a single result.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 2 or more than 2 strings.

The node ID inputs to the transform.

- UnionType – *Required:* UTF-8 string (valid values: ALL | DISTINCT).

Indicates the type of Union transform.

Specify ALL to join all rows from data sources to the resulting DynamicFrame. The resulting union does not remove duplicate rows.

Specify DISTINCT to remove duplicate rows in the resulting DynamicFrame.

PIIDetection structure

Specifies a transform that identifies, removes or masks PII data.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The node ID inputs to the transform.

- PiiType – *Required:* UTF-8 string (valid values: RowAudit | RowHashing | RowMasking | RowPartialMasking | ColumnAudit | ColumnHashing | ColumnMasking).

Indicates the type of PIIDetection transform.

- EntityTypesToDetect – *Required:* An array of UTF-8 strings.

Indicates the types of entities the PIIDetection transform will identify as PII data.

PII type entities include: PERSON_NAME, DATE, USA_SNN, EMAIL, USA_ITIN, USA_PASSPORT_NUMBER, PHONE_NUMBER, BANK_ACCOUNT, IP_ADDRESS, MAC_ADDRESS, USA_CPT_CODE, USA_HCPCS_CODE, USA_NATIONAL_DRUG_CODE, USA_MEDICARE_BENEFICIARY_IDENTIFIER, USA_HEALTH_INSURANCE_CLAIM_NUMBER, CREDIT_CARD, USA_NATIONAL_PROVIDER_IDENTIFIER, USA

- `OutputColumnName` – UTF-8 string, matching the [Custom string pattern #61](#).

Indicates the output column name that will contain any entity type detected in that row.

- `SampleFraction` – Number (double), not more than 1.

Indicates the fraction of the data to sample when scanning for PII entities.

- `ThresholdFraction` – Number (double), not more than 1.

Indicates the fraction of the data that must be met in order for a column to be identified as PII data.

- `MaskValue` – UTF-8 string, not more than 256 bytes long, matching the [Custom string pattern #58](#).

Indicates the value that will replace the detected entity.

- `RedactText` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies whether to redact the detected PII text. When set to `true`, PII content is replaced with redaction characters.

- `RedactChar` – UTF-8 string, matching the [Custom string pattern #61](#).

The character used to replace detected PII content when redaction is enabled. The default redaction character is `*`.

- `MatchPattern` – UTF-8 string, matching the [Custom string pattern #61](#).

A regular expression pattern used to identify additional PII content beyond the standard detection algorithms.

- `NumLeftCharsToExclude` – Number (integer), not more than None.

The number of characters to exclude from redaction on the left side of detected PII content. This allows preserving context around the sensitive data.

- `NumRightCharsToExclude` – Number (integer), not more than None.

The number of characters to exclude from redaction on the right side of detected PII content. This allows preserving context around the sensitive data.

- `DetectionParameters` – UTF-8 string, matching the [Custom string pattern #61](#).

Additional parameters for configuring PII detection behavior and sensitivity settings.

- `DetectionSensitivity` – UTF-8 string, matching the [Custom string pattern #61](#).

The sensitivity level for PII detection. Higher sensitivity levels detect more potential PII but may result in more false positives.

Aggregate structure

Specifies a transform that groups rows by chosen fields and computes the aggregated value by specified function.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

Specifies the fields and rows to use as inputs for the aggregate transform.

- `Groups` – *Required:* An array of UTF-8 strings.

Specifies the fields to group by.

- `Aggs` – *Required:* An array of [AggregateOperation](#) objects, not less than 1 or more than 30 structures.

Specifies the aggregate functions to be performed on specified fields.

DropDuplicates structure

Specifies a transform that removes rows of repeating data from a data set.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- **Columns** – An array of UTF-8 strings.

The name of the columns to be merged or removed if repeating.

GovernedCatalogTarget structure

Specifies a data target that writes to Amazon S3 using the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to write to.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- **SchemaChangePolicy** – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the governed catalog.

GovernedCatalogSource structure

Specifies the data store in the governed Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data store.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The database table to read from.

- **PartitionPredicate** – UTF-8 string, matching the [Custom string pattern #61](#).

Partitions satisfying this predicate are deleted. Files within the retention period in these partitions are not deleted. Set to "" – empty by default.

- **AdditionalOptions** – A [S3SourceAdditionalOptions](#) object.

Specifies additional connection options.

AggregateOperation structure

Specifies the set of parameters needed to perform aggregation in the aggregate transform.

Fields

- **Column** – *Required:* An array of UTF-8 strings.

Specifies the column on the data set on which the aggregation function will be applied.

- **AggFunc** – *Required:* UTF-8 string (valid values: avg | countDistinct | count | first | last | kurtosis | max | min | skewness | stddev_samp | stddev_pop | sum | sumDistinct | var_samp | var_pop).

Specifies the aggregation function to apply.

Possible aggregation functions include: avg, countDistinct, count, first, last, kurtosis, max, min, skewness, stddev_samp, stddev_pop, sum, sumDistinct, var_samp, var_pop

GlueSchema structure

Specifies a user-defined schema when a schema cannot be determined by Amazon Glue.

Fields

- `Columns` – An array of [GlueStudioSchemaColumn](#) objects.

Specifies the column definitions that make up a Amazon Glue schema.

GlueStudioSchemaColumn structure

Specifies a single column in a Amazon Glue schema definition.

Fields

- `Name` – *Required:* UTF-8 string, not more than 1024 bytes long, matching the [Single-line string pattern](#).

The name of the column in the Amazon Glue Studio schema.

- `Type` – UTF-8 string, not more than 131072 bytes long, matching the [Single-line string pattern](#).

The hive type for this column in the Amazon Glue Studio schema.

- `GlueStudioType` – UTF-8 string, not more than 131072 bytes long, matching the [Single-line string pattern](#).

The data type of the column as defined in Amazon Glue Studio.

GlueStudioColumn structure

Specifies a single column in Amazon GlueStudio.

Fields

- `Key` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The key of the column in Amazon Glue Studio.

- `FullPath` – *Required:* An array of UTF-8 strings.

The full URL of the column in Amazon Glue Studio.

- **Type** – *Required*: UTF-8 string (valid values: array="ARRAY" | bigint="BIGINT" | bigint array="BIGINT_ARRAY" | binary="BINARY" | binary array="BINARY_ARRAY" | boolean="BOOLEAN" | boolean array="BOOLEAN_ARRAY" | byte="BYTE" | byte array="BYTE_ARRAY" | char="CHAR" | char array="CHAR_ARRAY" | choice="CHOICE" | choice array="CHOICE_ARRAY" | date="DATE" | date array="DATE_ARRAY" | decimal="DECIMAL" | decimal array="DECIMAL_ARRAY" | double="DOUBLE" | double array="DOUBLE_ARRAY" | enum="ENUM" | enum array="ENUM_ARRAY" | float="FLOAT" | float array="FLOAT_ARRAY" | int="INT" | int array="INT_ARRAY" | interval="INTERVAL" | interval array="INTERVAL_ARRAY" | long="LONG" | long array="LONG_ARRAY" | object="OBJECT" | short="SHORT" | short array="SHORT_ARRAY" | smallint="SMALLINT" | smallint array="SMALLINT_ARRAY" | string="STRING" | string array="STRING_ARRAY" | timestamp="TIMESTAMP" | timestamp array="TIMESTAMP_ARRAY" | tinyint="TINYINT" | tinyint array="TINYINT_ARRAY" | varchar="VARCHAR" | varchar array="VARCHAR_ARRAY" | null="NULL" | unknown="UNKNOWN" | unknown array="UNKNOWN_ARRAY").

The type of the column in Amazon Glue Studio.

- **Children** – An array of a structures.

The children of the parent column in Amazon Glue Studio.

- **GlueStudioType** – UTF-8 string (valid values: array="ARRAY" | bigint="BIGINT" | bigint array="BIGINT_ARRAY" | binary="BINARY" | binary array="BINARY_ARRAY" | boolean="BOOLEAN" | boolean array="BOOLEAN_ARRAY" | byte="BYTE" | byte array="BYTE_ARRAY" | char="CHAR" | char array="CHAR_ARRAY" | choice="CHOICE" | choice array="CHOICE_ARRAY" | date="DATE" | date array="DATE_ARRAY" | decimal="DECIMAL" | decimal array="DECIMAL_ARRAY" | double="DOUBLE" | double array="DOUBLE_ARRAY" | enum="ENUM" | enum array="ENUM_ARRAY" | float="FLOAT" | float array="FLOAT_ARRAY" | int="INT" | int array="INT_ARRAY" | interval="INTERVAL" | interval array="INTERVAL_ARRAY" | long="LONG" | long array="LONG_ARRAY" | object="OBJECT" | short="SHORT" | short array="SHORT_ARRAY" | smallint="SMALLINT" | smallint array="SMALLINT_ARRAY" | string="STRING" | string array="STRING_ARRAY" | timestamp="TIMESTAMP" | timestamp array="TIMESTAMP_ARRAY" | tinyint="TINYINT" | tinyint array="TINYINT_ARRAY" | varchar="VARCHAR" | varchar array="VARCHAR_ARRAY" | null="NULL" | unknown="UNKNOWN" | unknown array="UNKNOWN_ARRAY").

The data type of the column as defined in Amazon Glue Studio.

DynamicTransform structure

Specifies the set of parameters needed to perform the dynamic transform.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the name of the dynamic transform.

- **TransformName** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the name of the dynamic transform as it appears in the Amazon Glue Studio visual editor.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

Specifies the inputs for the dynamic transform that are required.

- **Parameters** – An array of [TransformConfigParameter](#) objects.

Specifies the parameters of the dynamic transform.

- **FunctionName** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the name of the function of the dynamic transform.

- **Path** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the path of the dynamic transform source and config files.

- **Version** – UTF-8 string, matching the [Custom string pattern #61](#).

This field is not used and will be deprecated in future release.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the dynamic transform.

TransformConfigParameter structure

Specifies the parameters in the config file of the dynamic transform.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the name of the parameter in the config file of the dynamic transform.

- **Type** – *Required:* UTF-8 string (valid values: `str="STR" | int="INT" | float="FLOAT" | complex="COMPLEX" | bool="BOOL" | list="LIST" | null="NULL"`).

Specifies the parameter type in the config file of the dynamic transform.

- **ValidationRule** – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the validation rule in the config file of the dynamic transform.

- **ValidationMessage** – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the validation message in the config file of the dynamic transform.

- **Value** – An array of UTF-8 strings.

Specifies the value of the parameter in the config file of the dynamic transform.

- **ListType** – UTF-8 string (valid values: `str="STR" | int="INT" | float="FLOAT" | complex="COMPLEX" | bool="BOOL" | list="LIST" | null="NULL"`).

Specifies the list type of the parameter in the config file of the dynamic transform.

- **IsOptional** – Boolean.

Specifies whether the parameter is optional or not in the config file of the dynamic transform.

EvaluateDataQuality structure

Specifies your data quality evaluation criteria.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data quality evaluation.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The inputs of your data quality evaluation.

- **Ruleset** – *Required:* UTF-8 string, not less than 1 or more than 65536 bytes long, matching the [Custom string pattern #59](#).

The ruleset for your data quality evaluation.

- **Output** – UTF-8 string (valid values: PrimaryInput | EvaluationResults).

The output of your data quality evaluation.

- **PublishingOptions** – A [DQResultsPublishingOptions](#) object.

Options to configure how your results are published.

- **StopJobOnFailureOptions** – A [DQStopJobOnFailureOptions](#) object.

Options to configure how your job will stop if your data quality evaluation fails.

DQResultsPublishingOptions structure

Options to configure how your data quality evaluation results are published.

Fields

- **EvaluationContext** – UTF-8 string, matching the [Custom string pattern #60](#).

The context of the evaluation.

- **ResultsS3Prefix** – UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon S3 prefix prepended to the results.

- **CloudWatchMetricsEnabled** – Boolean.

Enable metrics for your data quality results.

- **ResultsPublishingEnabled** – Boolean.

Enable publishing for your data quality results.

DQStopJobOnFailureOptions structure

Options to configure how your job will stop if your data quality evaluation fails.

Fields

- **StopJobOnFailureTiming** – UTF-8 string (valid values: Immediate | AfterDataLoad).

When to stop job if your data quality evaluation fails. Options are Immediate or AfterDataLoad.

EvaluateDataQualityMultiFrame structure

Specifies your data quality evaluation criteria.

Fields

- Name – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).

The name of the data quality evaluation.

- Inputs – *Required*: An array of UTF-8 strings, at least 1 string.

The inputs of your data quality evaluation. The first input in this list is the primary data source.

- AdditionalDataSources – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #63](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

The aliases of all data sources except primary.

- Ruleset – *Required*: UTF-8 string, not less than 1 or more than 65536 bytes long, matching the [Custom string pattern #59](#).

The ruleset for your data quality evaluation.

- PublishingOptions – A [DQResultsPublishingOptions](#) object.

Options to configure how your results are published.

- AdditionalOptions – A map array of key-value pairs.

Each key is a UTF-8 string (valid values: performanceTuning.caching="CacheOption" | observations.scope="ObservationsOption" | compositeRuleEvaluation.method="CompositeOption").

Each value is a UTF-8 string.

Options to configure runtime behavior of the transform.

- StopJobOnFailureOptions – A [DQStopJobOnFailureOptions](#) object.

Options to configure how your job will stop if your data quality evaluation fails.

Recipe structure

A Amazon Glue Studio node that uses a Amazon Glue DataBrew recipe in Amazon Glue jobs.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Amazon Glue Studio node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the recipe node, identified by id.

- RecipeReference – A [RecipeReference](#) object.

A reference to the DataBrew recipe used by the node.

- RecipeSteps – An array of [RecipeStep](#) objects.

Transform steps used in the recipe node.

RecipeReference structure

A reference to a Amazon Glue DataBrew recipe.

Fields

- RecipeArn – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The ARN of the DataBrew recipe.

- RecipeVersion – *Required:* UTF-8 string, not less than 1 or more than 16 bytes long.

The RecipeVersion of the DataBrew recipe.

SnowflakeNodeData structure

Specifies configuration for Snowflake nodes in Amazon Glue Studio.

Fields

- SourceType – UTF-8 string, matching the [Custom string pattern #60](#).

Specifies how retrieved data is specified. Valid values: "table", "query".

- `Connection` – An [Option](#) object.

Specifies a Amazon Glue Data Catalog Connection to a Snowflake endpoint.

- `Schema` – UTF-8 string.

Specifies a Snowflake database schema for your node to use.

- `Table` – UTF-8 string.

Specifies a Snowflake table for your node to use.

- `Database` – UTF-8 string.

Specifies a Snowflake database for your node to use.

- `TempDir` – UTF-8 string, matching the [Custom string pattern #61](#).

Not currently used.

- `IamRole` – An [Option](#) object.

Not currently used.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional options passed to the Snowflake connector. If options are specified elsewhere in this node, this will take precedence.

- `SampleQuery` – UTF-8 string.

A SQL string used to retrieve data with the query sourcetype.

- `PreAction` – UTF-8 string.

A SQL string run before the Snowflake connector performs its standard actions.

- `PostAction` – UTF-8 string.

A SQL string run after the Snowflake connector performs its standard actions.

- `Action` – UTF-8 string.

Specifies what action to take when writing to a table with preexisting data. Valid values: `append`, `merge`, `truncate`, `drop`.

- `Upsert` – Boolean.

Used when Action is `append`. Specifies the resolution behavior when a row already exists. If true, preexisting rows will be updated. If false, those rows will be inserted.

- `MergeAction` – UTF-8 string, matching the [Custom string pattern #60](#).

Specifies a merge action. Valid values: `simple`, `custom`. If `simple`, merge behavior is defined by `MergeWhenMatched` and `MergeWhenNotMatched`. If `custom`, defined by `MergeClause`.

- `MergeWhenMatched` – UTF-8 string, matching the [Custom string pattern #60](#).

Specifies how to resolve records that match preexisting data when merging. Valid values: `update`, `delete`.

- `MergeWhenNotMatched` – UTF-8 string, matching the [Custom string pattern #60](#).

Specifies how to process records that do not match preexisting data when merging. Valid values: `insert`, `none`.

- `MergeClause` – UTF-8 string.

A SQL statement that specifies a custom merge behavior.

- `StagingTable` – UTF-8 string.

The name of a staging table used when performing `merge` or `upsert append` actions. Data is written to this table, then moved to `table` by a generated postaction.

- `SelectedColumns` – An array of [Option](#) objects.

Specifies the columns combined to identify a record when detecting matches for merges and upserts. A list of structures with `value`, `label` and `description` keys. Each structure describes a column.

- `AutoPushdown` – Boolean.

Specifies whether automatic query pushdown is enabled. If pushdown is enabled, then when a query is run on Spark, if part of the query can be "pushed down" to the Snowflake server, it is pushed down. This improves performance of some queries.

- `TableSchema` – An array of [Option](#) objects.

Manually defines the target schema for the node. A list of structures with `value`, `label` and `description` keys. Each structure defines a column.

SnowflakeSource structure

Specifies a Snowflake data source.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Snowflake data source.

- **Data** – *Required:* A [SnowflakeNodeData](#) object.

Configuration for the Snowflake data source.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies user-defined schemas for your output data.

SnowflakeTarget structure

Specifies a Snowflake target.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Snowflake target.

- **Data** – *Required:* A [SnowflakeNodeData](#) object.

Specifies the data of the Snowflake target node.

- **Inputs** – An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

ConnectorDataSource structure

Specifies a source generated with standard connection options.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of this source node.

- ConnectionType – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The connectionType, as provided to the underlying Amazon Glue library. This node type supports the following connection types:

- opensearch
 - azuresql
 - azurecosmos
 - bigquery
 - saphana
 - teradata
 - vertica
- Data – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A map specifying connection options for the node. You can find standard connection options for the corresponding connection type in the [Connection parameters](#) section of the Amazon Glue documentation.

- OutputSchemas – An array of [GlueSchema](#) objects.

Specifies the data schema for this source.

ConnectorDataTarget structure

Specifies a target generated with standard connection options.

Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of this target node.

- `connectionType` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The `connectionType`, as provided to the underlying Amazon Glue library. This node type supports the following connection types:

- `opensearch`
 - `azuresql`
 - `azurecosmos`
 - `bigquery`
 - `saphana`
 - `teradata`
 - `vertica`
- `Data` – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A map specifying connection options for the node. You can find standard connection options for the corresponding connection type in the [Connection parameters](#) section of the Amazon Glue documentation.

- `Inputs` – An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

RecipeStep structure

A recipe step used in a Amazon Glue Studio data preparation recipe node.

Fields

- `Action` – *Required:* A [RecipeAction](#) object.

The transformation action of the recipe step.

- `ConditionExpressions` – An array of [ConditionExpression](#) objects.

The condition expressions for the recipe step.

RecipeAction structure

Actions defined in the Amazon Glue Studio data preparation recipe node.

Fields

- **Operation** – *Required*: UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #56](#).

The operation of the recipe action.

- **Parameters** – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #57](#).

Each value is a UTF-8 string, not less than 1 or more than 32768 bytes long.

The parameters of the recipe action.

ConditionExpression structure

Condition expression defined in the Amazon Glue Studio data preparation recipe node.

Fields

- **Condition** – *Required*: UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #56](#).

The condition of the condition expression.

- **Value** – UTF-8 string, not more than 1024 bytes long.

The value of the condition expression.

- **TargetColumn** – *Required*: UTF-8 string, not less than 1 or more than 1024 bytes long.

The target column of the condition expressions.

S3CatalogIcebergSource structure

Specifies an Apache Iceberg data source that is registered in the Amazon Glue Data Catalog. The Iceberg data source must be stored in Amazon S3.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).
The name of the Iceberg data source.
- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).
The name of the database to read from.
- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).
The name of the table in the database to read from.
- **AdditionalIcebergOptions** – A map array of key-value pairs.
Each key is a UTF-8 string, matching the [Custom string pattern #61](#).
Each value is a UTF-8 string, matching the [Custom string pattern #61](#).
Specifies additional connection options for the Iceberg data source.
- **OutputSchemas** – An array of [GlueSchema](#) objects.
Specifies the data schema for the Iceberg source.

CatalogIcebergSource structure

Specifies an Apache Iceberg data source that is registered in the Amazon Glue Data Catalog.

Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).
The name of the Iceberg data source.
- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).
The name of the database to read from.
- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table in the database to read from.

- `AdditionalIcebergOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options for the Iceberg data source.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the Iceberg source.

S3IcebergCatalogTarget structure

Specifies an Apache Iceberg catalog target that writes data to Amazon S3 and registers the table in the Amazon Glue Data Catalog.

Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #63](#).

The name of the Iceberg catalog target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The input connection for the Iceberg catalog target.

- `PartitionKeys` – An array of UTF-8 strings.

A list of partition keys for the Iceberg table.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the table to write to in the catalog.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #61](#).

The name of the database to write to.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #61](#).

Each value is a UTF-8 string, matching the [Custom string pattern #61](#).

Specifies additional connection options for the Iceberg catalog target.

- `SchemaChangePolicy` – A [CatalogSchemaChangePolicy](#) object.

The policy for handling schema changes in the catalog target.

- `AutoDataQuality` – An [AutoDataQuality](#) object.

Specifies whether to automatically enable data quality evaluation for the S3 Iceberg catalog target. When set to `true`, data quality checks are performed automatically during the write operation.

DynamoDBELTConnectorSource structure

Specifies a DynamoDB ELT connector source for extracting data from DynamoDB tables.

Fields

- `Name` – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).

The name of the DynamoDB ELT connector source.

- `ConnectionOptions` – A [DDBELTConnectionOptions](#) object.

The connection options for the DynamoDB ELT connector source.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the DynamoDB ELT connector source.

DDBELTConnectionOptions structure

Specifies connection options for DynamoDB ELT (Extract, Load, Transform) operations. This structure contains configuration parameters for connecting to and extracting data from DynamoDB tables using the ELT connector.

Fields

- `DynamodbExport` – UTF-8 string (valid values: `ddb` | `s3`).

Specifies the export type for DynamoDB data extraction. This parameter determines how data is exported from the DynamoDB table during the ELT process.

- `DynamodbUnnestDDBJson` – Boolean.

A boolean value that specifies whether to unnest DynamoDB JSON format during data extraction. When set to `true`, the connector will flatten nested JSON structures from DynamoDB items. When set to `false`, the original DynamoDB JSON structure is preserved.

- `DynamodbTableArn` – *Required*: UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon Resource Name (ARN) of the DynamoDB table to extract data from. This parameter specifies the source table for the ELT operation.

- `DynamodbS3Bucket` – UTF-8 string, matching the [Custom string pattern #61](#).

The name of the Amazon S3 bucket used for intermediate storage during the DynamoDB ELT process. This bucket is used to temporarily store exported DynamoDB data before it is processed by the ELT job.

- `DynamodbS3Prefix` – UTF-8 string, matching the [Custom string pattern #61](#).

The S3 object key prefix for files stored in the intermediate S3 bucket during the DynamoDB ELT process. This prefix helps organize and identify the temporary files created during data extraction.

- `DynamodbS3BucketOwner` – UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon account ID of the owner of the S3 bucket specified in `DynamodbS3Bucket`. This parameter is required when the S3 bucket is owned by a different Amazon account than the one running the ELT job, enabling cross-account access to the intermediate storage bucket.

- `DynamodbStsRoleArn` – UTF-8 string, matching the [Custom string pattern #61](#).

The Amazon Resource Name (ARN) of the Amazon Security Token Service (STS) role to assume for accessing DynamoDB and S3 resources during the ELT operation. This role must have the necessary permissions to read from the DynamoDB table and write to the intermediate S3 bucket.

DDBELTCatalogAdditionalOptions structure

Specifies additional options for DynamoDB ELT catalog operations.

Fields

- `DynamodbExport` – UTF-8 string, matching the [Custom string pattern #61](#).

Specifies the DynamoDB export configuration for the ELT operation.

- `DynamodbUnnestDDBJson` – Boolean.

Specifies whether to unnest DynamoDB JSON format. When set to `true`, nested JSON structures in DynamoDB items are flattened.

Route structure

Specifies a route node that directs data to different output paths based on defined filtering conditions.

Fields

- `Name` – *Required*: UTF-8 string, matching the [Custom string pattern #63](#).

The name of the route node.

- `Inputs` – *Required*: An array of UTF-8 strings, not less than 1 or more than 1 strings.

The input connection for the route node.

- `GroupFiltersList` – *Required*: An array of [GroupFilters](#) objects.

A list of group filters that define the routing conditions and criteria for directing data to different output paths.

GroupFilters structure

Specifies a group of filters with a logical operator that determines how the filters are combined to evaluate routing conditions.

Fields

- `GroupName` – *Required*: UTF-8 string, matching the [Custom string pattern #60](#).

The name of the filter group.

- `Filters` – *Required*: An array of [FilterExpression](#) objects.

A list of filter expressions that define the conditions for this group.

- `LogicalOperator` – *Required*: UTF-8 string (valid values: AND | OR).

The logical operator used to combine the filters in this group. Determines whether all filters must match (AND) or any filter can match (OR).

AutoDataQuality structure

Specifies configuration options for automatic data quality evaluation in Amazon Glue jobs. This structure enables automated data quality checks and monitoring during ETL operations, helping to ensure data integrity and reliability without manual intervention.

Fields

- `IsEnabled` – Boolean.

Specifies whether automatic data quality evaluation is enabled. When set to `true`, data quality checks are performed automatically.

- `EvaluationContext` – UTF-8 string, matching the [Custom string pattern #61](#).

The evaluation context for the automatic data quality checks. This defines the scope and parameters for the data quality evaluation.

Jobs API

The Jobs API describes jobs data types and contains APIs for working with jobs, job runs, and triggers in Amazon Glue.

Topics

- [Jobs](#)
- [Job runs](#)
- [Triggers](#)

Jobs

The Jobs API describes the data types and API related to creating, updating, deleting, or viewing jobs in Amazon Glue.

Data types

- [Job structure](#)
- [ExecutionProperty structure](#)
- [NotificationProperty structure](#)
- [JobCommand structure](#)
- [ConnectionsList structure](#)
- [JobUpdate structure](#)
- [SourceControlDetails structure](#)

Job structure

Specifies a job definition.

Fields

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name you assign to this job definition.

- JobMode – UTF-8 string (valid values: SCRIPT="" | VISUAL="" | NOTEBOOK="").

A mode that describes how a job was created. Valid values are:

- SCRIPT - The job was created using the Amazon Glue Studio script editor.
- VISUAL - The job was created using the Amazon Glue Studio visual editor.
- NOTEBOOK - The job was created using an interactive sessions notebook.

When the JobMode field is missing or null, SCRIPT is assigned as the default value.

- JobRunQueuingEnabled – Boolean.

Specifies whether job run queuing is enabled for the job runs for this job.

A value of true means job run queuing is enabled for the job runs. If false or not populated, the job runs will not be considered for queuing.

If this field does not match the value set in the job run, then the value from the job run field will be used.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the job.

- **LogUri** – UTF-8 string.

This field is reserved for future use.

- **Role** – UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role associated with this job.

- **CreatedOn** – Timestamp.

The time and date that this job definition was created.

- **LastModifiedOn** – Timestamp.

The last point in time when this job definition was modified.

- **ExecutionProperty** – An [ExecutionProperty](#) object.

An ExecutionProperty specifying the maximum number of concurrent runs allowed for this job.

- **Command** – A [JobCommand](#) object.

The JobCommand that runs this job.

- **DefaultArguments** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The default arguments for every run of this job, specified as name-value pairs.

You can specify arguments here that your own job-execution script consumes, as well as arguments that Amazon Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a Amazon Glue Connection, Amazon Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling Amazon Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by Amazon Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- `NonOverridableArguments` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

Arguments for this job that are not overridden when providing job arguments in a job run, specified as name-value pairs.

- `Connections` – A [ConnectionsList](#) object.

The connections used for this job.

- `MaxRetries` – Number (integer).

The maximum number of times to retry this job after a JobRun fails.

- `AllocatedCapacity` – Number (integer).

This field is deprecated. Use `MaxCapacity` instead.

The number of Amazon Glue data processing units (DPUs) allocated to runs of this job. You can allocate a minimum of 2 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

- `Timeout` – Number (integer), at least 1.

The job timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters TIMEOUT status.

Jobs must have timeout values less than 7 days or 10080 minutes. Otherwise, the jobs will throw an exception.

When the value is left blank, the timeout is defaulted to 2880 minutes.

Any existing Amazon Glue jobs that had a timeout value greater than 7 days will be defaulted to 7 days. For instance if you have specified a timeout of 20 days for a batch job, it will be stopped on the 7th day.

For streaming jobs, if you have set up a maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of Amazon Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

For Glue version 2.0 or later jobs, you cannot specify a `Maximum capacity`. Instead, you should specify a `Worker type` and the `Number of workers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs.

Amazon Glue provides multiple worker types to accommodate different workload requirements:

G Worker Types (General-purpose compute workers):

- G.1X: 1 DPU (4 vCPUs, 16 GB memory, 94GB disk)
- G.2X: 2 DPU (8 vCPUs, 32 GB memory, 138GB disk)

- G.4X: 4 DPU (16 vCPUs, 64 GB memory, 256GB disk)
- G.8X: 8 DPU (32 vCPUs, 128 GB memory, 512GB disk)
- G.12X: 12 DPU (48 vCPUs, 192 GB memory, 768GB disk)
- G.16X: 16 DPU (64 vCPUs, 256 GB memory, 1024GB disk)

R Worker Types (Memory-optimized workers):

- R.1X: 1 M-DPU (4 vCPUs, 32 GB memory)
- R.2X: 2 M-DPU (8 vCPUs, 64 GB memory)
- R.4X: 4 M-DPU (16 vCPUs, 128 GB memory)
- R.8X: 8 M-DPU (32 vCPUs, 256 GB memory)
- NumberOfWorkers – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- SecurityConfiguration – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the SecurityConfiguration structure to be used with this job.

- NotificationProperty – A [NotificationProperty](#) object.

Specifies configuration properties of a job notification.

- Running – Boolean.

This field is reserved for future use.

- GlueVersion – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #48](#).

In Spark jobs, GlueVersion determines the versions of Apache Spark and Python that Amazon Glue available in a job. The Python version indicates the version supported for jobs of type Spark.

Ray jobs should set GlueVersion to 4.0 or greater. However, the versions of Ray, Python and additional libraries available in your Ray job are determined by the Runtime parameter of the Job command.

For more information about the available Amazon Glue versions and corresponding Spark and

Python versions, see [Glue version](#) in the developer guide.

Jobs that are created without specifying a Glue version default to Glue 0.9.

- `CodeGenConfigurationNodes` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #60](#).

Each value is a [CodeGenConfigurationNode](#) object.

The representation of a directed acyclic graph on which both the Glue Studio visual component and Glue Studio code generation is based.

- `ExecutionClass` – UTF-8 string, not more than 16 bytes long (valid values: `FLEX=""` | `STANDARD=""`).

Indicates whether the job is run with a standard or flexible execution class. The standard execution class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with Amazon Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to `FLEX`. The flexible execution class is available for Spark jobs.

- `SourceControlDetails` – A [SourceControlDetails](#) object.

The details for a source control configuration for a job, allowing synchronization of job artifacts to or from a remote repository.

- `MaintenanceWindow` – UTF-8 string, matching the [Custom string pattern #34](#).

This field specifies a day of the week and hour for a maintenance window for streaming jobs. Amazon Glue periodically performs maintenance activities. During these maintenance windows, Amazon Glue will need to restart your streaming jobs.

Amazon Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.

- `ProfileName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of an Amazon Glue usage profile associated with the job.

ExecutionProperty structure

An execution property of a job.

Fields

- `MaxConcurrentRuns` – Number (integer).

The maximum number of concurrent runs allowed for the job. The default is 1. An error is returned when this threshold is reached. The maximum value you can specify is controlled by a service limit.

NotificationProperty structure

Specifies configuration properties of a notification.

Fields

- `NotifyDelayAfter` – Number (integer), at least 1.

After a job run starts, the number of minutes to wait before sending a job run delay notification.

JobCommand structure

Specifies code that runs when a job is run.

Fields

- `Name` – UTF-8 string.

The name of the job command. For an Apache Spark ETL job, this must be `glueetl`. For a Python shell job, it must be `pythonshell`. For an Apache Spark streaming ETL job, this must be `gluestreaming`. For a Ray job, this must be `glueray`.

- `ScriptLocation` – UTF-8 string, not more than 400000 bytes long.

Specifies the Amazon Simple Storage Service (Amazon S3) path to a script that runs a job.

- `PythonVersion` – UTF-8 string, matching the [Custom string pattern #49](#).

The Python version being used to run a Python shell job. Allowed values are 2 or 3.

- **Runtime** – UTF-8 string, not more than 64 bytes long, matching the [Custom string pattern #33](#).

In Ray jobs, Runtime is used to specify the versions of Ray, Python and additional libraries available in your environment. This field is not used in other job types. For supported runtime environment values, see [Supported Ray runtime environments](#) in the Amazon Glue Developer Guide.

ConnectionsList structure

Specifies the connections used by a job.

Fields

- **Connections** – An array of UTF-8 strings, not more than 1000 strings.

A list of connections used by the job.

JobUpdate structure

Specifies information used to update an existing job definition. The previous job definition is completely overwritten by this information.

Fields

- **JobMode** – UTF-8 string (valid values: SCRIPT="" | VISUAL="" | NOTEBOOK="").

A mode that describes how a job was created. Valid values are:

- **SCRIPT** - The job was created using the Amazon Glue Studio script editor.
- **VISUAL** - The job was created using the Amazon Glue Studio visual editor.
- **NOTEBOOK** - The job was created using an interactive sessions notebook.

When the JobMode field is missing or null, SCRIPT is assigned as the default value.

- **JobRunQueuingEnabled** – Boolean.

Specifies whether job run queuing is enabled for the job runs for this job.

A value of true means job run queuing is enabled for the job runs. If false or not populated, the job runs will not be considered for queueing.

If this field does not match the value set in the job run, then the value from the job run field will be used.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

Description of the job being defined.

- **LogUri** – UTF-8 string.

This field is reserved for future use.

- **Role** – UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role associated with this job (required).

- **ExecutionProperty** – An [ExecutionProperty](#) object.

An [ExecutionProperty](#) specifying the maximum number of concurrent runs allowed for this job.

- **Command** – A [JobCommand](#) object.

The [JobCommand](#) that runs this job (required).

- **DefaultArguments** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The default arguments for every run of this job, specified as name-value pairs.

You can specify arguments here that your own job-execution script consumes, as well as arguments that Amazon Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a Amazon Glue Connection, Amazon Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling Amazon Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by Amazon Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- `NonOverridableArguments` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

Arguments for this job that are not overridden when providing job arguments in a job run, specified as name-value pairs.

- `Connections` – A [ConnectionsList](#) object.

The connections used for this job.

- `MaxRetries` – Number (integer).

The maximum number of times to retry this job if it fails.

- `AllocatedCapacity` – Number (integer).

This field is deprecated. Use `MaxCapacity` instead.

The number of Amazon Glue data processing units (DPUs) to allocate to this job. You can allocate a minimum of 2 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

- `Timeout` – Number (integer), at least 1.

The job timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters `TIMEOUT` status.

Jobs must have timeout values less than 7 days or 10080 minutes. Otherwise, the jobs will throw an exception.

When the value is left blank, the timeout is defaulted to 2880 minutes.

Any existing Amazon Glue jobs that had a timeout value greater than 7 days will be defaulted to 7 days. For instance if you have specified a timeout of 20 days for a batch job, it will be stopped on the 7th day.

For streaming jobs, if you have set up a maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of Amazon Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

For Glue version 2.0+ jobs, you cannot specify a `Maximum capacity`. Instead, you should specify a `Worker type` and the `Number of workers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of `G.1X`, `G.2X`, `G.4X`, `G.8X` or `G.025X` for Spark jobs. Accepts the value `Z.2X` for Ray jobs. For more information, see [Defining job properties for Spark jobs](#)

- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this job.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies the configuration properties of a job notification.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #48](#).

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python that Amazon Glue available in a job. The Python version indicates the version supported for jobs of type Spark.

Ray jobs should set `GlueVersion` to 4.0 or greater. However, the versions of Ray, Python and additional libraries available in your Ray job are determined by the `Runtime` parameter of the Job command.

For more information about the available Amazon Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

Jobs that are created without specifying a Glue version default to Glue 0.9.

- `CodeGenConfigurationNodes` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #60](#).

Each value is a [CodeGenConfigurationNode](#) object.

The representation of a directed acyclic graph on which both the Glue Studio visual component and Glue Studio code generation is based.

- `ExecutionClass` – UTF-8 string, not more than 16 bytes long (valid values: `FLEX=""` | `STANDARD=""`).

Indicates whether the job is run with a standard or flexible execution class. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with Amazon Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to `FLEX`. The flexible execution class is available for Spark jobs.

- `SourceControlDetails` – A [SourceControlDetails](#) object.

The details for a source control configuration for a job, allowing synchronization of job artifacts to or from a remote repository.

- `MaintenanceWindow` – UTF-8 string, matching the [Custom string pattern #34](#).

This field specifies a day of the week and hour for a maintenance window for streaming jobs. Amazon Glue periodically performs maintenance activities. During these maintenance windows, Amazon Glue will need to restart your streaming jobs.

Amazon Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.

- `ProfileName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of an Amazon Glue usage profile associated with the job.

SourceControlDetails structure

The details for a source control configuration for a job, allowing synchronization of job artifacts to or from a remote repository.

Fields

- `Provider` – UTF-8 string (valid values: GITHUB | AWS_CODE_COMMIT).

The provider for the remote repository.

- `Repository` – UTF-8 string, not less than 1 or more than 512 bytes long.

The name of the remote repository that contains the job artifacts.

- `Owner` – UTF-8 string, not less than 1 or more than 512 bytes long.

The owner of the remote repository that contains the job artifacts.

- `Branch` – UTF-8 string, not less than 1 or more than 512 bytes long.

An optional branch in the remote repository.

- `Folder` – UTF-8 string, not less than 1 or more than 512 bytes long.

An optional folder in the remote repository.

- `LastCommitId` – UTF-8 string, not less than 1 or more than 512 bytes long.

The last commit ID for a commit in the remote repository.

- LastSyncTimestamp – UTF-8 string, not less than 1 or more than 512 bytes long.

The date and time that the last job synchronization was performed.

- AuthStrategy – UTF-8 string (valid values: PERSONAL_ACCESS_TOKEN | AWS_SECRETS_MANAGER).

The type of authentication, which can be an authentication token stored in Amazon Secrets Manager, or a personal access token.

- AuthToken – UTF-8 string, not less than 1 or more than 512 bytes long.

The value of an authorization token.

Operations

- [CreateJob action \(Python: create_job\)](#)
- [UpdateJob action \(Python: update_job\)](#)
- [GetJob action \(Python: get_job\)](#)
- [GetJobs action \(Python: get_jobs\)](#)
- [DeleteJob action \(Python: delete_job\)](#)
- [ListJobs action \(Python: list_jobs\)](#)
- [BatchGetJobs action \(Python: batch_get_jobs\)](#)

CreateJob action (Python: create_job)

Creates a new job definition.

Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name you assign to this job definition. It must be unique in your account.

- JobMode – UTF-8 string (valid values: SCRIPT="" | VISUAL="" | NOTEBOOK="").

A mode that describes how a job was created. Valid values are:

- SCRIPT - The job was created using the Amazon Glue Studio script editor.

- VISUAL - The job was created using the Amazon Glue Studio visual editor.
- NOTEBOOK - The job was created using an interactive sessions notebook.

When the JobMode field is missing or null, SCRIPT is assigned as the default value.

- JobRunQueuingEnabled – Boolean.

Specifies whether job run queuing is enabled for the job runs for this job.

A value of true means job run queuing is enabled for the job runs. If false or not populated, the job runs will not be considered for queueing.

If this field does not match the value set in the job run, then the value from the job run field will be used.

- Description – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

Description of the job being defined.

- LogUri – UTF-8 string.

This field is reserved for future use.

- Role – *Required*: UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role associated with this job.

- ExecutionProperty – An [ExecutionProperty](#) object.

An ExecutionProperty specifying the maximum number of concurrent runs allowed for this job.

- Command – *Required*: A [JobCommand](#) object.

The JobCommand that runs this job.

- DefaultArguments – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The default arguments for every run of this job, specified as name-value pairs.

You can specify arguments here that your own job-execution script consumes, as well as arguments that Amazon Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a Amazon Glue Connection, Amazon Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling Amazon Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by Amazon Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- `NonOverridableArguments` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

Arguments for this job that are not overridden when providing job arguments in a job run, specified as name-value pairs.

- `Connections` – A [ConnectionsList](#) object.

The connections used for this job.

- `MaxRetries` – Number (integer).

The maximum number of times to retry this job if it fails.

- `AllocatedCapacity` – Number (integer).

This parameter is deprecated. Use `MaxCapacity` instead.

The number of Amazon Glue data processing units (DPUs) to allocate to this Job. You can allocate a minimum of 2 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

- `Timeout` – Number (integer), at least 1.

The job timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters TIMEOUT status.

Jobs must have timeout values less than 7 days or 10080 minutes. Otherwise, the jobs will throw an exception.

When the value is left blank, the timeout is defaulted to 2880 minutes.

Any existing Amazon Glue jobs that had a timeout value greater than 7 days will be defaulted to 7 days. For instance if you have specified a timeout of 20 days for a batch job, it will be stopped on the 7th day.

For streaming jobs, if you have set up a maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of Amazon Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

For Glue version 2.0+ jobs, you cannot specify a `Maximum capacity`. Instead, you should specify a `Worker type` and the `Number of workers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this job.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to use with this job. You may use tags to limit access to the job. For more information about tags in Amazon Glue, see [Amazon Tags in Amazon Glue](#) in the developer guide.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies configuration properties of a job notification.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #48](#).

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python that Amazon Glue available in a job. The Python version indicates the version supported for jobs of type Spark.

Ray jobs should set `GlueVersion` to 4.0 or greater. However, the versions of Ray, Python and additional libraries available in your Ray job are determined by the `Runtime` parameter of the Job command.

For more information about the available Amazon Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

Jobs that are created without specifying a Glue version default to Glue 0.9.

- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of G.1X, G.2X, G.4X, G.8X or G.025X for Spark jobs. Accepts the value Z.2X for Ray jobs.

- For the G.1X worker type, each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 94GB disk, and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.

- For the G.2X worker type, each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 138GB disk, and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the G.4X worker type, each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk, and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for Amazon Glue version 3.0 or later Spark ETL jobs in the following Amazon Regions: US East (Ohio), US East (N. Virginia), US West (N. California), US West (Oregon), Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Spain), Europe (Stockholm), and
- For the G.8X worker type, each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk, and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for Amazon Glue version 3.0 or later Spark ETL jobs, in the same Amazon Regions as supported for the G.4X worker type.
- For the G.025X worker type, each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk, and provides 1 executor per worker. We recommend this worker type for low volume streaming jobs. This worker type is only available for Amazon Glue version 3.0 or later streaming jobs.
- For the Z.2X worker type, each worker maps to 2 M-DPU (8vCPUs, 64 GB of memory) with 128 GB disk, and provides up to 8 Ray workers based on the autoscaler.
- CodeGenConfigurationNodes – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #60](#).

Each value is a A [CodeGenConfigurationNode](#) object.

The representation of a directed acyclic graph on which both the Glue Studio visual component and Glue Studio code generation is based.

- ExecutionClass – UTF-8 string, not more than 16 bytes long (valid values: FLEX="" | STANDARD="").

Indicates whether the job is run with a standard or flexible execution class. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with Amazon Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to FLEX. The flexible execution class is available for Spark jobs.

- `SourceControlDetails` – A [SourceControlDetails](#) object.

The details for a source control configuration for a job, allowing synchronization of job artifacts to or from a remote repository.

- `MaintenanceWindow` – UTF-8 string, matching the [Custom string pattern #34](#).

This field specifies a day of the week and hour for a maintenance window for streaming jobs. Amazon Glue periodically performs maintenance activities. During these maintenance windows, Amazon Glue will need to restart your streaming jobs.

Amazon Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.

- `ProfileName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of an Amazon Glue usage profile associated with the job.

Response

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique name that was provided for this job definition.

Errors

- `InvalidInputException`

- `IdempotentParameterMismatchException`
- `AlreadyExistsException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentModificationException`

UpdateJob action (Python: `update_job`)

Updates an existing job definition. The previous job definition is completely overwritten by this information.

Request

- `JobName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition to update.

- `JobUpdate` – *Required:* A [JobUpdate](#) object.

Specifies the values with which to update the job definition. Unspecified configuration is removed or reset to default values.

- `ProfileName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of an Amazon Glue usage profile associated with the job.

Response

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Returns the name of the updated job definition.

Errors

- `InvalidInputException`

- EntityNotFoundException
- InternalServiceException
- OperationTimeoutException
- ConcurrentModificationException

GetJob action (Python: `get_job`)

Retrieves an existing job definition.

Request

- JobName – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition to retrieve.

Response

- Job – A [Job](#) object.

The requested job definition.

Errors

- InvalidInputException
- EntityNotFoundException
- InternalServiceException
- OperationTimeoutException

GetJobs action (Python: `get_jobs`)

Retrieves all current job definitions.

Request

- NextToken – UTF-8 string.

A continuation token, if this is a continuation call.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of the response.

Response

- `Jobs` – An array of [Job](#) objects.

A list of job definitions.

- `NextToken` – UTF-8 string.

A continuation token, if not all job definitions have yet been returned.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServerErrorException`
- `OperationTimeoutException`

DeleteJob action (Python: `delete_job`)

Deletes a specified job definition. If the job definition is not found, no exception is thrown.

Request

- `JobName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition to delete.

Response

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition that was deleted.

Errors

- `InvalidInputException`
- `InternalServerErrorException`
- `OperationTimeoutException`

ListJobs action (Python: `list_jobs`)

Retrieves the names of all job resources in this Amazon account, or the resources with the specified tag. This operation allows you to see which resources are available in your account, and their names.

This operation takes the optional `Tags` field, which you can use as a filter on the response so that tagged resources can be retrieved as a group. If you choose to use tags filtering, only resources with the tag are retrieved.

Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Specifies to return only these tagged resources.

Response

- `JobNames` – An array of UTF-8 strings.

The names of all jobs in the account, or the jobs with the specified tags.

- NextToken – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

Errors

- InvalidInputException
- EntityNotFoundException
- InternalServiceException
- OperationTimeoutException

BatchGetJobs action (Python: `batch_get_jobs`)

Returns a list of resource metadata for a given list of job names. After calling the `ListJobs` operation, you can call this operation to access the data to which you have been granted permissions. This operation supports all IAM permissions, including permission conditions that uses tags.

Request

- JobNames – *Required*: An array of UTF-8 strings.

A list of job names, which might be the names returned from the `ListJobs` operation.

Response

- Jobs – An array of [Job](#) objects.

A list of job definitions.

- JobsNotFound – An array of UTF-8 strings.

A list of names of jobs not found.

Errors

- InternalServiceException

- `OperationTimeoutException`
- `InvalidInputException`

Job runs

The Jobs Runs API describes the data types and API related to starting, stopping, or viewing job runs, and resetting job bookmarks, in Amazon Glue. Job run history is accessible for 90 days for your workflow and job run.

Data types

- [JobRun structure](#)
- [Predecessor structure](#)
- [JobBookmarkEntry structure](#)
- [BatchStopJobRunSuccessfulSubmission structure](#)
- [BatchStopJobRunError structure](#)
- [NotificationProperty structure](#)

JobRun structure

Contains information about a job run.

Fields

- `Id` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of this job run.

- `Attempt` – Number (integer).

The number of the attempt to run this job.

- `PreviousRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the previous run of this job. For example, the `JobRunId` specified in the `StartJobRun` action.

- **TriggerName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger that started this job run.

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition being used in this run.

- **JobMode** – UTF-8 string (valid values: SCRIPT="" | VISUAL="" | NOTEBOOK="").

A mode that describes how a job was created. Valid values are:

- **SCRIPT** - The job was created using the Amazon Glue Studio script editor.
- **VISUAL** - The job was created using the Amazon Glue Studio visual editor.
- **NOTEBOOK** - The job was created using an interactive sessions notebook.

When the JobMode field is missing or null, SCRIPT is assigned as the default value.

- **JobRunQueuingEnabled** – Boolean.

Specifies whether job run queuing is enabled for the job run.

A value of true means job run queuing is enabled for the job run. If false or not populated, the job run will not be considered for queueing.

- **StartedOn** – Timestamp.

The date and time at which this job run was started.

- **LastModifiedOn** – Timestamp.

The last time that this job run was modified.

- **CompletedOn** – Timestamp.

The date and time that this job run completed.

- **JobRunState** – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT | ERROR | WAITING | EXPIRED).

The current state of the job run. For more information about the statuses of jobs that have terminated abnormally, see [Amazon Glue Job Run Statuses](#).

- **Arguments** – A map array of key value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The job arguments associated with this run. For this job run, they replace the default arguments set in the job definition itself.

You can specify arguments here that your own job-execution script consumes, as well as arguments that Amazon Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a Amazon Glue Connection, Amazon Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling Amazon Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by Amazon Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- `ErrorMessage` – UTF-8 string.

An error message associated with this job run.

- `PredecessorRuns` – An array of [Predecessor](#) objects.

A list of predecessors to this job run.

- `AllocatedCapacity` – Number (integer).

This field is deprecated. Use `MaxCapacity` instead.

The number of Amazon Glue data processing units (DPUs) allocated to this JobRun. From 2 to 100 DPUs can be allocated; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

- `ExecutionTime` – Number (integer).

The amount of time (in seconds) that the job run consumed resources.

- `Timeout` – Number (integer), at least 1.

The `JobRun` timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters `TIMEOUT` status. This value overrides the timeout value set in the parent job.

Jobs must have timeout values less than 7 days or 10080 minutes. Otherwise, the jobs will throw an exception.

When the value is left blank, the timeout is defaulted to 2880 minutes.

Any existing Amazon Glue jobs that had a timeout value greater than 7 days will be defaulted to 7 days. For instance if you have specified a timeout of 20 days for a batch job, it will be stopped on the 7th day.

For streaming jobs, if you have set up a maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of Amazon Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

For Glue version 2.0+ jobs, you cannot specify a `Maximum capacity`. Instead, you should specify a `Worker type` and the `Number of workers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of G.1X, G.2X, G.4X, G.8X or G.025X for Spark jobs. Accepts the value Z.2X for Ray jobs.

- For the G.1X worker type, each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 94GB disk, and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the G.2X worker type, each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 138GB disk, and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the G.4X worker type, each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk, and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for Amazon Glue version 3.0 or later Spark ETL jobs in the following Amazon Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).
- For the G.8X worker type, each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk, and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for Amazon Glue version 3.0 or later Spark ETL jobs, in the same Amazon Regions as supported for the G.4X worker type.
- For the G.025X worker type, each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk, and provides 1 executor per worker. We recommend this worker type for low volume streaming jobs. This worker type is only available for Amazon Glue version 3.0 or later streaming jobs.
- For the Z.2X worker type, each worker maps to 2 M-DPU (8vCPUs, 64 GB of memory) with 128 GB disk, and provides up to 8 Ray workers based on the autoscaler.
- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this job run.

- `LogGroupName` – UTF-8 string.

The name of the log group for secure logging that can be server-side encrypted in Amazon CloudWatch using Amazon KMS. This name can be `/aws-glue/jobs/`, in which case the default encryption is `NONE`. If you add a role name and `SecurityConfiguration` name (in other words, `/aws-glue/jobs-yourRoleName-yourSecurityConfigurationName/`), then that security configuration is used to encrypt the log group.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies configuration properties of a job run notification.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #48](#).

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python that Amazon Glue available in a job. The Python version indicates the version supported for jobs of type Spark.

Ray jobs should set `GlueVersion` to `4.0` or greater. However, the versions of Ray, Python and additional libraries available in your Ray job are determined by the `Runtime` parameter of the Job command.

For more information about the available Amazon Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

Jobs that are created without specifying a Glue version default to Glue 0.9.

- `DPUSeconds` – Number (double).

This field can be set for either job runs with execution class `FLEX` or when Auto Scaling is enabled, and represents the total time each executor ran during the lifecycle of a job run in seconds, multiplied by a DPU factor (1 for `G.1X`, 2 for `G.2X`, or 0.25 for `G.025X` workers). This value may be different than the `executionEngineRuntime * MaxCapacity` as in the case of Auto Scaling jobs, as the number of executors running at a given time may be less than the `MaxCapacity`. Therefore, it is possible that the value of `DPUSeconds` is less than `executionEngineRuntime * MaxCapacity`.

- `ExecutionClass` – UTF-8 string, not more than 16 bytes long (valid values: `FLEX=""` | `STANDARD=""`).

Indicates whether the job is run with a standard or flexible execution class. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with Amazon Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to FLEX. The flexible execution class is available for Spark jobs.

- `MaintenanceWindow` – UTF-8 string, matching the [Custom string pattern #34](#).

This field specifies a day of the week and hour for a maintenance window for streaming jobs. Amazon Glue periodically performs maintenance activities. During these maintenance windows, Amazon Glue will need to restart your streaming jobs.

Amazon Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.

- `ProfileName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of an Amazon Glue usage profile associated with the job run.

- `StateDetail` – UTF-8 string, not more than 400000 bytes long.

This field holds details that pertain to the state of a job run. The field is nullable.

For example, when a job run is in a WAITING state as a result of job run queuing, the field has the reason why the job run is in that state.

- `ExecutionRoleSessionPolicy` – UTF-8 string, not less than 2 or more than 2048 bytes long.

This inline session policy to the `StartJobRun` API allows you to dynamically restrict the permissions of the specified execution role for the scope of the job, without requiring the creation of additional IAM roles.

Predecessor structure

A job run that was used in the predicate of a conditional trigger that triggered this job run.

Fields

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition used by the predecessor job run.

- **RunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job-run ID of the predecessor job run.

JobBookmarkEntry structure

Defines a point that a job can resume processing.

Fields

- **JobName** – UTF-8 string.

The name of the job in question.

- **Version** – Number (integer).

The version of the job.

- **Run** – Number (integer).

The run ID number.

- **Attempt** – Number (integer).

The attempt ID number.

- **PreviousRunId** – UTF-8 string.

The unique run identifier associated with the previous job run.

- **RunId** – UTF-8 string.

The run ID number.

- **JobBookmark** – UTF-8 string.

The bookmark itself.

BatchStopJobRunSuccessfulSubmission structure

Records a successful request to stop a specified JobRun.

Fields

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition used in the job run that was stopped.

- **JobRunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The JobRunId of the job run that was stopped.

BatchStopJobRunError structure

Records an error that occurred when attempting to stop a specified job run.

Fields

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition that is used in the job run in question.

- **JobRunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The JobRunId of the job run in question.

- **ErrorDetail** – An [ErrorDetail](#) object.

Specifies details about the error that was encountered.

NotificationProperty structure

Specifies configuration properties of a notification.

Fields

- **NotifyDelayAfter** – Number (integer), at least 1.

After a job run starts, the number of minutes to wait before sending a job run delay notification.

Operations

- [StartJobRun action \(Python: start_job_run\)](#)
- [BatchStopJobRun action \(Python: batch_stop_job_run\)](#)
- [GetJobRun action \(Python: get_job_run\)](#)
- [GetJobRuns action \(Python: get_job_runs\)](#)
- [GetJobBookmark action \(Python: get_job_bookmark\)](#)
- [GetJobBookmarks action \(Python: get_job_bookmarks\)](#)
- [ResetJobBookmark action \(Python: reset_job_bookmark\)](#)

StartJobRun action (Python: start_job_run)

Starts a job run using a job definition.

Request

- **JobName** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition to use.

- **JobRunQueuingEnabled** – Boolean.

Specifies whether job run queuing is enabled for the job run.

A value of true means job run queuing is enabled for the job run. If false or not populated, the job run will not be considered for queuing.

- **JobRunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of a previous JobRun to retry.

- **Arguments** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The job arguments associated with this run. For this job run, they replace the default arguments set in the job definition itself.

You can specify arguments here that your own job-execution script consumes, as well as arguments that Amazon Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a Amazon Glue Connection, Amazon Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling Amazon Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by Amazon Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- `AllocatedCapacity` – Number (integer).

This field is deprecated. Use `MaxCapacity` instead.

The number of Amazon Glue data processing units (DPUs) to allocate to this JobRun. You can allocate a minimum of 2 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

- `Timeout` – Number (integer), at least 1.

The JobRun timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters TIMEOUT status. This value overrides the timeout value set in the parent job.

Jobs must have timeout values less than 7 days or 10080 minutes. Otherwise, the jobs will throw an exception.

When the value is left blank, the timeout is defaulted to 2880 minutes.

Any existing Amazon Glue jobs that had a timeout value greater than 7 days will be defaulted to 7 days. For instance if you have specified a timeout of 20 days for a batch job, it will be stopped on the 7th day.

For streaming jobs, if you have set up a maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of Amazon Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [Amazon Glue pricing page](#).

For Glue version 2.0+ jobs, you cannot specify a `MaximumCapacity`. Instead, you should specify a `WorkerType` and the `NumberOfWorkers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this job run.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies configuration properties of a job run notification.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of `G.1X`, `G.2X`, `G.4X`, `G.8X` or `G.025X` for Spark jobs. Accepts the value `Z.2X` for Ray jobs.

- For the G.1X worker type, each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 94GB disk, and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the G.2X worker type, each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 138GB disk, and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the G.4X worker type, each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk, and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for Amazon Glue version 3.0 or later Spark ETL jobs in the following Amazon Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).
- For the G.8X worker type, each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk, and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for Amazon Glue version 3.0 or later Spark ETL jobs, in the same Amazon Regions as supported for the G.4X worker type.
- For the G.025X worker type, each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk, and provides 1 executor per worker. We recommend this worker type for low volume streaming jobs. This worker type is only available for Amazon Glue version 3.0 or later streaming jobs.
- For the Z.2X worker type, each worker maps to 2 M-DPU (8vCPUs, 64 GB of memory) with 128 GB disk, and provides up to 8 Ray workers based on the autoscaler.
- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- `ExecutionClass` – UTF-8 string, not more than 16 bytes long (valid values: `FLEX=""` | `STANDARD=""`).

Indicates whether the job is run with a standard or flexible execution class. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with Amazon Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to `FLEX`. The flexible execution class is available for Spark jobs.

- `ProfileName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of an Amazon Glue usage profile associated with the job run.

- `ExecutionRoleSessionPolicy` – UTF-8 string, not less than 2 or more than 2048 bytes long.

This inline session policy to the `StartJobRun` API allows you to dynamically restrict the permissions of the specified execution role for the scope of the job, without requiring the creation of additional IAM roles.

Response

- `JobRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID assigned to this job run.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentRunsExceededException`

BatchStopJobRun action (Python: `batch_stop_job_run`)

Stops one or more job runs for a specified job definition.

Request

- **JobName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition for which to stop job runs.

- **JobRunIds** – *Required:* An array of UTF-8 strings, not less than 1 or more than 25 strings.

A list of the JobRunIds that should be stopped for that job definition.

Response

- **SuccessfulSubmissions** – An array of [BatchStopJobRunSuccessfulSubmission](#) objects.

A list of the JobRuns that were successfully submitted for stopping.

- **Errors** – An array of [BatchStopJobRunError](#) objects.

A list of the errors that were encountered in trying to stop JobRuns, including the JobRunId for which each error was encountered and details about the error.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

GetJobRun action (Python: `get_job_run`)

Retrieves the metadata for a given job run. Job run history is accessible for 365 days for your workflow and job run.

Request

- **JobName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the job definition being run.

- **RunId** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the job run.

- **PredecessorsIncluded** – Boolean.

True if a list of predecessor runs should be returned.

Response

- **JobRun** – A [JobRun](#) object.

The requested job-run metadata.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

GetJobRuns action (Python: `get_job_runs`)

Retrieves metadata for all runs of a given job definition.

`GetJobRuns` returns the job runs in chronological order, with the newest jobs returned first.

Request

- **JobName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition for which to retrieve all job runs.

- **NextToken** – UTF-8 string.

A continuation token, if this is a continuation call.

- **MaxResults** – Number (integer), not less than 1 or more than 200.

The maximum size of the response.

Response

- JobRuns – An array of [JobRun](#) objects.

A list of job-run metadata objects.

- NextToken – UTF-8 string.

A continuation token, if not all requested job runs have been returned.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

GetJobBookmark action (Python: `get_job_bookmark`)

Returns information on a job bookmark entry.

For more information about enabling and using job bookmarks, see:

- [Tracking processed data using job bookmarks](#)
- [Job parameters used by Amazon Glue](#)
- [Job structure](#)

Request

- JobName – *Required*: UTF-8 string.

The name of the job in question.

- Version – Number (integer).

The version of the job.

- **RunId** – UTF-8 string.

The unique run identifier associated with this job run.

Response

- **JobBookmarkEntry** – A [JobBookmarkEntry](#) object.

A structure that defines a point that a job can resume processing.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ValidationException`

GetJobBookmarks action (Python: `get_job_bookmarks`)

Returns information on the job bookmark entries. The list is ordered on decreasing version numbers.

For more information about enabling and using job bookmarks, see:

- [Tracking processed data using job bookmarks](#)
- [Job parameters used by Amazon Glue](#)
- [Job structure](#)

Request

- **JobName** – *Required:* UTF-8 string.

The name of the job in question.

- **MaxResults** – Number (integer).

The maximum size of the response.

- `NextToken` – Number (integer).

A continuation token, if this is a continuation call.

Response

- `JobBookmarkEntries` – An array of [JobBookmarkEntry](#) objects.

A list of job bookmark entries that defines a point that a job can resume processing.

- `NextToken` – Number (integer).

A continuation token, which has a value of 1 if all the entries are returned, or > 1 if not all requested job runs have been returned.

Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

ResetJobBookmark action (Python: `reset_job_bookmark`)

Resets a bookmark entry.

For more information about enabling and using job bookmarks, see:

- [Tracking processed data using job bookmarks](#)
- [Job parameters used by Amazon Glue](#)
- [Job structure](#)

Request

- `JobName` – *Required*: UTF-8 string.

The name of the job in question.

- `RunId` – UTF-8 string.

The unique run identifier associated with this job run.

Response

- JobBookmarkEntry – A [JobBookmarkEntry](#) object.

The reset bookmark entry.

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

Triggers

The Triggers API describes the data types and API related to creating, updating, or deleting, and starting and stopping job triggers in Amazon Glue.

Data types

- [Trigger structure](#)
- [TriggerUpdate structure](#)
- [Predicate structure](#)
- [Condition structure](#)
- [Action structure](#)
- [EventBatchingCondition structure](#)

Trigger structure

Information about a specific trigger.

Fields

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger.

- WorkflowName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow associated with the trigger.

- Id – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Reserved for future use.

- Type – UTF-8 string (valid values: SCHEDULED | CONDITIONAL | ON_DEMAND | EVENT).

The type of trigger that this is.

- State – UTF-8 string (valid values: CREATING | CREATED | ACTIVATING | ACTIVATED | DEACTIVATING | DEACTIVATED | DELETING | UPDATING).

The current state of the trigger.

- Description – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of this trigger.

- Schedule – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`).

- Actions – An array of [Action](#) objects.

The actions initiated by this trigger.

- Predicate – A [Predicate](#) object.

The predicate of this trigger, which defines when it will fire.

- EventBatchingCondition – An [EventBatchingCondition](#) object.

Batch condition that must be met (specified number of events received or batch time window expired) before EventBridge event trigger fires.

TriggerUpdate structure

A structure used to provide information used to update a trigger. This object updates the previous trigger definition by overwriting it completely.

Fields

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Reserved for future use.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of this trigger.

- **Schedule** – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- **Actions** – An array of [Action](#) objects.

The actions initiated by this trigger.

- **Predicate** – A [Predicate](#) object.

The predicate of this trigger, which defines when it will fire.

- **EventBatchingCondition** – An [EventBatchingCondition](#) object.

Batch condition that must be met (specified number of events received or batch time window expired) before EventBridge event trigger fires.

Predicate structure

Defines the predicate of the trigger, which determines when it fires.

Fields

- `Logical` – UTF-8 string (valid values: AND | ANY).

An optional field if only one condition is listed. If multiple conditions are listed, then this field is required.

- `Conditions` – An array of [Condition](#) objects, not more than 500 structures.

A list of the conditions that determine when the trigger will fire.

Condition structure

Defines a condition under which a trigger fires.

Fields

- `LogicalOperator` – UTF-8 string (valid values: EQUALS).

A logical operator.

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job whose JobRuns this condition applies to, and on which this trigger waits.

- `State` – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT | ERROR | WAITING | EXPIRED).

The condition state. Currently, the only job states that a trigger can listen for are SUCCEEDED, STOPPED, FAILED, and TIMEOUT. The only crawler states that a trigger can listen for are SUCCEEDED, FAILED, and CANCELLED.

- `CrawlerName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler to which this condition applies.

- `CrawlState` – UTF-8 string (valid values: RUNNING | CANCELLING | CANCELLED | SUCCEEDED | FAILED | ERROR).

The state of the crawler to which this condition applies.

Action structure

Defines an action to be initiated by a trigger.

Fields

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of a job to be run.

- **Arguments** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The job arguments used when this trigger fires. For this job run, they replace the default arguments set in the job definition itself.

You can specify arguments here that your own job-execution script consumes, as well as arguments that Amazon Glue itself consumes.

For information about how to specify and consume your own Job arguments, see the [Calling Amazon Glue APIs in Python](#) topic in the developer guide.

For information about the key-value pairs that Amazon Glue consumes to set up your job, see the [Special Parameters Used by Amazon Glue](#) topic in the developer guide.

- **Timeout** – Number (integer), at least 1.

The JobRun timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters TIMEOUT status. This overrides the timeout value set in the parent job.

Jobs must have timeout values less than 7 days or 10080 minutes. Otherwise, the jobs will throw an exception.

When the value is left blank, the timeout is defaulted to 2880 minutes.

Any existing Amazon Glue jobs that had a timeout value greater than 7 days will be defaulted to 7 days. For instance if you have specified a timeout of 20 days for a batch job, it will be stopped on the 7th day.

For streaming jobs, if you have set up a maintenance window, it will be restarted during the maintenance window after 7 days.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this action.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies configuration properties of a job run notification.

- `CrawlerName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler to be used with this action.

EventBatchingCondition structure

Batch condition that must be met (specified number of events received or batch time window expired) before EventBridge event trigger fires.

Fields

- `BatchSize` – *Required:* Number (integer), not less than 1 or more than 100.

Number of events that must be received from Amazon EventBridge before EventBridge event trigger fires.

- `BatchWindow` – Number (integer), not less than 1 or more than 900.

Window of time in seconds after which EventBridge event trigger fires. Window starts when first event is received.

Operations

- [CreateTrigger action \(Python: `create_trigger`\)](#)
- [StartTrigger action \(Python: `start_trigger`\)](#)
- [GetTrigger action \(Python: `get_trigger`\)](#)
- [GetTriggers action \(Python: `get_triggers`\)](#)

- [UpdateTrigger action \(Python: update_trigger\)](#)
- [StopTrigger action \(Python: stop_trigger\)](#)
- [DeleteTrigger action \(Python: delete_trigger\)](#)
- [ListTriggers action \(Python: list_triggers\)](#)
- [BatchGetTriggers action \(Python: batch_get_triggers\)](#)

CreateTrigger action (Python: create_trigger)

Creates a new trigger.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a Amazon Glue Connection, Amazon Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

Request

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger.

- **WorkflowName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow associated with the trigger.

- **Type** – *Required:* UTF-8 string (valid values: SCHEDULED | CONDITIONAL | ON_DEMAND | EVENT).

The type of the new trigger.

- **Schedule** – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`).

This field is required when the trigger type is SCHEDULED.

- **Predicate** – A [Predicate](#) object.

A predicate to specify when the new trigger should fire.

This field is required when the trigger type is `CONDITIONAL`.

- **Actions** – *Required:* An array of [Action](#) objects.

The actions initiated by this trigger when it fires.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the new trigger.

- **StartOnCreation** – Boolean.

Set to `true` to start `SCHEDULED` and `CONDITIONAL` triggers when created. `True` is not supported for `ON_DEMAND` triggers.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to use with this trigger. You may use tags to limit access to the trigger. For more information about tags in Amazon Glue, see [Amazon Tags in Amazon Glue](#) in the developer guide.

- **EventBatchingCondition** – An [EventBatchingCondition](#) object.

Batch condition that must be met (specified number of events received or batch time window expired) before EventBridge event trigger fires.

Response

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger.

Errors

- `AlreadyExistsException`
- `EntityNotFoundException`

- `InvalidInputException`
- `IdempotentParameterMismatchException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentModificationException`

StartTrigger action (Python: `start_trigger`)

Starts an existing trigger. See [Triggering Jobs](#) for information about how different types of trigger are started.

Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to start.

Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger that was started.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentRunsExceededException`

GetTrigger action (Python: `get_trigger`)

Retrieves the definition of a trigger.

Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to retrieve.

Response

- Trigger – A [Trigger](#) object.

The requested trigger definition.

Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

GetTriggers action (Python: `get_triggers`)

Gets all the triggers associated with a job.

Request

- NextToken – UTF-8 string.

A continuation token, if this is a continuation call.

- DependentJobName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job to retrieve triggers for. The trigger that can start this job is returned, and if there is no such trigger, all triggers are returned.

- `MaxResults` – Number (integer), not less than 1 or more than 200.

The maximum size of the response.

Response

- `Triggers` – An array of [Trigger](#) objects.

A list of triggers for the specified job.

- `NextToken` – UTF-8 string.

A continuation token, if not all the requested triggers have yet been returned.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

UpdateTrigger action (Python: `update_trigger`)

Updates a trigger definition.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a Amazon Glue Connection, Amazon Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

Request

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to update.

- `TriggerUpdate` – *Required:* A [TriggerUpdate](#) object.

The new values with which to update the trigger.

Response

- `Trigger` – A [Trigger](#) object.

The resulting trigger definition.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

StopTrigger action (Python: `stop_trigger`)

Stops a specified trigger.

Request

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to stop.

Response

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger that was stopped.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `EntityNotFoundException`

- `OperationTimeoutException`
- `ConcurrentModificationException`

DeleteTrigger action (Python: `delete_trigger`)

Deletes a specified trigger. If the trigger is not found, no exception is thrown.

Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to delete.

Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger that was deleted.

Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

ListTriggers action (Python: `list_triggers`)

Retrieves the names of all trigger resources in this Amazon account, or the resources with the specified tag. This operation allows you to see which resources are available in your account, and their names.

This operation takes the optional `Tags` field, which you can use as a filter on the response so that tagged resources can be retrieved as a group. If you choose to use tags filtering, only resources with the tag are retrieved.

Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `DependentJobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job for which to retrieve triggers. The trigger that can start this job is returned. If there is no such trigger, all triggers are returned.

- `MaxResults` – Number (integer), not less than 1 or more than 200.

The maximum size of a list to return.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Specifies to return only these tagged resources.

Response

- `TriggerNames` – An array of UTF-8 strings.

The names of all triggers in the account, or the triggers with the specified tags.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

BatchGetTriggers action (Python: `batch_get_triggers`)

Returns a list of resource metadata for a given list of trigger names. After calling the `ListTriggers` operation, you can call this operation to access the data to which you have been granted permissions. This operation supports all IAM permissions, including permission conditions that uses tags.

Request

- `TriggerNames` – *Required*: An array of UTF-8 strings.

A list of trigger names, which may be the names returned from the `ListTriggers` operation.

Response

- `Triggers` – An array of [Trigger](#) objects.

A list of trigger definitions.

- `TriggersNotFound` – An array of UTF-8 strings.

A list of names of triggers not found.

Errors

- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

Integration APIs in Amazon Glue

Data types

- [Integration structure](#)
- [IntegrationConfig structure](#)
- [IntegrationPartition structure](#)
- [IntegrationError structure](#)

- [IntegrationFilter structure](#)
- [InboundIntegration structure](#)
- [SourceProcessingProperties structure](#)
- [TargetProcessingProperties structure](#)
- [SourceTableConfig structure](#)
- [TargetTableConfig structure](#)

Integration structure

Describes a zero-ETL integration.

Fields

- `SourceArn` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN for the source of the integration.

- `TargetArn` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN for the target of the integration.

- `Description` – UTF-8 string, not more than 1000 bytes long, matching the [Custom string pattern #12](#).

A description for the integration.

- `IntegrationName` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

A unique name for the integration.

- `IntegrationArn` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The Amazon Resource Name (ARN) for the integration.

- `KmsKeyId` – UTF-8 string, not less than 1 or more than 2048 bytes long.

The ARN of a KMS key used for encrypting the channel.

- `AdditionalEncryptionContext` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

An optional set of non-secret key–value pairs that contains additional contextual information for encryption. This can only be provided if `KMSKeyId` is provided.

- `Tags` – An array of [Tag](#) objects.

Metadata assigned to the resource consisting of a list of key-value pairs.

- `Status` – *Required*: UTF-8 string (valid values: `CREATING` | `ACTIVE` | `MODIFYING` | `FAILED` | `DELETING` | `SYNCING` | `NEEDS_ATTENTION`).

The possible statuses are:

- `CREATING`: The integration is being created.
- `ACTIVE`: The integration creation succeeds.
- `MODIFYING`: The integration is being modified.
- `FAILED`: The integration creation fails.
- `DELETING`: The integration is deleted.
- `SYNCING`: The integration is synchronizing.
- `NEEDS_ATTENTION`: The integration needs attention, such as synchronization.
- `CreateTime` – *Required*: Timestamp.

The time that the integration was created, in UTC.

- `IntegrationConfig` – An [IntegrationConfig](#) object.

Properties associated with the integration.

- `Errors` – An array of [IntegrationError](#) objects.

A list of errors associated with the integration.

- `DataFilter` – UTF-8 string, not less than 1 or more than 2048 bytes long.

Selects source tables for the integration using Maxwell filter syntax.

IntegrationConfig structure

Properties associated with the integration.

Fields

- `RefreshInterval` – UTF-8 string, not less than 1 or more than 128 bytes long.

Specifies the frequency at which CDC (Change Data Capture) pulls or incremental loads should occur. This parameter provides flexibility to align the refresh rate with your specific data update patterns, system load considerations, and performance optimization goals. Time increment can be set from 15 minutes to 8640 minutes (six days).

- `SourceProperties` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A collection of key-value pairs that specify additional properties for the integration source. These properties provide configuration options that can be used to customize the behavior of the ODB source during data integration operations.

- `ContinuousSync` – Boolean.

Enables continuous synchronization for on-demand data extractions from SaaS applications to Amazon data services like Amazon Redshift and Amazon S3.

IntegrationPartition structure

A structure that describes how data is partitioned on the target.

Fields

- `FieldName` – UTF-8 string, not less than 1 or more than 128 bytes long.

The field name used to partition data on the target. Avoid using columns that have unique values for each row (for example, 'LastModifiedTimestamp', 'SystemModTimeStamp') as the partition column. These columns are not suitable for partitioning because they create a large number of small partitions, which can lead to performance issues.

- `FunctionSpec` – UTF-8 string, not less than 1 or more than 128 bytes long.

Specifies the function used to partition data on the target. The accepted values for this parameter are:

- `identity` - Uses source values directly without transformation
- `year` - Extracts the year from timestamp values (e.g., 2023)
- `month` - Extracts the month from timestamp values (e.g., 2023-01)

- `day` - Extracts the day from timestamp values (e.g., 2023-01-15)
- `hour` - Extracts the hour from timestamp values (e.g., 2023-01-15-14)
- `ConversionSpec` – UTF-8 string, not less than 1 or more than 128 bytes long.

Specifies the timestamp format of the source data. Valid values are:

- `epoch_sec` - Unix epoch timestamp in seconds
- `epoch_milli` - Unix epoch timestamp in milliseconds
- `iso` - ISO 8601 formatted timestamp

Note

Only specify `ConversionSpec` when using timestamp-based partition functions (`year`, `month`, `day`, or `hour`). Amazon Glue Zero-ETL uses this parameter to correctly transform source data into timestamp format before partitioning.

Do not use high-cardinality columns with the `identity` partition function. High-cardinality columns include:

- Primary keys
- Timestamp fields (such as `LastModifiedTimestamp`, `CreatedDate`)
- System-generated timestamps

Using high-cardinality columns with identity partitioning creates many small partitions, which can significantly degrade ingestion performance.

IntegrationError structure

An error associated with a zero-ETL integration.

Fields

- `ErrorCode` – UTF-8 string, not less than 1 or more than 128 bytes long.

The code associated with this error.

- `ErrorMessage` – UTF-8 string, not less than 1 or more than 2048 bytes long.

A message describing the error.

IntegrationFilter structure

A filter that can be used when invoking a DescribeIntegrations request.

Fields

- **Name** – UTF-8 string, not less than 1 or more than 128 bytes long.

The name of the filter.

- **Values** – An array of UTF-8 strings.

A list of filter values.

InboundIntegration structure

A structure for an integration that writes data into a resource.

Fields

- **SourceArn** – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN of the source resource for the integration.

- **TargetArn** – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN of the target resource for the integration.

- **IntegrationArn** – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN of the zero-ETL integration.

- **Status** – *Required:* UTF-8 string (valid values: CREATING | ACTIVE | MODIFYING | FAILED | DELETING | SYNCING | NEEDS_ATTENTION).

The possible statuses are:

- **CREATING:** The integration is being created.
- **ACTIVE:** The integration creation succeeds.
- **MODIFYING:** The integration is being modified.
- **FAILED:** The integration creation fails.
- **DELETING:** The integration is deleted.
- **SYNCING:** The integration is synchronizing.

- **NEEDS_ATTENTION**: The integration needs attention, such as synchronization.
- **CreateTime** – *Required*: Timestamp.

The time that the integration was created, in UTC.

- **IntegrationConfig** – An [IntegrationConfig](#) object.

Properties associated with the integration.

- **Errors** – An array of [IntegrationError](#) objects.

A list of errors associated with the integration.

SourceProcessingProperties structure

The resource properties associated with the integration source.

Fields

- **RoleArn** – UTF-8 string, not less than 1 or more than 128 bytes long.

The IAM role to access the Amazon Glue connection.

TargetProcessingProperties structure

The resource properties associated with the integration target.

Fields

- **RoleArn** – UTF-8 string, not less than 1 or more than 128 bytes long.

The IAM role to access the Amazon Glue database.

- **KmsArn** – UTF-8 string, not less than 1 or more than 2048 bytes long.

The ARN of the KMS key used for encryption.

- **ConnectionName** – UTF-8 string, not less than 1 or more than 128 bytes long.

The Amazon Glue network connection to configure the Amazon Glue job running in the customer VPC.

- **EventBusArn** – UTF-8 string, not less than 1 or more than 2048 bytes long.

The ARN of an Eventbridge event bus to receive the integration status notification.

SourceTableConfig structure

Properties used by the source leg to process data from the source.

Fields

- `Fields` – An array of UTF-8 strings.

A list of fields used for column-level filtering. Currently unsupported.

- `FilterPredicate` – UTF-8 string, not less than 1 or more than 128 bytes long.

A condition clause used for row-level filtering. Currently unsupported.

- `PrimaryKey` – An array of UTF-8 strings.

Provide the primary key set for this table. Currently supported specifically for SAP EntityOf entities upon request. Contact Amazon Support to make this feature available.

- `RecordUpdateField` – UTF-8 string, not less than 1 or more than 128 bytes long.

Incremental pull timestamp-based field. Currently unsupported.

TargetTableConfig structure

Properties used by the target leg to partition the data on the target.

Fields

- `UnnestSpec` – UTF-8 string (valid values: TOPLEVEL | FULL | NOUNNEST).

Specifies how nested objects are flattened to top-level elements. Valid values are: "TOPLEVEL", "FULL", or "NOUNNEST".

- `PartitionSpec` – An array of [IntegrationPartition](#) objects.

Determines the file layout on the target.

- `TargetTableName` – UTF-8 string, not less than 1 or more than 128 bytes long.

The optional name of a target table.

Operations

- [CreateIntegration action \(Python: create_integration\)](#)
- [ModifyIntegration action \(Python: modify_integration\)](#)
- [DescribeIntegrations action \(Python: describe_integrations\)](#)
- [DeleteIntegration action \(Python: delete_integration\)](#)

- [UpdateIntegrationResourceProperty action \(Python: update_integration_resource_property\)](#)
- [GetIntegrationResourceProperty action \(Python: get_integration_resource_property\)](#)
- [UntagResource action \(Python: untag_resource\)](#)
- [ListTagsForResource action \(Python: list_tags_for_resource\)](#)

CreateIntegration action (Python: create_integration)

Creates a Zero-ETL integration in the caller's account between two resources with Amazon Resource Names (ARNs): the `SourceArn` and `TargetArn`.

Request

- `IntegrationName` – *Required*: UTF-8 string, not less than 1 or more than 128 bytes long.

A unique name for an integration in Amazon Glue.

- `SourceArn` – *Required*: UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN of the source resource for the integration.

- `TargetArn` – *Required*: UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN of the target resource for the integration.

- `Description` – UTF-8 string, not more than 1000 bytes long, matching the [Custom string pattern #12](#).

A description of the integration.

- `DataFilter` – UTF-8 string, not less than 1 or more than 2048 bytes long.

Selects source tables for the integration using Maxwell filter syntax.

- `KmsKeyId` – UTF-8 string, not less than 1 or more than 2048 bytes long.

The ARN of a KMS key used for encrypting the channel.

- `AdditionalEncryptionContext` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

An optional set of non-secret key-value pairs that contains additional contextual information for encryption. This can only be provided if `KMSKeyId` is provided.

- `Tags` – An array of [Tag](#) objects.

Metadata assigned to the resource consisting of a list of key-value pairs.

- `IntegrationConfig` – An [IntegrationConfig](#) object.

The configuration settings.

Response

- `SourceArn` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN of the source resource for the integration.

- `TargetArn` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN of the target resource for the integration.

- `IntegrationName` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

A unique name for an integration in Amazon Glue.

- `Description` – UTF-8 string, not more than 1000 bytes long, matching the [Custom string pattern #12](#).

A description of the integration.

- `IntegrationArn` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The Amazon Resource Name (ARN) for the created integration.

- `KmsKeyId` – UTF-8 string, not less than 1 or more than 2048 bytes long.

The ARN of a KMS key used for encrypting the channel.

- `AdditionalEncryptionContext` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

An optional set of non-secret key–value pairs that contains additional contextual information for encryption.

- `Tags` – An array of [Tag](#) objects.

Metadata assigned to the resource consisting of a list of key-value pairs.

- `Status` – *Required*: UTF-8 string (valid values: CREATING | ACTIVE | MODIFYING | FAILED | DELETING | SYNCING | NEEDS_ATTENTION).

The status of the integration being created.

The possible statuses are:

- `CREATING`: The integration is being created.
- `ACTIVE`: The integration creation succeeds.
- `MODIFYING`: The integration is being modified.
- `FAILED`: The integration creation fails.
- `DELETING`: The integration is deleted.
- `SYNCING`: The integration is synchronizing.
- `NEEDS_ATTENTION`: The integration needs attention, such as synchronization.
- `CreateTime` – *Required*: Timestamp.

The time when the integration was created, in UTC.

- `Errors` – An array of [IntegrationError](#) objects.

A list of errors associated with the integration creation.

- `DataFilter` – UTF-8 string, not less than 1 or more than 2048 bytes long.

Selects source tables for the integration using Maxwell filter syntax.

- IntegrationConfig – An [IntegrationConfig](#) object.

The configuration settings.

Errors

- ValidationException
- AccessDeniedException
- ResourceNotFoundException
- InternalServerErrorException
- IntegrationConflictOperationFault
- IntegrationQuotaExceededFault
- KMSKeyNotAccessibleFault
- EntityNotFoundException
- InternalServiceException
- ConflictException
- ResourceNumberLimitExceededException
- InvalidInputException

ModifyIntegration action (Python: modify_integration)

Modifies a Zero-ETL integration in the caller's account.

Request

- IntegrationIdentifier – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The Amazon Resource Name (ARN) for the integration.

- Description – UTF-8 string, not more than 1000 bytes long, matching the [Custom string pattern #12](#).

A description of the integration.

- `DataFilter` – UTF-8 string, not less than 1 or more than 2048 bytes long.

Selects source tables for the integration using Maxwell filter syntax.

- `IntegrationConfig` – An [IntegrationConfig](#) object.

The configuration settings for the integration. Currently, only the `RefreshInterval` can be modified.

- `IntegrationName` – UTF-8 string, not less than 1 or more than 128 bytes long.

A unique name for an integration in Amazon Glue.

Response

- `SourceArn` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN of the source for the integration.

- `TargetArn` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The ARN of the target for the integration.

- `IntegrationName` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

A unique name for an integration in Amazon Glue.

- `Description` – UTF-8 string, not more than 1000 bytes long, matching the [Custom string pattern #12](#).

A description of the integration.

- `IntegrationArn` – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long.

The Amazon Resource Name (ARN) for the integration.

- `KmsKeyId` – UTF-8 string, not less than 1 or more than 2048 bytes long.

The ARN of a KMS key used for encrypting the channel.

- `AdditionalEncryptionContext` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

An optional set of non-secret key–value pairs that contains additional contextual information for encryption.

- **Tags** – An array of [Tag](#) objects.

Metadata assigned to the resource consisting of a list of key-value pairs.

- **Status** – *Required*: UTF-8 string (valid values: CREATING | ACTIVE | MODIFYING | FAILED | DELETING | SYNCING | NEEDS_ATTENTION).

The status of the integration being modified.

The possible statuses are:

- **CREATING**: The integration is being created.
- **ACTIVE**: The integration creation succeeds.
- **MODIFYING**: The integration is being modified.
- **FAILED**: The integration creation fails.
- **DELETING**: The integration is deleted.
- **SYNCING**: The integration is synchronizing.
- **NEEDS_ATTENTION**: The integration needs attention, such as synchronization.
- **CreateTime** – *Required*: Timestamp.

The time when the integration was created, in UTC.

- **Errors** – An array of [IntegrationError](#) objects.

A list of errors associated with the integration modification.

- **DataFilter** – UTF-8 string, not less than 1 or more than 2048 bytes long.

Selects source tables for the integration using Maxwell filter syntax.

- **IntegrationConfig** – An [IntegrationConfig](#) object.

The updated configuration settings for the integration.

Errors

- `ValidationException`
- `AccessDeniedException`

- `InternalServerErrorException`
- `IntegrationNotFoundFault`
- `IntegrationConflictOperationFault`
- `InvalidIntegrationStateFault`
- `EntityNotFoundExpection`
- `InternalServiceException`
- `ConflictException`
- `InvalidStateException`
- `InvalidInputException`

DescribeIntegrations action (Python: `describe_integrations`)

The API is used to retrieve a list of integrations.

Request

- `IntegrationIdentifier` – UTF-8 string, not less than 1 or more than 128 bytes long.

The Amazon Resource Name (ARN) for the integration.

- `Marker` – UTF-8 string, not less than 1 or more than 128 bytes long.

A value that indicates the starting point for the next set of response records in a subsequent request.

- `MaxRecords` – Number (integer).

The total number of items to return in the output.

- `Filters` – An array of [IntegrationFilter](#) objects.

A list of key and values, to filter down the results. Supported keys are "Status", "IntegrationName", and "SourceArn". IntegrationName is limited to only one value.

Response

- `Integrations` – An array of [Integration](#) objects.

A list of zero-ETL integrations.

- `Marker` – UTF-8 string, not less than 1 or more than 128 bytes long.

A value that indicates the starting point for the next set of response records in a subsequent request.

Errors

- `ValidationException`
- `AccessDeniedException`
