

Amazon Glue

Amazon Glue: User Guide

Table of Contents

What is Amazon Glue?	1
Amazon Glue features	2
Learning about innovations in Amazon Glue	3
Getting started with Amazon Glue	3
Accessing Amazon Glue	4
Related services	4
How it works	5
Serverless ETL jobs run in isolation	6
Concepts	7
Amazon Glue terminology	9
Components	12
Amazon Glue console	12
Amazon Glue Data Catalog	13
Amazon Glue crawlers and classifiers	14
Amazon Glue ETL operations	14
Streaming ETL in Amazon Glue	14
The Amazon Glue jobs system	15
Visual ETL components	15
Amazon Glue for Spark and Amazon Glue for Ray	21
What is Amazon Glue for Ray?	22
Converting semi-structured schemas to relational schemas	23
Amazon Glue types	25
Amazon Glue Data Catalog Types	25
Types in Amazon Glue with Spark scripts	25
Amazon Glue Crawler Types	26
Getting started	27
Overview of using Amazon Glue	27
Setting up IAM permissions	29
Next steps	34
Setting up for Amazon Glue Studio	34
Getting started with notebooks in Amazon Glue Studio	46
Setting up usage profiles	48
Managing usage profiles	49
Usage profiles and jobs	57

Getting started with the Amazon Glue Data Catalog	58
Overview	58
Step 1: Create a database	58
Step 2. Create a table	60
Next steps	61
Setting up network access to data stores	64
Setting up a VPC to connect to PyPI for Amazon Glue	65
Setting up DNS in your VPC	67
Setting up encryption	68
Setting up networking for development	71
Setting up your network for a development endpoint	72
Setting up Amazon EC2 for a notebook server	74
Data discovery and cataloging	75
Populating the Data Catalog	78
Using an Amazon Glue crawler	79
Defining metadata manually	163
Integrating with other Amazon services	182
Data Catalog settings	184
Populating and managing transactional tables	187
Creating Iceberg tables	187
Optimizing Iceberg tables	191
Optimizing query performance for Iceberg tables	231
Managing the Data Catalog	233
Updating the schema and adding new partitions	234
Optimizing query performance using column statistics	241
Encrypting your Data Catalog	266
Securing your Data Catalog using Lake Formation	266
Working with Amazon Glue Data Catalog views	266
Accessing the Data Catalog	271
Connecting to the Data Catalog using Amazon Glue Iceberg REST endpoint	272
Connecting to the Data Catalog using Amazon Glue Iceberg REST extension endpoint	275
Amazon Glue REST APIs for Apache Iceberg	275
Connecting to Data Catalog from a standalone Spark application	295
Data mapping between Amazon Redshift and Apache Iceberg	296
Considerations and limitations when using Amazon Glue Iceberg REST Catalog APIs	297
Data Catalog best practices	298

Monitoring Data Catalog usage metrics in Amazon CloudWatch	299
Overview of Data Catalog metrics	299
Adding metrics to your CloudWatch dashboard	300
Amazon Glue Schema registry	301
Schemas	303
Registries	305
Schema versioning and compatibility	306
Open source Serde libraries	311
Quotas of the Schema Registry	311
How it works	312
Getting started	314
Connecting to data	368
Overview of using connectors and connections	368
Unified connections	369
Supported authentication types	373
Considerations	373
Available connections	374
Limitations	376
REST API Connections	376
Creating a REST connection type in Amazon Glue	377
Amazon Glue connection properties	378
Required connection properties	379
JDBC connection properties	380
MongoDB and MongoDB Atlas connection properties	385
Salesforce connection properties	386
Snowflake connection	386
Vertica connection	387
SAP HANA connection	388
Azure SQL connection	389
Teradata Vantage connection	390
OpenSearch Service connection	391
Azure Cosmos connection	392
SSL connection properties	392
Kafka connection properties for authentication	395
Google BigQuery connection	396
Vertica connection	387

Storing connection credentials in Amazon Secrets Manager	396
Adding an Amazon Glue connection	397
Connecting to Amazon Redshift	398
Connecting to Azure Cosmos DB	402
Connecting to Azure SQL	406
Connecting to Google BigQuery	409
Connecting to Microsoft Dynamics 365 CRM	414
Connecting to MongoDB	422
Connecting to OpenSearch Service	426
Connecting to a REST API	429
Connecting to Salesforce	436
Connecting to SAP HANA	448
Connecting to SAP OData	452
Connecting to Snowflake	475
Connecting to Teradata	479
Connecting to Vertica	483
Adding a JDBC connection using your own JDBC drivers	486
Using custom connectors and connections	491
Creating custom connectors	493
Creating connections for connectors	497
Authoring jobs with custom connectors	504
Managing connectors and connections	511
Developing custom connectors	514
Restrictions for using connectors and connections in Amazon Glue Studio	517
Testing an Amazon Glue connection	517
Configuring Amazon calls to go through your VPC	518
Connecting to a JDBC data store in a VPC	519
Accessing VPC Data Using elastic network interfaces	519
Elastic network interface properties	520
Using a MongoDB or MongoDB Atlas connection	521
Crawling an Amazon S3 data store using a VPC endpoint	521
Prerequisites	522
Creating the connection to Amazon S3	523
Testing the connection to Amazon S3	526
Creating a crawler for an Amazon S3 data store	527
Creating a crawler for Amazon S3 backed Data Catalog tables	530

Running a crawler	531
Troubleshooting	531
Working with Amazon Lake Formation-protected data	531
Full Table Access	531
Troubleshooting connection issues	533
Tutorial: Using the Amazon Glue Connector for Elasticsearch	534
Prerequisites	534
Step 1: (Optional) Create an Amazon secret for your OpenSearch cluster information	535
Step 2: Subscribe to the connector	535
Step 3: Activate the connector in Amazon Glue Studio and create a connection	537
Step 4: Configure an IAM role for your ETL job	537
Step 5: Create a job that uses the OpenSearch connection	538
Step 6: Run the job	539
Building Amazon Glue jobs with interactive sessions	540
Overview of Amazon Glue interactive sessions	540
Limitations	541
Getting started with Amazon Glue interactive sessions	541
Prerequisites for setting up interactive sessions locally	541
Installing Jupyter and Amazon Glue interactive sessions Jupyter kernels	541
Running Jupyter	541
Configuring session credentials and region	542
Upgrading from the interactive sessions preview	543
Using interactive sessions with SageMaker AI Studio	544
Using interactive sessions with Microsoft Visual Studio Code	544
Interactive sessions with IAM	547
Configuring Amazon Glue interactive sessions for Jupyter and Amazon Glue Studio notebooks	556
Introduction to Jupyter Magics	556
Magics supported by Amazon Glue interactive sessions for Jupyter	556
Naming sessions	573
Specifying an IAM role for interactive sessions	574
Configuring sessions with named profiles	574
Converting a script or notebook into an Amazon Glue job	575
Working with streaming operations in Amazon Glue interactive sessions	576
Switching streaming session type	576
Sampling input stream for interactive development	576

Running streaming applications in interactive sessions	578
Amazon Glue interactive session pricing	579
Configure your Amazon Glue interactive sessions	579
Developing and testing locally	579
Developing using Amazon Glue Studio	580
Developing using interactive sessions	580
Developing Amazon Glue jobs locally with Docker	580
Dev endpoints	590
Migrating from dev endpoints to interactive sessions	591
Developing scripts using development endpoints	593
Managing notebooks	621
Building visual ETL jobs	623
Build visual ETL jobs with Amazon Glue Studio	623
Signing in to the console	623
Next steps for creating a job in Amazon Glue Studio	624
Build visual ETL flows with Amazon SageMaker	624
Starting visual ETL jobs in Amazon Glue Studio	624
Starting jobs in Amazon Glue Studio	625
Job editor features	626
Transform data with Amazon Glue managed transforms	634
Transform data with custom visual transforms	707
Using Data Lake frameworks with Amazon Glue Studio	724
Connecting to data sources	735
Configuring data target nodes	744
Editing or uploading a job script	749
Changing the parent nodes for a node in the job diagram	753
Deleting nodes from the job diagram	754
Adding source and target parameters to the Amazon Glue Data Catalog node	758
Using Git version control systems in Amazon Glue	760
Authoring code with Amazon Glue Studio notebooks	768
Limitations	768
Overview of using notebooks	769
Creating an ETL job using notebooks in Amazon Glue Studio	770
Notebook editor components	771
Saving your notebook and job script	772
Managing notebook sessions	773

Using Amazon Q Developer with Amazon Glue Studio notebooks	774
Monitoring job runs	775
Accessing the job monitoring dashboard	775
Overview of the job monitoring dashboard	775
Job runs view	776
Viewing the job run logs	779
Viewing the details of a job run	780
Viewing Amazon CloudWatch metrics for a Spark job run	783
Viewing Amazon CloudWatch metrics for a Ray job run	783
Detect and process sensitive data	785
Choosing how you want the data to be scanned	786
Choosing the PII entities to detect	787
Specifying the level of detection sensitivity	791
Choosing what to do with identified PII data	791
Adding fine-grained action overrides	792
Managing jobs	793
Start a job run	794
Schedule job runs	794
Manage job schedules	796
Stop job runs	796
View your jobs	797
View information for recent job runs	797
View the job script	798
Modify the job properties	799
Save the job	801
Clone a job	804
Delete jobs	804
Working with jobs	806
Amazon Glue versions	806
Amazon Glue versions	806
Amazon Glue version support policy	825
Migrating Amazon Glue for Spark jobs to Amazon Glue version 5.1	827
Migrating Amazon Glue for Spark jobs to Amazon Glue version 5.0	835
Migrating Amazon Glue for Spark jobs to Amazon Glue version 4.0	849
Upgrade analysis with AI	863
Working with Spark jobs	879

Job parameters	879
Spark and PySpark jobs	889
Worker types	1050
Streaming ETL jobs	1055
Record matching with FindMatches	1070
Migrate Spark programs	1104
Working with Ray jobs	1112
Getting started with Amazon Glue for Ray	1113
Supported Ray runtime environments	1114
Accounting for workers in Ray jobs	1115
Ray job parameters	1115
Ray job metrics	1118
Configuring Python shell job properties	1120
Limitations	1120
Execution environment	1121
Defining job properties for Python shell jobs	1121
Supported libraries for Python shell jobs	1123
Providing your own Python library	1125
Use Amazon CloudFormation with Python shell jobs in Amazon Glue	1128
Migrating from Python shell 3.6 to Python shell 3.9	1129
Migrate from Amazon Glue Python shell jobs	1129
Monitoring	1131
Amazon tags	1132
Automating with EventBridge	1137
Monitoring resources	1140
Logging using CloudTrail	1143
Amazon Glue Streaming	1147
Use cases for streaming	1147
What are the benefits of using Amazon Glue Streaming?	1148
When to use Amazon Glue Streaming?	1149
Supported data sources	1150
Supported data targets	1150
Tutorial: Build your first streaming workload using Amazon Glue Studio	1150
Prerequisites	1151
Consume streaming data from Amazon Kinesis	1151
Tutorial: Build your first streaming workload using Amazon Glue Studio notebooks	1162

Prerequisites	1163
Consume streaming data from Amazon Kinesis	1163
Streaming concepts	1170
Anatomy of a Amazon Glue streaming job	1170
Streaming connections	1174
Kafka connections	1174
Kinesis connections	1181
Amazon Glue streaming autoscaling	1188
Enabling Auto Scaling in Amazon Glue Studio	1188
Enabling Auto Scaling with the Amazon CLI or SDK	1189
How it works	1190
Maintenance windows	1192
Setting up a maintenance window	1192
Maintenance window behavior	1193
Job monitoring	1194
Data loss handling	1196
Advanced Amazon Glue streaming concepts	1197
Time considerations when processing streams	1197
Windowing	1198
Handling late data and watermarks	1203
Monitoring Amazon Glue streaming jobs	1205
Visualizing Amazon Glue streaming metrics	1206
Using Amazon Glue streaming metrics	1207
How to get the best performance	1212
Zero-ETL integrations	1214
Zero-ETL capabilities in Amazon Glue	1214
Prerequisites	1215
Setting up source resources	1216
Setting up target resources	1217
Creating an Amazon Redshift data warehouse	1222
Setting up a VPC	1223
Setting up cross-account integration	1226
Configuring a source	1227
Support for Special SAP Entities	1227
Amazon DynamoDB source	1228
Salesforce source	1230

Salesforce MCAE source	1230
Additional Salesforce Configuration	1231
SAP OData source	1231
ServiceNow source	1231
Zendesk source	1232
Zoho CRM source	1232
Facebook Ads source	1233
Instagram Ads source	1234
Unsupported Salesforce fields	1234
Unsupported SAP entities	1237
Unsupported ServiceNow fields	1237
Configuring a target	1243
SageMaker Lakehouse with S3 storage	1243
S3 Tables target	1244
SageMaker Lakehouse with Amazon Redshift storage	1248
Amazon Redshift data warehouse target	1249
Configuring the integration target	1250
Partition and schema unnesting	1251
Default unnesting & partitioning behavior	1252
Schema unnesting	1252
Data partitioning	1256
Limitations	1263
Common tasks	1263
Creating an integration	1264
Modifying an integration	1265
Deleting an integration	1266
Using APIs	1266
Monitoring an integration	1267
Integration states	1267
Viewing logs	1267
Viewing metrics	1270
Event notifications	1270
Limitations	1271
Amazon Glue Data Quality	1281
Benefits and key features	1281
How it works	1282

Data quality for the Amazon Glue Data Catalog	1282
Data quality for Amazon Glue ETL jobs	1283
Comparing Amazon Glue Data Quality entry points	1283
Considerations	1285
Terminology	1285
Limits	1286
Release notes for Amazon Glue Data Quality	1286
General availability: new features	1287
Nov 27, 2023 (Preview)	1287
Mar 12, 2024	1287
June 26, 2024	1287
August 7, 2024	1288
Nov 22, 2024	1288
Dec 6, 2024	1288
Jul 7, 2025	1288
Nov 21, 2025	1288
Anomaly detection in Amazon Glue Data Quality	1289
How it works	1290
Details of the Anomaly Detection algorithm	1294
IAM permissions for Amazon Glue Data Quality	1295
IAM permissions	1295
IAM setup required for scheduling evaluation runs	1298
Example IAM policies	1299
Getting started with Amazon Glue Data Quality for the Data Catalog	1304
Prerequisites	1305
Step-by-step example	1305
Generating rule recommendations	1305
Monitoring rule recommendations	1307
Editing recommended rulesets	1307
Creating a new ruleset	1308
Running a ruleset to evaluate data quality	1310
Viewing the data quality score and results	1311
Using preprocessing queries	1312
Supported source types	1315
Related topics	1316
Evaluating data quality with Amazon Glue Studio	1317

Benefits	1317
Evaluating data quality for ETL jobs in Amazon Glue Studio	1317
Data Quality rule builder	1328
Configuring anomaly detection in Amazon Glue ETL jobs	1333
Viewing data quality scores and anomalies	1336
Data Quality for ETL jobs in Amazon Glue Studio notebooks	1339
Prerequisites	1340
Creating an ETL job in Amazon Glue Studio	1340
Data Quality Definition Language (DQDL) reference	1345
Syntax	1347
Rule type reference	1366
Using APIs to measure and manage data quality	1422
Prerequisites	1422
Working with Amazon Glue Data Quality recommendations	1422
Working with Amazon Glue Data Quality rulesets	1425
Working with Amazon Glue Data Quality runs	1428
Working with Amazon Glue Data Quality results	1433
Setting up alerts, deployments, and scheduling	1439
Setting up alerts and notifications in Amazon EventBridge integration	1439
Set up alerts and notifications in CloudWatch integration	1447
Querying data quality results	1448
Deploying data quality rules	1452
Scheduling data quality rules	1452
Data encryption at rest for Amazon Glue Data Quality	1453
Amazon owned keys	1453
Customer managed keys	1453
Create a Customer Managed Key	1456
Create a security configuration	1458
Amazon Glue Data Quality encryption context	1459
Monitoring your encryption keys for Amazon Glue Data Quality	1460
Learn more	1464
Troubleshooting Amazon Glue Data Quality errors	1465
Error: missing module	1466
Error: insufficient permissions	1466
Error: rulesets not unique	1466
Error: tables with special characters	1466

Error: overflow with a large ruleset	1466
Error: rule status is failed	1467
AnalysisException: Unable to verify existence of default database	1467
Provided key map not suitable for given data frames	1467
java.lang.RuntimeException : Failed to fetch data.	1468
LAUNCH ERROR: Error downloading from S3 for bucket	1468
InvalidInputException (status: 400): DataQuality rules cannot be parsed	1468
Error: Eventbridge is not triggering Glue DQ jobs based on the schedule I setup	1469
CustomSQL errors	1469
Dynamic Rules	1470
Exception in User Class: org.apache.spark.sql.AnalysisException: org.apache.hadoop.hive.ql.metadata.HiveException	1472
UNCLASSIFIED_ERROR; IllegalArgumentException: Parsing Error: No rules or analyzers provided., no viable alternative at input	1472
Amazon Q data integration in Amazon Glue	1473
What is Amazon Q?	1473
Amazon Q data integration in Amazon Glue	1473
Working with Amazon Q data integration	1474
Best practices	1475
Service improvement	1476
Considerations	1476
Setting up Amazon Q data integration	1476
Configuring IAM permissions	1476
Supported code generation	1479
Example interactions	1480
Amazon Q chat interactions	1480
Amazon Glue Studio notebook interactions	1481
Using context awareness	1481
Example: interactions	1482
Limitations	1485
Orchestration	1486
Starting jobs and crawlers using triggers	1486
Amazon Glue triggers	1486
Adding triggers	1489
Activating and deactivating triggers	1493
Performing complex ETL activities using blueprints and workflows	1494

Overview of workflows	1494
Creating and building out a workflow manually	1498
Starting a workflow with an EventBridge event	1503
Viewing the EventBridge events that started a workflow	1510
Running and monitoring a workflow	1511
Stopping a workflow run	1513
Repairing and resuming a workflow run	1514
Getting and setting workflow run properties	1520
Querying workflows using the Amazon Glue API	1521
Blueprint and workflow restrictions	1526
Troubleshooting blueprint errors	1527
Permissions for blueprint personas and roles	1532
Developing blueprints	1536
Overview of blueprints	1537
Developing blueprints	1540
Registering a blueprint	1565
Viewing blueprints	1567
Updating a blueprint	1569
Creating a workflow from a blueprint	1571
Viewing blueprint runs	1572
Amazon CloudFormation for Amazon Glue	1574
Sample database	1576
Sample database, table, partitions	1577
Sample grok classifier	1581
Sample JSON classifier	1582
Sample XML classifier	1583
Sample Amazon S3 crawler	1584
Sample connection	1587
Sample connection	1588
Sample connection	1589
Sample JDBC crawler	1591
Sample job for Amazon S3 to Amazon S3	1593
Sample job for JDBC to Amazon S3	1595
Sample On-Demand trigger	1597
Sample scheduled trigger	1598
Sample conditional trigger	1599

Sample machine learning transform	1600
Sample data quality ruleset	1601
Sample data quality ruleset with EventBridge scheduler	1603
Sample development endpoint	1605
Amazon Glue programming guide	1607
Providing your own custom scripts	1607
Amazon Glue for Spark	1608
Tutorial: Writing a Spark script	1608
ETL in PySpark	1621
ETL in Scala	1867
Features and optimizations	1951
Amazon Glue for Ray	2218
Tutorial: Writing a Ray script	2218
Using Ray Core and Ray Data in Amazon Glue for Ray	2224
Providing files and Python libraries	2226
Connecting to data	2231
Working with Amazon SDKs	2233

What is Amazon Glue?

Amazon Glue is a serverless data integration service that makes it easy for analytics users to discover, prepare, move, and integrate data from multiple sources. You can use it for analytics, machine learning, and application development. It also includes additional productivity and data ops tooling for authoring, running jobs, and implementing business workflows.

With Amazon Glue, you can discover and connect to more than 70 diverse data sources and manage your data in a centralized data catalog. You can visually create, run, and monitor extract, transform, and load (ETL) pipelines to load data into your data lakes. Also, you can immediately search and query cataloged data using Amazon Athena, Amazon EMR, and Amazon Redshift Spectrum.

Amazon Glue consolidates major data integration capabilities into a single service. These include data discovery, modern ETL, cleansing, transforming, and centralized cataloging. It's also serverless, which means there's no infrastructure to manage. With flexible support for all workloads like ETL, ELT, and streaming in one service, Amazon Glue supports users across various workloads and types of users.

Also, Amazon Glue makes it easy to integrate data across your architecture. It integrates with Amazon analytics services and Amazon S3 data lakes. Amazon Glue has integration interfaces and job-authoring tools that are easy to use for all users, from developers to business users, with tailored solutions for varied technical skill sets.

With the ability to scale on demand, Amazon Glue helps you focus on high-value activities that maximize the value of your data. It scales for any data size, and supports all data types and schema variances. To increase agility and optimize costs, Amazon Glue provides built-in high availability and pay-as-you-go billing.

For pricing information, see [Amazon Glue pricing](#).

Amazon Glue Studio

Amazon Glue Studio is a graphical interface that makes it easy to create, run, and monitor data integration jobs in Amazon Glue. You can visually compose data transformation workflows and seamlessly run them on the Apache Spark-based serverless ETL engine in Amazon Glue.

With Amazon Glue Studio, you can create and manage jobs that gather, transform, and clean data. You can also use Amazon Glue Studio to troubleshoot and edit job scripts.

Topics

Amazon Glue features

Amazon Glue features fall into three major categories:

- Discover and organize data
- Transform, prepare, and clean data for analysis
- Build and monitor data pipelines

Discover and organize data

- **Unify and search across multiple data stores** – Store, index, and search across multiple data sources and sinks by cataloging all your data in Amazon.
- **Automatically discover data** – Use Amazon Glue crawlers to automatically infer schema information and integrate it into your Amazon Glue Data Catalog.
- **Manage schemas and permissions** – Validate and control access to your databases and tables.
- **Connect to a wide variety of data sources** – Tap into multiple data sources, both on premises and on Amazon, using Amazon Glue connections to build your data lake.

Transform, prepare, and clean data for analysis

- **Visually transform data with a job canvas interface** – Define your ETL process in the visual job editor and automatically generate the code to extract, transform, and load your data.
- **Build complex ETL pipelines with simple job scheduling** – Invoke Amazon Glue jobs on a schedule, on demand, or based on an event.
- **Clean and transform streaming data in transit** – Enable continuous data consumption, and clean and transform it in transit. This makes it available for analysis in seconds in your target data store.

- **Deduplicate and cleanse data with built-in machine learning** – Clean and prepare your data for analysis without becoming a machine learning expert by using the FindMatches feature. This feature deduplicates and finds records that are imperfect matches for each other.
- **Built-in job notebooks** – Amazon Glue job notebooks provide serverless notebooks with minimal setup in Amazon Glue so you can get started quickly.
- **Edit, debug, and test ETL code** – With Amazon Glue interactive sessions, you can interactively explore and prepare data. You can explore, experiment on, and process data interactively using the IDE or notebook of your choice.
- **Define, detect, and remediate sensitive data** – Amazon Glue sensitive data detection lets you define, identify, and process sensitive data in your data pipeline and in your data lake.

Build and monitor data pipelines

- **Automatically scale based on workload** – Dynamically scale resources up and down based on workload. This assigns workers to jobs only when needed.
- **Automate jobs with event-based triggers** – Start crawlers or Amazon Glue jobs with event-based triggers, and design a chain of dependent jobs and crawlers.
- **Run and monitor jobs** – Run Amazon Glue jobs with your choice of engine, Spark or Ray. Monitor them with automated monitoring tools, Amazon Glue job run insights, and Amazon CloudTrail. Improve your monitoring of Spark-backed jobs with the Apache Spark UI.
- **Define workflows for ETL and integration activities** – Define workflows for ETL and integration activities for multiple crawlers, jobs, and triggers.

Learning about innovations in Amazon Glue

Learn about the latest innovations in Amazon Glue and hear how customers use Amazon Glue to enable self-service data preparation across their organization.

Learn about how customers scale Amazon Glue beyond the traditional setup and how they configure Amazon Glue for job monitoring and performance.

Getting started with Amazon Glue

We recommend that you start with the following sections:

- [Overview of using Amazon Glue](#)

- [Amazon Glue concepts](#)
- [Setting up IAM permissions for Amazon Glue](#)
- [Getting started with the Amazon Glue Data Catalog](#)
- [Authoring jobs in Amazon Glue](#)
- [Getting started with Amazon Glue interactive sessions](#)
- [Orchestration in Amazon Glue](#)

Accessing Amazon Glue

You can create, view, and manage your Amazon Glue jobs using the following interfaces:

- **Amazon Glue console** – Provides a web interface for you to create, view, and manage your Amazon Glue jobs. To access the console, see [Amazon Glue](#).
- **Amazon Glue Studio** – Provides a graphical interface for you to create and edit your Amazon Glue jobs visually. For more information, see [Building visual ETL jobs](#).
- **Amazon Glue section of the Amazon CLI Reference** – Provides Amazon CLI commands that you can use with Amazon Glue. For more information, see [Amazon CLI Reference for Amazon Glue](#).
- **Amazon Glue API** – Provides a complete API reference for developers. For more information, see [Amazon Glue API](#).

Related services

Users of Amazon Glue also use:

- [Amazon Lake Formation](#) – A service that is an authorization layer that provides fine-grained access control to resources in the Amazon Glue Data Catalog.
- [Amazon Glue DataBrew](#) – A visual data preparation tool that you can use to clean and normalize data without writing any code.

Amazon Glue: How it works

Amazon Glue uses other Amazon services to orchestrate your ETL (extract, transform, and load) jobs to build data warehouses and data lakes and generate output streams. Amazon Glue calls API operations to transform your data, create runtime logs, store your job logic, and create notifications to help you monitor your job runs. The Amazon Glue console connects these services into a managed application, so you can focus on creating and monitoring your ETL work. The console performs administrative and job development operations on your behalf. You supply credentials and other properties to Amazon Glue to access your data sources and write to your data targets.

Amazon Glue takes care of provisioning and managing the resources that are required to run your workload. You don't need to create the infrastructure for an ETL tool because Amazon Glue does it for you. When resources are required, to reduce startup time, Amazon Glue uses an instance from its warm pool of instances to run your workload.

With Amazon Glue, you create jobs using table definitions in your Data Catalog. Jobs consist of scripts that contain the instructions that execute the desired data transformation tasks. You use triggers to initiate jobs either on a schedule or as a result of a specified event. You determine where your target data resides and which source data populates your target. Based on your inputs, Amazon Glue transforms your data from the source to the target format. Alternatively, you can also provide custom scripts in the Amazon Glue console or API to process your data according to your specific requirements.

Data sources and destinations

Amazon Glue for Spark allows you to read and write data from multiple systems and databases including:

- Amazon S3
- Amazon DynamoDB
- Amazon Redshift
- Amazon Relational Database Service (Amazon RDS)
- Third-party JDBC-accessible databases
- MongoDB and Amazon DocumentDB (with MongoDB compatibility)
- Other marketplace connectors and Apache Spark plugins

Data streams

Amazon Glue for Spark can stream data from the following systems:

- Amazon Kinesis Data Streams
- Apache Kafka

Amazon Glue is available in several Amazon Regions. For more information, see [Amazon Regions and Endpoints](#) in the Amazon Web Services General Reference.

Serverless ETL jobs run in isolation

Amazon Glue runs your ETL jobs in a serverless environment with your choice of engine, Spark or Ray. Amazon Glue runs these jobs on virtual resources that it provisions and manages in its own service account.

Amazon Glue is designed to do the following:

- Segregate customer data.
- Protect customer data in transit and at rest.
- Access customer data only as needed in response to customer requests, using temporary, scoped-down credentials, or with a customer's consent to IAM roles in their account.

During provisioning of an ETL job, you provide input data sources and output data targets in your virtual private cloud (VPC). In addition, you provide the IAM role, VPC ID, subnet ID, and security group that are needed to access data sources and targets. For each tuple (customer account ID, IAM role, subnet ID, and security group), Amazon Glue creates a new environment that is isolated at

the network and management level from all other environments inside your Amazon Glue service account.

You create and configure Amazon Glue resources, such as Data Catalogs, Jobs, and Crawlers within your Amazon account. These resources are then associated with the IAM role and network settings (subnet and security group) you specify during the creation process.

Amazon Glue creates elastic network interfaces in your subnet using private IP addresses. Jobs use these elastic network interfaces to access your data sources and data targets. Traffic in, out, and within the job run environment is governed by your VPC and networking policies with one exception: Calls made to Amazon Glue libraries can proxy traffic to Amazon Glue API operations through the Amazon Glue VPC. All Amazon Glue API calls are logged; thus, data owners can audit API access by enabling [Amazon CloudTrail](#), which delivers audit logs to your account.

Amazon Glue managed environments that run your ETL jobs are protected with the same security practices followed by other Amazon services. For an overview of the practices and shared security responsibilities, see the [Introduction to Amazon Security Processes](#) whitepaper.

Amazon Glue concepts

Amazon Glue is a fully managed ETL (extract, transform, load) service that allows you to easily move data between different data sources and targets. The key components are:

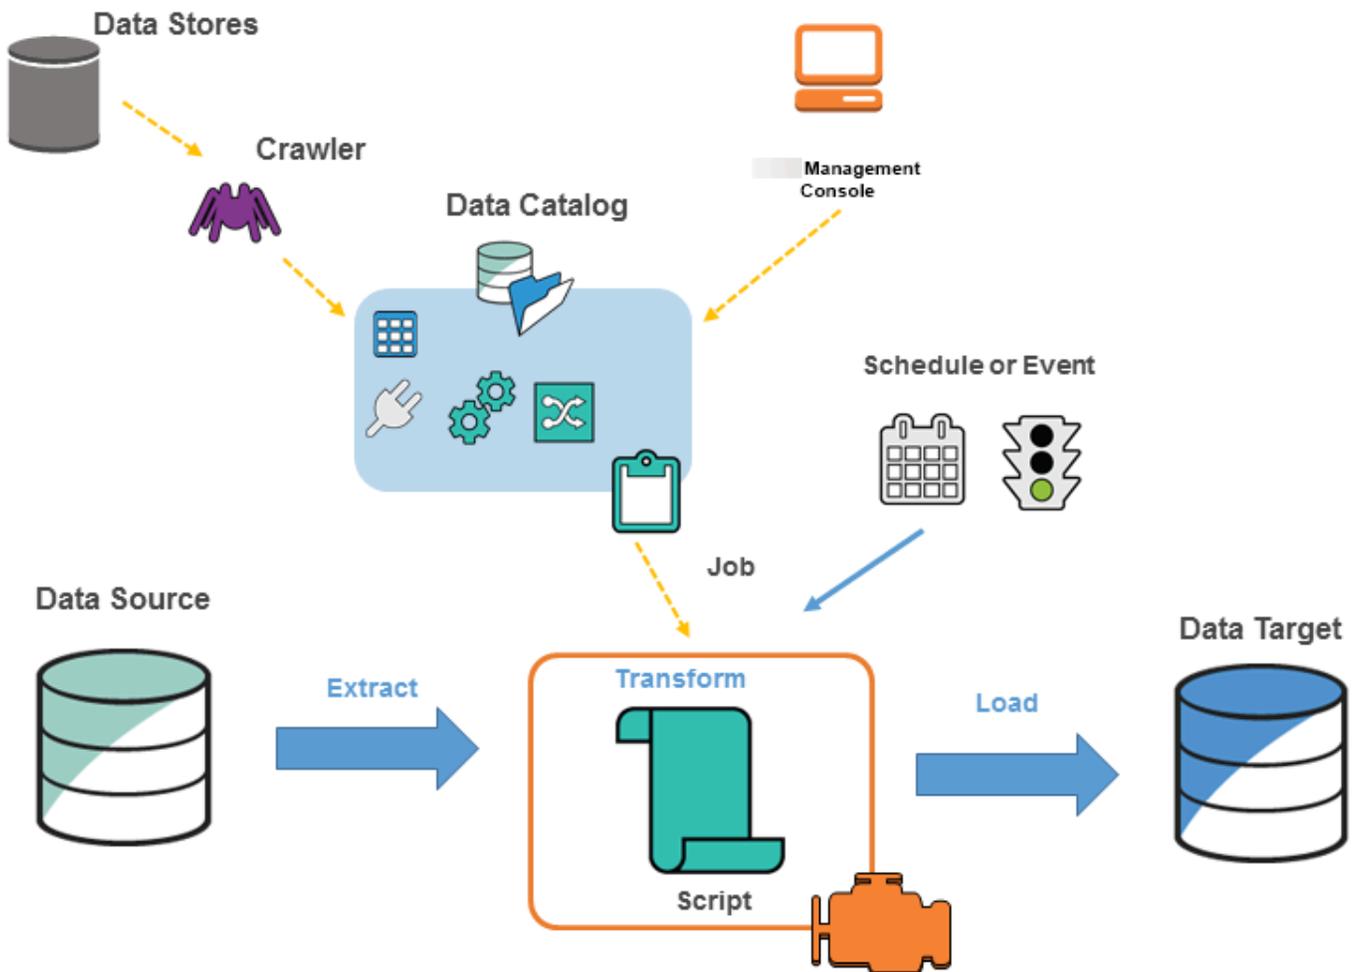

- **Data Catalog:** A metadata store containing table definitions, job definitions, and other control information for your ETL workflows.
- **Crawlers:** Programs that connect to data sources, infer data schemas, and create metadata table definitions in the Data Catalog.
- **ETL Jobs:** The business logic to extract data from sources, transform it using Apache Spark scripts, and load it into targets.
- **Triggers:** Mechanisms to initiate job runs based on schedules or events.

The typical workflow involves:

1. Define data sources and targets in the Data Catalog.
2. Use Crawlers to populate the Data Catalog with table metadata from data sources.
3. Define ETL jobs with transformation scripts to move and process data.
4. Run jobs on-demand or based on triggers.

5. Monitor job performance using dashboards.

The following diagram shows the architecture of an Amazon Glue environment.

You define *jobs* in Amazon Glue to accomplish the work that's required to extract, transform, and load (ETL) data from a data source to a data target. You typically perform the following actions:

- For data store sources, you define a *crawler* to populate your Amazon Glue Data Catalog with metadata table definitions. You point your crawler at a data store, and the crawler creates table definitions in the Data Catalog. For streaming sources, you manually define Data Catalog tables and specify data stream properties.

In addition to table definitions, the Amazon Glue Data Catalog contains other metadata that is required to define ETL jobs. You use this metadata when you define a job to transform your data.

- Amazon Glue can generate a script to transform your data. Or, you can provide the script in the Amazon Glue console or API.
- You can run your job on demand, or you can set it up to start when a specified *trigger* occurs. The trigger can be a time-based schedule or an event.

When your job runs, a script extracts data from your data source, transforms the data, and loads it to your data target. The script runs in an Apache Spark environment in Amazon Glue.

Important

Tables and databases in Amazon Glue are objects in the Amazon Glue Data Catalog. They contain metadata; they don't contain data from a data store.

Text-based data, such as CSVs, must be encoded in UTF-8 for Amazon Glue to process it successfully. For more information, see [UTF-8](#) in Wikipedia.

Amazon Glue terminology

Amazon Glue relies on the interaction of several components to create and manage your extract, transform, and load (ETL) workflow.

Amazon Glue Data Catalog

The persistent metadata store in Amazon Glue. It contains table definitions, job definitions, and other control information to manage your Amazon Glue environment. Each Amazon account has one Amazon Glue Data Catalog per region.

Classifier

Determines the schema of your data. Amazon Glue provides classifiers for common file types, such as CSV, JSON, AVRO, XML, and others. It also provides classifiers for common relational database management systems using a JDBC connection. You can write your own classifier by using a grok pattern or by specifying a row tag in an XML document.

Connection

A Data Catalog object that contains the properties that are required to connect to a particular data store.

Crawler

A program that connects to a data store (source or target), progresses through a prioritized list of classifiers to determine the schema for your data, and then creates metadata tables in the Amazon Glue Data Catalog.

Database

A set of associated Data Catalog table definitions organized into a logical group.

Data store, data source, data target

A *data store* is a repository for persistently storing your data. Examples include Amazon S3 buckets and relational databases. A *data source* is a data store that is used as input to a process or transform. A *data target* is a data store that a process or transform writes to.

Development endpoint

An environment that you can use to develop and test your Amazon Glue ETL scripts.

Dynamic Frame

A distributed table that supports nested data such as structures and arrays. Each record is self-describing, designed for schema flexibility with semi-structured data. Each record contains both data and the schema that describes that data. You can use both dynamic frames and Apache Spark DataFrames in your ETL scripts, and convert between them. Dynamic frames provide a set of advanced transformations for data cleaning and ETL.

Job

The business logic that is required to perform ETL work. It is composed of a transformation script, data sources, and data targets. Job runs are initiated by triggers that can be scheduled or triggered by events.

Job performance dashboard

Amazon Glue provides a comprehensive run dashboard for your ETL jobs. The dashboard displays information about job runs from a specific time frame.

Notebook interface

An enhanced notebook experience with one-click setup for easy job authoring and data exploration. The notebook and connections are configured automatically for you. You can use the notebook interface based on Jupyter Notebook to interactively develop, debug, and deploy scripts and workflows using Amazon Glue serverless Apache Spark ETL infrastructure. You can also perform ad-hoc queries, data analysis, and visualization (for example, tables and graphs) in the notebook environment.

Script

Code that extracts data from sources, transforms it, and loads it into targets. Amazon Glue generates PySpark or Scala scripts.

Table

The metadata definition that represents your data. Whether your data is in an Amazon Simple Storage Service (Amazon S3) file, an Amazon Relational Database Service (Amazon RDS) table, or another set of data, a table defines the schema of your data. A table in the Amazon Glue Data Catalog consists of the names of columns, data type definitions, partition information, and other metadata about a base dataset. The schema of your data is represented in your Amazon Glue table definition. The actual data remains in its original data store, whether it be in a file or a relational database table. Amazon Glue catalogs your files and relational database tables in the Amazon Glue Data Catalog. They are used as sources and targets when you create an ETL job.

Transform

The code logic that is used to manipulate your data into a different format.

Trigger

Initiates an ETL job. Triggers can be defined based on a scheduled time or an event.

Visual job editor

The visual job editor is a graphical interface that makes it easy to create, run, and monitor extract, transform, and load (ETL) jobs in Amazon Glue. You can visually compose data transformation workflows, seamlessly run them on Amazon Glue's Apache Spark-based serverless ETL engine, and inspect the schema and data results in each step of the job.

Worker

With Amazon Glue, you only pay for the time your ETL job takes to run. There are no resources to manage, no upfront costs, and you are not charged for startup or shutdown time. You are charged an hourly rate based on the number of **Data Processing Units** (or DPUs) used to run your ETL job. A single Data Processing Unit (DPU) is also referred to as a *worker*. Amazon Glue comes with multiple worker types to help you select the configuration that meets your job latency and cost requirements. Workers come in Standard, G.1X, G.2X, G.4X, G.8X, G.12X, G.16X, G.025X, and memory-optimized R.1X, R.2X, R.4X, R.8X configurations.

Amazon Glue components

Amazon Glue provides a console and API operations to set up and manage your extract, transform, and load (ETL) workload. You can use API operations through several language-specific SDKs and the Amazon Command Line Interface (Amazon CLI). For information about using the Amazon CLI, see [Amazon CLI Command Reference](#).

Amazon Glue uses the Amazon Glue Data Catalog to store metadata about data sources, transforms, and targets. The Data Catalog is a drop-in replacement for the Apache Hive Metastore. The Amazon Glue Jobs system provides a managed infrastructure for defining, scheduling, and running ETL operations on your data. For more information about the Amazon Glue API, see [Amazon Glue API](#).

Amazon Glue console

You use the Amazon Glue console to define and orchestrate your ETL workflow. The console calls several API operations in the Amazon Glue Data Catalog and Amazon Glue Jobs system to perform the following tasks:

- Define Amazon Glue objects such as jobs, tables, crawlers, and connections.
- Schedule when crawlers run.

- Define events or schedules for job triggers.
- Search and filter lists of Amazon Glue objects.
- Edit transformation scripts.

Amazon Glue Data Catalog

The Amazon Glue Data Catalog is your persistent technical metadata store in the Amazon Cloud.

Each Amazon account has one Amazon Glue Data Catalog per Amazon Region. Each Data Catalog is a highly scalable collection of tables organized into databases. A table is metadata representation of a collection of structured or semi-structured data stored in sources such as Amazon RDS, Apache Hadoop Distributed File System, Amazon OpenSearch Service, and others. The Amazon Glue Data Catalog provides a uniform repository where disparate systems can store and find metadata to keep track of data in data silos. You can then use the metadata to query and transform that data in a consistent manner across a wide variety of applications.

You use the Data Catalog together with Amazon Identity and Access Management policies and Lake Formation to control access to the tables and databases. By doing this, you can allow different groups in your enterprise to safely publish data to the wider organization while protecting sensitive information in a highly granular fashion.

The Data Catalog, along with CloudTrail and Lake Formation, also provides you with comprehensive audit and governance capabilities, with schema change tracking and data access controls. This helps ensure that data is not inappropriately modified or inadvertently shared.

For information about securing and auditing the Amazon Glue Data Catalog, see:

- **Amazon Lake Formation** – For more information, see [What Is Amazon Lake Formation?](#) in the *Amazon Lake Formation Developer Guide*.
- **CloudTrail** – For more information, see [What Is CloudTrail?](#) in the *Amazon CloudTrail User Guide*.

The following are other Amazon services and open-source projects that use the Amazon Glue Data Catalog:

- **Amazon Athena** – For more information, see [Understanding Tables, Databases, and the Data Catalog](#) in the *Amazon Athena User Guide*.
- **Amazon Redshift Spectrum** – For more information, see [Using Amazon Redshift Spectrum to Query External Data](#) in the *Amazon Redshift Database Developer Guide*.

- **Amazon EMR** – For more information, see [Use Resource-Based Policies for Amazon EMR Access to Amazon Glue Data Catalog](#) in the *Amazon EMR Management Guide*.
- **Amazon Glue Data Catalog client for Apache Hive metastore** – For more information about this GitHub project, see [Amazon Glue Data Catalog Client for Apache Hive Metastore](#).

Amazon Glue crawlers and classifiers

Amazon Glue also lets you set up crawlers that can scan data in all kinds of repositories, classify it, extract schema information from it, and store the metadata automatically in the Amazon Glue Data Catalog. The Amazon Glue Data Catalog can then be used to guide ETL operations.

For information about how to set up crawlers and classifiers, see [Using crawlers to populate the Data Catalog](#). For information about how to program crawlers and classifiers using the Amazon Glue API, see [Crawlers and classifiers API](#).

Amazon Glue ETL operations

Using the metadata in the Data Catalog, Amazon Glue can automatically generate Scala or PySpark (the Python API for Apache Spark) scripts with Amazon Glue extensions that you can use and modify to perform various ETL operations. For example, you can extract, clean, and transform raw data, and then store the result in a different repository, where it can be queried and analyzed. Such a script might convert a CSV file into a relational form and save it in Amazon Redshift.

For more information about how to use Amazon Glue ETL capabilities, see [Programming Spark scripts](#).

Streaming ETL in Amazon Glue

Amazon Glue enables you to perform ETL operations on streaming data using continuously-running jobs. Amazon Glue streaming ETL is built on the Apache Spark Structured Streaming engine, and can ingest streams from Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK). Streaming ETL can clean and transform streaming data and load it into Amazon S3 or JDBC data stores. Use Streaming ETL in Amazon Glue to process event data like IoT streams, clickstreams, and network logs.

If you know the schema of the streaming data source, you can specify it in a Data Catalog table. If not, you can enable schema detection in the streaming ETL job. The job then automatically determines the schema from the incoming data.

The streaming ETL job can use both Amazon Glue built-in transforms and transforms that are native to Apache Spark Structured Streaming. For more information, see [Operations on streaming DataFrames/Datasets](#) on the Apache Spark website.

For more information, see [the section called “Streaming ETL jobs”](#).

The Amazon Glue jobs system

The Amazon Glue Jobs system provides managed infrastructure to orchestrate your ETL workflow. You can create jobs in Amazon Glue that automate the scripts you use to extract, transform, and transfer data to different locations. Jobs can be scheduled and chained, or they can be triggered by events such as the arrival of new data.

For more information about using the Amazon Glue Jobs system, see [Monitoring Amazon Glue](#). For information about programming using the Amazon Glue Jobs system API, see [Jobs API](#).

Visual ETL components

Amazon Glue allows you to create ETL jobs through a visual canvas that you can manipulate.

The screenshot displays the Amazon Glue Visual job editor. At the top, there's a header with 'Untitled job' and several action buttons: 'Try new UI', 'Actions', 'Save', and 'Run'. Below this is a navigation bar with tabs for 'Visual', 'Script', 'Job details', 'Runs', 'Data quality New', 'Schedules', and 'Version Control'. The main workspace is a grid-based canvas where a workflow is being built. It consists of three primary nodes connected vertically: a 'Data source - S3 bucket S3 bucket' node, a 'Transform - ApplyMapping ApplyMapping' node, and a 'Data target - S3 bucket S3 bucket' node. To the right of the first node, there is another 'Data source - S3 bucket Amazon S3' node. On the right side of the canvas, there is a vertical toolbar with icons for zooming, panning, and deleting. In the bottom right corner, a notification box indicates 'Unsaved job found. We found an unsaved graph, do you wish to restore it?' with a 'Restore' button.

ETL job menu

Menu options at the top of the canvas allow you to access the various views and configuration details about your job.

- **Visual** – The Visual job editor canvas. This is where you can add nodes to create a job.
- **Script** – The script representation of your ETL job. Amazon Glue generates the script based on the visual representation of your job. You can also edit your script or download it.

Note

If you choose to edit the script, the job authoring experience is permanently converted to a script-only mode. Afterwards, you cannot use the visual editor to edit the job anymore.

You should add all the job sources, transforms, and targets, and make all the changes you require with the visual editor before choosing to edit the script.

- **Job details** – The Job details tab allows you to configure your job by setting job properties. There are basic properties, such as name and description of your job, IAM role, job type, Amazon Glue version, language, worker type, number of workers, job bookmark, flex execution, number of retries, and job timeout, and there are advanced properties, such as connections, libraries, job parameters, and tags.
- **Runs** – After your job runs, this tab can be accessed to view your past job runs.
- **Data quality** – Data quality evaluates and monitors the quality of your data assets. You can learn more about how to use data quality on this tab and add a data quality transform to your job.
- **Schedules** – Jobs that you've scheduled appear in this tab. If there are no schedules attached to this job, then this tab is not accessible.
- **Version control** – You can use Git with your job by configuring your job to a Git repository.

Visual ETL panels

When you work in the canvas, several panels are available to help you configure your nodes, or help you to preview your data and view the output schema.

- **Properties** – The Properties panel appears when you choose a node on your canvas.
- **Data preview** – The Data preview panel provides a preview of the data output so that you can make decisions before you run your job and examine your output.
- **Output schema** – The Output schema tab allows you to view and edit the schema of your transform nodes.

Resizing panels

You can resize the Properties panel on the right-hand side of the screen and the bottom panel which contains the Data preview and Output schema tabs by clicking on the edge of the panel and dragging it left and right or up and down.

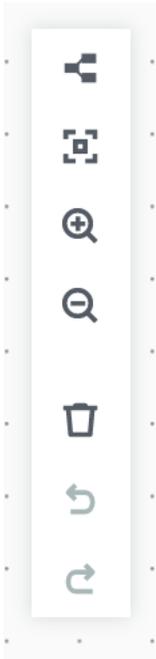

- **Properties panel** – Resize the properties panel by clicking and dragging the edge of the canvas on the right side of the screen and drag it left to expand its width. By default, the panel is collapsed and when a node is selected, the properties panel opens up to its default size.

- **Data preview and Output schema panel** – Resize the bottom panel by clicking and dragging the bottom edge of the canvas at the bottom of the screen and drag it up to expand its height. By default, the panel is collapsed and when a node is selected, the bottom panel opens up to its default size.

Job canvas

You can add, remove, and move/reorder nodes directly on the Visual ETL canvas. Think of it as your workspace to create a fully functional ETL job that starts with a data source and can end with a data target.

When you work with nodes on the canvas, you have a toolbar that can help you zoom in and out, remove nodes, make or edit connections between nodes, change the job flow orientation, and undo or redo an action.

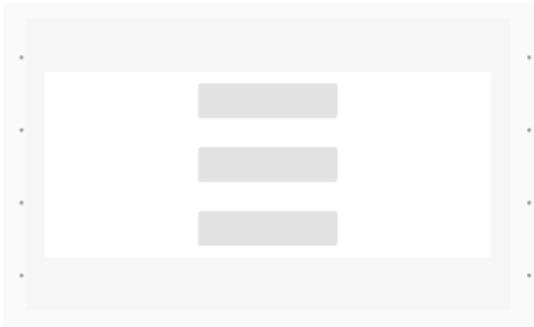

The floating toolbar is anchored to the upper right-hand side of the canvas and contains several images that perform actions:

- **Layout icon** – The first icon in the toolbar is the layout icon. By default, the direction of visual jobs is top to bottom. It rearranges the direction of your visual job by arranging the nodes horizontally from left to right. Clicking the layout icon again changes the direction back to top to bottom.

- **Recenter icon** – The recenter icon changes the canvas view by centering it. You can use this with large jobs to get back to the center position.
- **Zoom in icon** – The zoom in icon enlarges the size of the nodes on the canvas.
- **Zoom out icon** – The zoom out icon decreases the size of the nodes on the canvas.
- **Trash icon** – The trash icon removes a node from the visual job. You must select a node first.
- **Undo icon** – The undo icon reverses the last action taken on the visual job.
- **Redo icon** – The redo icon repeats the last action taken on the visual job.

Using the mini-map

Resource panel

The resource panel contains all of the data sources, transform actions, and connections available to you. Open the resource panel on the canvas by clicking the "+" icon. This will open the resource panel.

To close the resource panel, click the **X** in the upper-right hand corner of the resource panel. This will hide the panel until you're ready to open it again.

Read from an Apache Kafka or Amazon MSK topic.
- Relational DB**

AWS Glue Data Catalog table with a relational database as the data source.
- Amazon Redshift**

Read your data from Amazon Redshift.
- MySQL**

AWS Glue Data Catalog table with MySQL as the data source.
- PostgreSQL**

AWS Glue Data Catalog table with PostgreSQL as the data source.
- Oracle SQL**

AWS Glue Data Catalog table with Oracle SQL as the data source.
- Microsoft SQL Server**

AWS Glue Data Catalog table with SQL Server as the data source.
- Amazon DynamoDB**

AWS Glue Data Catalog table with DynamoDB as the data source.
- Snowflake**

Read your data from Snowflake.

Popular transforms & data

At the top of the panel is a collection of **Popular transforms & data**. These nodes are commonly used in Amazon Glue. Choose one to add it to the canvas. You can also hide the **Popular transforms & data** by clicking the triangle next to the **Popular transforms & data** heading.

Beneath the **Popular transforms & data** section, you can search for transforms and data source nodes. Results appear as you type. The more letters you add to your search query, the list of results will get smaller. Search results are populated from the node name and/or description. Choose the node to add it to your canvas.

Transforms and Data

There are two tabs that organize the nodes into **Transforms** and **Data**.

Transforms – When you choose the **Transforms** tab, all of the available transforms can be selected. Choose a transform to add it to the canvas. You can also choose **Add Transform** at the bottom of the Transforms list which will open a new page to the documentation for creating [Custom visual transforms](#). Following the steps will allow you to create transforms of your own. Your transforms will then appear in the list of available transforms.

Data – The data tab contains all of the nodes for **Sources** and **Targets**. You can hide the Sources and Targets by clicking the triangle next to the Sources or Targets heading. You can unhide the Sources and Targets by clicking the triangle again. Choose a source or target node to add it to the canvas. You can also choose **Manage Connections** to add a new connection. This will open the Connectors page in the console.

Amazon Glue for Spark and Amazon Glue for Ray

In Amazon Glue on Apache Spark (Amazon Glue ETL), you can use PySpark to write Python code to handle data at scale. Spark is a familiar solution for this problem, but data engineers with Python-focused backgrounds can find the transition unintuitive. The Spark DataFrame model is not seamlessly "Pythonic", which reflects the Scala language and Java runtime it is built upon.

In Amazon Glue, you can use Python shell jobs to run native Python data integrations. These jobs run on a single Amazon EC2 instance and are limited by the capacity of that instance. This restricts the throughput of the data you can process, and becomes expensive to maintain when dealing with big data.

Amazon Glue for Ray allows you to scale up Python workloads without substantial investment into learning Spark. You can take advantage of certain scenarios where Ray performs better. By offering you a choice, you can use the strengths of both Spark and Ray.

Amazon Glue ETL and Amazon Glue for Ray are different underneath, so they support different features. Please check the documentation to determine supported features.

What is Amazon Glue for Ray?

Ray is an open-source distributed computation framework that you can use to scale up workloads, with a focus on Python. For more information about Ray, see the [Ray website](#). Amazon Glue Ray jobs and interactive sessions allow you to use Ray within Amazon Glue.

You can use Amazon Glue for Ray to write Python scripts for computations that will run in parallel across multiple machines. In Ray jobs and interactive sessions, you can use familiar Python libraries, like pandas, to make your workflows easy to write and run. For more information about Ray datasets, see [Ray Datasets](#) in the Ray documentation. For more information about pandas, see the [Pandas website](#).

When you use Amazon Glue for Ray, you can run your pandas workflows against big data at enterprise scale—with only a few lines of code. You can create a Ray job from the Amazon Glue console or the Amazon SDK. You can also open an Amazon Glue interactive session to run your code on a serverless Ray environment. Visual jobs in Amazon Glue Studio are not yet supported.

Amazon Glue for Ray jobs allow you to run a script on a schedule or in response to an event from Amazon EventBridge. Jobs store log information and monitoring statistics in CloudWatch that enable you to understand the health and reliability of your script. For more information about the Amazon Glue job system, see [the section called “Working with Ray jobs”](#).

Ray automates the work of scaling Python code by distributing the processing across a cluster of machines that it reconfigures in real time, based on the load. This can lead to improved performance per dollar for certain workloads. With Ray jobs, we have built auto scaling natively into the Amazon Glue job model, so you can fully take advantage of this feature. Ray jobs run on Amazon Graviton, leading to higher overall price performance.

In addition to cost savings, you can use native auto scaling to run Ray workloads without investing time into cluster maintenance, tuning, and administration. You can use familiar open-source libraries out of the box, such as pandas, and the Amazon SDK for Pandas. These improve iteration speed while you're developing on Amazon Glue for Ray. When you use Amazon Glue for Ray, you will be able to rapidly develop and run cost-effective data integration workloads.

Converting semi-structured schemas to relational schemas with Amazon Glue

It's common to want to convert semi-structured data into relational tables. Conceptually, you are flattening a hierarchical schema to a relational schema. Amazon Glue can perform this conversion for you on-the-fly.

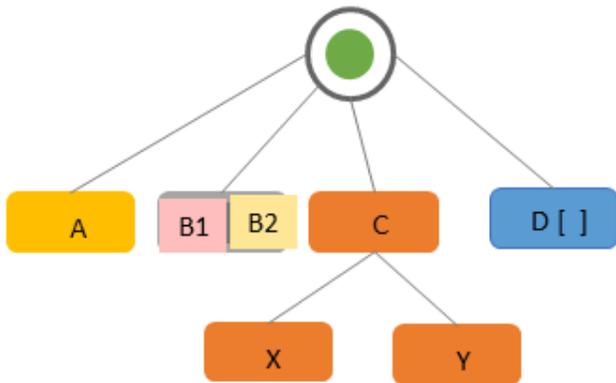

Semi-structured data typically contains mark-up to identify entities within the data. It can have nested data structures with no fixed schema. For more information about semi-structured data, see [Semi-structured data](#) in Wikipedia.

Relational data is represented by tables that consist of rows and columns. Relationships between tables can be represented by a primary key (PK) to foreign key (FK) relationship. For more information, see [Relational database](#) in Wikipedia.

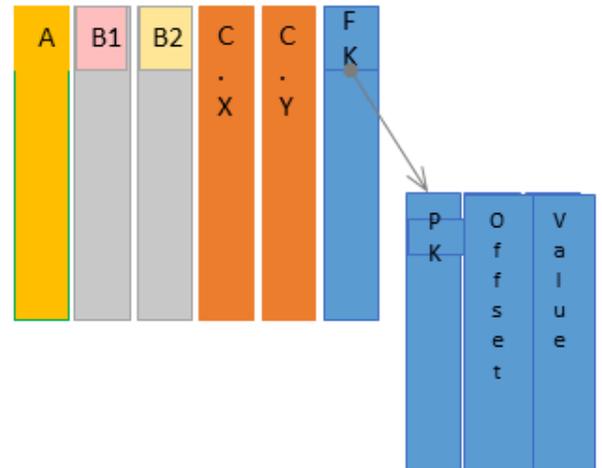

Amazon Glue uses crawlers to infer schemas for semi-structured data. It then transforms the data to a relational schema using an ETL (extract, transform, and load) job. For example, you might want to parse JSON data from Amazon Simple Storage Service (Amazon S3) source files to Amazon Relational Database Service (Amazon RDS) tables. Understanding how Amazon Glue handles the differences between schemas can help you understand the transformation process.

This diagram shows how Amazon Glue transforms a semi-structured schema to a relational schema.

Semi-structured schema

Relational schema

The diagram illustrates the following:

- Single value A converts directly to a relational column.
- The pair of values, B1 and B2, convert to two relational columns.
- Structure C, with children X and Y, converts to two relational columns.
- Array D[] converts to a relational column with a foreign key (FK) that points to another relational table. Along with a primary key (PK), the second relational table has columns that contain the offset and value of the items in the array.

Amazon Glue type systems

Amazon Glue uses multiple type systems to provide a versatile interface over data systems that store data in very different ways. This document disambiguates Amazon Glue type systems and data standards.

Amazon Glue Data Catalog Types

The Data Catalog is a registry of tables and fields stored in various data systems, a metastore. When Amazon Glue components, such as Amazon Glue crawlers and Amazon Glue with Spark jobs, write to the Data Catalog, they do so with an internal type system for tracking the types of fields. These values are shown in the **Data type** column of the table schema in the Amazon Glue Console. This type system is based on Apache Hive's type system. For more information about the Apache Hive type system, see [Types](#) in the Apache Hive wiki. For more information about specific types and support, examples are provided in the Amazon Glue Console, as part of the Schema Builder.

Validation, compatibility and other uses

The Data Catalog does not validate types written to type fields. When Amazon Glue components read and write to the Data Catalog, they will be compatible with each other. Amazon Glue components also aim to preserve a high degree of compatibility with the Hive types. However, Amazon Glue components do not guarantee compatibility with all Hive types. This allows for interoperability with tools like Athena DDL when working with tables in the Data Catalog.

Since the Data Catalog does not validate types, other services may use the Data Catalog to track types using systems that strictly conform to the Hive type system, or any other system.

Types in Amazon Glue with Spark scripts

When a Amazon Glue with Spark script interprets or transforms a dataset, we provide `DynamicFrame`, an in-memory representation of your dataset as it is used in your script. The goal of a `DynamicFrame` is similar to that of the Spark `DataFrame`— it models your dataset so that Spark can schedule and execute transforms on your data. We guarantee that the type representation of `DynamicFrame` is intercompatible with `DataFrame` by providing the `toDF` and `fromDF` methods.

If type information can be inferred or provided to a `DataFrame`, it can be inferred or provided to a `DynamicFrame`, unless otherwise documented. When we provide optimized readers or writers for specific data formats, if Spark can read or write your data, our provided readers and writers will

be able to, subject to documented limitations. For more information about readers and writers, see [the section called "Data format options"](#).

The Choice Type

`DynamicFrames` provide a mechanism for modeling fields in a dataset whose value may have inconsistent types on disk across rows. For instance, a field may hold a number stored as a string in certain rows, and an integer in others. This mechanism is an in-memory type called `Choice`. We provide transforms such as the `ResolveChoice` method, to resolve `Choice` columns to a concrete type. Amazon Glue ETL will not write the `Choice` type to the Data Catalog in the normal course of operation; `Choice` types only exist in the context of `DynamicFrame` memory models of datasets. For an example of `Choice` type usage, see [the section called "Data preparation sample"](#).

Amazon Glue Crawler Types

Crawlers aim to produce a consistent, usable schema for your dataset, then store it in Data Catalog for use in other Amazon Glue components and Athena. Crawlers deal with types as described in the previous section on the Data Catalog, [the section called "Amazon Glue Data Catalog Types"](#). To produce a usable type in "Choice" type scenarios, where a column contains values of two or more types, Crawlers will create a `struct` type that models the potential types.

Getting started with Amazon Glue

The following sections provide information on setting up Amazon Glue. Not all of the setting up sections are required to start using Amazon Glue. You can use the instructions as needed to set up IAM permissions, encryption, and DNS (if you're using a VPC environment to access data stores or if you're using interactive sessions).

Topics

- [Overview of using Amazon Glue](#)
- [Setting up IAM permissions for Amazon Glue](#)
- [Setting up Amazon Glue usage profiles](#)
- [Getting started with the Amazon Glue Data Catalog](#)
- [Setting up network access to data stores](#)
- [Setting up encryption in Amazon Glue](#)
- [Setting up networking for development for Amazon Glue](#)

Overview of using Amazon Glue

With Amazon Glue, you store metadata in the Amazon Glue Data Catalog. You use this metadata to orchestrate ETL jobs that transform data sources and load your data warehouse or data lake. The following steps describe the general workflow and some of the choices that you make when working with Amazon Glue.

Note

You can use the following steps, or you can create a workflow that automatically performs steps 1 through 3. For more information, see [the section called “Performing complex ETL activities using blueprints and workflows”](#).

1. Populate the Amazon Glue Data Catalog with table definitions.

In the console, for persistent data stores, you can add a crawler to populate the Amazon Glue Data Catalog. You can start the **Add crawler** wizard from the list of tables or the list of crawlers. You choose one or more data stores for your crawler to access. You can also create a schedule to

determine the frequency of running your crawler. For data streams, you can manually create the table definition, and define stream properties.

Optionally, you can provide a custom classifier that infers the schema of your data. You can create custom classifiers using a grok pattern. However, Amazon Glue provides built-in classifiers that are automatically used by crawlers if a custom classifier does not recognize your data. When you define a crawler, you don't have to select a classifier. For more information about classifiers in Amazon Glue, see [Defining and managing classifiers](#).

Crawling some types of data stores requires a connection that provides authentication and location information. If needed, you can create a connection that provides this required information in the Amazon Glue console.

The crawler reads your data store and creates data definitions and named tables in the Amazon Glue Data Catalog. These tables are organized into a database of your choosing. You can also populate the Data Catalog with manually created tables. With this method, you provide the schema and other metadata to create table definitions in the Data Catalog. Because this method can be a bit tedious and error prone, it's often better to have a crawler create the table definitions.

For more information about populating the Amazon Glue Data Catalog with table definitions, see [Creating tables](#).

2. Define a job that describes the transformation of data from source to target.

Generally, to create a job, you have to make the following choices:

- Choose a table from the Amazon Glue Data Catalog to be the source of the job. Your job uses this table definition to access your data source and interpret the format of your data.
- Choose a table or location from the Amazon Glue Data Catalog to be the target of the job. Your job uses this information to access your data store.
- Tell Amazon Glue to generate a script to transform your source to target. Amazon Glue generates the code to call built-in transforms to convert data from its source schema to target schema format. These transforms perform operations such as copy data, rename columns, and filter data to transform data as necessary. You can modify this script in the Amazon Glue console.

For more information about defining jobs in Amazon Glue, see [Building visual ETL jobs](#).

3. Run your job to transform your data.

You can run your job on demand, or start it based on a one of these trigger types:

- A trigger that is based on a cron schedule.
- A trigger that is event-based; for example, the successful completion of another job can start an Amazon Glue job.
- A trigger that starts a job on demand.

For more information about triggers in Amazon Glue, see [Starting jobs and crawlers using triggers](#).

4. Monitor your scheduled crawlers and triggered jobs.

Use the Amazon Glue console to view the following:

- Job run details and errors.
- Crawler run details and errors.
- Any notifications about Amazon Glue activities

For more information about monitoring your crawlers and jobs in Amazon Glue, see [Monitoring Amazon Glue](#).

Setting up IAM permissions for Amazon Glue

The instructions in this topic help you quickly set up Amazon Identity and Access Management (IAM) permissions for Amazon Glue. You will complete the following tasks:

- Grant your IAM identities access to Amazon Glue resources.
- Create a service role for running jobs, accessing data, and running Amazon Glue Data Quality tasks.

For detailed instructions that you can use to customize IAM permissions for Amazon Glue, see [Configuring IAM permissions for Amazon Glue](#).

To set up IAM permissions for Amazon Glue in the Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Getting started**.

3. Under **Prepare your account for Amazon Glue**, choose **Set up IAM permissions**.
4. Choose the IAM identities (roles or users) that you want to give Amazon Glue permissions to. Amazon Glue attaches the [AWSGlueConsoleFullAccess](#) managed policy to these identities. You can skip this step if you want to set these permissions manually or only want to set a default service role.
5. Choose **Next**.
6. Choose the level of Amazon S3 access that your roles and users need. The options that you choose in this step are applied to all of the identities that you selected.
 - a. Under **Choose S3 locations**, choose the Amazon S3 locations that you want to grant access to.
 - b. Next, select whether your identities should have **Read only (recommended)** or **Read and write** access to the locations that you previously selected. Amazon Glue adds permissions policies to your identities based on the combination of locations and read or write permissions you select.

The following table displays the permissions that Amazon Glue attaches for Amazon S3 access.

If you choose ...	Amazon Glue attaches ...
No change	No permissions. Amazon Glue won't make any changes to your identity's permissions.
Grant access to specific Amazon S3 locations (read only)	<p>The customer-managed policy, <code>AWSGlueConsole-S3-read-only-policy</code>, grants access to specific Amazon S3 locations with read-only permissions.</p> <p>JSON</p> <pre data-bbox="1013 1724 1507 1894"> { "Version": "2012-10-17", "Statement": [</pre>

If you choose ...	Amazon Glue attaches ...
	<pre data-bbox="1008 212 1507 1213">{ "Effect": "Allow", "Action": ["s3:GetObject"], "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket1/*", "arn:aws:s3:::amzn-s3-demo-bucket2/*", "arn:aws:s3:::amzn-s3-demo-bucket3", "arn:aws:s3:::amzn-s3-demo-bucket"], "Condition": { "StringEquals": { "aws:ResourceAccount": "000000000000" } } }</pre>

If you choose ...	Amazon Glue attaches ...
Grant access to specific Amazon S3 locations (read and write)	<p>The <code>AWSGlueConsole-S3-read-and-write-policy</code> grants access to specific Amazon S3 locations with read and write permissions.</p> <p>JSON</p> <pre data-bbox="1008 554 1507 1864">{ "Version": "2012-10-17", "Statement": [{ "Effect": "Allow", "Action": ["s3:GetObject", "s3:PutObject"], "Resource": ["arn:aws:s3:::aes-siem-000000000000-log/*", "arn:aws:s3:::aes-siem-000000000000-snapshot/*", "arn:aws:s3:::aes-siem-000000000000-log", "arn:aws:s3:::aes-siem-000000000000-snapshot"], "Condition": { "StringEquals": { "aws:ResourceAccount": "000000000000" } } }] }</pre>

7. Choose **Next**.
8. Choose a default Amazon Glue service role for your account. A service role is an IAM role that Amazon Glue uses to access resources in other Amazon services on your behalf. For more information, see [Service roles for Amazon Glue](#).
 - When you choose the standard Amazon Glue service role, Amazon Glue creates a new IAM role in your Amazon Web Services account named `AWSGlueServiceRole` with the following managed policies attached. If your account already has an IAM role named `AWSGlueServiceRole`, Amazon Glue attaches these policies to the existing role.
 - [AWSGlueServiceRole](#) – This managed policy is required for Amazon Glue to access and manage resources on your behalf. It allows Amazon Glue to create, update, and delete various resources such as Amazon Glue jobs, crawlers, and connections. This policy also grants permissions for Amazon Glue to access Amazon CloudWatch logs for logging purposes. For the purposes of getting started, we recommend using this policy to learn how to use Amazon Glue. As you get more comfortable with Amazon Glue, you can create policies that allow you to fine-tune access to resources as needed.
 - [AWSGlueConsoleFullAccess](#) – This managed policy grants full access to the Amazon Glue service through the Amazon Web Services Management Console. This policy grants permissions to perform any operation within Amazon Glue, enabling you to create, modify, and delete any Amazon Glue resource as needed. However, it's important to note that this policy does not grant permissions to access the underlying data stores or other Amazon services that may be involved in the ETL process. Due to the broad scope of permissions granted by the `AWSGlueConsoleFullAccess` policy, it should be assigned with caution and following the principle of least privilege. It is generally recommended to create and use more granular policies tailored to specific use cases and requirements whenever possible.
 - [AWSGlueConsole-S3-read-only-policy](#) – This policy allows Amazon Glue to read data from specified Amazon S3 buckets, but it does not grant permissions to write or modify data in Amazon S3 or

[AWSGlueConsole-S3-read-and-write](#) – This policy allows Amazon Glue to read and write data to specified Amazon S3 buckets as part of the ETL process.
 - When you choose an existing IAM role, Amazon Glue sets the role as the default, but doesn't add `AWSGlueServiceRole` permissions to it. Ensure that you've configured the role to use as a service role for Amazon Glue. For more information, see [Step 1: Create an IAM policy for the Amazon Glue service](#) and [Step 2: Create an IAM role for Amazon Glue](#).

9. Choose **Next**.
10. Finally, review the permissions you've selected and then choose **Apply changes**. When you apply the changes, Amazon Glue adds IAM permissions to the identities that you selected. You can view or modify the new permissions in the IAM console at <https://console.amazonaws.cn/iam/>.

You've now completed the minimum IAM permissions setup for Amazon Glue. In a production environment, we recommend that you familiarize yourself with [Security in Amazon Glue](#) and [Identity and access management for Amazon Glue](#) to help you secure Amazon resources for your use case.

Next steps

Now that you have IAM permissions set up, you can explore the following topics to get started using Amazon Glue:

- [Getting Started with Amazon Glue in Amazon Skill Builder](#)
- [Getting started with the Amazon Glue Data Catalog](#)

Setting up for Amazon Glue Studio

Complete the tasks in this section when you're using Amazon Glue for the visual ETL for the first time:

Topics

- [Review IAM permissions needed for the Amazon Glue Studio user](#)
- [Review IAM permissions needed for ETL jobs](#)
- [Set up IAM permissions for Amazon Glue Studio](#)
- [Configure a VPC for your ETL job](#)

Review IAM permissions needed for the Amazon Glue Studio user

To use Amazon Glue Studio, the user must have access to various Amazon resources. The user must be able to view and select Amazon S3 buckets, IAM policies and roles, and Amazon Glue Data Catalog objects.

Amazon Glue service permissions

Amazon Glue Studio uses the actions and resources of the Amazon Glue service. Your user needs permissions on these actions and resources to effectively use Amazon Glue Studio. You can grant the Amazon Glue Studio user the `AWSGlueConsoleFullAccess` managed policy, or create a custom policy with a smaller set of permissions.

Important

Per security best practices, it is recommended to restrict access by tightening policies to further restrict access to Amazon S3 bucket and Amazon CloudWatch log groups. For an example Amazon S3 policy, see [Writing IAM Policies: How to Grant Access to an Amazon S3 Bucket](#).

Creating Custom IAM Policies for Amazon Glue Studio

You can create a custom policy with a smaller set of permissions for Amazon Glue Studio. The policy can grant permissions for a subset of objects or actions. Use the following information when creating a custom policy.

To use the Amazon Glue Studio APIs, include `glue:UseGlueStudio` in the action policy in your IAM permissions. Using `glue:UseGlueStudio` will allow you to access all Amazon Glue Studio actions even as more actions are added to the API over time.

For more information on actions defined by Amazon Glue, see [Actions defined by Amazon Glue](#).

Data preparation authoring Actions

- `SendRecipeAction`
- `GetRecipeAction`

Directed acyclic graph (DAG) Actions

- `CreateDag`
- `UpdateDag`
- `GetDag`
- `DeleteDag`

Job Actions

- SaveJob
- GetJob
- CreateJob
- DeleteJob
- GetJobs
- UpdateJob

Job run Actions

- StartJobRun
- GetJobRuns
- BatchStopJobRun
- GetJobRun
- QueryJobRuns
- QueryJobs
- QueryJobRunsAggregated

Schema Actions

- GetSchema
- GetInferredSchema

Database Actions

- GetDatabases

Plan Actions

- GetPlan

Table Actions

- SearchTables
- GetTables
- GetTable

Connection Actions

- CreateConnection
- DeleteConnection
- UpdateConnection
- GetConnections
- GetConnection

Mapping Actions

- GetMapping

S3 Proxy Actions

- ListBuckets
- ListObjectsV2
- GetBucketLocation

Security Configuration Actions

- GetSecurityConfigurations

Script Actions

- CreateScript (different from API of same name in Amazon Glue)

Accessing Amazon Glue Studio APIs

To access Amazon Glue Studio, add `glue:UseGlueStudio` in the actions policy list in the IAM permissions.

In the example below, `glue:UseGlueStudio` is included in the action policy, but the Amazon Glue Studio APIs are not individually identified. That is because when you include `glue:UseGlueStudio`, you are automatically granted access to the internal APIs without having to specify the individual Amazon Glue Studio APIs in the IAM permissions.

In the example, the additional listed action policies (for example, `glue:SearchTables`) are not Amazon Glue Studio APIs, so they will need to be included in the IAM permissions as required. You may also want to include Amazon S3 Proxy actions to specify the level of Amazon S3 access to grant. The example policy below provides access to open Amazon Glue Studio, create a visual job, and save/run it if the IAM role selected has sufficient access.

Notebook and data preview permissions

Data previews and notebooks allow you to see a sample of your data at any stage of your job (reading, transforming, writing), without having to run the job. You specify an Amazon Identity and Access Management (IAM) role for Amazon Glue Studio to use when accessing the data. IAM roles are intended to be assumable and do not have standard long-term credentials such as a password or access keys associated with it. Instead, when Amazon Glue Studio assumes the role, IAM provides it with temporary security credentials.

To ensure data previews and notebook commands work correctly, use a role that has a name that starts with the string `AWSGlueServiceRole`. If you choose to use a different name for your role, then you must add the `iam:passrole` permission and configure a policy for the role in IAM. For more information, see [Create an IAM policy for roles not named "AWSGlueServiceRole"](#).

Warning

If a role grants the `iam:passrole` permission for a notebook, and you implement role chaining, a user could unintentionally gain access to the notebook. There is currently no auditing implemented which would allow you to monitor which users have been granted access to the notebook.

If you would like to deny an IAM identity the ability to create data preview sessions, consult the following example [the section called "Deny an identity the ability to create data preview sessions"](#).

Amazon CloudWatch permissions

You can monitor your Amazon Glue Studio jobs using Amazon CloudWatch, which collects and processes raw data from Amazon Glue into readable, near-real-time metrics. By default, Amazon

Glue metrics data is sent to CloudWatch automatically. For more information, see [What Is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*, and [Amazon Glue Metrics](#) in the *Amazon Glue Developer Guide*.

To access CloudWatch dashboards, the user accessing Amazon Glue Studio needs one of the following:

- The AdministratorAccess policy
- The CloudWatchFullAccess policy
- A custom policy that includes one or more of these specific permissions:
 - `cloudwatch:GetDashboard` and `cloudwatch:ListDashboards` to view dashboards
 - `cloudwatch:PutDashboard` to create or modify dashboards
 - `cloudwatch:DeleteDashboards` to delete dashboards

For more information for changing permissions for an IAM user using policies, see [Changing Permissions for an IAM User](#) in the *IAM User Guide*.

Review IAM permissions needed for ETL jobs

When you create a job using Amazon Glue Studio, the job assumes the permissions of the IAM role that you specify when you create it. This IAM role must have permission to extract data from your data source, write data to your target, and access Amazon Glue resources.

The name of the role that you create for the job must start with the string `AWSGlueServiceRole` for it to be used correctly by Amazon Glue Studio. For example, you might name your role `AWSGlueServiceRole-FlightDataJob`.

Data source and data target permissions

An Amazon Glue Studio job must have access to Amazon S3 for any sources, targets, scripts, and temporary directories that you use in your job. You can create a policy to provide fine-grained access to specific Amazon S3 resources.

- Data sources require `s3:ListBucket` and `s3:GetObject` permissions.
- Data targets require `s3:ListBucket`, `s3:PutObject`, and `s3:DeleteObject` permissions.

Note

Your IAM policy needs to allow `s3:GetObject` for the specific buckets used for hosting Amazon Glue transforms.

The following buckets are owned by the Amazon service account and is worldwide readable. These buckets serve as a repository for the source code pertinent to a subset of transformations accessible via the Amazon Glue Studio visual editor. Permissions on the bucket are set up to deny any other API action on the bucket. Anybody can read those scripts we provide for the transformations, but nobody outside our service team can "put" anything in them. When your Amazon Glue job runs, that file is pulled in as a local import so the file is downloaded to the local container. After that, there is no further communication with that account.

Region: Bucket name

- af-south-1: aws-glue-studio-transforms-762339736633-prod-af-south-1

- eusc-de-east-1: aws-glue-studio-transforms-780995497573-prod-eusc-de-east-1-555

If you choose Amazon Redshift as your data source, you can provide a role for cluster permissions. Jobs that run against a Amazon Redshift cluster issue commands that access Amazon S3 for temporary storage using temporary credentials. If your job runs for more than an hour, these credentials will expire causing the job to fail. To avoid this problem, you can assign a role to the Amazon Redshift cluster itself that grants the necessary permissions to jobs using temporary credentials. For more information, see [Moving Data to and from Amazon Redshift](#) in the *Amazon Glue Developer Guide*.

If the job uses data sources or targets other than Amazon S3, then you must attach the necessary permissions to the IAM role used by the job to access these data sources and targets. For more information, see [Setting Up Your Environment to Access Data Stores](#) in the *Amazon Glue Developer Guide*.

If you're using connectors and connections for your data store, you need additional permissions, as described in [the section called "Permissions required for using connectors"](#).

Permissions required for deleting jobs

In Amazon Glue Studio you can select multiple jobs in the console to delete. To perform this action, you must have the `glue:BatchDeleteJob` permission. This is different from the Amazon Glue console, which requires the `glue:DeleteJob` permission for deleting jobs.

Amazon Key Management Service permissions

If you plan to access Amazon S3 sources and targets that use server-side encryption with Amazon Key Management Service (Amazon KMS), then attach a policy to the Amazon Glue Studio role used by the job that enables the job to decrypt the data. The job role needs the `kms:ReEncrypt`, `kms:GenerateDataKey`, and `kms:DescribeKey` permissions. Additionally, the job role needs the `kms:Decrypt` permission to upload or download an Amazon S3 object that is encrypted with an Amazon KMS customer master key (CMK).

There are additional charges for using Amazon KMS CMKs. For more information, see [Amazon Key Management Service Concepts - Customer Master Keys \(CMKs\)](#) and [Amazon Key Management Service Pricing](#) in the *Amazon Key Management Service Developer Guide*.

Permissions required for using connectors

If you're using an Amazon Glue Custom Connector and connection to access a data store, the role used to run the Amazon Glue ETL job needs additional permissions attached:

- The AWS managed policy `AmazonEC2ContainerRegistryReadOnly` for accessing connectors purchased from Amazon Web Services Marketplace.
- The `glue:GetJob` and `glue:GetJobs` permissions.
- Amazon Secrets Manager permissions for accessing secrets that are used with connections. Refer to [Example: Permission to retrieve secret values](#) for example IAM policies.

If your Amazon Glue ETL job runs within a VPC running Amazon VPC, then the VPC must be configured as described in [the section called "Configure a VPC for your ETL job"](#).

Set up IAM permissions for Amazon Glue Studio

You can create the roles and assign policies to users and job roles by using the Amazon administrator user.

You can use the **AWSGlueConsoleFullAccess** Amazon managed policy to provide the necessary permissions for using the Amazon Glue Studio console.

To create your own policy, follow the steps documented in [Create an IAM Policy for the Amazon Glue Service](#) in the *Amazon Glue Developer Guide*. Include the IAM permissions described previously in [Review IAM permissions needed for the Amazon Glue Studio user](#).

Topics

- [Attach policies to the Amazon Glue Studio user](#)
- [Create an IAM policy for roles not named "AWSGlueServiceRole*"](#)

Attach policies to the Amazon Glue Studio user

Any Amazon user that signs in to the Amazon Glue Studio console must have permissions to access specific resources. You provide those permissions by using assigning IAM policies to the user.

To attach the **AWSGlueConsoleFullAccess** managed policy to a user

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, select the check box next to the **AWSGlueConsoleFullAccess**. You can use the **Filter** menu and the search box to filter the list of policies.
4. Choose **Policy actions**, and then choose **Attach**.
5. Choose the user to attach the policy to. You can use the **Filter** menu and the search box to filter the list of principal entities. After choosing the user to attach the policy to, choose **Attach policy**.
6. Repeat the previous steps to attach additional policies to the user, as needed.

Create an IAM policy for roles not named "AWSGlueServiceRole*"

To configure an IAM policy for roles used by Amazon Glue Studio

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. Add a new IAM policy. You can add to an existing policy or create a new IAM inline policy. To create an IAM policy:
 1. Choose **Policies**, and then choose **Create Policy**. If a **Get Started** button appears, choose it, and then choose **Create Policy**.

2. Next to **Create Your Own Policy**, choose **Select**.
 3. For **Policy Name**, type any value that is easy for you to refer to later. Optionally, type descriptive text in **Description**.
 4. For **Policy Document**, type a policy statement with the following format, and then choose **Create Policy**:
3. Copy and paste the following blocks into the policy under the "Statement" array, replacing *my-interactive-session-role-prefix* with the prefix for all common roles to associate with permissions for Amazon Glue.

```
{
  "Action": [
    "iam:PassRole"
  ],
  "Effect": "Allow",
  "Resource": "arn:aws:iam::*:role/my-interactive-session-role-prefix",
  "Condition": {
    "StringLike": {
      "iam:PassedToService": [
        "glue.amazonaws.com "
      ]
    }
  }
}
```

Here is the full example with the Version and Statement arrays included in the policy

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "iam:PassRole"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:iam::*:role/my-interactive-session-role-prefix",
      "Condition": {
        "StringLike": {
```

```
        "iam:PassedToService": [
            "glue.amazonaws.com "
        ]
    }
}
]
```

4. To enable the policy for a user, choose **Users**.
5. Choose the user to whom you want to attach the policy.

Configure a VPC for your ETL job

You can use Amazon Virtual Private Cloud (Amazon VPC) to define a virtual network in your own logically isolated area within the Amazon Web Services Cloud, known as a *virtual private cloud (VPC)*. You can launch your Amazon resources, such as instances, into your VPC. Your VPC closely resembles a traditional network that you might operate in your own data center, with the benefits of using the scalable infrastructure of Amazon. You can configure your VPC; you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings. You can connect instances in your VPC to the internet. You can connect your VPC to your own corporate data center, making the Amazon Web Services Cloud an extension of your data center. To protect the resources in each subnet, you can use multiple layers of security, including security groups and network access control lists. For more information, see the [Amazon VPC User Guide](#).

You can configure your Amazon Glue ETL jobs to run within a VPC when using connectors. You must configure your VPC for the following, as needed:

- Public network access for data stores not in Amazon. All data stores that are accessed by the job must be available from the VPC subnet.
- If your job needs to access both VPC resources and the public internet, the VPC needs to have a network address translation (NAT) gateway inside the VPC.

For more information, see [Setting Up Your Environment to Access Data Stores](#) in the *Amazon Glue Developer Guide*.

Getting started with notebooks in Amazon Glue Studio

When you start a notebook through Amazon Glue Studio, all the configuration steps are done for you so that you can explore your data and start developing your job script after only a few seconds.

The following sections describe how to create a role and grant the appropriate permissions to use notebooks in Amazon Glue Studio for ETL jobs.

For more information on actions defined by Amazon Glue, see [Actions defined by Amazon Glue](#).

Topics

- [Granting permissions for the IAM role](#)

Granting permissions for the IAM role

Setting up Amazon Glue Studio is a pre-requisite to using notebooks.

To use notebooks in Amazon Glue, your role requires the following:

- A trust relationship with Amazon Glue for the `sts:AssumeRole` action and, if you want tagging then `sts:TagSession`.
- An IAM policy containing all the permissions for notebooks, Amazon Glue, and interactive sessions.
- An IAM policy for a pass role since the role needs to be able to pass itself from the notebook to interactive sessions.

For example, when you create a new role, you can add a standard Amazon managed policy like `AWSGlueConsoleFullAccessRole` to the role, and then add a new policy for the notebook operations and another for the IAM PassRole policy.

Actions needed for a trust relationship with Amazon Glue

When starting a notebook session, you must add the `sts:AssumeRole` to the trust relationship of the role that is passed to the notebook. If your session includes tags, you must also pass the `sts:TagSession` action. Without these actions, the notebook session cannot start.

For example:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Policies containing IAM permissions for notebooks

The following sample policy describes the required Amazon IAM permissions for notebooks. If you are creating a new role, create a policy that contains the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartNotebook",
        "glue:TerminateNotebook",
        "glue:GlueNotebookRefreshCredentials",
        "glue:DeregisterDataPreview",
        "glue:GetNotebookInstanceStatus",
        "glue:GlueNotebookAuthorize"
      ],
      "Resource": "*"
    }
  ]
}
```

You can use the following IAM policies to allow access to specific resources:

- *AwsGlueSessionUserRestrictedNotebookServiceRole*: Provides full access to all Amazon Glue resources except for sessions. Allows users to create and use only the notebook sessions that are associated with the user. This policy also includes other permissions needed by Amazon Glue to manage Amazon Glue resources in other Amazon services.
- *AwsGlueSessionUserRestrictedNotebookPolicy*: Provides permissions that allows users to create and use only the notebook sessions that are associated with the user. This policy also includes permissions to explicitly allow users to pass a restricted Amazon Glue session role.

IAM policy to pass a role

When you create a notebook with a role, that role is then passed to interactive sessions so that the same role can be used in both places. As such, the `iam:PassRole` permission needs to be part of the role's policy.

Create a new policy for your role using the following example. Replace the account number with your own and the role name.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::111122223333:role/<role_name>"
    }
  ]
}
```

Setting up Amazon Glue usage profiles

One of the main advantages of using a cloud platform is its flexibility. However, with this ease of creating compute resources comes a risk of spiraling cloud costs when left unmanaged and without guardrails. As a result, admins need to balance avoiding high infrastructure costs while at the same time allowing users to work without unnecessary friction.

With Amazon Glue usage profiles, admins can create different profiles for various classes of users within the account, such as developers, testers, and product teams. Each profile is a unique set of parameters that can be assigned to different types of users. For example, developers may need more workers and can have a higher number of maximum workers while product teams may need fewer workers and a lower timeout or idle timeout value.

Example of jobs and job runs behavior

Suppose that a job is created by user A with profile A. The job is saved with certain parameter values. User B with profile B will try to run the job.

When user A authored the job, if he didn't set a specific number of workers, the default set in user A's profile was applied and was saved with the job's definitions.

When user B runs the job, it runs with whatever values were saved for it. If user B's own profile is more restrictive and not allowed to run with that many workers, the job run will fail.

Usage profile as a resource

An Amazon Glue usage profile is a resource identified by an Amazon Resource Name (ARN). All the default IAM (Identity and Access Management) controls apply, including action-based and resource-based authorization. Admins should update the IAM policy of users who create Amazon Glue resources, granting them access to use the profiles.

Topics

- [Creating and managing usage profiles](#)
- [Usage profiles and jobs](#)

Creating and managing usage profiles

Creating an Amazon Glue usage profile

Admins should create usage profiles and then assign them to the various users. When creating a usage profile, you specify default values as well as a range of allowed values for various job and session parameters. You must configure at least one parameter for jobs or interactive sessions. You can customize the default value to be used when a parameter value is not provided for the job, and/or set up a range limit or a set of allowed values for validation if a user provides a parameter value when using this profile.

Defaults are a best practice set by the admin to assist job authors. When a user creates a new job and doesn't set a timeout value, the usage profile's default timeout will apply. If the author doesn't have a profile, then the Amazon Glue service defaults would apply and be saved in the job's definition. At runtime, Amazon Glue enforces the limits set in the profile (min, max, allowed workers).

Once a parameter is configured, all other parameters are optional. Parameters that can be customized for jobs or interactive sessions are:

- **Number of workers** – restrict the number of workers to avoid excessive use of compute resources. You can set a default, minimum, and maximum value. The minimum is 1.
- **Worker type** – restrict the relevant worker types for your workloads. You can set a default type and allow worker types for a user profile.
- **Timeout** – define the maximum time a job or interactive session can run and consume resources before it is terminated. Set up timeout values to avoid long-running jobs.

You can set a default, minimum, and maximum value in minutes. The minimum is 1 (minute). While the Amazon Glue default time out is 2880 minutes, you can set any default value in the usage profile.

It is a best practice to set a value for 'default'. This value will be used for the job or session creation if no value was set by the user.

- **Idle timeout** – define the number of minutes an interactive session is inactive before timing out after a cell has been run. Define idle timeout for interactive sessions to terminate after the work completed. Idle timeout range should be within the limit of timeout.

You can set a default, minimum, and maximum value in minutes. The minimum is 1 (minute). While the Amazon Glue default time out is 2880 minutes, you can set any default value in the usage profile.

It is a best practice to set a value for 'default'. This value will be used for the session creation if no value was set by the user.

To create an Amazon Glue usage profile as an admin (console)

1. In the left navigation menu, choose **Cost management**.
2. Choose **Create usage profile**.
3. Enter the **Usage profile name** for the usage profile.

4. Enter an optional description that will help others recognize the purpose of the usage profile.
5. Define at least one parameter in the profile. Any field in the form is a parameter. For example, the session idle timeout minimum.
6. Define any optional tags that apply to the usage profile.
7. Choose **Save**.

To create a usage profile (Amazon CLI)

1. Enter the following command.

```
aws glue create-usage-profile --name profile-name --configuration file://  
config.json --tags list-of-tags
```

where the config.json can define parameter values for interactive sessions (SessionConfiguration) and jobs (JobConfiguration):

```
//config.json (There is a separate blob for session/job configuration  
{  
  "SessionConfiguration": {  
    "timeout": {  
      "DefaultValue": "2880",  
      "MinValue": "100",  
      "MaxValue": "4000"  
    },  
    "idleTimeout": {  
      "DefaultValue": "30",  
      "MinValue": "10",  
      "MaxValue": "4000"  
    },  
    "workerType": {  
      "DefaultValue": "G.2X",  
      "AllowedValues": [  
        "G.1X",  
        "G.2X",  
        "G.4X",  
        "G.8X",  
        "G.12X",  
        "G.16X",  
        "R.1X",  
        "R.2X",  
      ]  
    }  
  }  
}
```

```
        "R.4X",
        "R.8X"
    ]
},
"numberOfWorkers": {
    "DefaultValue": "10",
    "MinValue": "1",
    "MaxValue": "10"
}
},
"JobConfiguration": {
    "timeout": {
        "DefaultValue": "2880",
        "MinValue": "100",
        "MaxValue": "4000"
    },
    "workerType": {
        "DefaultValue": "G.2X",
        "AllowedValues": [
            "G.1X",
            "G.2X",
            "G.4X",
            "G.8X",
            "G.12X",
            "G.16X",
            "R.1X",
            "R.2X",
            "R.4X",
            "R.8X"
        ]
    },
    "numberOfWorkers": {
        "DefaultValue": "10",
        "MinValue": "1",
        "MaxValue": "10"
    }
}
}
```

2. Enter the following command to see the usage profile created:

```
aws glue get-usage-profile --name profile-name
```

The response:

```
{
  "ProfileName": "foo",
  "Configuration": {
    "SessionConfiguration": {
      "numberOfWorkers": {
        "DefaultValue": "10",
        "MinValue": "1",
        "MaxValue": "10"
      },
      "workerType": {
        "DefaultValue": "G.2X",
        "AllowedValues": [
          "G.1X",
          "G.2X",
          "G.4X",
          "G.8X",
          "G.12X",
          "G.16X",
          "R.1X",
          "R.2X",
          "R.4X",
          "R.8X"
        ]
      },
      "timeout": {
        "DefaultValue": "2880",
        "MinValue": "100",
        "MaxValue": "4000"
      },
      "idleTimeout": {
        "DefaultValue": "30",
        "MinValue": "10",
        "MaxValue": "4000"
      }
    },
    "JobConfiguration": {
      "numberOfWorkers": {
        "DefaultValue": "10",
        "MinValue": "1",
        "MaxValue": "10"
      },
    },
  },
}
```

```

        "workerType": {
            "DefaultValue": "G.2X",
            "AllowedValues": [
                "G.1X",
                "G.2X",
                "G.4X",
                "G.8X",
                "G.12X",
                "G.16X",
                "R.1X",
                "R.2X",
                "R.4X",
                "R.8X"
            ]
        },
        "timeout": {
            "DefaultValue": "2880",
            "MinValue": "100",
            "MaxValue": "4000"
        }
    },
    "CreatedOn": "2024-01-19T23:15:24.542000+00:00"
}

```

Additional CLI commands used to manage usage profiles:

- `aws glue list-usage-profiles`
- `aws glue update-usage-profile --name profile-name --configuration file://config.json`
- `aws glue delete-usage-profile --name profile-name`

Editing a usage profile

Admins can edit usage profiles that they have created, to change the profile parameter values for jobs and interactive sessions.

To edit a usage profile:

To edit an Amazon Glue usage profile as an admin (console)

1. In the left navigation menu, choose **Cost management**.

2. Choose a usage profile that you have permissions to edit and choose **Edit**.
3. Make changes as needed to the profile. By default, the parameters that already have values are expanded.
4. Choose **Save Edits**.

To edit a usage profile (Amazon CLI)

- Enter the following command. The same `--configuration` file syntax is used as shown above in the create command.

```
aws glue update-usage-profile --name profile-name --configuration file://  
config.json
```

where the `config.json` defines parameter values for interactive sessions (SessionConfiguration) and jobs (JobConfiguration):

Assigning a usage profile

The **Utilization status** column in the **Usage profiles** page shows whether a usage profile is assigned to users. Hovering over the status shows the assigned IAM entities.

The admin can assign an Amazon Glue usage profile to users/roles who create Amazon Glue resources. Assigning a profile is a combination of two actions:

- Updating the IAM user/role tag with the `glue:UsageProfile` key, then
- Updating the IAM policy of the user/role.

For users who use Amazon Glue Studio to create jobs/interactive sessions, the admin tags the following roles:

- For restrictions on jobs, the admin tags the logged in console role
- For restrictions on interactive sessions, the admin tags the role the user provides when they create the notebook

The following is example policy that admin needs to update on the IAM users/roles who create Amazon Glue resources:

```
{
  "Effect": "Allow",
  "Action": [
    "glue:GetUsageProfile"
  ],
  "Resource": [
    "arn:aws:glue:us-east-1:123456789012:usageProfile/foo"
  ]
}
```

Amazon Glue validates job, job run, and session requests based on the values specified in the Amazon Glue usage profile and raises an exception if the request is disallowed. For synchronous APIs, an error will be thrown to the user. For asynchronous paths, a failed job run is created with the error message that the input parameter is outside of the allowed range for the assigned profile of the user/role.

To assign a usage profile to a user/role:

1. Open the (Identity and Access Management) IAM console.
2. In the left navigation, choose **Users** or **Roles**.
3. Choose a user or role.
4. Choose the **Tags** tab.
5. Choose **Add new tag**
6. Add a tag with the **Key** of `glue:UsageProfile` and the **Value** of the name of your usage profile.
7. Choose **Save changes**

Viewing your assigned usage profile

Users can view their assigned usage profiles and use them when making API calls to create Amazon Glue job and session resources, or starting a job.

Profile permissions are provided in IAM policies. As long as the caller policy has the `glue:UsageProfile` permission, a user can see the profile. Otherwise, you will get an access denied error.

To view an assigned usage profile:

1. In the left navigation menu, choose **Cost management**.
2. Choose a usage profile that you have permissions to view.

Usage profiles and jobs

Authoring jobs with usage profiles

While authoring jobs, the limits and defaults set in your usage profile will apply. Your profile will be assigned to the job upon save.

Running jobs with usage profiles

When you start a job run, Amazon Glue enforces the limits set in your caller's profile. If there is no direct caller, Glue will then apply the limits from the profile assigned to the job by its author.

Note

When a job is ran on a schedule (by Amazon Glue workflows or Amazon Glue triggers), the profile assigned to the job the author will apply.
When a job is ran by an external service (Step Functions, MWAA) or a `StartJobRun` API, the caller's profile limit will be enforced.

For Amazon Glue workflows or Amazon Glue triggers: pre-existing jobs need to be updated to save the new profile name so that profile's limits (min, max, and allowed workers) will be enforced at runtime for scheduled runs.

Viewing a usage profile assigned for jobs

To view the profile assigned to your jobs (that will be used at runtime with scheduled Amazon Glue workflows or Amazon Glue triggers), you may look at the job **Details** tab. You may also look at the profile used in past runs in the job runs details tab.

Updating or deleting a usage profile attached to a job

The profile assigned to a job is changed upon update. If the author isn't assigned a usage profile, any profile previously attached to the job will be removed from it.

Getting started with the Amazon Glue Data Catalog

The Amazon Glue Data Catalog is your persistent technical metadata store. It is a managed service that you can use to store, annotate, and share metadata in the Amazon Cloud. For more information, see [Amazon Glue Data Catalog](#).

The Amazon Glue console and some user interfaces were recently updated.

Overview

You can use this tutorial to create your first Amazon Glue Data Catalog, which uses an Amazon S3 bucket as your data source.

In this tutorial, you'll do the following using the Amazon Glue console:

1. Create a database
2. Create a table
3. Use an Amazon S3 bucket as a data source

After completing these steps, you will have successfully used an Amazon S3 bucket as the data source to populate the Amazon Glue Data Catalog.

Step 1: Create a database

To get started, sign in to the Amazon Web Services Management Console and open the [Amazon Glue console](#).

To create a database using the Amazon Glue console:

1. In the Amazon Glue console, choose **Databases** under **Data catalog** from the left-hand menu.
2. Choose **Add database**.
3. In the Create a database page, enter a name for the database. In the **Location - optional** section, set the URI location for use by clients of the Data Catalog. If you don't know this, you can continue with creating the database.
4. (Optional). Enter a description for the database.
5. Choose **Create database**.

Congratulations, you've just set up your first database using the Amazon Glue console. Your new database will appear in the list of available databases. You can edit the database by choosing the database's name from the **Databases** dashboard.

Next steps

Other ways to create a database:

You just created a database using the Amazon Glue console, but there are other ways to create a database:

- You can use crawlers to create a database and tables for you automatically. To set up a database using crawlers, see [Working with Crawlers in the Amazon Glue Console](#).
- You can use Amazon CloudFormation templates. See [Creating Amazon Glue Resources Using Amazon Glue Data Catalog Templates](#).
- You can also create a database using the Amazon Glue Database API operations.

To create a database using the `create` operation, structure the request by including the `DatabaseInput` (required) parameters.

For example:

The following are examples of how you can use the CLI, Boto3, or DDL to define a table based on the same `flights_data.csv` file from the S3 bucket that you used in the tutorial.

CLI

```
aws glue create-database --database-input "{\"Name\":\"clidb\"}"
```

Boto3

```
glueClient = boto3.client('glue')

response = glueClient.create_database(
    DatabaseInput={
        'Name': 'boto3db'
    }
)
```

For more information about the Database API data types, structure, and operations, see [Database API](#).

Next Steps

In the next section, you'll create a table and add that table to your database.

You can also explore the settings and permissions for your Data Catalog. See [Working with Data Catalog Settings in the Amazon Glue Console](#).

Step 2. Create a table

In this step, you create a table using the Amazon Glue console.

1. In the Amazon Glue console, choose **Tables** in the left-hand menu.
2. Choose **Add table**.
3. Set your table's properties by entering a name for your table in **Table details**.
4. In the **Databases** section, choose the database that you created in Step 1 from the drop-down menu.
5. In **Add a data store** section, **S3** will be selected by default as the type of source.
6. For **Data is located in**, choose **Specified path in another account**.
7. Copy and paste the path for the **Include path** input field:

```
s3://crawler-public-us-west-2/flight/2016/csv/
```
8. In the section **Data format**, for **Classification**, choose **CSV**. and for **Delimiter**, choose **comma (,)**. Choose **Next**.
9. You are asked to define a schema. A schema defines the structure and format of a data record. Choose **Add column**. (For more information, see [See Schema registries](#)).
10. Specify the column properties:
 - a. Enter a column name.
 - b. For **Column type**, 'string' is already selected by default.
 - c. For **Column number**, '1' is already selected by default.
 - d. Choose **Add**.
11. You are asked to add partition indexes. This is optional. To skip this step, choose **Next**.
12. A summary of the table properties is displayed. If everything looks as expected, choose **Create**. Otherwise, choose **Back** and make edits as needed.

Congratulations, you've successfully created a table manually and associated it to a database. Your newly created table will appear in the Tables dashboard. From the dashboard, you can modify and manage all your tables.

For more information, see [Working with Tables in the Amazon Glue Console](#).

Next steps

Next steps

Now that the Data Catalog is populated, you can begin authoring jobs in Amazon Glue. See [Building visual ETL jobs with Amazon Glue Studio](#).

In addition to using the console, there are other ways to define tables in the Data Catalog including:

- [Creating and running a crawler](#)
- [Adding classifiers to a crawler in Amazon Glue](#)
- [Using the Amazon Glue Table API](#)
- [Using the Amazon Glue Data Catalog template](#)
- [Migrating an Apache Hive metastore](#)
- [Using the Amazon CLI](#), Boto3, or data definition language (DDL)

The following are examples of how you can use the CLI, Boto3, or DDL to define a table based on the same `flights_data.csv` file from the S3 bucket that you used in the tutorial.

See the documentation on how to structure an Amazon CLI command. The CLI example contains the JSON syntax for the `'aws glue create-table --table-input'` value.

CLI

```
{
  "Name": "flights_data_cli",
  "StorageDescriptor": {
    "Columns": [
      {
        "Name": "year",
        "Type": "bigint"
      },
      {
        "Name": "quarter",
```

```

        "Type": "bigint"
    }
],
"Location": "s3://crawler-public-us-west-2/flight/2016/csv",

"org.apache.hadoop.hive.q1.io.HiveIgnoreKeyTextOutputFormat",
"Compressed": false,
"NumberOfBuckets": -1,
"SerdeInfo": {
    "SerializationLibrary":
"org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe",
    "Parameters": {
        "field.delim": ",",
        "serialization.format": ","
    }
}
},
"PartitionKeys": [
    {
        "Name": "mon",
        "Type": "string"
    }
],
"TableType": "EXTERNAL_TABLE",
"Parameters": {
    "EXTERNAL": "TRUE",
    "classification": "csv",
    "columnsOrdered": "true",
    "compressionType": "none",
    "delimiter": ",",
    "skip.header.line.count": "1",
    "typeOfData": "file"
}
}

```

Boto3

```

import boto3

glue_client = boto3.client("glue")

```

```
response = glue_client.create_table(  
    DatabaseName='sampledb',  
    TableInput={  
        'Name': 'flights_data_manual',  
        'StorageDescriptor': {  
            'Columns': [{  
                'Name': 'year',  
                'Type': 'bigint'  
            }], {  
                'Name': 'quarter',  
                'Type': 'bigint'  
            }  
        ]},  
        'Location': 's3://crawler-public-us-west-2/flight/2016/csv',  
        'InputFormat': 'org.apache.hadoop.mapred.TextInputFormat',  
        'OutputFormat':  
        'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat',  
        'Compressed': False,  
        'NumberOfBuckets': -1,  
        'SerdeInfo': {  
            'SerializationLibrary':  
            'org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe',  
            'Parameters': {  
                'field.delim': ',',  
                'serialization.format': ','  
            }  
        },  
        'PartitionKeys': [{  
            'Name': 'mon',  
            'Type': 'string'  
        }],  
        'TableType': 'EXTERNAL_TABLE',  
        'Parameters': {  
            'EXTERNAL': 'TRUE',  
            'classification': 'csv',  
            'columnsOrdered': 'true',  
            'compressionType': 'none',  
            'delimiter': ',',  
            'skip.header.line.count': '1',  
            'typeOfData': 'file'  
        }  
    }  
)
```

DDL

```
CREATE EXTERNAL TABLE `sampledb`.`flights_data` (  
  `year` bigint,  
  `quarter` bigint)  
PARTITIONED BY (  
  `mon` string)  
ROW FORMAT DELIMITED  
  FIELDS TERMINATED BY ','  
STORED AS INPUTFORMAT  
  'org.apache.hadoop.mapred.TextInputFormat'  
OUTPUTFORMAT  
  'org.apache.hadoop.hive.q1.io.HiveIgnoreKeyTextOutputFormat'  
LOCATION  
  's3://crawler-public-us-west-2/flight/2016/csv/'  
TBLPROPERTIES (  
  'classification'='csv',  
  'columnsOrdered'='true',  
  'compressionType'='none',  
  'delimiter'=',',  
  'skip.header.line.count'='1',  
  'typeOfData'='file')
```

Setting up network access to data stores

To run your extract, transform, and load (ETL) jobs, Amazon Glue must be able to access your data stores. If a job doesn't need to run in your virtual private cloud (VPC) subnet—for example, transforming data from Amazon S3 to Amazon S3—no additional configuration is needed.

If a job needs to run in your VPC subnet—for example, transforming data from a JDBC data store in a private subnet—Amazon Glue sets up [elastic network interfaces](#) that enable your jobs to connect securely to other resources within your VPC. Each elastic network interface is assigned a private IP address from the IP address range within the subnet you specified. No public IP addresses are assigned. Security groups specified in the Amazon Glue connection are applied on each of the elastic network interfaces. For more information, see [Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from Amazon Glue](#).

All JDBC data stores that are accessed by the job must be available from the VPC subnet. To access Amazon S3 from within your VPC, a [VPC endpoint](#) is required. If your job needs to access both VPC resources and the public internet, the VPC needs to have a Network Address Translation (NAT) gateway inside the VPC.

A job or development endpoint can only access one VPC (and subnet) at a time. If you need to access data stores in different VPCs, you have the following options:

- Use VPC peering to access the data stores. For more about VPC peering, see [VPC Peering Basics](#)
- Use an Amazon S3 bucket as an intermediary storage location. Split the work into two jobs, with the Amazon S3 output of job 1 as the input to job 2.

For details on how to connect to a Amazon Redshift data store using Amazon VPC, see [the section called "Configure Redshift"](#).

For details on how to connect to Amazon RDS data stores using Amazon VPC, see [the section called "Setting up Amazon VPC to connect to Amazon RDS data stores"](#).

Once necessary rules are set in Amazon VPC, you create a connection in Amazon Glue with the necessary properties to connect to your data stores. For more information about the connection, see [Connecting to data](#).

Note

Make sure you set up your DNS environment for Amazon Glue. For more information, see [Setting up DNS in your VPC](#).

Topics

- [Setting up a VPC to connect to PyPI for Amazon Glue](#)
- [Setting up DNS in your VPC](#)

Setting up a VPC to connect to PyPI for Amazon Glue

The Python Package Index (PyPI) is a repository of software for the Python programming language. This topic addresses the details needed to support the use of pip installed packages (as specified by the session creator using the `--additional-python-modules` flag).

Using Amazon Glue interactive sessions with a connector results in the use of VPC network via the subnet specified for the connector. Consequently Amazon services and other network destinations are not available unless you set up a special configuration.

The resolutions to this issue include:

- Use of an internet gateway which is reachable by your session.
- Set up and use of an S3 bucket with a PyPI/simple repo containing the transitive closure of a package set's dependencies.
- Use of a CodeArtifact repository which is mirroring PyPI and attached to your VPC.

Setting up an internet gateway

The technical aspects are detailed in [NAT gateway use cases](#) but note these requirements for using `--additional-python-modules`. Specifically, `--additional-python-modules` requires access to pypi.org which is determined by the configuration of your VPC. Note the following requirements:

1. The requirement of installing additional python modules via `pip install` for a user's session. If the session uses a connector, your configuration may be affected.
2. When a connector is being used with `--additional-python-modules`, when the session is started the subnet associated with the connector's `PhysicalConnectionRequirements` has to provide a network path for reaching pypi.org.
3. You must determine whether or not your configuration is correct.

Setting up an Amazon S3 bucket to host a targeted PyPI/simple repo

This example sets up a PyPI mirror in Amazon S3 for a set of packages and their dependencies.

To set up the PyPI mirror for a set of packages:

```
# pip download all the dependencies
pip download -d s3pypi --only-binary :all: plotly ggplot
pip download -d s3pypi --platform manylinux_2_17_x86_64 --only-binary :all: psycopg2-
binary
# create and upload the pypi/simple index and wheel files to the s3 bucket
s3pypi -b test-domain-name --put-root-index -v s3pypi/*
```

If you already have an existing artifact repository, it will have an index URL for pip's use that you can provide in place of the example URL for the Amazon S3 bucket as above.

To use the custom index-url, with some example packages:

```
%%configure
{
  "--additional-python-modules": "psycopy2_binary==2.9.5",
  "python-modules-installer-option": "--no-cache-dir --verbose --index-url https://
test-domain-name.s3.amazonaws.com/ --trusted-host test-domain-name.s3.amazonaws.com"
}
```

Setting up a CodeArtifact mirror of pypi attached to your VPC

To set up a mirror:

1. Create a repository in the same region as the subnet used by the connector.

Select `Public upstream repositories` and choose `pypi-store`.

2. Provide access to the repository from the VPC for the subnet.
3. Specify the correct `--index-url` using the `python-modules-installer-option`.

```
%%configure
{
  "--additional-python-modules": "psycopy2_binary==2.9.5",
  "python-modules-installer-option": "--no-cache-dir --verbose --index-url https://
test-domain-name.s3.amazonaws.com/ --trusted-host test-domain-name.s3.amazonaws.com"
}
```

For more information, see [Use CodeArtifact from a VPC](#).

Setting up DNS in your VPC

Domain Name System (DNS) is a standard by which names used on the internet are resolved to their corresponding IP addresses. A DNS hostname uniquely names a computer and consists of a host name and a domain name. DNS servers resolve DNS hostnames to their corresponding IP addresses.

To set up DNS in your VPC, ensure that DNS hostnames and DNS resolution are both enabled in your VPC. The VPC network attributes `enableDnsHostnames` and `enableDnsSupport`

must be set to `true`. To view and modify these attributes, go to the VPC console at <https://console.amazonaws.cn/vpc/>.

For more information, see [Using DNS with your VPC](#). Also, you can use the Amazon CLI and call the [modify-vpc-attribute](#) command to configure the VPC network attributes.

Note

If you are using Route 53, confirm that your configuration does not override DNS network attributes.

Setting up encryption in Amazon Glue

The following example workflow highlights the options to configure when you use encryption with Amazon Glue. The example demonstrates the use of specific Amazon Key Management Service (Amazon KMS) keys, but you might choose other settings based on your particular needs. This workflow highlights only the options that pertain to encryption when setting up Amazon Glue.

1. If the user of the Amazon Glue console doesn't use a permissions policy that allows all Amazon Glue API operations (for example, `"glue:*"`), confirm that the following actions are allowed:
 - `"glue:GetDataCatalogEncryptionSettings"`
 - `"glue:PutDataCatalogEncryptionSettings"`
 - `"glue:CreateSecurityConfiguration"`
 - `"glue:GetSecurityConfiguration"`
 - `"glue:GetSecurityConfigurations"`
 - `"glue>DeleteSecurityConfiguration"`
2. Any client that accesses or writes to an encrypted catalog—that is, any console user, crawler, job, or development endpoint—needs the following permissions.
3. Any user or role that accesses an encrypted connection password needs the following permissions.
4. The role of any extract, transform, and load (ETL) job that writes encrypted data to Amazon S3 needs the following permissions.

JSON

```
{
```

```

"Version": "2012-10-17",
"Statement": {
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt",
    "kms:Encrypt",
    "kms:GenerateDataKey"
  ],
  "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-id"
}
}

```

5. Any ETL job or crawler that writes encrypted Amazon CloudWatch Logs requires the following permissions in the key and IAM policies.

In the key policy (not the IAM policy):

```

{
  "Effect": "Allow",
  "Principal": {
    "Service": "logs.region.amazonaws.com"
  },
  "Action": [
    "kms:Encrypt*",
    "kms:Decrypt*",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:Describe*"
  ],
  "Resource": "<arn of key used for ETL/crawler cloudwatch encryption>"
}

```

For more information about key policies, see [Using Key Policies in Amazon KMS](#) in the *Amazon Key Management Service Developer Guide*.

In the IAM policy attach the `logs:AssociateKmsKey` permission:

```

{
  "Effect": "Allow",
  "Principal": {
    "Service": "logs.region.amazonaws.com"
  },

```

```
"Action": [
  "logs:AssociateKmsKey"
],
"Resource": "<arn of key used for ETL/crawler cloudwatch encryption>"
}
```

6. Any ETL job that uses an encrypted job bookmark needs the following permissions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:Decrypt",
      "kms:Encrypt"
    ],
    "Resource": "arn:aws:kms:us-east-1:111122223333:key/*"
  }
}
```

7. On the Amazon Glue console, choose **Settings** in the navigation pane.

- a. On the **Data catalog settings** page, encrypt your Data Catalog by selecting **Metadata encryption**. This option encrypts all the objects in the Data Catalog with the Amazon KMS key that you choose.
- b. For **Amazon KMS key**, choose **aws/glue**. You can also choose a Amazon KMS key that you created.

Important

Amazon Glue supports only symmetric customer master keys (CMKs). The **Amazon KMS key** list displays only symmetric keys. However, if you select **Choose a Amazon KMS key ARN**, the console lets you enter an ARN for any key type. Ensure that you enter only ARNs for symmetric keys.

When encryption is enabled, the client that is accessing the Data Catalog must have Amazon KMS permissions.

8. In the navigation pane, choose **Security configurations**. A security configuration is a set of security properties that can be used to configure Amazon Glue processes. Then choose **Add security configuration**. In the configuration, choose any of the following options:
 - a. Select **S3 encryption**. For **Encryption mode**, choose **SSE-KMS**. For the **Amazon KMS key**, choose **aws/s3** (ensure that the user has permission to use this key). This enables data written by the job to Amazon S3 to use the Amazon managed Amazon Glue Amazon KMS key.
 - b. Select **CloudWatch logs encryption**, and choose a CMK. (Ensure that the user has permission to use this key). For more information, see [Encrypt Log Data in CloudWatch Logs Using Amazon KMS](#) in the *Amazon Key Management Service Developer Guide*.

 **Important**

Amazon Glue supports only symmetric customer master keys (CMKs). The **Amazon KMS key** list displays only symmetric keys. However, if you select **Choose a Amazon KMS key ARN**, the console lets you enter an ARN for any key type. Ensure that you enter only ARNs for symmetric keys.

- c. Choose **Advanced properties**, and select **Job bookmark encryption**. For the **Amazon KMS key**, choose **aws/glue** (ensure that the user has permission to use this key). This enables encryption of job bookmarks written to Amazon S3 with the Amazon Glue Amazon KMS key.
9. In the navigation pane, choose **Connections**.
 - a. Choose **Add connection** to create a connection to the Java Database Connectivity (JDBC) data store that is the target of your ETL job.
 - b. To enforce that Secure Sockets Layer (SSL) encryption is used, select **Require SSL connection**, and test your connection.
10. In the navigation pane, choose **Jobs**.
 - a. Choose **Add job** to create a job that transforms data.
 - b. In the job definition, choose the security configuration that you created.
11. On the Amazon Glue console, run your job on demand. Verify that any Amazon S3 data written by the job, the CloudWatch Logs written by the job, and the job bookmarks are all encrypted.

Setting up networking for development for Amazon Glue

To run your extract, transform, and load (ETL) scripts with Amazon Glue, you can develop and test your scripts using a *development endpoint*. Development endpoints are not supported for use

with Amazon Glue version 2.0 jobs. For versions 2.0 and later, the preferred development method is using Jupyter Notebook with one of the Amazon Glue kernels. For more information, see [the section called “Getting started with Amazon Glue interactive sessions”](#).

Setting up your network for a development endpoint

When you set up a development endpoint, you specify a virtual private cloud (VPC), subnet, and security groups.

Note

Make sure you set up your DNS environment for Amazon Glue. For more information, see [Setting up DNS in your VPC](#).

To enable Amazon Glue to access required resources, add a row in your subnet route table to associate a prefix list for Amazon S3 to the VPC endpoint. A prefix list ID is required for creating an outbound security group rule that allows traffic from a VPC to access an Amazon service through a VPC endpoint. To ease connecting to a notebook server that is associated with this development endpoint, from your local machine, add a row to the route table to add an internet gateway ID. For more information, see [VPC Endpoints](#). Update the subnet routes table to be similar to the following table:

Destination	Target		
10.0.0.0/16	local		
pl-id for Amazon S3	vpce-id		
0.0.0.0/0	igw-xxxx		

To enable Amazon Glue to communicate between its components, specify a security group with a self-referencing inbound rule for all TCP ports. By creating a self-referencing rule, you can restrict the source to the same security group in the VPC, and it's not open to all networks. The default security group for your VPC might already have a self-referencing inbound rule for ALL Traffic.

To set up a security group

1. Sign in to the Amazon Web Services Management Console and open the Amazon EC2 console at <https://console.amazonaws.cn/ec2/>.
2. In the left navigation pane, choose **Security Groups**.
3. Either choose an existing security group from the list, or **Create Security Group** to use with the development endpoint.
4. In the security group pane, navigate to the **Inbound** tab.
5. Add a self-referencing rule to allow Amazon Glue components to communicate. Specifically, add or confirm that there is a rule of **Type** All TCP, **Protocol** is TCP, **Port Range** includes all ports, and whose **Source** is the same security group name as the **Group ID**.

The inbound rule looks similar to this:

Type	Protocol	Port range	Source
All TCP	TCP	0–65535	<i>security-group</i>

The following shows an example of a self-referencing inbound rule:

Security Group: **sg-19e1b768** ...

Description **Inbound** Outbound Tags

Edit

Type ⓘ	Protocol ⓘ	Port Range ⓘ	Source ⓘ
SSH	TCP	22	0.0.0.0/0
HTTPS	TCP	443	0.0.0.0/0

6. Add a rule to for outbound traffic also. Either open outbound traffic to all ports, or create a self-referencing rule of **Type** All TCP, **Protocol** is TCP, **Port Range** includes all ports, and whose **Source** is the same security group name as the **Group ID**.

The outbound rule looks similar to one of these rules:

Type	Protocol	Port range	Destination
All TCP	TCP	0–65535	<i>security-group</i>
All Traffic	ALL	ALL	0.0.0.0/0

Setting up Amazon EC2 for a notebook server

With a development endpoint, you can create a notebook server to test your ETL scripts with Jupyter notebooks. To enable communication to your notebook, specify a security group with inbound rules for both HTTPS (port 443) and SSH (port 22). Ensure that the rule's source is either 0.0.0.0/0 or the IP address of the machine that is connecting to the notebook.

To set up a security group

1. Sign in to the Amazon Web Services Management Console and open the Amazon EC2 console at <https://console.amazonaws.cn/ec2/>.
2. In the left navigation pane, choose **Security Groups**.
3. Either choose an existing security group from the list, or **Create Security Group** to use with your notebook server. The security group that is associated with your development endpoint is also used to create your notebook server.
4. In the security group pane, navigate to the **Inbound** tab.
5. Add inbound rules similar to this:

Type	Protocol	Port range	Source
SSH	TCP	22	0.0.0.0/0
HTTPS	TCP	443	0.0.0.0/0

The following shows an example of the inbound rules for the security group:

Data discovery and cataloging in Amazon Glue

The Amazon Glue Data Catalog is a centralized repository that stores metadata about your organization's data sets. It acts as an index to the location, schema, and runtime metrics of your data sources. The metadata is stored in metadata tables, where each table represents a single data store.

You can populate the Data Catalog using a crawler, which automatically scans your data sources and extracts metadata. A crawler can connect to data sources that are internal (Amazon-based) and external to Amazon.

For more information about the supported data sources, see [Supported data sources for crawling](#)

You can also create tables in the Data Catalog manually by defining the table structure, schema, and partitioning structure according to your specific requirements.

For more information about creating metadata tables manually, see [Defining metadata manually](#).

You can use the information in the Data Catalog to create and monitor your ETL jobs. The Data Catalog integrates with other Amazon analytics services, providing a unified view of data sources making it easier to manage and analyze data.

- Amazon Athena – Store and query table metadata in the Data Catalog for the Amazon S3 data using SQL.
- Amazon Lake Formation – Centrally define and manage fine-grained data access policies and audit data access.
- Amazon EMR – Access data sources defined in the Data Catalog for big data processing.
- Amazon SageMaker AI – Quickly and confidently build, train, and deploy machine learning models.

Key features of the Data Catalog

The following are the key aspects of the Data Catalog.

Metadata repository

The Data Catalog acts as a central metadata repository, storing information about the location, schema, and properties of your data sources. This metadata is organized into databases and tables, similar to a traditional relational database catalog.

Automatic data discoverability

Amazon Glue crawlers can automatically discover and catalog new or updated data sources, reducing the overhead of manual metadata management and ensuring that your Data Catalog remains up-to-date. By cataloging your data sources, the Data Catalog makes it easier for users and applications to discover and understand the available data assets within your organization, promoting data reuse and collaboration.

The Data Catalog supports a wide range of data sources, including Amazon S3, Amazon RDS, Amazon Redshift, Apache Hive, and more. It can automatically infer and store metadata from these sources using Amazon Glue crawlers.

For more information see, [Using crawlers to populate the Data Catalog](#) .

Schema management

The Data Catalog automatically captures and manages the schema of your data sources, including schema inference, evolution, and versioning. You can update your schema and partitions in the Data Catalog using Amazon Glue ETL jobs.

Table optimization

For better read performance by Amazon analytics services such as Amazon Athena and Amazon EMR, and Amazon Glue ETL jobs, the Data Catalog provides managed compaction (a process that compacts small Amazon S3 objects into larger objects) for Iceberg tables in the Data Catalog. You can use Amazon Glue console, Amazon Lake Formation console, Amazon CLI, or Amazon API to enable or disable compaction for individual Iceberg tables that are in the Data Catalog.

For more information, see [Optimizing Iceberg tables](#).

Column statistics

You can compute column-level statistics for Data Catalog tables in data formats such as Parquet, ORC, JSON, ION, CSV, and XML without setting up additional data pipelines. Column statistics help you to understand data profiles by getting insights about values within a column. The Data Catalog supports generating statistics for column values such as minimum value, maximum value, total null values, total distinct values, average length of values, and total occurrences of true values.

For more information, see [Optimizing query performance using column statistics](#).

Data lineage

The Data Catalog maintains a record of the transformations and operations performed on your data, providing data lineage information. This lineage information is valuable for auditing, compliance, and understanding the data's provenance.

Integration with other Amazon services

The Data Catalog seamlessly integrates with other Amazon services, such as Amazon Lake Formation, Amazon Athena, Amazon Redshift Spectrum, and Amazon EMR. This integration allows you to query and analyze data across various data stores using a single, consistent metadata layer.

Security and access control

Amazon Glue integrates with Amazon Lake Formation to support fine-grained access control for Data Catalog resources, allowing you to manage permissions and secure access to your data assets based on your organization's policies and requirements. Amazon Glue integrates with Amazon Key Management Service (Amazon KMS) to encrypt metadata that's stored in the Data Catalog.

Materialized views

The Data Catalog supports Apache Iceberg materialized views, which are managed tables that store precomputed results of SQL queries and automatically refresh as underlying source data changes. Materialized views simplify data transformation pipelines and accelerate query performance by eliminating redundant computation.

You can create materialized views using Apache Spark SQL in Amazon Glue version 5.1 and later, Amazon EMR release 7.12.0 and later, and Amazon Athena. The Data Catalog automatically monitors source Apache Iceberg tables and refreshes materialized views using managed compute infrastructure. Spark engines across Amazon Glue, Amazon EMR, and Amazon Athena can automatically rewrite queries to use materialized views when they provide better performance.

Materialized views are stored as Apache Iceberg tables in Amazon S3 Tables buckets or Amazon S3 general purpose buckets within your account, making them accessible from multiple query engines. The Data Catalog manages all aspects of materialized view lifecycle, including automatic refresh scheduling, incremental updates, and metadata management.

For more information, see [Using materialized views with Amazon Glue](#) and [Using materialized views with Amazon EMR](#).

Topics

- [Populating the Amazon Glue Data Catalog](#)
- [Populating and managing transactional tables](#)
- [Managing the Data Catalog](#)

- [Monitoring Data Catalog usage metrics in Amazon CloudWatch](#)
- [Amazon Glue Schema registry](#)

Populating the Amazon Glue Data Catalog

You can populate the Amazon Glue Data Catalog using the following methods:

- Amazon Glue crawler – An Amazon Glue crawler can automatically discover and catalog data sources like databases, data lakes, and streaming data. The crawlers are the most common and recommended method to populate the Data Catalog as they can automatically discover and infer metadata for a wide variety of data sources.
- Manually adding metadata – You can manually define databases, tables, and connection details and add them to the Data Catalog using the Amazon Glue console, Lake Formation console, Amazon CLI, or Amazon Glue APIs. Manual entry is useful when you want to catalog data sources that cannot be crawled.
- Integrating with other Amazon services – You can populate the Data Catalog with metadata from services like Amazon Lake Formation and Amazon Athena. These services can discover and register data sources in the Data Catalog.
- Populating from an existing metadata repository – If you have an existing metadata store like Apache Hive Metastore, you can use Amazon Glue to import that metadata into the Data Catalog. For more information, see [Migration between the Hive Metastore and the Amazon Glue Data Catalog](#) on GitHub.

Topics

- [Using crawlers to populate the Data Catalog](#)
- [Defining metadata manually](#)
- [Integrating with other Amazon services](#)

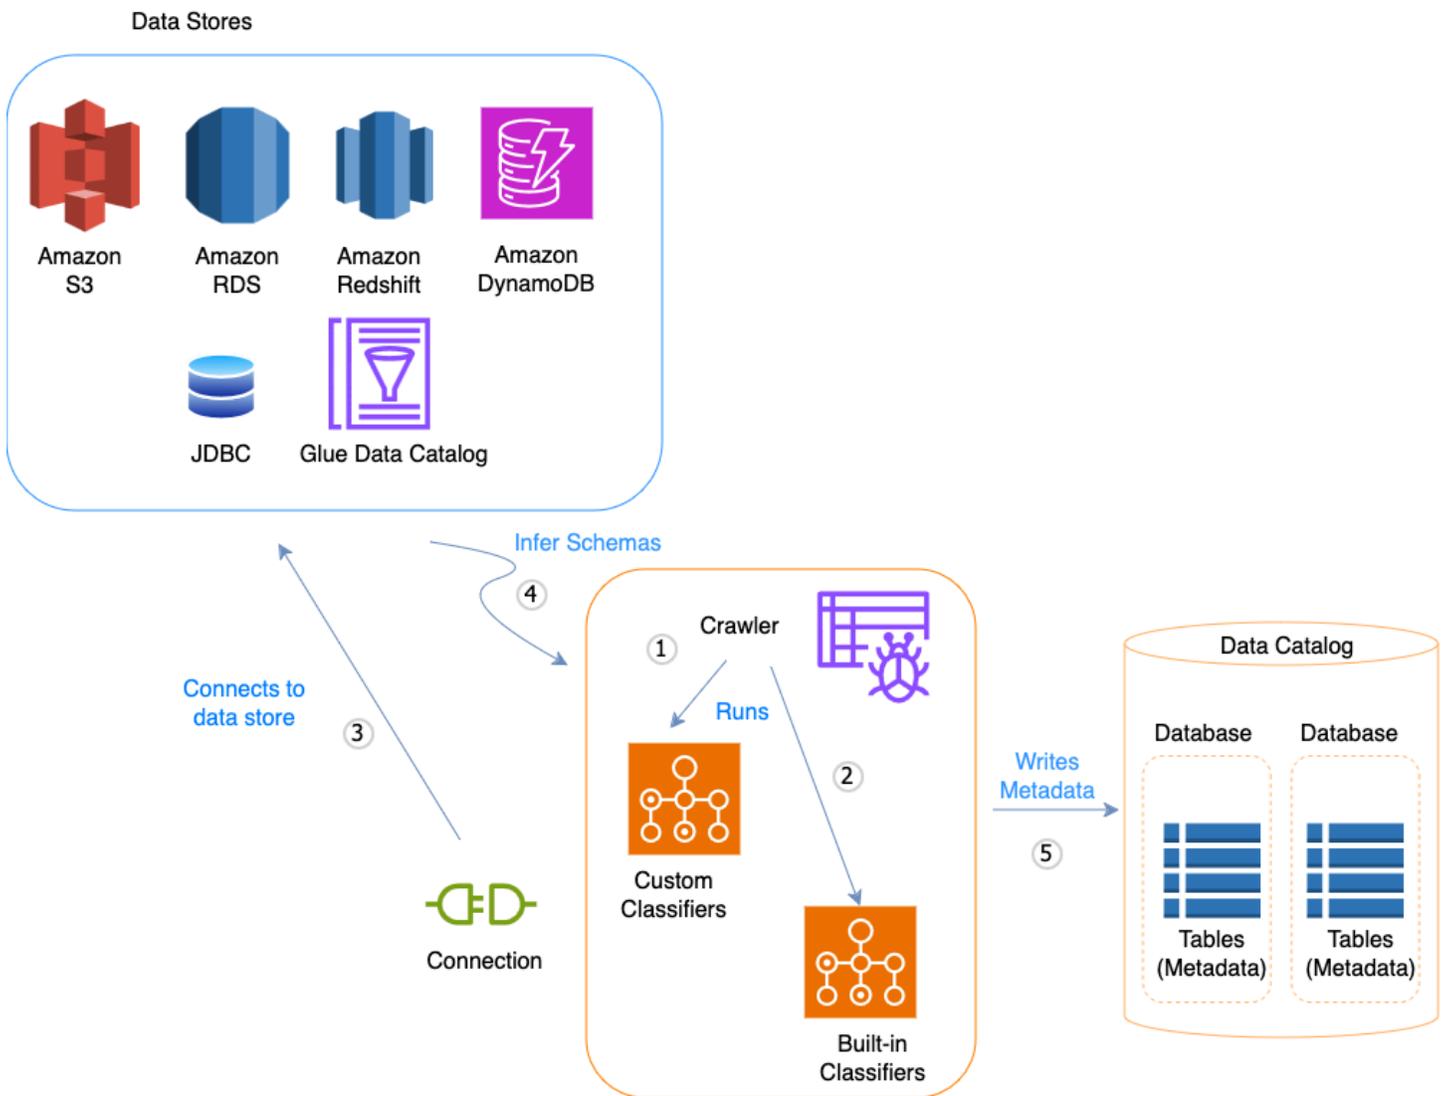

- [Data Catalog settings](#)

Using crawlers to populate the Data Catalog

You can use an Amazon Glue crawler to populate the Amazon Glue Data Catalog with databases and tables. This is the primary method used by most Amazon Glue users. A crawler can crawl multiple data stores in a single run. Upon completion, the crawler creates or updates one or more tables in your Data Catalog. Extract, transform, and load (ETL) jobs that you define in Amazon Glue use these Data Catalog tables as sources and targets. The ETL job reads from and writes to the data stores that are specified in the source and target Data Catalog tables.

Workflow

The following workflow diagram shows how Amazon Glue crawlers interact with data stores and other elements to populate the Data Catalog.

The following is the general workflow for how a crawler populates the Amazon Glue Data Catalog:

1. A crawler runs any custom *classifiers* that you choose to infer the format and schema of your data. You provide the code for custom classifiers, and they run in the order that you specify.

The first custom classifier to successfully recognize the structure of your data is used to create a schema. Custom classifiers lower in the list are skipped.

2. If no custom classifier matches your data's schema, built-in classifiers try to recognize your data's schema. An example of a built-in classifier is one that recognizes JSON.
3. The crawler connects to the data store. Some data stores require connection properties for crawler access.
4. The inferred schema is created for your data.

5. The crawler writes metadata to the Data Catalog. A table definition contains metadata about the data in your data store. The table is written to a database, which is a container of tables in the Data Catalog. Attributes of a table include classification, which is a label created by the classifier that inferred the table schema.

- [Defining and managing classifiers](#)
- [Configuring a crawler](#)
- [Scheduling a crawler](#)
- [Viewing crawler results and details](#)
- [Customizing crawler behavior](#)
- [Tutorial: Adding an Amazon Glue crawler](#)

How crawlers work

When a crawler runs, it takes the following actions to interrogate a data store:

- **Classifies data to determine the format, schema, and associated properties of the raw data** – You can configure the results of classification by creating a custom classifier.
- **Groups data into tables or partitions** – Data is grouped based on crawler heuristics.
- **Writes metadata to the Data Catalog** – You can configure how the crawler adds, updates, and deletes tables and partitions.

When you define a crawler, you choose one or more classifiers that evaluate the format of your data to infer a schema. When the crawler runs, the first classifier in your list to successfully recognize your data store is used to create a schema for your table. You can use built-in classifiers or define your own. You define your custom classifiers in a separate operation, before you define the crawlers. Amazon Glue provides built-in classifiers to infer schemas from common files with formats that include JSON, CSV, and Apache Avro. For the current list of built-in classifiers in Amazon Glue, see [Built-in classifiers](#).

The metadata tables that a crawler creates are contained in a database when you define a crawler. If your crawler does not specify a database, your tables are placed in the default database. In addition, each table has a classification column that is filled in by the classifier that first successfully recognized the data store.

If the file that is crawled is compressed, the crawler must download it to process it. When a crawler runs, it interrogates files to determine their format and compression type and writes these properties into the Data Catalog. Some file formats (for example, Apache Parquet) enable you to compress parts of the file as it is written. For these files, the compressed data is an internal component of the file, and Amazon Glue does not populate the `compressionType` property when it writes tables into the Data Catalog. In contrast, if an *entire file* is compressed by a compression algorithm (for example, gzip), then the `compressionType` property is populated when tables are written into the Data Catalog.

The crawler generates the names for the tables that it creates. The names of the tables that are stored in the Amazon Glue Data Catalog follow these rules:

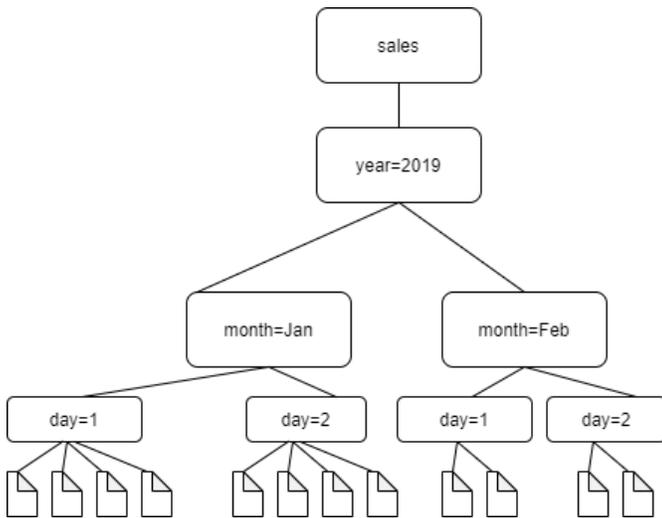

- Only alphanumeric characters and underscore (`_`) are allowed.
- Any custom prefix cannot be longer than 64 characters.
- The maximum length of the name cannot be longer than 128 characters. The crawler truncates generated names to fit within the limit.
- If duplicate table names are encountered, the crawler adds a hash string suffix to the name.

If your crawler runs more than once, perhaps on a schedule, it looks for new or changed files or tables in your data store. The output of the crawler includes new tables and partitions found since a previous run.

How does a crawler determine when to create partitions?

When an Amazon Glue crawler scans Amazon S3 data store and detects multiple folders in a bucket, it determines the root of a table in the folder structure and which folders are partitions of a table. The name of the table is based on the Amazon S3 prefix or folder name. You provide an **Include path** that points to the folder level to crawl. When the majority of schemas at a folder level are similar, the crawler creates partitions of a table instead of separate tables. To influence the crawler to create separate tables, add each table's root folder as a separate data store when you define the crawler.

For example, consider the following Amazon S3 folder structure.

The paths to the four lowest level folders are the following:

```

S3://sales/year=2019/month=Jan/day=1
S3://sales/year=2019/month=Jan/day=2
S3://sales/year=2019/month=Feb/day=1
S3://sales/year=2019/month=Feb/day=2
  
```

Assume that the crawler target is set at Sales, and that all files in the $day=n$ folders have the same format (for example, JSON, not encrypted), and have the same or very similar schemas. The crawler will create a single table with four partitions, with partition keys `year`, `month`, and `day`.

In the next example, consider the following Amazon S3 structure:

```

s3://bucket01/folder1/table1/partition1/file.txt
s3://bucket01/folder1/table1/partition2/file.txt
s3://bucket01/folder1/table1/partition3/file.txt
s3://bucket01/folder1/table2/partition4/file.txt
s3://bucket01/folder1/table2/partition5/file.txt
  
```

If the schemas for files under `table1` and `table2` are similar, and a single data store is defined in the crawler with **Include path** `s3://bucket01/folder1/`, the crawler creates a single table with two partition key columns. The first partition key column contains `table1` and `table2`, and the second partition key column contains `partition1` through `partition3` for the `table1` partition and `partition4` and `partition5` for the `table2` partition. To create two separate tables, define the crawler with two data stores. In this example, define the first **Include path** as `s3://bucket01/folder1/table1/` and the second as `s3://bucket01/folder1/table2/`.

Note

In Amazon Athena, each table corresponds to an Amazon S3 prefix with all the objects in it. If objects have different schemas, Athena does not recognize different objects within the same prefix as separate tables. This can happen if a crawler creates multiple tables from the same Amazon S3 prefix. This might lead to queries in Athena that return zero results. For Athena to properly recognize and query tables, create the crawler with a separate **Include path** for each different table schema in the Amazon S3 folder structure. For more information, see [Best Practices When Using Athena with Amazon Glue](#) and this [Amazon Knowledge Center article](#).

Supported data sources for crawling

Crawlers can crawl the following file-based and table-based data stores.

Access type that crawler uses	Data stores
Native client	<ul style="list-style-type: none"> • Amazon Simple Storage Service (Amazon S3) • Amazon DynamoDB • Delta Lake 2.0.x • Apache Iceberg 1.5 • Apache Hudi 0.14
JDBC	<p>Amazon Redshift</p> <p>Snowflake</p> <p>Within Amazon Relational Database Service (Amazon RDS) or external to Amazon RDS:</p> <ul style="list-style-type: none"> • Amazon Aurora • MariaDB • Microsoft SQL Server • MySQL • Oracle

Access type that crawler uses	Data stores
	<ul style="list-style-type: none"> PostgreSQL
MongoDB client	<ul style="list-style-type: none"> MongoDB MongoDB Atlas Amazon DocumentDB (with MongoDB compatibility)

 **Note**

Currently Amazon Glue does not support crawlers for data streams.

For JDBC, MongoDB, MongoDB Atlas, and Amazon DocumentDB (with MongoDB compatibility) data stores, you must specify an Amazon Glue *connection* that the crawler can use to connect to the data store. For Amazon S3, you can optionally specify a connection of type Network. A connection is a Data Catalog object that stores connection information, such as credentials, URL, Amazon Virtual Private Cloud information, and more. For more information, see [Connecting to data](#).

The following are the versions of drivers supported by the crawler:

Product	Crawler supported driver
PostgreSQL	42.2.1
Amazon Aurora	Same as native crawler drivers
MariaDB	8.0.13
Microsoft SQL Server	6.1.0
MySQL	8.0.13
Oracle	11.2.2
Amazon Redshift	4.1
Snowflake	3.13.20

Product	Crawler supported driver
MongoDB	4.7.2
MongoDB Atlas	4.7.2

The following are notes about the various data stores.

Amazon S3

You can choose to crawl a path in your account or in another account. If all the Amazon S3 files in a folder have the same schema, the crawler creates one table. Also, if the Amazon S3 object is partitioned, only one metadata table is created and partition information is added to the Data Catalog for that table.

Amazon S3 and Amazon DynamoDB

Crawlers use an Amazon Identity and Access Management (IAM) role for permission to access your data stores. *The role you pass to the crawler must have permission to access Amazon S3 paths and Amazon DynamoDB tables that are crawled.*

Amazon DynamoDB

When defining a crawler using the Amazon Glue console, you specify one DynamoDB table. If you're using the Amazon Glue API, you can specify a list of tables. You can choose to crawl only a small sample of the data to reduce crawler run times.

Delta Lake

For each Delta Lake data store, you specify how to create the Delta tables:

- **Create Native tables:** Allow integration with query engines that support querying of the Delta transaction log directly. For more information, see [Querying Delta Lake tables](#).
- **Create Symlink tables:** Create a `_symlink_manifest` folder with manifest files partitioned by the partition keys, based on the specified configuration parameters.

Iceberg

For each Iceberg data store, you specify an Amazon S3 path that contains the metadata for your Iceberg tables. If crawler discovers Iceberg table metadata, it registers it in the Data Catalog. You can set a schedule for the crawler to keep the tables updated.

You can define these parameters for the data store:

- **Exclusions:** Allows you to skip certain folders.
- **Maximum Traversal Depth:** Sets the depth limit the crawler can crawl in your Amazon S3 bucket. The default maximum traversal depth is 10 and the maximum depth you can set is 20.

Hudi

For each Hudi data store, you specify an Amazon S3 path that contains the metadata for your Hudi tables. If crawler discovers Hudi table metadata, it registers it in the Data Catalog. You can set a schedule for the crawler to keep the tables updated.

You can define these parameters for the data store:

- **Exclusions:** Allows you to skip certain folders.
- **Maximum Traversal Depth:** Sets the depth limit the crawler can crawl in your Amazon S3 bucket. The default maximum traversal depth is 10 and the maximum depth you can set is 20.

Note

Timestamp columns with `millis` as logical types will be interpreted as `bigint`, due to an incompatibility with Hudi 0.13.1 and timestamp types. A resolution may be provided in the upcoming Hudi release.

Hudi tables are categorized as follows, with specific implications for each:

- **Copy on Write (CoW):** Data is stored in a columnar format (Parquet), and each update creates a new version of files during a write.
- **Merge on Read (MoR):** Data is stored using a combination of columnar (Parquet) and row-based (Avro) formats. Updates are logged to row-based delta files and are compacted as needed to create new versions of the columnar files.

With CoW datasets, each time there is an update to a record, the file that contains the record is rewritten with the updated values. With a MoR dataset, each time there is an update, Hudi writes only the row for the changed record. MoR is better suited for write- or change-heavy workloads with fewer reads. CoW is better suited for read-heavy workloads on data that change less frequently.

Hudi provides three query types for accessing the data:

- **Snapshot queries:** Queries that see the latest snapshot of the table as of a given commit or compaction action. For MoR tables, snapshot queries expose the most recent state of the table by merging the base and delta files of the latest file slice at the time of the query.

- Incremental queries: Queries only see new data written to the table, since a given commit/compaction. This effectively provides change streams to enable incremental data pipelines.
- Read optimized queries: For MoR tables, queries see the latest data compacted. For CoW tables, queries see the latest data committed.

For Copy-On-Write tables, the crawlers creates a single table in the Data Catalog with the ReadOptimized serde `org.apache.hudi.hadoop.HoodieParquetInputFormat`.

For Merge-On-Read tables, the crawler creates two tables in the Data Catalog for the same table location:

- A table with suffix `_ro` which uses the ReadOptimized serde `org.apache.hudi.hadoop.HoodieParquetInputFormat`.
- A table with suffix `_rt` which uses the RealTime Serde allowing for Snapshot queries: `org.apache.hudi.hadoop.realtime.HoodieParquetRealtimeInputFormat`.

MongoDB and Amazon DocumentDB (with MongoDB compatibility)

MongoDB versions 3.2 and later are supported. You can choose to crawl only a small sample of the data to reduce crawler run times.

Relational database

Authentication is with a database user name and password. Depending on the type of database engine, you can choose which objects are crawled, such as databases, schemas, and tables.

Snowflake

The Snowflake JDBC crawler supports crawling the Table, External Table, View, and Materialized View. The Materialized View Definition will not be populated.

For Snowflake external tables, the crawler only will crawl if it points to an Amazon S3 location. In addition to the the table schema, the crawler will also crawl the Amazon S3 location, file format and output as table parameters in the Data Catalog table. Note that the partition information of the partitioned external table is not populated.

ETL is currently not supported for Data Catalog tables created using the Snowflake crawler.

Crawler prerequisites

The crawler assumes the permissions of the Amazon Identity and Access Management (IAM) role that you specify when you define it. This IAM role must have permissions to extract data from your

data store and write to the Data Catalog. The Amazon Glue console lists only IAM roles that have attached a trust policy for the Amazon Glue principal service. From the console, you can also create an IAM role with an IAM policy to access Amazon S3 data stores accessed by the crawler. For more information about providing roles for Amazon Glue, see [Identity-based policies for Amazon Glue](#).

 **Note**

When crawling a Delta Lake data store, you must have Read/Write permissions to the Amazon S3 location.

For your crawler, you can create a role and attach the following policies:

- The `AWSGlueServiceRole` Amazon managed policy, which grants the required permissions on the Data Catalog
- An inline policy that grants permissions on the data source.
- An inline policy that grants `iam:PassRole` permission on the role.

A quicker approach is to let the Amazon Glue console crawler wizard create a role for you. The role that it creates is specifically for the crawler, and includes the `AWSGlueServiceRole` Amazon managed policy plus the required inline policy for the specified data source.

If you specify an existing role for a crawler, ensure that it includes the `AWSGlueServiceRole` policy or equivalent (or a scoped down version of this policy), plus the required inline policies. For example, for an Amazon S3 data store, the inline policy would at a minimum be the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws-cn:s3:::bucket/object*"
      ]
    }
  ]
}
```

```

    ]
  }
]
}

```

For an Amazon DynamoDB data store, the policy would at a minimum be the following:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:DescribeTable",
        "dynamodb:Scan"
      ],
      "Resource": [
        "arn:aws:dynamodb:us-east-1:111122223333:table/table-name"
      ]
    }
  ]
}

```

In addition, if the crawler reads Amazon Key Management Service (Amazon KMS) encrypted Amazon S3 data, then the IAM role must have decrypt permission on the Amazon KMS key. For more information, see [Step 2: Create an IAM role for Amazon Glue](#).

Defining and managing classifiers

A classifier reads the data in a data store. If it recognizes the format of the data, it generates a schema. The classifier also returns a certainty number to indicate how certain the format recognition was.

Amazon Glue provides a set of built-in classifiers, but you can also create custom classifiers. Amazon Glue invokes custom classifiers first, in the order that you specify in your crawler definition. Depending on the results that are returned from custom classifiers, Amazon Glue might also invoke built-in classifiers. If a classifier returns `certainty=1.0` during processing, it indicates

that it's 100 percent certain that it can create the correct schema. Amazon Glue then uses the output of that classifier.

If no classifier returns `certainty=1.0`, Amazon Glue uses the output of the classifier that has the highest certainty. If no classifier returns a certainty greater than `0.0`, Amazon Glue returns the default classification string of UNKNOWN.

When do I use a classifier?

You use classifiers when you crawl a data store to define metadata tables in the Amazon Glue Data Catalog. You can set up your crawler with an ordered set of classifiers. When the crawler invokes a classifier, the classifier determines whether the data is recognized. If the classifier can't recognize the data or is not 100 percent certain, the crawler invokes the next classifier in the list to determine whether it can recognize the data.

For more information about creating a classifier using the Amazon Glue console, see [Creating classifiers using the Amazon Glue console](#).

Custom classifiers

The output of a classifier includes a string that indicates the file's classification or format (for example, json) and the schema of the file. For custom classifiers, you define the logic for creating the schema based on the type of classifier. Classifier types include defining schemas based on grok patterns, XML tags, and JSON paths.

If you change a classifier definition, any data that was previously crawled using the classifier is not reclassified. A crawler keeps track of previously crawled data. New data is classified with the updated classifier, which might result in an updated schema. If the schema of your data has evolved, update the classifier to account for any schema changes when your crawler runs. To reclassify data to correct an incorrect classifier, create a new crawler with the updated classifier.

For more information about creating custom classifiers in Amazon Glue, see [Writing custom classifiers for diverse data formats](#).

Note

If your data format is recognized by one of the built-in classifiers, you don't need to create a custom classifier.

Built-in classifiers

Amazon Glue provides built-in classifiers for various formats, including JSON, CSV, web logs, and many database systems.

If Amazon Glue doesn't find a custom classifier that fits the input data format with 100 percent certainty, it invokes the built-in classifiers in the order shown in the following table. The built-in classifiers return a result to indicate whether the format matches (`certainty=1.0`) or does not match (`certainty=0.0`). The first classifier that has `certainty=1.0` provides the classification string and schema for a metadata table in your Data Catalog.

Classifier type	Classification string	Notes
Apache Avro	avro	Reads the schema at the beginning of the file to determine format.
Apache ORC	orc	Reads the file metadata to determine format.
Apache Parquet	parquet	Reads the schema at the end of the file to determine format.
JSON	json	Reads the beginning of the file to determine format.
Binary JSON	bson	Reads the beginning of the file to determine format.
XML	xml	Reads the beginning of the file to determine format. Amazon Glue determines the table schema based on XML tags in the document. For information about creating a custom XML classifier to specify rows in the document, see Writing XML custom classifiers .
Amazon Ion	ion	Reads the beginning of the file to determine format.

Classifier type	Classification string	Notes
Combined Apache log	combined_apache	Determines log formats through a grok pattern.
Apache log	apache	Determines log formats through a grok pattern.
Linux kernel log	linux_kernel	Determines log formats through a grok pattern.
Microsoft log	microsoft_log	Determines log formats through a grok pattern.
Ruby log	ruby_logger	Reads the beginning of the file to determine format.
Squid 3.x log	squid	Reads the beginning of the file to determine format.
Redis monitor log	redismonlog	Reads the beginning of the file to determine format.
Redis log	redislog	Reads the beginning of the file to determine format.
CSV	csv	Checks for the following delimiters: comma (,), pipe (), tab (\t), semicolon (;), and Ctrl-A (\u0001). Ctrl-A is the Unicode control character for Start Of Heading.
Amazon Redshift	redshift	Uses JDBC connection to import metadata.
MySQL	mysql	Uses JDBC connection to import metadata.
PostgreSQL	postgresql	Uses JDBC connection to import metadata.
Oracle database	oracle	Uses JDBC connection to import metadata.
Microsoft SQL Server	sqlserver	Uses JDBC connection to import metadata.

Classifier type	Classification string	Notes
Amazon DynamoDB	dynamodb	Reads data from the DynamoDB table.

Files in the following compressed formats can be classified:

- ZIP (supported for archives containing only a single file). Note that Zip is not well-supported in other services (because of the archive).
- BZIP
- GZIP
- LZ4
- Snappy (supported for both standard and Hadoop native Snappy formats)

Built-in CSV classifier

The built-in CSV classifier parses CSV file contents to determine the schema for an Amazon Glue table. This classifier checks for the following delimiters:

- Comma (,)
- Pipe (|)
- Tab (\t)
- Semicolon (;)
- Ctrl-A (\u0001)

Ctrl-A is the Unicode control character for Start Of Heading.

To be classified as CSV, the table schema must have at least two columns and two rows of data. The CSV classifier uses a number of heuristics to determine whether a header is present in a given file. If the classifier can't determine a header from the first row of data, column headers are displayed as col1, col2, col3, and so on. The built-in CSV classifier determines whether to infer a header by evaluating the following characteristics of the file:

- Every column in a potential header parses as a STRING data type.

- Except for the last column, every column in a potential header has content that is fewer than 150 characters. To allow for a trailing delimiter, the last column can be empty throughout the file.
- Every column in a potential header must meet the Amazon Glue `regex` requirements for a column name.
- The header row must be sufficiently different from the data rows. To determine this, one or more of the rows must parse as other than `STRING` type. If all columns are of type `STRING`, then the first row of data is not sufficiently different from subsequent rows to be used as the header.

Note

If the built-in CSV classifier does not create your Amazon Glue table as you want, you might be able to use one of the following alternatives:

- Change the column names in the Data Catalog, set the `SchemaChangePolicy` to `LOG`, and set the partition output configuration to `InheritFromTable` for future crawler runs.
- Create a custom grok classifier to parse the data and assign the columns that you want.
- The built-in CSV classifier creates tables referencing the `LazySimpleSerDe` as the serialization library, which is a good choice for type inference. However, if the CSV data contains quoted strings, edit the table definition and change the `SerDe` library to `OpenCSVSerDe`. Adjust any inferred types to `STRING`, set the `SchemaChangePolicy` to `LOG`, and set the partitions output configuration to `InheritFromTable` for future crawler runs. For more information about `SerDe` libraries, see [SerDe Reference](#) in the Amazon Athena User Guide.

Writing custom classifiers for diverse data formats

You can provide a custom classifier to classify your data in Amazon Glue. You can create a custom classifier using a grok pattern, an XML tag, JavaScript Object Notation (JSON), or comma-separated values (CSV). An Amazon Glue crawler calls a custom classifier. If the classifier recognizes the data, it returns the classification and schema of the data to the crawler. You might need to define a custom classifier if your data doesn't match any built-in classifiers, or if you want to customize the tables that are created by the crawler.

For more information about creating a classifier using the Amazon Glue console, see [Creating classifiers using the Amazon Glue console](#).

Amazon Glue runs custom classifiers before built-in classifiers, in the order you specify. When a crawler finds a classifier that matches the data, the classification string and schema are used in the definition of tables that are written to your Amazon Glue Data Catalog.

Topics

- [Writing grok custom classifiers](#)
- [Writing XML custom classifiers](#)
- [Writing JSON custom classifiers](#)
- [Writing CSV custom classifiers](#)

Writing grok custom classifiers

Grok is a tool that is used to parse textual data given a matching pattern. A grok pattern is a named set of regular expressions (regex) that are used to match data one line at a time. Amazon Glue uses grok patterns to infer the schema of your data. When a grok pattern matches your data, Amazon Glue uses the pattern to determine the structure of your data and map it into fields.

Amazon Glue provides many built-in patterns, or you can define your own. You can create a grok pattern using built-in patterns and custom patterns in your custom classifier definition. You can tailor a grok pattern to classify custom text file formats.

Note

Amazon Glue grok custom classifiers use the `GrokSerDe` serialization library for tables created in the Amazon Glue Data Catalog. If you are using the Amazon Glue Data Catalog with Amazon Athena, Amazon EMR, or Redshift Spectrum, check the documentation about those services for information about support of the `GrokSerDe`. Currently, you might encounter problems querying tables created with the `GrokSerDe` from Amazon EMR and Redshift Spectrum.

The following is the basic syntax for the components of a grok pattern:

```
%{PATTERN:field-name}
```

Data that matches the named PATTERN is mapped to the field-name column in the schema, with a default data type of string. Optionally, the data type for the field can be cast to byte, boolean, double, short, int, long, or float in the resulting schema.

```
%{PATTERN:field-name:data-type}
```

For example, to cast a num field to an int data type, you can use this pattern:

```
%{NUMBER:num:int}
```

Patterns can be composed of other patterns. For example, you can have a pattern for a SYSLOG timestamp that is defined by patterns for month, day of the month, and time (for example, Feb 1 06:25:43). For this data, you might define the following pattern:

```
SYSLOGTIMESTAMP %{MONTH} +%{MONTHDAY} %{TIME}
```

Note

Grok patterns can process only one line at a time. Multiple-line patterns are not supported. Also, line breaks within a pattern are not supported.

Custom values for grok classifier

When you define a grok classifier, you supply the following values to create the custom classifier.

Name

Name of the classifier.

Classification

The text string that is written to describe the format of the data that is classified; for example, special-logs.

Grok pattern

The set of patterns that are applied to the data store to determine whether there is a match. These patterns are from Amazon Glue [built-in patterns](#) and any custom patterns that you define.

The following is an example of a grok pattern:

```
%{TIMESTAMP_IS08601:timestamp} \[%{MESSAGEPREFIX:message_prefix}\]
%{CRAWLERLOGLEVEL:loglevel} : %{GREEDYDATA:message}
```

When the data matches `TIMESTAMP_IS08601`, a schema column `timestamp` is created. The behavior is similar for the other named patterns in the example.

Custom patterns

Optional custom patterns that you define. These patterns are referenced by the grok pattern that classifies your data. You can reference these custom patterns in the grok pattern that is applied to your data. Each custom component pattern must be on a separate line. [Regular expression \(regex\)](#) syntax is used to define the pattern.

The following is an example of using custom patterns:

```
CRAWLERLOGLEVEL (BENCHMARK|ERROR|WARN|INFO|TRACE)
MESSAGEPREFIX .*-.*-.*-.*-.*
```

The first custom named pattern, `CRAWLERLOGLEVEL`, is a match when the data matches one of the enumerated strings. The second custom pattern, `MESSAGEPREFIX`, tries to match a message prefix string.

Amazon Glue keeps track of the creation time, last update time, and version of your classifier.

Built-in patterns

Amazon Glue provides many common patterns that you can use to build a custom classifier. You add a named pattern to the grok pattern in a classifier definition.

The following list consists of a line for each pattern. In each line, the pattern name is followed its definition. [Regular expression \(regex\)](#) syntax is used in defining the pattern.

```
#<noLOC>&GLU;</noLOC> Built-in patterns

Writing XML custom classifiers

XML defines the structure of a document with the use of tags in the file. With an XML custom classifier, you can specify the tag name used to define a row.

Custom classifier values for an XML classifier

When you define an XML classifier, you supply the following values to Amazon Glue to create the classifier. The classification field of this classifier is set to `xml`.

Name

Name of the classifier.

Row tag

The XML tag name that defines a table row in the XML document, without angle brackets `< >`. The name must comply with XML rules for a tag.

Note

The element containing the row data **cannot** be a self-closing empty element. For example, this empty element is **not** parsed by Amazon Glue:

```
<row att1="xx" att2="yy" />
```

Empty elements can be written as follows:

```
<row att1="xx" att2="yy"> </row>
```

Amazon Glue keeps track of the creation time, last update time, and version of your classifier.

For example, suppose that you have the following XML file. To create an Amazon Glue table that only contains columns for author and title, create a classifier in the Amazon Glue console with **Row tag** as `AnyCompany`. Then add and run a crawler that uses this custom classifier.

```
<?xml version="1.0"?>
<catalog>
  <book id="bk101">
    <AnyCompany>
      <author>Rivera, Martha</author>
      <title>AnyCompany Developer Guide</title>
    </AnyCompany>
  </book>
  <book id="bk102">
    <AnyCompany>
      <author>Stiles, John</author>
      <title>Style Guide for AnyCompany</title>
    </AnyCompany>
  </book>
</catalog>
```

Writing JSON custom classifiers

JSON is a data-interchange format. It defines data structures with name-value pairs or an ordered list of values. With a JSON custom classifier, you can specify the JSON path to a data structure that is used to define the schema for your table.

Custom classifier values in Amazon Glue

When you define a JSON classifier, you supply the following values to Amazon Glue to create the classifier. The classification field of this classifier is set to `json`.

Name

Name of the classifier.

JSON path

A JSON path that points to an object that is used to define a table schema. The JSON path can be written in dot notation or bracket notation. The following operators are supported:

Description

Root element of a JSON object. This starts all path expressions

Wildcard character. Available anywhere a name or numeric are required in the JSON path.

Dot-notated child. Specifies a child field in a JSON object.

Description

Bracket-notated child. Specifies child field in a JSON object. Only a single child field can be specified.

Array index. Specifies the value of an array by index.

Amazon Glue keeps track of the creation time, last update time, and version of your classifier.

Example Using a JSON classifier to pull records from an array

Suppose that your JSON data is an array of records. For example, the first few lines of your file might look like the following:

```
[
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:ak",
    "name": "Alaska"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:1",
    "name": "Alabama's 1st congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:2",
    "name": "Alabama's 2nd congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:3",
    "name": "Alabama's 3rd congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:4",
    "name": "Alabama's 4th congressional district"
  },
]
```

```
{
  "type": "constituency",
  "id": "ocd-division\country:us\state:al\cd:5",
  "name": "Alabama's 5th congressional district"
},
{
  "type": "constituency",
  "id": "ocd-division\country:us\state:al\cd:6",
  "name": "Alabama's 6th congressional district"
},
{
  "type": "constituency",
  "id": "ocd-division\country:us\state:al\cd:7",
  "name": "Alabama's 7th congressional district"
},
{
  "type": "constituency",
  "id": "ocd-division\country:us\state:ar\cd:1",
  "name": "Arkansas's 1st congressional district"
},
{
  "type": "constituency",
  "id": "ocd-division\country:us\state:ar\cd:2",
  "name": "Arkansas's 2nd congressional district"
},
{
  "type": "constituency",
  "id": "ocd-division\country:us\state:ar\cd:3",
  "name": "Arkansas's 3rd congressional district"
},
{
  "type": "constituency",
  "id": "ocd-division\country:us\state:ar\cd:4",
  "name": "Arkansas's 4th congressional district"
}
]
```

When you run a crawler using the built-in JSON classifier, the entire file is used to define the schema. Because you don't specify a JSON path, the crawler treats the data as one object, that is, just an array. For example, the schema might look like the following:

```
root
```

```
|-- record: array
```

However, to create a schema that is based on each record in the JSON array, create a custom JSON classifier and specify the JSON path as `$[*]`. When you specify this JSON path, the classifier interrogates all 12 records in the array to determine the schema. The resulting schema contains separate fields for each object, similar to the following example:

```
root
|-- type: string
|-- id: string
|-- name: string
```

Example Using a JSON classifier to examine only parts of a file

Suppose that your JSON data follows the pattern of the example JSON file `s3://awsglue-datasets/examples/us-legislators/all/areas.json` drawn from <http://everypolitician.org/>. Example objects in the JSON file look like the following:

```
{
  "type": "constituency",
  "id": "ocd-division/country:us/state:ak",
  "name": "Alaska"
}
{
  "type": "constituency",
  "identifiers": [
    {
      "scheme": "dmoz",
      "identifier": "Regional/North_America/United_States/Alaska/"
    },
    {
      "scheme": "freebase",
      "identifier": "\/m\/0hjy"
    },
    {
      "scheme": "fips",
      "identifier": "US02"
    },
    {
      "scheme": "quora",
```

```

    "identifier": "Alaska-state"
  },
  {
    "scheme": "britannica",
    "identifier": "place\Alaska"
  },
  {
    "scheme": "wikidata",
    "identifier": "Q797"
  }
],
"other_names": [
  {
    "lang": "en",
    "note": "multilingual",
    "name": "Alaska"
  },
  {
    "lang": "fr",
    "note": "multilingual",
    "name": "Alaska"
  },
  {
    "lang": "nov",
    "note": "multilingual",
    "name": "Alaska"
  }
],
"id": "ocd-division\country:us\state:ak",
"name": "Alaska"
}

```

When you run a crawler using the built-in JSON classifier, the entire file is used to create the schema. You might end up with a schema like this:

```

root
|-- type: string
|-- id: string
|-- name: string
|-- identifiers: array
|   |-- element: struct

```

```

|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string

```

However, to create a schema using just the "id" object, create a custom JSON classifier and specify the JSON path as \$.id. Then the schema is based on only the "id" field:

```

root
|-- record: string

```

The first few lines of data extracted with this schema look like this:

```

{"record": "ocd-division/country:us/state:ak"}
{"record": "ocd-division/country:us/state:al/cd:1"}
{"record": "ocd-division/country:us/state:al/cd:2"}
{"record": "ocd-division/country:us/state:al/cd:3"}
{"record": "ocd-division/country:us/state:al/cd:4"}
{"record": "ocd-division/country:us/state:al/cd:5"}
{"record": "ocd-division/country:us/state:al/cd:6"}
{"record": "ocd-division/country:us/state:al/cd:7"}
{"record": "ocd-division/country:us/state:ar/cd:1"}
{"record": "ocd-division/country:us/state:ar/cd:2"}
{"record": "ocd-division/country:us/state:ar/cd:3"}
{"record": "ocd-division/country:us/state:ar/cd:4"}
{"record": "ocd-division/country:us/state:as"}
{"record": "ocd-division/country:us/state:az/cd:1"}
{"record": "ocd-division/country:us/state:az/cd:2"}
{"record": "ocd-division/country:us/state:az/cd:3"}
{"record": "ocd-division/country:us/state:az/cd:4"}
{"record": "ocd-division/country:us/state:az/cd:5"}
{"record": "ocd-division/country:us/state:az/cd:6"}
{"record": "ocd-division/country:us/state:az/cd:7"}

```

To create a schema based on a deeply nested object, such as "identifier," in the JSON file, you can create a custom JSON classifier and specify the JSON path as

`$.identifiers[*].identifier`. Although the schema is similar to the previous example, it is based on a different object in the JSON file.

The schema looks like the following:

```
root
|-- record: string
```

Listing the first few lines of data from the table shows that the schema is based on the data in the "identifier" object:

```
{"record": "Regional/North_America/United_States/Alaska/"}
```

```
{"record": "/m/0hjy"}
```

```
{"record": "US02"}
```

```
{"record": "5879092"}
```

```
{"record": "4001016-8"}
```

```
{"record": "destination/alaska"}
```

```
{"record": "1116270"}
```

```
{"record": "139487266"}
```

```
{"record": "n79018447"}
```

```
{"record": "01490999-8dec-4129-8254-eef6e80fad33"}
```

```
{"record": "Alaska-state"}
```

```
{"record": "place/Alaska"}
```

```
{"record": "Q797"}
```

```
{"record": "Regional/North_America/United_States/Alabama/"}
```

```
{"record": "/m/0gyh"}
```

```
{"record": "US01"}
```

```
{"record": "4829764"}
```

```
{"record": "4084839-5"}
```

```
{"record": "161950"}
```

```
{"record": "131885589"}
```

To create a table based on another deeply nested object, such as the "name" field in the "other_names" array in the JSON file, you can create a custom JSON classifier and specify the JSON path as `$.other_names[*].name`. Although the schema is similar to the previous example, it is based on a different object in the JSON file. The schema looks like the following:

```
root
```

```
|-- record: string
```

Listing the first few lines of data in the table shows that it is based on the data in the "name" object in the "other_names" array:

```
{"record": "Alaska"}
{"record": "Alaska"}
{"record": "Аляска"}
{"record": "Alaska"}
{"record": "#####"}
{"record": "#####"}
{"record": "#####"}
{"record": "Alaska"}
{"record": "Alyaska"}
{"record": "Alaska"}
{"record": "Alaska"}
{"record": "Штат Аляска"}
{"record": "Аляска"}
{"record": "Alaska"}
{"record": "#####"}

```

Writing CSV custom classifiers

Custom CSV classifiers allows you to specify datatypes for each column in the custom csv classifier field. You can specify each column's datatype separated by a comma. By specifying datatypes, you can override the crawlers inferred datatypes and ensure data will be classified appropriately.

You can set the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog.

When you create a custom classifier, you can also re-use the classifier for different crawlers.

- For csv files with only headers (no data), these files will be classified as UNKNOWN since not enough information is provided. If you specify that the CSV 'Has headings' in the *Column headings* option, and provide the datatypes, we can classify these files correctly.

You can use a custom CSV classifier to infer the schema of various types of CSV data. The custom attributes that you can provide for your classifier include delimiters, a CSV SerDe option, options about the header, and whether to perform certain validations on the data.

Custom classifier values in Amazon Glue

When you define a CSV classifier, you provide the following values to Amazon Glue to create the classifier. The classification field of this classifier is set to `csv`.

Classifier name

Name of the classifier.

CSV Serde

Sets the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Options are Open CSV SerDe, Lazy Simple SerDe, and None. You can specify the None value when you want the crawler to do the detection.

Column delimiter

A custom symbol to denote what separates each column entry in the row. Provide a unicode character. If you cannot type your delimiter, you can copy and paste it. This works for printable characters, including those your system does not support (typically shown as □).

Quote symbol

A custom symbol to denote what combines content into a single column value. Must be different from the column delimiter. Provide a unicode character. If you cannot type your delimiter, you can copy and paste it. This works for printable characters, including those your system does not support (typically shown as □).

Column headings

Indicates the behavior for how column headings should be detected in the CSV file. If your custom CSV file has column headings, enter a comma-delimited list of the column headings.

Processing options: Allow files with single column

Enables the processing of files that contain only one column.

Processing options: Trim white space before identifying column values

Specifies whether to trim values before identifying the type of column values.

Custom datatypes - *optional*

Enter the custom datatype separated by a comma. Specifies the custom datatypes in the CSV file. The custom datatype must be a supported datatype. Supported datatypes are: "BINARY", "BOOLEAN", "DATE", "DECIMAL", "DOUBLE", "FLOAT", "INT", "LONG", "SHORT", "STRING", "TIMESTAMP". Unsupported datatypes will display an error.

Creating classifiers using the Amazon Glue console

A classifier determines the schema of your data. You can write a custom classifier and point to it from Amazon Glue.

Creating classifiers

To add a classifier in the Amazon Glue console, choose **Add classifier**. When you define a classifier, you supply values for the following:

- **Classifier name** – Provide a unique name for your classifier.
- **Classifier type** – The classification type of tables inferred by this classifier.
- **Last updated** – The last time this classifier was updated.

Classifier name

Provide a unique name for your classifier.

Classifier type

Choose the type of classifier to create.

Depending on the type of classifier you choose, configure the following properties for your classifier:

Grok

- **Classification**

Describe the format or type of data that is classified or provide a custom label.

- **Grok pattern**

This is used to parse your data into a structured schema. The grok pattern is composed of named patterns that describe the format of your data store. You write this grok pattern using the named built-in patterns provided by Amazon Glue and custom patterns you write and include in the **Custom patterns** field. Although grok debugger results might not match the results from Amazon Glue exactly, we suggest that you try your pattern using some sample data with a grok debugger. You can find grok debuggers on the web. The named built-in patterns provided by Amazon Glue are generally compatible with grok patterns that are available on the web.

Build your grok pattern by iteratively adding named patterns and check your results in a debugger. This activity gives you confidence that when the Amazon Glue crawler runs your grok pattern, your data can be parsed.

- **Custom patterns**

For grok classifiers, these are optional building blocks for the **Grok pattern** that you write. When built-in patterns cannot parse your data, you might need to write a custom pattern. These custom patterns are defined in this field and referenced in the **Grok pattern** field. Each custom pattern is defined on a separate line. Just like the built-in patterns, it consists of a named pattern definition that uses [regular expression \(regex\)](#) syntax.

For example, the following has the name MESSAGEPREFIX followed by a regular expression definition to apply to your data to determine whether it follows the pattern.

```
MESSAGEPREFIX .*-.*-.*-.*-.*
```

XML

- **Row tag**

For XML classifiers, this is the name of the XML tag that defines a table row in the XML document. Type the name without angle brackets < >. The name must comply with XML rules for a tag.

For more information, see [Writing XML custom classifiers](#).

JSON

- **JSON path**

For JSON classifiers, this is the JSON path to the object, array, or value that defines a row of the table being created. Type the name in either dot or bracket JSON syntax using Amazon Glue supported operators.

For more information, see the list of operators in [Writing JSON custom classifiers](#).

CSV

- **Column delimiter**

A single character or symbol to denote what separates each column entry in the row. Choose the delimiter from the list, or choose `Other` to enter a custom delimiter.

- **Quote symbol**

A single character or symbol to denote what combines content into a single column value. Must be different from the column delimiter. Choose the quote symbol from the list, or choose `Other` to enter a custom quote character.

- **Column headings**

Indicates the behavior for how column headings should be detected in the CSV file. You can choose `Has headings`, `No headings`, or `Detect headings`. If your custom CSV file has column headings, enter a comma-delimited list of the column headings.

- **Allow files with single column**

To be classified as CSV, the data must have at least two columns and two rows of data. Use this option to allow the processing of files that contain only one column.

- **Trim whitespace before identifying column values**

This option specifies whether to trim values before identifying the type of column values.

- **Custom datatype**

(Optional) - Enter custom datatypes in a comma-delimited list. The supported datatypes are: `"BINARY"`, `"BOOLEAN"`, `"DATE"`, `"DECIMAL"`, `"DOUBLE"`, `"FLOAT"`, `"INT"`, `"LONG"`, `"SHORT"`, `"STRING"`, `"TIMESTAMP"`.

- **CSV Serde**

(Optional) - A SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Choose from Open CSV SerDe, Lazy Simple SerDe, or None. You can specify the None value when you want the crawler to do the detection.

For more information, see [Writing custom classifiers for diverse data formats](#).

Viewing classifiers

To see a list of all the classifiers that you have created, open the Amazon Glue console at <https://console.amazonaws.cn/glue/>, and choose the **Classifiers** tab.

The list displays the following properties about each classifier:

- **Classifier** – The classifier name. When you create a classifier, you must provide a name for it.
- **Classification** – The classification type of tables inferred by this classifier.
- **Last updated** – The last time this classifier was updated.

Managing classifiers

From the **Classifiers** list in the Amazon Glue console, you can add, edit, and delete classifiers. To see more details for a classifier, choose the classifier name in the list. Details include the information you defined when you created the classifier.

Configuring a crawler

A crawler accesses your data store, identifies metadata, and creates table definitions in the Amazon Glue Data Catalog. The **Crawlers** pane in the Amazon Glue console lists all the crawlers that you create. The list displays status and metrics from the last run of your crawler.

This topic contains the step-by-step process of configuring a crawler, covering essential aspects such as setting up the crawler's parameters, defining the data sources to crawl, setting up security, and managing the crawled data.

Topics

- [Step 1: Set crawler properties](#)
- [Step 2: Choose data sources and classifiers](#)

- [Step 3: Configure security settings](#)
- [Step 4: Set output and scheduling](#)
- [Step 5: Review and create](#)

Step 1: Set crawler properties

To configure a crawler

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>. Choose **Crawlers** in the navigation pane.
2. Choose **Create crawler**, and follow the instructions in the **Add crawler** wizard. The wizard will guide you the steps required to create a crawler. If you want to add custom classifiers to define the schema, see [Defining and managing classifiers](#).
3. Enter a name for your crawler and description (optional). Optionally, you can tag your crawler with a **Tag key** and optional **Tag value**. Once created, tag keys are read-only. Use tags on some resources to help you organize and identify them. For more information, see Amazon tags in Amazon Glue.

Name

Name may contain letters (A-Z), numbers (0-9), hyphens (-), or underscores (_), and can be up to 255 characters long.

Description

Descriptions can be up to 2048 characters long.

Tags

Use tags to organize and identify your resources. For more information, see the following:

- [Amazon tags in Amazon Glue](#)

Step 2: Choose data sources and classifiers

Next, configure the data sources and classifiers for the crawler.

For more information about supported data sources, see [Supported data sources for crawling](#).

Data source configuration

Select the appropriate option for **Is your data already mapped to Amazon Glue tables?** choose 'Not yet' or 'Yes'. By default, 'Not yet' is selected.

The crawler can access data stores directly as the source of the crawl, or it can use existing tables in the Data Catalog as the source. If the crawler uses existing catalog tables, it crawls the data stores that are specified by those catalog tables.

- **Not yet:** Select one or more data sources to be crawled. A crawler can crawl multiple data stores of different types (Amazon S3, JDBC, and so on).

You can configure only one data store at a time. After you have provided the connection information and include paths and exclude patterns, you then have the option of adding another data store.

- **Yes:** Select existing tables from your Amazon Glue Data Catalog. The catalog tables specify the data stores to crawl. The crawler can crawl only catalog tables in a single run; it can't mix in other source types.

A common reason to specify a catalog table as the source is when you create the table manually (because you already know the structure of the data store) and you want a crawler to keep the table updated, including adding new partitions. For a discussion of other reasons, see [Updating manually created Data Catalog tables using crawlers](#).

When you specify existing tables as the crawler source type, the following conditions apply:

- Database name is optional.
- Only catalog tables that specify Amazon S3, Amazon DynamoDB, or Delta Lake data stores are permitted.
- No new catalog tables are created when the crawler runs. Existing tables are updated as needed, including adding new partitions.
- Deleted objects found in the data stores are ignored; no catalog tables are deleted. Instead, the crawler writes a log message. (`SchemaChangePolicy.DeleteBehavior=LOG`)
- The crawler configuration option to create a single schema for each Amazon S3 path is enabled by default and cannot be disabled. (`TableGroupingPolicy=CombineCompatibleSchemas`) For more information, see [Creating a single schema for each Amazon S3 include path](#).
- You can't mix catalog tables as a source with any other source types (for example Amazon S3 or Amazon DynamoDB).

To use Delta tables, first create a Delta table using Athena DDL or the Amazon Glue API.

Using Athena, set the location to your Amazon S3 folder and the table type to 'DELTA'.

```
CREATE EXTERNAL TABLE database_name.table_name
LOCATION 's3://bucket/folder/'
TBLPROPERTIES ('table_type' = 'DELTA')
```

Using the Amazon Glue API, specify the table type within the table parameters map. The table parameters need to include the following key/value pair. For more information on how to create a table, see [Boto3 documentation for create_table](#).

```
{
  "table_type": "delta"
}
```

Data sources

Select or add the list of data sources to be scanned by the crawler.

(Optional) If you choose JDBC as the data source, you can use your own JDBC drivers when specifying the Connection access where the driver info is stored.

Include path

When evaluating what to include or exclude in a crawl, a crawler starts by evaluating the required include path. For Amazon S3, MongoDB, MongoDB Atlas, Amazon DocumentDB (with MongoDB compatibility), and relational data stores, you must specify an include path.

For an Amazon S3 data store

Choose whether to specify a path in this account or in a different account, and then browse to choose an Amazon S3 path.

For Amazon S3 data stores, include path syntax is `bucket-name/folder-name/file-name.ext`. To crawl all objects in a bucket, you specify just the bucket name in the include path. The exclude pattern is relative to the include path

For a Delta Lake data store

Specify one or more Amazon S3 paths to Delta tables as `s3://bucket/prefix/object`.

For an Iceberg or Hudi data store

Specify one or more Amazon S3 paths that contain folders with Iceberg or Hudi table metadata as `s3://bucket/prefix`.

For Iceberg and Hudi data stores, the Iceberg/Hudi folder may be located in a child folder of the root folder. The crawler will scan all folders underneath a path for a Hudi folder.

For a JDBC data store

Enter `<database>/<schema>/<table>` or `<database>/<table>`, depending on the database product. Oracle Database and MySQL don't support schema in the path. You can substitute the percent (%) character for `<schema>` or `<table>`. For example, for an Oracle database with a system identifier (SID) of `orcl`, enter `orcl/%` to import all tables to which the user named in the connection has access.

Important

This field is case-sensitive.

Note

If you choose to bring in your own JDBC driver versions, Amazon Glue crawlers will consume resources in Amazon Glue jobs and Amazon S3 buckets to ensure your provided driver are run in your environment. The additional usage of resources will be reflected in your account. Drivers are limited to the properties described in [Adding an Amazon Glue connection](#).

For a MongoDB, MongoDB Atlas, or Amazon DocumentDB data store

For MongoDB, MongoDB Atlas, and Amazon DocumentDB (with MongoDB compatibility), the syntax is `database/collection`.

For JDBC data stores, the syntax is either `database-name/schema-name/table-name` or `database-name/table-name`. The syntax depends on whether the database engine supports schemas within a database. For example, for database engines such as MySQL or Oracle, don't specify a schema-name in your include path. You can substitute the percent sign (%) for a

schema or table in the include path to represent all schemas or all tables in a database. You cannot substitute the percent sign (%) for database in the include path.

Maximum transversal depth (for Iceberg or Hudi data stores only)

Defines the maximum depth of the Amazon S3 path that the crawler can traverse to discover the Iceberg or Hudi metadata folder in your Amazon S3 path. The purpose of this parameter is to limit the crawler run time. The default value is 10 and the maximum is 20.

Exclude patterns

These enable you to exclude certain files or tables from the crawl. The exclude path is relative to the include path. For example, to exclude a table in your JDBC data store, type the table name in the exclude path.

A crawler connects to a JDBC data store using an Amazon Glue connection that contains a JDBC URI connection string. The crawler only has access to objects in the database engine using the JDBC user name and password in the Amazon Glue connection. *The crawler can only create tables that it can access through the JDBC connection.* After the crawler accesses the database engine with the JDBC URI, the include path is used to determine which tables in the database engine are created in the Data Catalog. For example, with MySQL, if you specify an include path of `MyDatabase/%`, then all tables within `MyDatabase` are created in the Data Catalog. When accessing Amazon Redshift, if you specify an include path of `MyDatabase/%`, then all tables within all schemas for database `MyDatabase` are created in the Data Catalog. If you specify an include path of `MyDatabase/MySchema/%`, then all tables in database `MyDatabase` and schema `MySchema` are created.

After you specify an include path, you can then exclude objects from the crawl that your include path would otherwise include by specifying one or more Unix-style `glob` exclude patterns. These patterns are applied to your include path to determine which objects are excluded. These patterns are also stored as a property of tables created by the crawler. Amazon Glue PySpark extensions, such as `create_dynamic_frame.from_catalog`, read the table properties and exclude objects defined by the exclude pattern.

Amazon Glue supports the following `glob` patterns in the exclude pattern.

Exclude pattern	Description
*.csv	Matches an Amazon S3 path that represents an object name in the current folder ending in .csv
.	Matches all object names that contain a dot
*.{csv,avro}	Matches object names ending with .csv or .avro
foo.?	Matches object names starting with foo. that are followed by a single character extension
myfolder/*	Matches objects in one level of subfolder from myfolder, such as /myfolder/mysource
myfolder/**	Matches objects in two levels of subfolders from myfolder, such as /myfolder/mysource/data
myfolder/***	Matches objects in all subfolders of myfolder, such as /myfolder/mysource/mydata and /myfolder/mysource/data
myfolder**	Matches subfolder myfolder as well as files below myfolder, such as /myfolder and /myfolder/mydata.txt
Market*	Matches tables in a JDBC database with names that begin with Market, such as Market_us and Market_fr

Amazon Glue interprets glob exclude patterns as follows:

- The slash (/) character is the delimiter to separate Amazon S3 keys into a folder hierarchy.
- The asterisk (*) character matches zero or more characters of a name component without crossing folder boundaries.
- A double asterisk (**) matches zero or more characters crossing folder or schema boundaries.
- The question mark (?) character matches exactly one character of a name component.
- The backslash (\) character is used to escape characters that otherwise can be interpreted as special characters. The expression \\ matches a single backslash, and \{ matches a left brace.
- Brackets [] create a bracket expression that matches a single character of a name component out of a set of characters. For example, [abc] matches a, b, or c. The hyphen (-) can be used to specify a range, so [a-z] specifies a range that matches from a through z (inclusive). These forms can be mixed, so [abce-g] matches a, b, c, e, f, or g. If the character after the bracket ([]) is an exclamation point (!), the bracket expression is negated. For example, [!a-c] matches any character except a, b, or c.

Within a bracket expression, the *, ?, and \ characters match themselves. The hyphen (-) character matches itself if it is the first character within the brackets, or if it's the first character after the ! when you are negating.

- Braces ({ }) enclose a group of subpatterns, where the group matches if any subpattern in the group matches. A comma (,) character is used to separate the subpatterns. Groups cannot be nested.
- Leading period or dot characters in file names are treated as normal characters in match operations. For example, the * exclude pattern matches the file name .hidden.

Example Amazon S3 exclude patterns

Each exclude pattern is evaluated against the include path. For example, suppose that you have the following Amazon S3 directory structure:

```
/mybucket/myfolder/  
  departments/  
    finance.json  
    market-us.json  
    market-emea.json  
    market-ap.json  
  employees/  
    hr.json
```

```
john.csv
jane.csv
juan.txt
```

Given the include path `s3://mybucket/myfolder/`, the following are some sample results for exclude patterns:

Exclude pattern	Results
<code>departments/**</code>	Excludes all files and folders below <code>departments</code> and includes the <code>employees</code> folder and its files
<code>departments/market*</code>	Excludes <code>market-us.json</code> , <code>market-em-ea.json</code> , and <code>market-ap.json</code>
<code>** .csv</code>	Excludes all objects below <code>myfolder</code> that have a name ending with <code>.csv</code>
<code>employees/*.csv</code>	Excludes all <code>.csv</code> files in the <code>employees</code> folder

Example Excluding a subset of Amazon S3 partitions

Suppose that your data is partitioned by day, so that each day in a year is in a separate Amazon S3 partition. For January 2015, there are 31 partitions. Now, to crawl data for only the first week of January, you must exclude all partitions except days 1 through 7:

```
2015/01/{[!0],0[8-9]}**, 2015/0[2-9]**, 2015/1[0-2]**
```

Take a look at the parts of this glob pattern. The first part, `2015/01/{[!0],0[8-9]}**,` excludes all days that don't begin with a "0" in addition to day 08 and day 09 from month 01 in year 2015. Notice that `"**"` is used as the suffix to the day number pattern and crosses folder boundaries to lower-level folders. If `"**"` is used, lower folder levels are not excluded.

The second part, `2015/0[2-9]**,` excludes days in months 02 to 09, in year 2015.

The third part, `2015/1[0-2]/**`, excludes days in months 10, 11, and 12, in year 2015.

Example JDBC exclude patterns

Suppose that you are crawling a JDBC database with the following schema structure:

```
MyDatabase/MySchema/
  HR_us
  HR_fr
  Employees_Table
  Finance
  Market_US_Table
  Market_EMEA_Table
  Market_AP_Table
```

Given the include path `MyDatabase/MySchema/%`, the following are some sample results for exclude patterns:

Exclude pattern	Results
HR*	Excludes the tables with names that begin with HR
Market_*	Excludes the tables with names that begin with Market_
**_Table	Excludes all tables with names that end with _Table

Additional crawler source parameters

Each source type requires a different set of additional parameters.

Connection

Select or add an Amazon Glue connection. For information about connections, see [Connecting to data](#).

Additional metadata - optional (for JDBC data stores)

Select additional metadata properties for the crawler to crawl.

- **Comments:** Crawl associated table level and column level comments.
- **Raw types:** Persist the raw datatypes of the table columns in additional metadata. As a default behavior, the crawler translates the raw datatypes to Hive-compatible types.

JDBC Driver Class name - optional (for JDBC data stores)

Type a custom JDBC driver class name for the crawler to connect to the data source:

- **Postgres:** `org.postgresql.Driver`
- **MySQL:** `com.mysql.jdbc.Driver`, `com.mysql.cj.jdbc.Driver`
- **Redshift:** `com.amazon.redshift.jdbc.Driver`, `com.amazon.redshift.jdbc42.Driver`
- **Oracle:** `oracle.jdbc.driver.OracleDriver`
- **SQL Server:** `com.microsoft.sqlserver.jdbc.SQLServerDriver`

JDBC Driver S3 Path - optional (for JDBC data stores)

Choose an existing Amazon S3 path to a `.jar` file. This is where the `.jar` file will be stored when using a custom JDBC driver for the crawler to connect to the data source.

Enable data sampling (for Amazon DynamoDB, MongoDB, MongoDB Atlas, and Amazon DocumentDB data stores only)

Select whether to crawl a data sample only. If not selected the entire table is crawled. Scanning all the records can take a long time when the table is not a high throughput table.

Create tables for querying (for Delta Lake data stores only)

Select how you want to create the Delta Lake tables:

- **Create Native tables:** Allow integration with query engines that support querying of the Delta transaction log directly.
- **Create Symlink tables:** Create a symlink manifest folder with manifest files partitioned by the partition keys, based on the specified configuration parameters.

Scanning rate - optional (for DynamoDB data stores only)

Specify the percentage of the DynamoDB table Read Capacity Units to use by the crawler. Read capacity units is a term defined by DynamoDB, and is a numeric value that acts as rate limiter for the number of reads that can be performed on that table per second. Enter a value between 0.1 and 1.5. If not specified, defaults to 0.5 for provisioned tables and 1/4 of maximum configured capacity for on-demand tables. Note that only provisioned capacity mode should be used with Amazon Glue crawlers.

Note

For DynamoDB data stores, set the provisioned capacity mode for processing reads and writes on your tables. The Amazon Glue crawler should not be used with the on-demand capacity mode.

Network connection - optional (for Amazon S3, Delta, Iceberg, Hudi and Catalog target data stores)

Optionally include a Network connection to use with this Amazon S3 target. Note that each crawler is limited to one Network connection so any other Amazon S3 targets will also use the same connection (or none, if left blank).

For information about connections, see [Connecting to data](#).

Sample only a subset of files and Sample size (for Amazon S3 data stores only)

Specify the number of files in each leaf folder to be crawled when crawling sample files in a dataset. When this feature is turned on, instead of crawling all the files in this dataset, the crawler randomly selects some files in each leaf folder to crawl.

The sampling crawler is best suited for customers who have previous knowledge about their data formats and know that schemas in their folders do not change. Turning on this feature will significantly reduce crawler runtime.

A valid value is an integer between 1 and 249. If not specified, all the files are crawled.

Subsequent crawler runs

This field is a global field that affects all Amazon S3 data sources.

- Crawl all sub-folders: Crawl all folders again with every subsequent crawl.
- Crawl new sub-folders only: Only Amazon S3 folders that were added since the last crawl will be crawled. If the schemas are compatible, new partitions will be added to existing tables. For more information, see [the section called "Scheduling incremental crawls"](#).
- Crawl based on events: Rely on Amazon S3 events to control what folders to crawl. For more information, see [Accelerating crawls using Amazon S3 event notifications](#).

Custom classifiers - optional

Define custom classifiers before defining crawlers. A classifier checks whether a given file is in a format the crawler can handle. If it is, the classifier creates a schema in the form of a `StructType` object that matches that data format.

For more information, see [Defining and managing classifiers](#).

Step 3: Configure security settings

IAM role

The crawler assumes this role. It must have permissions similar to the Amazon managed policy `AWSGlueServiceRole`. For Amazon S3 and DynamoDB sources, it must also have permissions to access the data store. If the crawler reads Amazon S3 data encrypted with Amazon Key Management Service (Amazon KMS), then the role must have decrypt permissions on the Amazon KMS key.

For an Amazon S3 data store, additional permissions attached to the role would be similar to the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws-cn:s3:::bucket/object*"
      ]
    }
  ]
}
```

For an Amazon DynamoDB data store, additional permissions attached to the role would be similar to the following:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:DescribeTable",
        "dynamodb:Scan"
      ],
      "Resource": [
        "arn:aws-cn:dynamodb:*:111122223333:table/table-name*"
      ]
    }
  ]
}

```

In order to add your own JDBC driver, additional permissions need to be added.

- Grant permissions for the following job actions: CreateJob, DeleteJob, GetJob, GetJobRun, StartJobRun.
- Grant permissions for Amazon S3 actions: s3:DeleteObjects, s3:GetObject, s3:ListBucket, s3:PutObject.

 **Note**

The s3:ListBucket is not needed if the Amazon S3 bucket policy is disabled.

- Grant service principal access to bucket/folder in the Amazon S3 policy.

Example Amazon S3 policy:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [

```

```

        "s3:PutObject",
        "s3:GetObject",
        "s3:ListBucket",
        "s3:DeleteObject"
    ],
    "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/driver-parent-folder/
driver.jar",
        "arn:aws:s3:::amzn-s3-demo-bucket"
    ]
    }
]
}

```

Amazon Glue creates the following folders (`_crawler` and `_glue_job_crawler` at the same level as the JDBC driver in your Amazon S3 bucket. For example, if the driver path is `<s3-path/driver_folder/driver.jar>`, then the following folders will be created if they do not already exist:

- `<s3-path/driver_folder/_crawler>`
- `<s3-path/driver_folder/_glue_job_crawler>`

Optionally, you can add a security configuration to a crawler to specify at-rest encryption options.

For more information, see [Step 2: Create an IAM role for Amazon Glue](#) and [Identity and access management for Amazon Glue](#).

Lake Formation configuration - optional

Allow the crawler to use Lake Formation credentials for crawling the data source.

Checking **Use Lake Formation credentials for crawling S3 data source** will allow the crawler to use Lake Formation credentials for crawling the data source. If the data source belongs to another account, you must provide the registered account ID. Otherwise, the crawler will crawl only those data sources associated to the account. Only applicable to Amazon S3 and Data Catalog data sources.

Security configuration - optional

Settings include security configurations. For more information, see the following:

- [Encrypting data written by Amazon Glue](#)

Note

Once a security configuration has been set on a crawler, you can change, but you cannot remove it. To lower the level of security on a crawler, explicitly set the security feature to DISABLED within your configuration, or create a new crawler.

Step 4: Set output and scheduling**Output configuration**

Options include how the crawler should handle detected schema changes, deleted objects in the data store, and more. For more information, see [Customizing crawler behavior](#)

Crawler schedule

You can run a crawler on demand or define a time-based schedule for your crawlers and jobs in Amazon Glue. The definition of these schedules uses the Unix-like cron syntax. For more information, see [Scheduling a crawler](#).

Step 5: Review and create

Review the crawler settings you configured, and create the crawler.

Scheduling a crawler

You can run an Amazon Glue crawler on demand or on a regular schedule. When you set up a crawler based on a schedule, you can specify certain constraints, such as the frequency of the crawler runs, which days of the week it runs, and at what time. You can create these custom schedules in *cron* format. For more information, see [cron](#) in Wikipedia.

When setting up a crawler schedule, you should consider the features and limitations of cron. For example, if you choose to run your crawler on day 31 each month, keep in mind that some months don't have 31 days.

Topics

- [Create a crawler schedule](#)
- [Create a schedule for an existing crawler](#)

Create a crawler schedule

You can create a schedule for the crawler using the Amazon Glue console or Amazon CLI.

Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console, and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Crawlers** in the navigation pane.
3. Follow steps 1-3 in the [Configuring a crawler](#) section.
4. In [Step 4: Set output and scheduling](#), choose a **Crawler schedule** to set the frequency of the run. You can choose the crawler to run hourly, daily, weekly, monthly or define custom schedule using cron expressions.

A cron expression is a string representing a schedule pattern, consisting of 6 fields separated by spaces: * * * * * <minute> <hour> <day of month> <month> <day of week> <year>

For example, to run a task every day at midnight, the cron expression is: 0 0 * * ? *

For more information, see [Cron expressions](#).

5. Review the crawler settings you configured, and create the crawler to run on a schedule.

Amazon CLI

```
aws glue create-crawler
--name myCrawler \
--role AWSGlueServiceRole-myCrawler \
--targets '{"S3Targets":[{"Path="s3://amzn-s3-demo-bucket/"}]}' \
--schedule cron(15 12 * * ? *)
```

For more information about using cron to schedule jobs and crawlers, see [Time-based schedules for jobs and crawlers](#).

Create a schedule for an existing crawler

Follow these steps to set up a recurring schedule for an existing crawler.

Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Crawlers** in the navigation pane.
3. Choose a crawler that you want to schedule from the available list.
4. Choose **Edit** from the **Actions menu**.
5. Scroll down to **Step 4: Set output and scheduling**, and choose **Edit**.
6. Update your crawler schedule under **Crawler schedule**.
7. Choose **Update**.

Amazon CLI

Use the following CLI command to update an existing crawler configuration:

```
aws glue update-crawler-schedule
  --crawler-name myCrawler
  --schedule cron(15 12 * * ? *)
```

Viewing crawler results and details

After the crawler runs successfully, it creates table definitions in the Data Catalog. Choose **Tables** in the navigation pane to see the tables that were created by your crawler in the database that you specified.

You can view information related to the crawler itself as follows:

- The **Crawlers** page on the Amazon Glue console displays the following properties for a crawler:

Property	Description
Name	When you create a crawler, you must give it a unique name.
Status	A crawler can be ready, starting, stopping, scheduled, or schedule paused. A running

Property	Description
	crawler progresses from starting to stopping. You can resume or pause a schedule attached to a crawler.
Schedule	You can choose to run your crawler on demand or choose a frequency with a schedule. For more information about scheduling a crawler, see Scheduling a crawler .
Last run	The date and time of the last time the crawler was run.
Log	Links to any available logs from the last run of the crawler.
Tables changes from last run	The number of tables in the Amazon Glue Data Catalog that were updated by the latest run of the crawler.

- To view the history of a crawler, choose **Crawlers** in the navigation pane to see the crawlers you created. Choose a crawler from the list of available crawlers. You can view the crawler properties and view the crawler history in the **Crawler runs** tab.

The Crawler runs tab displays information about each time the crawler ran, including **Start time (UTC)**, **End time (UTC)**, **Duration**, **Status**, **DPU hours**, and **Table changes**.

The Crawler runs tab displays only the crawls that have occurred since the launch date of the crawler history feature, and only retains up to 12 months of crawls. Older crawls will not be returned.

- To see additional information, choose a tab in the crawler details page. Each tab will display information related to the crawler.
 - **Schedule:** Any schedules created for the crawler will be visible here.
 - **Data sources:** All data sources scanned by the crawler will be visible here.
 - **Classifiers:** All classifiers assigned to the crawler will be visible here.
 - **Tags:** Any tags created and assigned to an Amazon resource will be visible here.

Parameters set on Data Catalog tables by crawler

These table properties are set by Amazon Glue crawlers. We expect users to consume the `classification` and `compressionType` properties. Other properties, including table size estimates, are used for internal calculations, and we do not guarantee their accuracy or applicability to customer use cases. Changing these parameters may alter the behavior of the crawler, we do not support this workflow.

Property key	Property value
<code>UPDATED_BY_CRAWLER</code>	Name of crawler performing update.
<code>connectionName</code>	The name of the connection in the Data Catalog for the crawler used to connect the to the data store.
<code>recordCount</code>	Estimate count of records in table, based on file sizes and headers.
<code>skip.header.line.count</code>	Rows skipped to skip header. Set on tables classified as CSV.
<code>CrawlerSchemaSerializerVersion</code>	For internal use
<code>classification</code>	Format of data, inferred by crawler. For more information about data formats supported by Amazon Glue crawlers see the section called "Built-in classifiers" .
<code>CrawlerSchemaDeserializerVersion</code>	For internal use
<code>sizeKey</code>	Combined size of files in table crawled.
<code>averageRecordSize</code>	Average size of row in table, in bytes.

Property key	Property value
compressionType	Type of compression used on data in the table. For more information about compression types supported by Amazon Glue crawlers see the section called "Built-in classifiers" .
typeOfData	file, table or view.
objectCount	Number of objects under Amazon S3 path for table.

These additional table properties are set by Amazon Glue crawlers for Snowflake data stores.

Property key	Property value
aws:RawTableLastAltered	Records the last altered timestamp of the Snowflake table.
ViewOriginalText	View SQL statement.
ViewExpandedText	View SQL statement encoded in Base64 format.
ExternalTable:S3Location	Amazon S3 location of the Snowflake external table.
ExternalTable:FileFormat	Amazon S3 file format of the Snowflake external table.

These additional table properties are set by Amazon Glue crawlers for JDBC-type data stores such as Amazon Redshift, Microsoft SQL Server, MySQL, PostgreSQL, and Oracle.

Property key	Property value
<code>aws:RawType</code>	When a crawler store the data in the Data Catalog it translates the datatypes to Hive-compatible types, which many times causes the information on the native datatype to be lost. The crawler outputs the <code>aws:RawType</code> parameter to provide the native-level datatype.
<code>aws:RawColumnComment</code>	<p>If a comment is associated with a column in the database, the crawler outputs the corresponding comment in the catalog table. The comment string is truncated to 255 bytes.</p> <p>Comments are not supported for Microsoft SQL Server.</p>
<code>aws:RawTableComment</code>	<p>If a comment is associated with a table in the database, the crawler outputs corresponding comment in the catalog table. The comment string is truncated to 255 bytes.</p> <p>Comments are not supported for Microsoft SQL Server.</p>

Customizing crawler behavior

When you configure an Amazon Glue crawler, you have several options for defining the behavior of your crawler.

- **Incremental crawls** – You can configure a crawler to run incremental crawls to add only new partitions to the table schema.
- **Partition indexes** – A crawler creates partition indexes for Amazon S3 and Delta Lake targets by default to provide efficient lookup for specific partitions.
- **Accelerate crawl time by using Amazon S3 events** – You can configure a crawler to use Amazon S3 events to identify the changes between two crawls by listing all the files from the subfolder which triggered the event instead of listing the full Amazon S3 or Data Catalog target.
- **Handling schema changes** – You can prevent a crawlers from making any schema changes to the existing schema. You can use the Amazon Web Services Management Console or the Amazon Glue API to configure how your crawler processes certain types of changes.
- **A single schema for multiple Amazon S3 paths** – You can configure a crawler to create a single schema for each S3 path if the data is compatible.

- **Table location and partitioning levels** – The table level crawler option provides you the flexibility to tell the crawler where the tables are located, and how you want partitions created.
- **Table threshold** – You can specify the maximum number of tables the crawler is allowed to create by specifying a table threshold.
- **Amazon Lake Formation credentials** – You can configure a crawler to use Lake Formation credentials to access an Amazon S3 data store or a Data Catalog table with an underlying Amazon S3 location within the same Amazon Web Services account or another Amazon Web Services account.

For more information about using the Amazon Glue console to add a crawler, see [Configuring a crawler](#).

Topics

- [Scheduling incremental crawls for adding new partitions](#)
- [Generating partition indexes](#)
- [Preventing a crawler from changing an existing schema](#)
- [Creating a single schema for each Amazon S3 include path](#)
- [Specifying the table location and partitioning level](#)
- [Specifying the maximum number of tables the crawler is allowed to create](#)
- [Configuring a crawler to use Lake Formation credentials](#)
- [Accelerating crawls using Amazon S3 event notifications](#)

Scheduling incremental crawls for adding new partitions

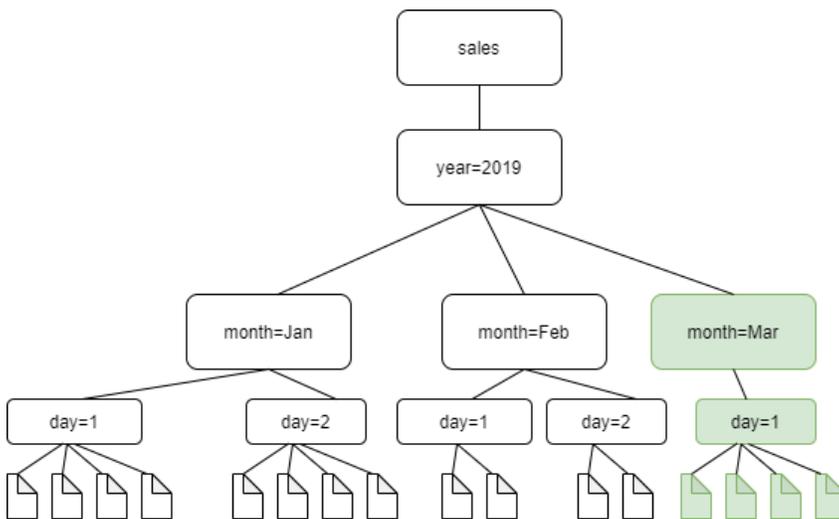

You can configure an Amazon Glue crawler run incremental crawls to add only new partitions to the table schema. When the crawler runs for the first time, it performs a full crawl to processes the entire data source to record the complete schema and all existing partitions in the Amazon Glue Data Catalog.

Subsequent crawls after the initial full crawl will be incremental, where the crawler identifies and adds only the new partitions that have been introduced since the previous crawl. This approach results in faster crawl times, as the crawler no longer needs to process the entire data source for each run, but instead focuses only on the new partitions.

Note

Incremental crawls don't detect modifications or deletions of existing partitions. This configuration is best suited for data sources with a stable schema. If a one-time major schema change occurs, it is advisable to temporarily set the crawler to perform a full crawl to capture the new schema accurately, and then switch back to incremental crawling mode.

The following diagram shows that with the incremental crawl setting enabled, the crawler will only detect and add the newly added folder, month=March, to the catalog.

Follow these steps to update your crawler to perform incremental crawls:

Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Crawlers** under the **Data Catalog**.
3. Choose a crawler that you want to set up to crawl incrementally.
4. Choose **Edit**.
5. Choose **Step 2. Choose data sources and classifiers**.
6. Choose the data source that you want to incrementally crawl.
7. Choose **Edit**.
8. Choose **Crawl new sub-folders only** under **Subsequent crawler runs**.
9. Choose **Update**.

To create a schedule for a crawler, see [the section called “Scheduling a crawler”](#).

Amazon CLI

```
aws glue update-crawler \  
  --name myCrawler \  
  --recrawl-policy RecrawlBehavior=CRAWL_NEW_FOLDERS_ONLY \  
  --schema-change-policy UpdateBehavior=LOG,DeleteBehavior=LOG
```

Notes and restrictions

When this option is turned on, you can't change the Amazon S3 target data stores when editing the crawler. This option affects certain crawler configuration settings. When turned on, it forces the update behavior and delete behavior of the crawler to LOG. This means that:

- If it discovers objects where schemas are not compatible, the crawler will not add the objects in the Data Catalog, and adds this detail as a log in CloudWatch Logs.
- It will not update deleted objects in the Data Catalog.

Generating partition indexes

The Data Catalog supports creating partition indexes to provide efficient lookup for specific partitions. For more information, see [Creating partition indexes](#). The Amazon Glue crawler creates partition indexes for Amazon S3 and Delta Lake targets by default.

Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Crawlers** under the **Data Catalog**.
3. When you define a crawler, the option to **Create partition indexes automatically** is enabled by default under **Advanced options** on the **Set output and scheduling** page.

To disable this option, you can unselect the checkbox **Create partition indexes automatically** in the console.

4. Complete the crawler configuration and choose **Create crawler**.

Amazon CLI

You can also disable this option by using the Amazon CLI, set the `CreatePartitionIndex` in the configuration parameter. The default value is true.

```
aws glue update-crawler \  
  --name myCrawler \  
  --configuration '{"Version": 1.0, "CreatePartitionIndex": false }'
```

Usage notes for partition indexes

- Tables created by the crawler do not have the variable `partition_filtering.enabled` by default. For more information, see [Amazon Glue partition indexing and filtering](#).
- Creating partition indexes for encrypted partitions is not supported.

Preventing a crawler from changing an existing schema

You can prevent Amazon Glue crawlers from making any schema changes to the Data Catalog when they run. By default, crawlers updates the schema in the Data Catalog to match the data source being crawled. However, in some cases, you may want to prevent the Crawler from modifying the existing schema, especially if you have transformed or cleaned the data and don't want the original schema to overwrite the changes.

Follow these steps to configure your crawler not to overwrite the existing schema in a table definition.

Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Crawlers** under the **Data Catalog**.
3. Choose a crawler from the list, and choose **Edit**.
4. Choose **step 4, Set output and scheduling**.
5. Under **Advance options**, choose **Add new columns only** or **Ignore the change and don't update the table in the Data Catalog**.
6. You can also set a configuration option to **Update all new and existing partitions with metadata from the table**. This sets partition schemas to inherit from the table.

7. Choose **Update**.

Amazon CLI

The following example shows how to configure a crawler to not change existing schema, only add new columns:

```
aws glue update-crawler \  
  --name myCrawler \  
  --configuration '{"Version": 1.0, "CrawlerOutput": {"Tables":  
{"AddOrUpdateBehavior": "MergeNewColumns"}}}'
```

The following example shows how to configure a crawler to not change the existing schema, and not add new columns:

```
aws glue update-crawler \  
  --name myCrawler \  
  --schema-change-policy UpdateBehavior=LOG \  
  --configuration '{"Version": 1.0, "CrawlerOutput": {"Partitions":  
{ "AddOrUpdateBehavior": "InheritFromTable" }}}'
```

API

If you don't want a table schema to change at all when a crawler runs, set the schema change policy to LOG.

When you configure the crawler using the API, set the following parameters:

- Set the `UpdateBehavior` field in `SchemaChangePolicy` structure to LOG.
- Set the `Configuration` field with a string representation of the following JSON object in the crawler API; for example:

```
{  
  "Version": 1.0,  
  "CrawlerOutput": {  
    "Partitions": { "AddOrUpdateBehavior": "InheritFromTable" }  
  }  
}
```

Creating a single schema for each Amazon S3 include path

By default, when a crawler defines tables for data stored in Amazon S3, it considers both data compatibility and schema similarity. Data compatibility factors that it considers include whether the data is of the same format (for example, JSON), the same compression type (for example, GZIP), the structure of the Amazon S3 path, and other data attributes. Schema similarity is a measure of how closely the schemas of separate Amazon S3 objects are similar.

To help illustrate this option, suppose that you define a crawler with an include path `s3://amzn-s3-demo-bucket/table1/`. When the crawler runs, it finds two JSON files with the following characteristics:

- **File 1** – `S3://amzn-s3-demo-bucket/table1/year=2017/data1.json`
- *File content* – `{"A": 1, "B": 2}`
- *Schema* – `A:int, B:int`

- **File 2** – `S3://amzn-s3-demo-bucket/table1/year=2018/data2.json`
- *File content* – `{"C": 3, "D": 4}`
- *Schema* – `C: int, D: int`

By default, the crawler creates two tables, named `year_2017` and `year_2018` because the schemas are not sufficiently similar. However, if the option **Create a single schema for each S3 path** is selected, and if the data is compatible, the crawler creates one table. The table has the schema `A:int,B:int,C:int,D:int` and `partitionKey year:string`.

Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Crawlers** under the **Data Catalog**.
3. When you configure a new crawler, under **Output and scheduling**, select the option **Create a single schema for each S3 path** under Advance options.

Amazon CLI

You can configure a crawler to `CombineCompatibleSchemas` into a common table definition when possible. With this option, the crawler still considers data compatibility, but ignores the

similarity of the specific schemas when evaluating Amazon S3 objects in the specified include path.

When you configure the crawler using the Amazon CLI, set the following configuration option:

```
aws glue update-crawler \  
  --name myCrawler \  
  --configuration '{"Version": 1.0, "Grouping": {"TableGroupingPolicy":  
  "CombineCompatibleSchemas" }}'
```

API

When you configure the crawler using the API, set the following configuration option:

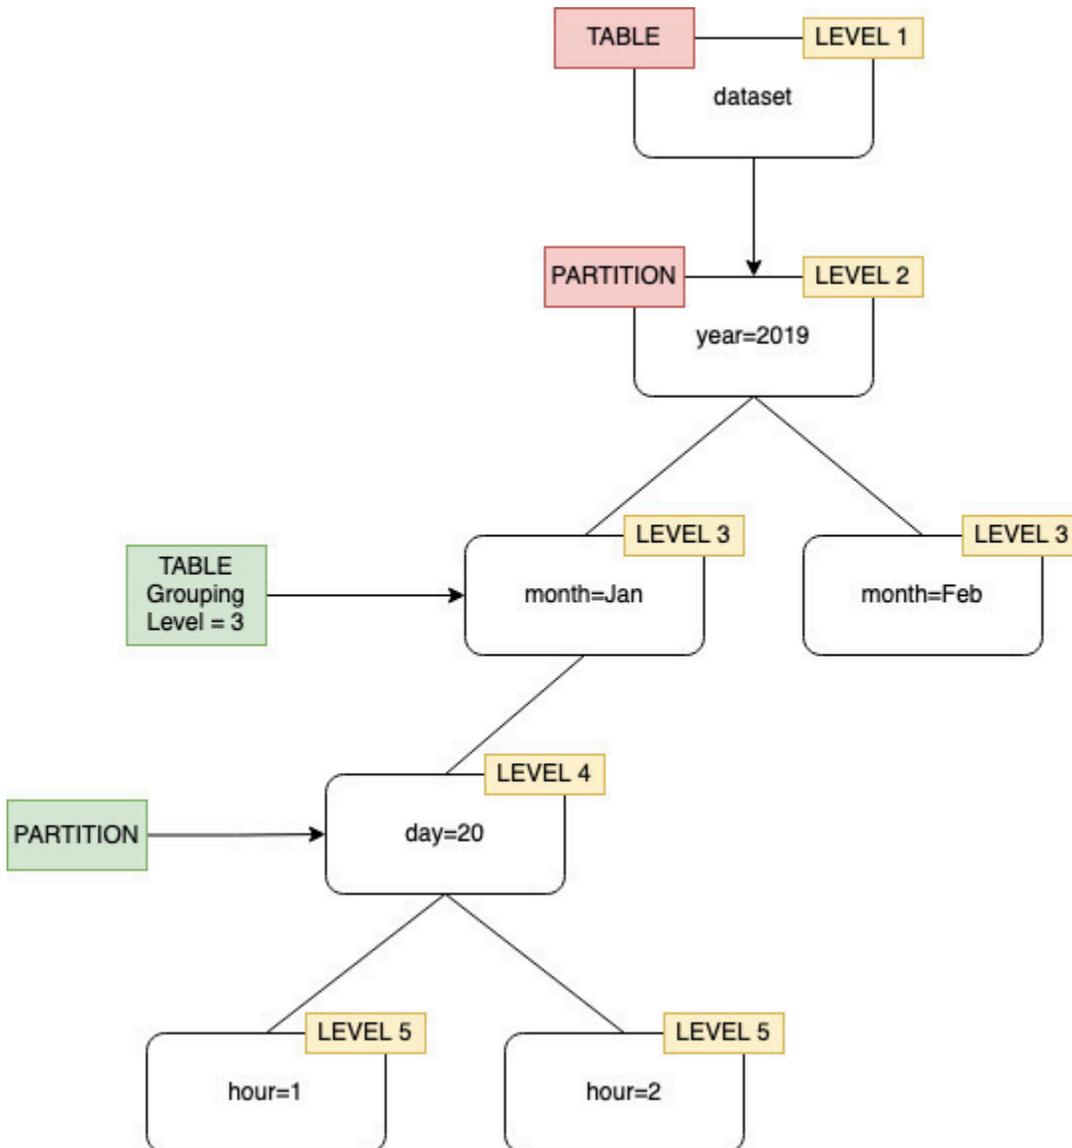

Set the `Configuration` field with a string representation of the following JSON object in the crawler API; for example:

```
{  
  "Version": 1.0,  
  "Grouping": {  
    "TableGroupingPolicy": "CombineCompatibleSchemas" }  
}
```

Specifying the table location and partitioning level

By default, when a crawler defines tables for data stored in Amazon S3 the crawler attempts to merge schemas together, and create top-level tables (`year=2019`). In some cases, you may expect the crawler to create a table for the folder `month=Jan` but instead the crawler creates a partition since a sibling folder (`month=Mar`) was merged into the same table.

The table level crawler option provides you the flexibility to tell the crawler where the tables are located, and how you want partitions created. When you specify a **Table level**, the table is created at that absolute level from the Amazon S3 bucket.

When configuring the crawler on the console, you can specify a value for the **Table level** crawler option. The value must be a positive integer that indicates the table location (the absolute level in the dataset). The level for the top level folder is 1. For example, for the path `mydataset/year/month/day/hour`, if the level is set to 3, the table is created at location `mydataset/year/month`.

Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Crawlers** under the **Data Catalog**.

- When you configure a crawler, under **Output and scheduling**, choose **Table level** under **Advance options**.

Step 1
Set crawler properties

Step 2
Choose data sources and classifiers

Step 3
Configure security settings

Step 4
Set output and scheduling

Step 5
Review and create

Set output and scheduling

Output configuration

Target database
0-test-catalog

Clear selection Add database

Table name prefix - *optional*
Type a prefix added to table names

Maximum table threshold - *optional*
This field sets the maximum number of tables the crawler is allowed to generate. In the event that this number is surpassed, the crawl will fail with an error. If not set, the crawler will automatically generate the number of tables depending on the data schema.
Type a number greater than 0

Advanced options

S3 schema grouping

Create a single schema for each S3 path
By default, when a crawler defines tables for data stored in S3, it considers both data compatibility and schema similarity. Select this check box to group compatible schemas into a single table definition across all S3 objects under the provided include path. Other criteria will still be considered to determine proper grouping.

Table level - *optional*
The value must be a positive integer that indicates table location (the absolute level in the dataset). The level for the top level folder is 1. For example, for the path mydataset/a/b, if the level is set to 3, the table is created at location mydataset/a/b.

3

Amazon CLI

When you configure the crawler using the Amazon CLI, set the configuration parameter as shown in the example code:

```
aws glue update-crawler \
  --name myCrawler \
  --configuration '{"Version": 1.0, "Grouping": { "TableLevelConfiguration": 2 } }'
```

API

When you configure the crawler using the API, set the Configuration field with a string representation of the following JSON object; for example:

```
configuration = jsonencode(
{
  "Version": 1.0,
```

```
"Grouping": {
    TableLevelConfiguration = 2
}
})
```

CloudFormation

In this example, you set the **Table level** option available in the console within your CloudFormation template:

```
"Configuration": "{
  \"Version\":1.0,
  \"Grouping\":{\"TableLevelConfiguration\":2}
}"
```

Specifying the maximum number of tables the crawler is allowed to create

You can optionally specify the maximum number of tables the crawler is allowed to create by specifying a `TableThreshold` via the Amazon Glue console or Amazon CLI. If the tables detected by the crawler during its crawl is greater than this input value, the crawl fails and no data is written to the Data Catalog.

This parameter is useful when the tables that would be detected and created by the crawler are much greater more than what you expect. There can be multiple reasons for this, such as:

- When using an Amazon Glue job to populate your Amazon S3 locations you can end up with empty files at the same level as a folder. In such cases when you run a crawler on this Amazon S3 location, the crawler creates multiple tables due to files and folders present at the same level.
- If you do not configure `"TableGroupingPolicy": "CombineCompatibleSchemas"` you may end up with more tables than expected.

You specify the `TableThreshold` as an integer value greater than 0. This value is configured on a per crawler basis. That is, for every crawl this value is considered. For example: a crawler has the `TableThreshold` value set as 5. In each crawl Amazon Glue compares the number of tables detected with this table threshold value (5) and if the number of tables detected is less than 5, Amazon Glue writes the tables to the Data Catalog and if not, the crawl fails without writing to the Data Catalog.

Amazon Web Services Management Console

To set `TableThreshold` using the Amazon Web Services Management Console:

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. When configuring a crawler, in **Output and scheduling**, set the **Maximum table threshold** to the number of tables the crawler is allowed generate.

Set output and scheduling

Output configuration Info

Target database

Table name prefix - optional

Maximum table threshold - optional
This field sets the maximum number of tables the crawler is allowed to generate. In the event that this number is surpassed, the crawl will fail with an error. If not set, the crawler will automatically generate the number of tables depending on the data schema.

[▶ Advanced options](#)

Amazon CLI

To set `TableThreshold` using the Amazon CLI:

```
aws glue update-crawler \
  --name myCrawler \
  --configuration '{"Version": 1.0, "CrawlerOutput": {"Tables":
  { "TableThreshold": 5 }}}'
```

API

To set `TableThreshold` using the API:

```
"{"Version":1.0,
"CrawlerOutput":
{"Tables":{"AddOrUpdateBehavior":"MergeNewColumns",
"TableThreshold":5}}};"
```

Error messages are logged to help you identify table paths and clean-up your data. Example log in your account if the crawler fails because the table count was greater than table threshold value provided:

```
Table Threshold value = 28, Tables detected - 29
```

In CloudWatch, we log all table locations detected as an INFO message. An error is logged as the reason for the failure.

```
ERROR com.amazonaws.services.glue.customerLogs.CustomerLogService - CustomerLogService
received CustomerFacingException with message
The number of tables detected by crawler: 29 is greater than the table threshold value
provided: 28. Failing crawler without writing to Data Catalog.
com.amazonaws.services.glue.exceptions.CustomerFacingInternalException: The number of
tables detected by crawler: 29 is greater than the table threshold value provided:
28.
Failing crawler without writing to Data Catalog.
```

Configuring a crawler to use Lake Formation credentials

You can configure a crawler to use Amazon Lake Formation credentials to access an Amazon S3 data store or a Data Catalog table with an underlying Amazon S3 location within the same Amazon Web Services account or another Amazon Web Services account. You can configure an existing Data Catalog table as a crawler's target, if the crawler and the Data Catalog table reside in the same account. Currently, only a single catalog target with a single catalog table is allowed when using a Data Catalog table as a crawler's target.

Note

When you are defining a Data Catalog table as a crawler target, make sure that the underlying location of the Data Catalog table is an Amazon S3 location. Crawlers that use Lake Formation credentials only support Data Catalog targets with underlying Amazon S3 locations.

Setup required when the crawler and registered Amazon S3 location or Data Catalog table reside in the same account (in-account crawling)

To allow the crawler to access a data store or Data Catalog table by using Lake Formation credentials, you need to register the data location with Lake Formation. Also, the crawler's IAM role must have permissions to read the data from the destination where the Amazon S3 bucket is registered.

You can complete the following configuration steps using the Amazon Web Services Management Console or Amazon Command Line Interface (Amazon CLI).

Amazon Web Services Management Console

1. Before configuring a crawler to access the crawler source, register the data location of the data store or the Data Catalog with Lake Formation. In the Lake Formation console (<https://console.amazonaws.cn/lakeformation/>), register an Amazon S3 location as the root location of your data lake in the Amazon Web Services account where the crawler is defined. For more information, see [Registering an Amazon S3 location](#).
2. Grant **Data location** permissions to the IAM role that's used for the crawler run so that the crawler can read the data from the destination in Lake Formation. For more information, see [Granting data location permissions \(same account\)](#).
3. Grant the crawler role access permissions (Create) to the database, which is specified as the output database. For more information, see [Granting database permissions using the Lake Formation console and the named resource method](#).
4. In the IAM console (<https://console.amazonaws.cn/iam/>), create an IAM role for the crawler. Add the `lakeformation:GetDataAccess` policy to the role.
5. In the Amazon Glue console (<https://console.amazonaws.cn/glue/>), while configuring the crawler, select the option **Use Lake Formation credentials for crawling Amazon S3 data source**.

Note

The `accountId` field is optional for in-account crawling.

Amazon CLI

```
aws glue --profile demo create-crawler --debug --cli-input-json '{
  "Name": "prod-test-crawler",
  "Role": "arn:aws:iam::111122223333:role/service-role/AWSGlueServiceRole-prod-
test-run-role",
  "DatabaseName": "prod-run-db",
  "Description": "",
  "Targets": {
  "S3Targets": [
    {
```

```

        "Path": "s3://amzn-s3-demo-bucket"
    }
]
},
"SchemaChangePolicy": {
    "UpdateBehavior": "LOG",
    "DeleteBehavior": "LOG"
},
"RecrawlPolicy": {
    "RecrawlBehavior": "CRAWL_EVERYTHING"
},
"LineageConfiguration": {
    "CrawlerLineageSettings": "DISABLE"
},
"LakeFormationConfiguration": {
    "UseLakeFormationCredentials": true,
    "AccountId": "111122223333"
},
"Configuration": {
    "Version": 1.0,
    "CrawlerOutput": {
        "Partitions": { "AddOrUpdateBehavior": "InheritFromTable" },
        "Tables": { "AddOrUpdateBehavior": "MergeNewColumns" }
    },
    "Grouping": { "TableGroupingPolicy": "CombineCompatibleSchemas" }
},
"CrawlerSecurityConfiguration": "",
"Tags": {
    "KeyName": ""
}
}'

```

Setup required when the crawler and registered Amazon S3 location reside in different accounts (cross-account crawling)

To allow the crawler to access a data store in a different account using Lake Formation credentials, you must first register the Amazon S3 data location with Lake Formation. Then, you grant data location permissions to the crawler's account by taking the following steps.

You can complete the following steps using the Amazon Web Services Management Console or Amazon CLI.

Amazon Web Services Management Console

1. In the account where the Amazon S3 location is registered (account B):
 - a. Register an Amazon S3 path with Lake Formation. For more information, see [Registering Amazon S3 location](#).
 - b. Grant **Data location** permissions to the account (account A) where the crawler will be run. For more information, see [Grant data location permissions](#).
 - c. Create an empty database in Lake Formation with the underlying location as the target Amazon S3 location. For more information, see [Creating a database](#).
 - d. Grant account A (the account where the crawler will be run) access to the database that you created in the previous step. For more information, see [Granting database permissions](#).
2. In the account where the crawler is created and will be run (account A):
 - a. Using the Amazon RAM console, accept the database that was shared from the external account (account B). For more information, see [Accepting a resource share invitation from Amazon Resource Access Manager](#).
 - b. Create an IAM role for the crawler. Add `lakeformation:GetDataAccess` policy to the role.
 - c. In the Lake Formation console (<https://console.amazonaws.cn/lakeformation/>), grant **Data location** permissions on the target Amazon S3 location to the IAM role used for the crawler run so that the crawler can read the data from the destination in Lake Formation. For more information, see [Granting data location permissions](#).
 - d. Create a resource link on the shared database. For more information, see [Create a resource link](#).
 - e. Grant the crawler role access permissions (`Create`) on the shared database and (`Describe`) the resource link. The resource link is specified in the output for the crawler.
 - f. In the Amazon Glue console (<https://console.amazonaws.cn/glue/>), while configuring the crawler, select the option **Use Lake Formation credentials for crawling Amazon S3 data source**.

For cross-account crawling, specify the Amazon Web Services account ID where the target Amazon S3 location is registered with Lake Formation. For in-account crawling, the `accountId` field is optional.

Step 1

  "KeyName": ""
}
}'

```

Note

- A crawler using Lake Formation credentials is only supported for Amazon S3 and Data Catalog targets.
- For targets using Lake Formation credential vending, the underlying Amazon S3 locations must belong to the same bucket. For example, customers can use multiple targets (`s3://amzn-s3-demo-bucket1/folder1`, `s3://amzn-s3-demo-bucket1/folder2`) as long as all target locations are under the same bucket (`amzn-s3-demo-bucket1`). Specifying different buckets (`s3://amzn-s3-demo-bucket1/folder1`, `s3://amzn-s3-demo-bucket2/folder2`) is not allowed.
- Currently for Data Catalog target crawlers, only a single catalog target with a single catalog table is allowed.

Accelerating crawls using Amazon S3 event notifications

Instead of listing the objects from an Amazon S3 or Data Catalog target, you can configure the crawler to use Amazon S3 events to find any changes. This feature improves the recrawl time by

using Amazon S3 events to identify the changes between two crawls by listing all the files from the subfolder which triggered the event instead of listing the full Amazon S3 or Data Catalog target.

The first crawl lists all Amazon S3 objects from the target. After the first successful crawl, you can choose to recrawl manually or on a set schedule. The crawler will list only the objects from those events instead of listing all objects.

When the target is a Data Catalog table, the crawler updates the existing tables in the Data Catalog with changes (for example, extra partitions in a table).

The advantages of moving to an Amazon S3 event based crawler are:

- A faster recrawl as the listing of all the objects from the target is not required, instead the listing of specific folders is done where objects are added or deleted.
- A reduction in the overall crawl cost as the listing of specific folders is done where objects are added or deleted.

The Amazon S3 event crawl runs by consuming Amazon S3 events from the SQS queue based on the crawler schedule. There will be no cost if there are no events in the queue. Amazon S3 events can be configured to go directly to the SQS queue or in cases where multiple consumers need the same event, a combination of SNS and SQS. For more information, see [the section called "Setting up your account for Amazon S3 event notifications"](#).

After creating and configuring the crawler in event mode, the first crawl runs in listing mode by performing full a listing of the Amazon S3 or Data Catalog target. The following log confirms the operation of the crawl by consuming Amazon S3 events after the first successful crawl: "The crawl is running by consuming Amazon S3 events."

After creating the Amazon S3 event crawl and updating the crawler properties which may impact the crawl, the crawl operates in list mode and the following log is added: "Crawl is not running in S3 event mode".

 **Note**

The maximum number of messages to consume is 100,000 messages per crawl.

Considerations and limitations

The following considerations and limitations apply when you configure a crawler to use Amazon S3 event notifications to find any changes.

- **Important behavior with deleted partitions**

When using Amazon S3 event crawlers with Data Catalog tables:

- If you delete a partition using the `DeletePartition` API call, you must also delete all S3 objects under that partition, and select **All object removal events** when you configure your S3 event notifications. If deletion events are not configured, the crawler recreates the deleted partition during its next run.
- Only a single target is supported by the crawler, whether for Amazon S3 or Data Catalog targets.
- SQS on private VPC is not supported.
- Amazon S3 sampling is not supported.
- The crawler target should be a folder for an Amazon S3 target, or one or more Amazon Glue Data Catalog tables for a Data Catalog target.
- The 'everything' path wildcard is not supported: `s3://%`
- For a Data Catalog target, all catalog tables should point to same Amazon S3 bucket for Amazon S3 event mode.
- For a Data Catalog target, a catalog table should not point to an Amazon S3 location in the Delta Lake format (containing `_symlink` folders, or checking the catalog table's `InputFormat`).

Topics

- [Setting up a crawler for Amazon S3 event notifications for an Amazon S3 target](#)
- [Setting up a crawler for Amazon S3 event notifications for a Data Catalog table](#)

Setting up your account for Amazon S3 event notifications

Complete the following setup tasks. Note the values in parenthesis reference the configurable settings from the script.

1. You need to set up event notifications for your Amazon S3 bucket.

For more information, see [Amazon S3 event notifications](#).

2. To use the Amazon S3 event based crawler, you should enable event notification on the Amazon S3 bucket with events filtered from the prefix which is the same as the S3 target and store in SQS. You can set up SQS and event notification through the console by following the steps in [Walkthrough: Configuring a bucket for notifications](#).
3. Add the following SQS policy to the role used by the crawler.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "sqs:DeleteMessage",
        "sqs:GetQueueUrl",
        "sqs:ListDeadLetterSourceQueues",
        "sqs:ReceiveMessage",
        "sqs:GetQueueAttributes",
        "sqs:ListQueueTags",
        "sqs:SetQueueAttributes",
        "sqs:PurgeQueue"
      ],
      "Resource": "arn:aws:sqs:us-east-1:111122223333:cfn-sqs-queue"
    }
  ]
}
```

Setting up a crawler for Amazon S3 event notifications for an Amazon S3 target

Follow these steps to set up a crawler for Amazon S3 event notifications for an Amazon S3 target using the Amazon Web Services Management Console or Amazon CLI.

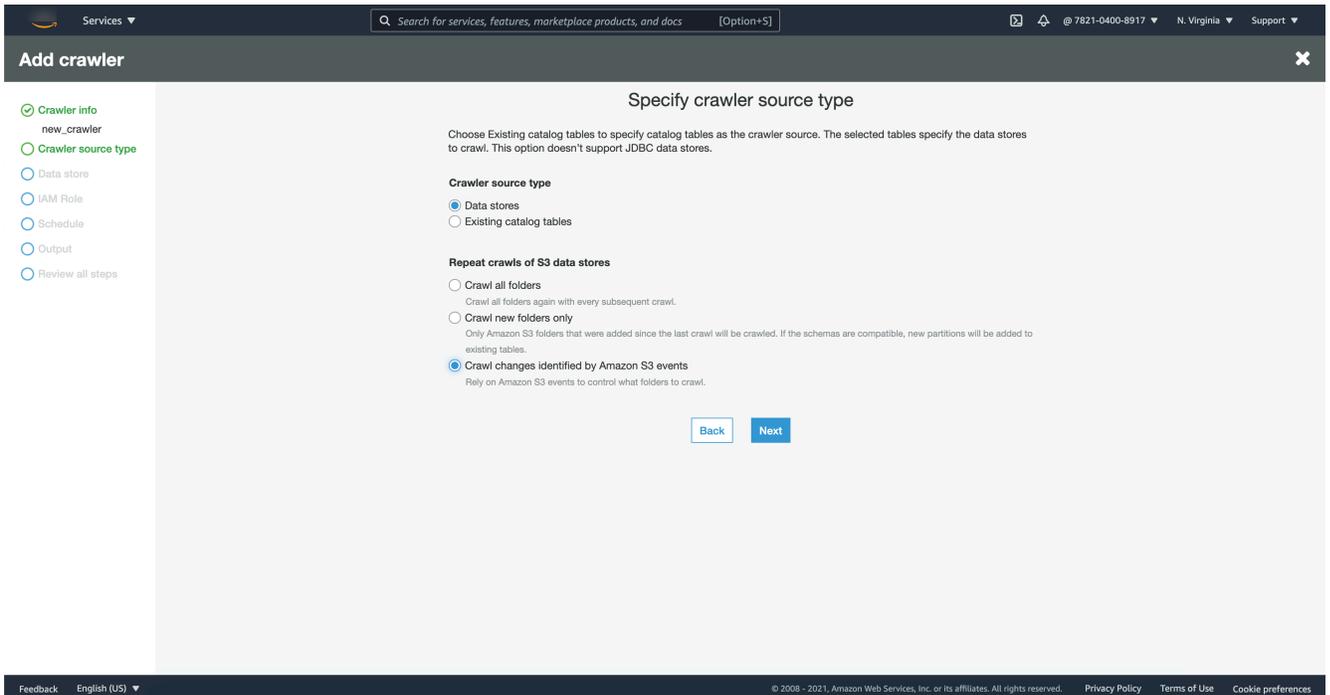

Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the GuardDuty console at <https://console.amazonaws.cn/guardduty/>.
2. Set your crawler properties. For more information, see [Setting Crawler Configuration Options on the Amazon Glue console](#).

3. In the section **Data source configuration**, you are asked *Is your data already mapped to Amazon Glue tables?*

By default **Not yet** is already selected. Leave this as the default as you are using an Amazon S3 data source and the data is not already mapped to Amazon Glue tables.

4. In the section **Data sources**, choose **Add a data source**.

5. In the **Add data source** modal, configure the Amazon S3 data source:
 - **Data source:** By default, Amazon S3 is selected.
 - **Network connection (Optional):** Choose **Add new connection**.
 - **Location of Amazon S3 data:** By default, **In this account** is selected.
 - **Amazon S3 path:** Specify the Amazon S3 path where folders and files are crawled.
 - **Subsequent crawler runs:** Choose **Crawl based on events** to use Amazon S3 event notifications for your crawler.
 - **Include SQS ARN:** Specify the data store parameters including the a valid SQS ARN. (For example, `arn:aws:sqs:region:account:sqs`).
 - **Include dead-letter SQS ARN (Optional):** Specify a valid Amazon dead-letter SQS ARN. (For example, `arn:aws:sqs:region:account:deadLetterQueue`).
 - Choose **Add an Amazon S3 data source**.

Amazon CLI

The following is an example Amazon S3 Amazon CLI call to configure a crawler to use event notifications to crawl an Amazon S3 target bucket.

```
Create Crawler:
aws glue update-crawler \
  --name myCrawler \
  --recrawl-policy RecrawlBehavior=CRAWL_EVENT_MODE \
  --schema-change-policy UpdateBehavior=UPDATE_IN_DATABASE,DeleteBehavior=LOG
  --targets '{"S3Targets":[{"Path":"s3://amzn-s3-demo-bucket/", "EventQueueArn":
"arn:aws:sqs:us-east-1:012345678910:MyQueue"}]}'
```

Setting up a crawler for Amazon S3 event notifications for a Data Catalog table

When you have a Data Catalog table, set up a crawler for Amazon S3 event notifications using the Amazon Glue console:

1. Set your crawler properties. For more information, see [Setting Crawler Configuration Options on the Amazon Glue console](#).
2. In the section **Data source configuration**, you are asked *Is your data already mapped to Amazon Glue tables?*

Select **Yes** to select existing tables from your Data Catalog as your data source.

3. In the section **Glue tables**, choose **Add tables**.

4. In the **Add table** modal, configure the database and tables:
 - **Network connection** (Optional): Choose **Add new connection**.
 - **Database**: Select a database in the Data Catalog.
 - **Tables**: Select one or more tables from that database in the Data Catalog.
 - **Subsequent crawler runs**: Choose **Crawl based on events** to use Amazon S3 event notifications for your crawler.
 - **Include SQS ARN**: Specify the data store parameters including the a valid SQS ARN. (For example, `arn:aws:sqs:region:account:sqs`).
 - **Include dead-letter SQS ARN** (Optional): Specify a valid Amazon dead-letter SQS ARN. (For example, `arn:aws:sqs:region:account:deadLetterQueue`).
 - Choose **Confirm**.

Add Glue tables ✕

Network connection - optional
Optionally include a Network connection to use with this Catalog target. Note that only one Catalog target is allowed for Catalog Crawlers with a VPC connection.

↕ ↻

Database
Select a Glue Catalog database

↕ ↻

Tables
Select one or more Glue Catalog Tables

↕ ↻

Subsequent crawler runs
This field is a global field that affects all glue table sources.

Crawl all sub-folders
Crawl all folders again with every subsequent crawl.

Crawl based on events
Rely on Amazon S3 events to control what folders to crawl.

Include SQS ARN
Specify the SQS ARN to use for identifying changes to crawl.

SQS ARN must follow the following syntax: arn:aws:sqs:region:account:sqs

Include dead-letter SQS ARN - optional
Optionally specify a corresponding Dead-letter SQS ARN for unprocessed messages.

Dead-letter SQS ARN must follow the following syntax:
arn:aws:sqs:region:account:deadLetterQueue

Tutorial: Adding an Amazon Glue crawler

For this Amazon Glue scenario, you're asked to analyze arrival data for major air carriers to calculate the popularity of departure airports month over month. You have flights data for the year 2016 in CSV format stored in Amazon S3. Before you transform and analyze your data, you catalog its metadata in the Amazon Glue Data Catalog.

In this tutorial, let's add a crawler that infers metadata from these flight logs in Amazon S3 and creates a table in your Data Catalog.

Topics

- [Prerequisites](#)
- [Step 1: Add a crawler](#)
- [Step 2: Run the crawler](#)
- [Step 3: View Amazon Glue Data Catalog objects](#)

Prerequisites

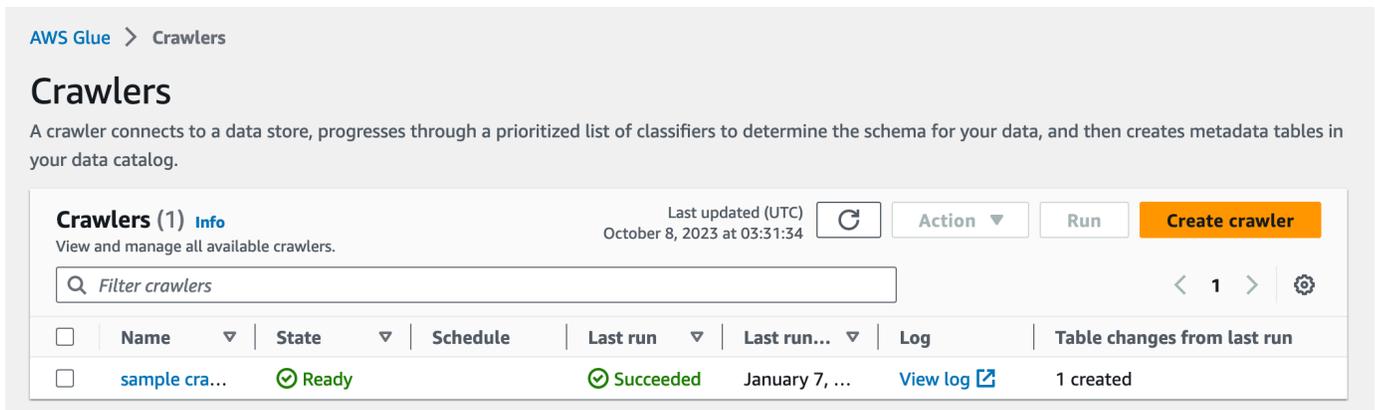

This tutorial assumes that you have an Amazon account and access to Amazon Glue.

Step 1: Add a crawler

Use these steps to configure and run a crawler that extracts the metadata from a CSV file stored in Amazon S3.

To create a crawler that reads files stored on Amazon S3

1. On the Amazon Glue service console, on the left-side menu, choose **Crawlers**.
2. On the Crawlers page, choose **Create crawler**. This starts a series of pages that prompt you for the crawler details.

The screenshot shows the AWS Glue console interface for the 'Crawlers' page. At the top, there is a breadcrumb 'AWS Glue > Crawlers' and a title 'Crawlers'. Below the title is a description: 'A crawler connects to a data store, progresses through a prioritized list of classifiers to determine the schema for your data, and then creates metadata tables in your data catalog.' The main content area features a summary for 'Crawlers (1) Info' with a refresh button and an 'Action' dropdown. A search bar labeled 'Filter crawlers' is present. Below this is a table with columns: Name, State, Schedule, Last run, Last run..., Log, and Table changes from last run. One crawler is listed with the name 'sample cra...', state 'Ready', and a last run status of 'Succeeded' on January 7, ... with a 'View log' link and '1 created' table changes.

3. In the Crawler name field, enter **Flights Data Crawler**, and choose **Next**.

Crawlers invoke classifiers to infer the schema of your data. This tutorial uses the built-in classifier for CSV by default.

4. For the crawler source type, choose **Data stores** and choose **Next**.
5. Now let's point the crawler to your data. On the **Add a data store** page, choose the Amazon S3 data store. This tutorial doesn't use a connection, so leave the **Connection** field blank if it's visible.

For the option **Crawl data in**, choose **Specified path in another account**. Then, for the **Include path**, enter the path where the crawler can find the flights data, which is **s3://crawler-public-us-east-1/flight/2016/csv**. After you enter the path, the title of this field changes to **Include path**. Choose **Next**.

6. You can crawl multiple data stores with a single crawler. However, in this tutorial, we're using only a single data store, so choose **No**, and then choose **Next**.
7. The crawler needs permissions to access the data store and create objects in the Amazon Glue Data Catalog. To configure these permissions, choose **Create an IAM role**. The IAM role name starts with `AWSGlueServiceRole-`, and in the field, you enter the last part of the role name. Enter **CrawlerTutorial**, and then choose **Next**.

 **Note**

To create an IAM role, your AWS user must have `CreateRole`, `CreatePolicy`, and `AttachRolePolicy` permissions.

The wizard creates an IAM role named `AWSGlueServiceRole-CrawlerTutorial`, attaches the Amazon managed policy `AWSGlueServiceRole` to this role, and adds an inline policy that allows read access to the Amazon S3 location `s3://crawler-public-us-east-1/flight/2016/csv`.

8. Create a schedule for the crawler. For **Frequency**, choose **Run on demand**, and then choose **Next**.
9. Crawlers create tables in your Data Catalog. Tables are contained in a database in the Data Catalog. First, choose **Add database** to create a database. In the pop-up window, enter **test-flights-db** for the database name, and then choose **Create**.

Next, enter **flights** for **Prefix added to tables**. Use the default values for the rest of the options, and choose **Next**.

10. Verify the choices you made in the **Add crawler** wizard. If you see any mistakes, you can choose **Back** to return to previous pages and make changes.

After you have reviewed the information, choose **Finish** to create the crawler.

Step 2: Run the crawler

After creating a crawler, the wizard sends you to the Crawlers view page. Because you create the crawler with an on-demand schedule, you're given the option to run the crawler.

To run the crawler

1. The banner near the top of this page lets you know that the crawler was created, and asks if you want to run it now. Choose **Run it now?** to run the crawler.

The banner changes to show "Attempting to run" and "Running" messages for your crawler. After the crawler starts running, the banner disappears, and the crawler display is updated to show a status of Starting for your crawler. After a minute, you can click the Refresh icon to update the status of the crawler that is displayed in the table.

2. When the crawler completes, a new banner appears that describes the changes made by the crawler. You can choose the **test-flights-db** link to view the Data Catalog objects.

Step 3: View Amazon Glue Data Catalog objects

The crawler reads data at the source location and creates tables in the Data Catalog. A table is the metadata definition that represents your data, including its schema. The tables in the Data Catalog do not contain data. Instead, you use these tables as a source or target in a job definition.

To view the Data Catalog objects created by the crawler

1. In the left-side navigation, under **Data catalog**, choose **Databases**. Here you can view the `flights-db` database that is created by the crawler.
2. In the left-side navigation, under **Data catalog** and below **Databases**, choose **Tables**. Here you can view the `flightscsv` table created by the crawler. If you choose the table name, then you can view the table settings, parameters, and properties. Scrolling down in this view, you can view the schema, which is information about the columns and data types of the table.
3. If you choose **View partitions** on the table view page, you can see the partitions created for the data. The first column is the partition key.

Defining metadata manually

The Amazon Glue Data Catalog is a central repository that stores metadata about your data sources and data sets. While a crawler can automatically crawl and populate metadata for

supported data sources, there are certain scenarios where you may need to define metadata manually in the Data Catalog:

- **Unsupported data formats** – If you have data sources that are not supported by the crawler, you need to manually define the metadata for those data sources in the Data Catalog.
- **Custom metadata requirements** – The Amazon Glue crawler infers metadata based on predefined rules and conventions. If you have specific metadata requirements that are not covered by the Amazon Glue crawler inferred metadata, you can manually define the metadata to meet your needs
- **Data governance and standardization** – In some cases, you may want to have more control over the metadata definitions for data governance, compliance, or security reasons. Manually defining metadata allows you to ensure that the metadata adheres to your organization's standards and policies.
- **Placeholder for future data ingestion** – If you have data sources that are not immediately available or accessible, you can create empty schema tables as placeholders. Once the data sources become available, you can populate the tables with the actual data, while maintaining the predefined structure.

To define metadata manually, you can use the Amazon Glue console, Lake Formation console, Amazon Glue API, or the Amazon Command Line Interface (Amazon CLI). You can create databases, tables, and partitions, and specify metadata properties such as column names, data types, descriptions, and other attributes.

Creating databases

Databases are used to organize metadata tables in the Amazon Glue. When you define a table in the Amazon Glue Data Catalog, you add it to a database. A table can be in only one database.

Your database can contain tables that define data from many different data stores. This data can include objects in Amazon Simple Storage Service (Amazon S3) and relational tables in Amazon Relational Database Service.

Note

When you delete a database from the Amazon Glue Data Catalog, all the tables in the database are also deleted.

To view the list of databases, sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>. Choose **Databases**, and then choose a database name in the list to view the details.

From the **Databases** tab in the Amazon Glue console, you can add, edit, and delete databases:

- To create a new database, choose **Add database** and provide a name and description. For compatibility with other metadata stores, such as Apache Hive, the name is folded to lowercase characters.

Note

If you plan to access the database from Amazon Athena, then provide a name with only alphanumeric and underscore characters. For more information, see [Athena names](#).

- To edit the description for a database, select the check box next to the database name and choose **Edit**.
- To delete a database, select the check box next to the database name and choose **Remove**.
- To display the list of tables contained in the database, choose the database name and the database properties will display all tables in the database.

To change the database that a crawler writes to, you must change the crawler definition. For more information, see [Using crawlers to populate the Data Catalog](#).

Database resource links

The Amazon Glue console was recently updated. The current version of the console does not support Database Resource Links.

The Data Catalog can also contain *resource links* to databases. A database resource link is a link to a local or shared database. Currently, you can create resource links only in Amazon Lake Formation. After you create a resource link to a database, you can use the resource link name wherever you would use the database name. Along with databases that you own or that are shared with you, database resource links are returned by `glue:GetDatabases()` and appear as entries on the **Databases** page of the Amazon Glue console.

The Data Catalog can also contain table resource links.

For more information about resource links, see [Creating Resource Links](#) in the *Amazon Lake Formation Developer Guide*.

Creating tables

Even though running a crawler is the recommended method to take inventory of the data in your data stores, you can add metadata tables to the Amazon Glue Data Catalog manually. This approach allows you to have more control over the metadata definitions and customize them according to your specific requirements.

You can also add tables to the Data Catalog manually in the following ways:

- Use the Amazon Glue console to manually create a table in the Amazon Glue Data Catalog. For more information, see [Creating tables using the console](#).
- Use the CreateTable operation in the [Amazon Glue API](#) to create a table in the Amazon Glue Data Catalog. For more information, see [CreateTable action \(Python: create_table\)](#).
- Use Amazon CloudFormation templates. For more information, see [Amazon CloudFormation for Amazon Glue](#).

When you define a table manually using the console or an API, you specify the table schema and the value of a classification field that indicates the type and format of the data in the data source. If a crawler creates the table, the data format and schema are determined by either a built-in classifier or a custom classifier. For more information about creating a table using the Amazon Glue console, see [Creating tables using the console](#).

- [Data Catalog table properties](#)

Table partitions

An Amazon Glue table definition of an Amazon Simple Storage Service (Amazon S3) folder can describe a partitioned table. For example, to improve query performance, a partitioned table might

separate monthly data into different files using the name of the month as a key. In Amazon Glue, table definitions include the partitioning key of a table. When Amazon Glue evaluates the data in Amazon S3 folders to catalog a table, it determines whether an individual table or a partitioned table is added.

You can create partition indexes on a table to fetch a subset of the partitions instead of loading all the partitions in the table. For information about working with partition indexes, see [Creating partition indexes](#).

All the following conditions must be true for Amazon Glue to create a partitioned table for an Amazon S3 folder:

- The schemas of the files are similar, as determined by Amazon Glue.
- The data format of the files is the same.
- The compression format of the files is the same.

For example, you might own an Amazon S3 bucket named `my-app-bucket`, where you store both iOS and Android app sales data. The data is partitioned by year, month, and day. The data files for iOS and Android sales have the same schema, data format, and compression format. In the Amazon Glue Data Catalog, the Amazon Glue crawler creates one table definition with partitioning keys for year, month, and day.

The following Amazon S3 listing of `my-app-bucket` shows some of the partitions. The `=` symbol is used to assign partition key values.

```
my-app-bucket/Sales/year=2010/month=feb/day=1/iOS.csv
my-app-bucket/Sales/year=2010/month=feb/day=1/Android.csv
my-app-bucket/Sales/year=2010/month=feb/day=2/iOS.csv
my-app-bucket/Sales/year=2010/month=feb/day=2/Android.csv
...
my-app-bucket/Sales/year=2017/month=feb/day=4/iOS.csv
my-app-bucket/Sales/year=2017/month=feb/day=4/Android.csv
```

Table resource links

The Amazon Glue console was recently updated. The current version of the console does not support Table Resource Links.

The Data Catalog can also contain *resource links* to tables. A table resource link is a link to a local or shared table. Currently, you can create resource links only in Amazon Lake Formation. After you create a resource link to a table, you can use the resource link name wherever you would use the table name. Along with tables that you own or that are shared with you, table resource links are returned by `glue:GetTables()` and appear as entries on the **Tables** page of the Amazon Glue console.

The Data Catalog can also contain database resource links.

For more information about resource links, see [Creating Resource Links](#) in the *Amazon Lake Formation Developer Guide*.

Creating tables using the console

A table in the Amazon Glue Data Catalog is the metadata definition that represents the data in a data store. You create tables when you run a crawler, or you can create a table manually in the Amazon Glue console. The **Tables** list in the Amazon Glue console displays values of your table's metadata. You use table definitions to specify sources and targets when you create ETL (extract, transform, and load) jobs.

Note

With recent changes to the Amazon management console, you may need to modify your existing IAM roles to have the [SearchTables](#) permission. For new role creation, the `SearchTables` API permission has already been added as default.

To get started, sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>. Choose the **Tables** tab, and use the **Add tables** button to create tables either with a crawler or by manually typing attributes.

Adding tables on the console

To use a crawler to add tables, choose **Add tables, Add tables using a crawler**. Then follow the instructions in the **Add crawler** wizard. When the crawler runs, tables are added to the Amazon Glue Data Catalog. For more information, see [Using crawlers to populate the Data Catalog](#).

If you know the attributes that are required to create an Amazon Simple Storage Service (Amazon S3) table definition in your Data Catalog, you can create it with the table wizard. Choose **Add tables, Add table manually**, and follow the instructions in the **Add table** wizard.

When adding a table manually through the console, consider the following:

- If you plan to access the table from Amazon Athena, then provide a name with only alphanumeric and underscore characters. For more information, see [Athena names](#).
- The location of your source data must be an Amazon S3 path.
- The data format of the data must match one of the listed formats in the wizard. The corresponding classification, SerDe, and other table properties are automatically populated based on the format chosen. You can define tables with the following formats:

Avro

Apache Avro JSON binary format.

CSV

Character separated values. You also specify the delimiter of either comma, pipe, semicolon, tab, or Ctrl-A.

JSON

JavaScript Object Notation.

XML

Extensible Markup Language format. Specify the XML tag that defines a row in the data. Columns are defined within row tags.

Parquet

Apache Parquet columnar storage.

ORC

Optimized Row Columnar (ORC) file format. A format designed to efficiently store Hive data.

- You can define a partition key for the table.
- Currently, partitioned tables that you create with the console cannot be used in ETL jobs.

Table attributes

The following are some important attributes of your table:

Name

The name is determined when the table is created, and you can't change it. You refer to a table name in many Amazon Glue operations.

Database

The container object where your table resides. This object contains an organization of your tables that exists within the Amazon Glue Data Catalog and might differ from an organization in your data store. When you delete a database, all tables contained in the database are also deleted from the Data Catalog.

Description

The description of the table. You can write a description to help you understand the contents of the table.

Table format

Specify creating a standard Amazon Glue table, or a table in Apache Iceberg format.

The Data Catalog provides following table optimization options to manage table storage and improve query performance for Iceberg tables.

- **Compaction** – Data files are merged and rewritten remove obsolete data and consolidate fragmented data into larger, more efficient files.
- **Snapshot retention** – Snapshots are timestamped versions of an Iceberg table. Snapshot retention configurations allow customers to enforce how long to retain snapshots and how many snapshots to retain. Configuring a snapshot retention optimizer can help manage storage overhead by removing older, unnecessary snapshots and their associated underlying files.
- **Orphan file deletion** – Orphan files are files that are no longer referenced by the Iceberg table metadata. These files can accumulate over time, especially after operations like table deletions or failed ETL jobs. Enabling orphan file deletion allows Amazon Glue to periodically identify and remove these unnecessary files, freeing up storage.

For more information, see [Optimizing Iceberg tables](#).

Optimization configuration

You can either use the default settings or customize the settings for enabling the table optimizers.

IAM role

To run the table optimizers, the service assumes an IAM role on your behalf. You can choose an IAM role using the drop-down. Ensure that the role has the permissions required to enable compaction.

To learn more about the required permissions for the IAM role, see [Table optimization prerequisites](#).

Location

The pointer to the location of the data in a data store that this table definition represents.

Classification

A categorization value provided when the table was created. Typically, this is written when a crawler runs and specifies the format of the source data.

Last updated

The time and date (UTC) that this table was updated in the Data Catalog.

Date added

The time and date (UTC) that this table was added to the Data Catalog.

Deprecated

If Amazon Glue discovers that a table in the Data Catalog no longer exists in its original data store, it marks the table as deprecated in the data catalog. If you run a job that references a deprecated table, the job might fail. Edit jobs that reference deprecated tables to remove them as sources and targets. We recommend that you delete deprecated tables when they are no longer needed.

Connection

If Amazon Glue requires a connection to your data store, the name of the connection is associated with the table.

Viewing and managing table details

To see the details of an existing table, choose the table name in the list, and then choose **Action, View details**.

The table details include properties of your table and its schema. This view displays the schema of the table, including column names in the order defined for the table, data types, and key columns for partitions. If a column is a complex type, you can choose **View properties** to display details of the structure of that field, as shown in the following example:

```
{
  "StorageDescriptor":
    {
      "cols": {
        "FieldSchema": [
          {
            "name": "primary-1",
            "type": "CHAR",
            "comment": ""
          },
          {
            "name": "second ",
            "type": "STRING",
            "comment": ""
          }
        ]
      },
      "location": "s3://aws-logs-111122223333-us-east-1",
      "inputFormat": "",
      "outputFormat": "org.apache.hadoop.hive.q1.io.HiveIgnoreKeyTextOutputFormat",
      "compressed": "false",
      "numBuckets": "0",
      "SerDeInfo": {
        "name": "",
        "serializationLib": "org.apache.hadoop.hive.serde2.OpenCSVSerde",
        "parameters": {
          "separatorChar": "|"
        }
      },
      "bucketCols": [],
      "sortCols": [],
      "parameters": {},
      "SkewedInfo": {},
      "storedAsSubDirectories": "false"
    },
  "parameters": {
    "classification": "csv"
  }
}
```

```
}
```

For more information about the properties of a table, such as `StorageDescriptor`, see [StorageDescriptor structure](#).

To change the schema of a table, choose **Edit schema** to add and remove columns, change column names, and change data types.

To compare different versions of a table, including its schema, choose **Compare versions** to see a side-by-side comparison of two versions of the schema for a table. For more information, see [Comparing table schema versions](#).

To display the files that make up an Amazon S3 partition, choose **View partition**. For Amazon S3 tables, the **Key** column displays the partition keys that are used to partition the table in the source data store. Partitioning is a way to divide a table into related parts based on the values of a key column, such as date, location, or department. For more information about partitions, search the internet for information about "hive partitioning."

Note

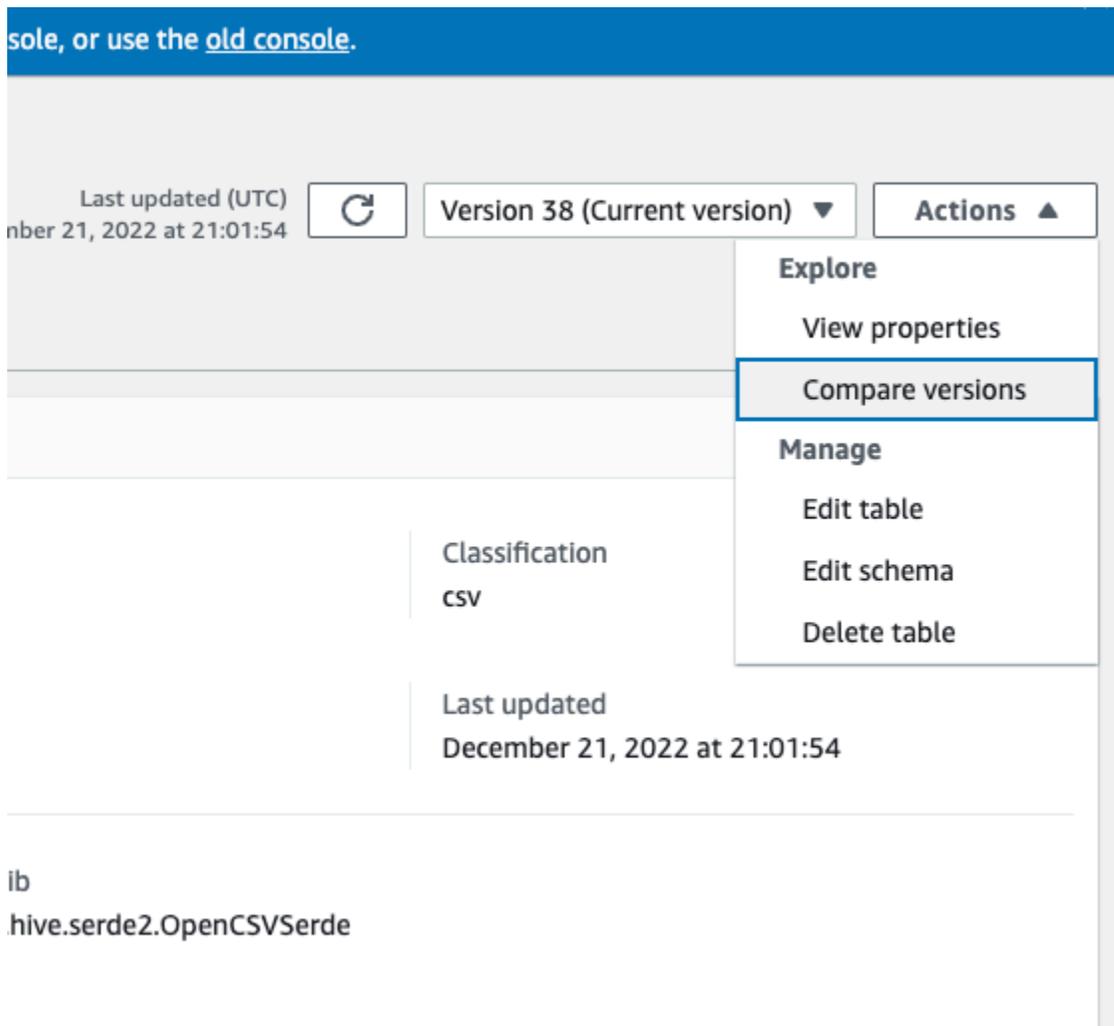

To get step-by-step guidance for viewing the details of a table, see the **Explore table** tutorial in the console.

Comparing table schema versions

When you compare two versions of table schemas, you can compare nested row changes by expanding and collapsing nested rows, compare schemas of two versions side-by-side, and view table properties side-by-side.

To compare versions

1. From the Amazon Glue console, choose **Tables**, then **Actions** and choose **Compare versions**.

2. Choose a version to compare by choosing the version drop-down menu. When comparing schemas, the Schema tab is highlighted in orange.
3. When you compare tables between two versions, the table schemas are presented to you on the left and right side of the screen. This enables you to determine changes visually by comparing the Column name, data type, key, and comment fields side-by-side. When there is a change, a colored icon displays the type of change that was made.
 - Deleted – displayed by a red icon indicates where the column was removed from a previous version of the table schema.
 - Edited or Moved – displayed by a blue icon indicates where the column was modified or moved in a newer version of the table schema.
 - Added – displayed by a green icon indicates where the column was added to a newer version of the table schema.

- Nested changes – displayed by a yellow icon indicates where the nested column contains changes. Choose the column to expand and view the columns that have either been deleted, edited, moved, or added.

Compare versions: cloudtrail_data

Legend: Deleted Edited/Moved Added Nested Changes Deleted

4. Use the filter fields search bar to display fields based on the characters you enter here. If you enter a column name in either table version, the filtered fields are displayed in both table versions to show you where the changes have occurred.
5. To compare properties, choose the **Properties** tab.
6. To stop comparing versions, choose **Stop comparing** to return to the list of tables.

Creating partition indexes

Over time, hundreds of thousands of partitions get added to a table. The [GetPartitions API](#) is used to fetch the partitions in the table. The API returns partitions that match the expression provided in the request.

Lets take a *sales_data* table as an example which is partitioned by the keys *Country*, *Category*, *Year*, *Month*, and *creationDate*. If you want to obtain sales data for all the items sold for the *Books* category in the year 2020 after 2020-08-15, you have to make a GetPartitions request with the expression "Category = 'Books' and creationDate > '2020-08-15'" to the Data Catalog.

If no partition indexes are present on the table, Amazon Glue loads all the partitions of the table, and then filters the loaded partitions using the query expression provided by the user in the GetPartitions request. The query takes more time to run as the number of partitions increase on a table with no indexes. With an index, the GetPartitions query will try to fetch a subset of the partitions instead of loading all the partitions in the table.

Topics

- [About partition indexes](#)
- [Creating a table with partition indexes](#)
- [Adding a partition index to an existing table](#)
- [Describing partition indexes on a table](#)
- [Limitations on using partition indexes](#)
- [Using indexes for an optimized GetPartitions call](#)
- [Integration with engines](#)

About partition indexes

When you create a partition index, you specify a list of partition keys that already exist on a given table. Partition index is sub list of partition keys defined in the table. A partition index can be created on any permutation of partition keys defined on the table. For the above *sales_data* table, the possible indexes are (country, category, creationDate), (country, category, year), (country, category), (country), (category, country, year, month), and so on.

The Data Catalog will concatenate the partition values in the order provided at the time of index creation. The index is built consistently as partitions are added to the table. Indexes can be created

for String (string, char, and varchar), Numeric (int, bigint, long, tinyint, and smallint), and Date (yyyy-MM-dd) column types.

Supported data types

- Date – A date in ISO format, such as YYYY-MM-DD. For example, date 2020-08-15. The format uses hyphens (-) to separate the year, month, and day. The permissible range for dates for indexing spans from 0000-01-01 to 9999-12-31.
- String – A string literal enclosed in single or double quotes.
- Char – Fixed length character data, with a specified length between 1 and 255, such as char(10).
- Varchar – Variable length character data, with a specified length between 1 and 65535, such as varchar(10).
- Numeric – int, bigint, long, tinyint, and smallint

Indexes on Numeric, String, and Date data types support =, >, >=, <, <= and between operators. The indexing solution currently only supports the AND logical operator. Sub-expressions with the operators "LIKE", "IN", "OR", and "NOT" are ignored in the expression for filtering using an index. Filtering for the ignored sub-expression is done on the partitions fetched after applying index filtering.

For each partition added to a table, there is a corresponding index item created. For a table with 'n' partitions, 1 partition index will result in 'n' partition index items. 'm' partition index on same table will result into 'm*n' partition index items. Each partition index item will be charged according to the current Amazon Glue pricing policy for data catalog storage. For details on storage object pricing, see [Amazon Glue pricing](#).

Creating a table with partition indexes

You can create a partition index during table creation. The CreateTable request takes a list of [PartitionIndex objects](#) as an input. A maximum of 3 partition indexes can be created on a given table. Each partition index requires a name and a list of partitionKeys defined for the table. Created indexes on a table can be fetched using the [GetPartitionIndexes API](#)

Adding a partition index to an existing table

To add a partition index to an existing table, use the CreatePartitionIndex operation. You can create one PartitionIndex per CreatePartitionIndex operation. Adding an index does

not affect the availability of a table, as the table continues to be available while indexes are being created.

The index status for an added partition is set to `CREATING` and the creation of the index data is started. If the process for creating the indexes is successful, the `indexStatus` is updated to `ACTIVE` and for an unsuccessful process, the index status is updated to `FAILED`. Index creation can fail for multiple reasons, and you can use the `GetPartitionIndexes` operation to retrieve the failure details. The possible failures are:

- `ENCRYPTED_PARTITION_ERROR` — Index creation on a table with encrypted partitions is not supported.
- `INVALID_PARTITION_TYPE_DATA_ERROR` — Observed when the `partitionKey` value is not a valid value for the corresponding `partitionKey` data type. For example: a `partitionKey` with the 'int' datatype has a value 'foo'.
- `MISSING_PARTITION_VALUE_ERROR` — Observed when the `partitionValue` for an `indexedKey` is not present. This can happen when a table is not partitioned consistently.
- `UNSUPPORTED_PARTITION_CHARACTER_ERROR` — Observed when the value for an indexed partition key contains the characters `\u0000`, `\u0001` or `\u0002`.
- `INTERNAL_ERROR` — An internal error occurred while indexes were being created.

Describing partition indexes on a table

To fetch the partition indexes created on a table, use the `GetPartitionIndexes` operation. The response returns all the indexes on the table, along with the current status of each index (the `IndexStatus`).

The `IndexStatus` for a partition index will be one of the following:

- `CREATING` — The index is currently being created, and is not yet available for use.
- `ACTIVE` — The index is ready for use. Requests can use the index to perform an optimized query.
- `DELETING` — The index is currently being deleted, and can no longer be used. An index in the active state can be deleted using the `DeletePartitionIndex` request, which moves the status from `ACTIVE` to `DELETING`.
- `FAILED` — The index creation on an existing table failed. Each table stores the last 10 failed indexes.

The possible state transitions for indexes created on an existing table are:

- CREATING → ACTIVE → DELETING
- CREATING → FAILED

Limitations on using partition indexes

Once you have created a partition index, note these changes to table and partition functionality:

New partition creation (after Index Addition)

After a partition index is created on a table, all new partitions added to the table will be validated for the data type checks for indexed keys. The partition value of the indexed keys will be validated for data type format. If the data type check fails, the create partition operation will fail. For the *sales_data* table, if an index is created for keys (category, year) where the category is of type `string` and year of type `int`, the creation of the new partition with a value of YEAR as "foo" will fail.

After indexes are enabled, the addition of partitions with indexed key values having the characters U+0000, U+00001, and U+0002 will start to fail.

Table updates

Once a partition index is created on a table, you cannot modify the partition key names for existing partition keys, and you cannot change the type, or order, of keys which are registered with the index.

Using indexes for an optimized GetPartitions call

When you call `GetPartitions` on a table with an index, you can include an expression, and if applicable the Data Catalog will use an index if possible. The first key of the index should be passed in the expression for the indexes to be used in filtering. Index optimization in filtering is applied as a best effort. The Data Catalog tries to use index optimization as much as possible, but in case of a missing index, or unsupported operator, it falls back to the existing implementation of loading all partitions.

For the *sales_data* table above, let's add the index [Country, Category, Year]. If "Country" is not passed in the expression, the registered index will not be able to filter partitions using indexes. You can add up to 3 indexes to support various query patterns.

Lets take some example expressions and see how indexes work on them:

Expressions	How index will be used
Country = 'US'	Index will be used to filter partitions.
Country = 'US' and Category = 'Shoes'	Index will be used to filter partitions.
Category = 'Shoes'	Indexes will not be used as "country" is not provided in the expression. All partitions will be loaded to return a response.
Country = 'US' and Category = 'Shoes' and Year > '2018'	Index will be used to filter partitions.
Country = 'US' and Category = 'Shoes' and Year > '2018' and month = 2	Index will be used to fetch all partitions with country = "US" and category = "shoes" and year > 2018. Then, filtering on the month expression will be performed.
Country = 'US' AND Category = 'Shoes' OR Year > '2018'	Indexes will not be used as an OR operator is present in the expression.
Country = 'US' AND Category = 'Shoes' AND (Year = 2017 OR Year = '2018')	Index will be used to fetch all partitions with country = "US" and category = "shoes", and then filtering on the year expression will be performed.
Country in ('US', 'UK') AND Category = 'Shoes'	Indexes will not be used for filtering as the IN operator is not supported currently.
Country = 'US' AND Category in ('Shoes', 'Books')	Index will be used to fetch all partitions with country = "US", and then filtering on the Category expression will be performed.
Country = 'US' AND Category in ('Shoes', 'Books') AND (creationDate > '2023-9-01')	Index will be used to fetch all partitions with country = "US", with creationDate > '2023-9-01', and then filtering on the Category expression will be performed.

Integration with engines

Redshift Spectrum, Amazon EMR and Amazon Glue ETL Spark DataFrames are able to utilize indexes for fetching partitions after indexes are in an ACTIVE state in Amazon Glue. [Athena](#) and [Amazon Glue ETL Dynamic frames](#) require you to follow extra steps to utilize indexes for query improvement.

Enable partition filtering

To enable partition filtering in Athena, you need to update the table properties as follows:

1. In the Amazon Glue console, under **Data Catalog**, choose **Tables**.
2. Choose a table.
3. Under **Actions**, choose **Edit table**.
4. Under **Table properties**, add the following:
 - Key – `partition_filtering.enabled`
 - Value – `true`
5. Choose **Apply**.

Alternatively, you can set this parameter by running an [ALTER TABLE SET PROPERTIES](#) query in Athena.

```
ALTER TABLE partition_index.table_with_index
SET TBLPROPERTIES ('partition_filtering.enabled' = 'true')
```

Updating manually created Data Catalog tables using crawlers

You might want to create Amazon Glue Data Catalog tables manually and then keep them updated with Amazon Glue crawlers. Crawlers running on a schedule can add new partitions and update the tables with any schema changes. This also applies to tables migrated from an Apache Hive metastore.

To do this, when you define a crawler, instead of specifying one or more data stores as the source of a crawl, you specify one or more existing Data Catalog tables. The crawler then crawls the data stores specified by the catalog tables. In this case, no new tables are created; instead, your manually created tables are updated.

The following are other reasons why you might want to manually create catalog tables and specify catalog tables as the crawler source:

- You want to choose the catalog table name and not rely on the catalog table naming algorithm.
- You want to prevent new tables from being created in the case where files with a format that could disrupt partition detection are mistakenly saved in the data source path.

For more information, see [Step 2: Choose data sources and classifiers](#).

Data Catalog table properties

Table properties, or parameters, as they are known in the Amazon CLI, are unvalidated key and value strings. You can set your own properties on the table to support uses of the Data Catalog outside of Amazon Glue. Other services using the Data Catalog may do so as well. Amazon Glue sets some table properties when running jobs or crawlers. Unless otherwise described, these properties are for internal use, we do not support that they will continue to exist in their current form, or support product behavior if these properties are manually changed.

For more information about table properties set by Amazon Glue crawlers, see [the section called "Parameters set on Data Catalog tables by crawler"](#).

Integrating with other Amazon services

While you can use Amazon Glue crawlers to populate the Amazon Glue Data Catalog, there are several Amazon services that can automatically integrate with and populate the catalog for you. The following sections provide more information about the specific use cases supported by Amazon services that can populate the Data Catalog.

Topics

- [Amazon Lake Formation](#)
- [Amazon Athena](#)

Amazon Lake Formation

Amazon Lake Formation is a service that makes it easier to set up a secure data lake in Amazon. Lake Formation is built on Amazon Glue, and Lake Formation and Amazon Glue share the same Amazon Glue Data Catalog. You can register your Amazon S3 data location with Lake Formation,

and use Lake Formation console to create databases and tables in the Amazon Glue Data Catalog, define data access policies, and audit data access across your data lake from a central place. You can use the Lake Formation fine-grained access control to manage your existing Data Catalog resources and Amazon S3 data locations.

With data registered with Lake Formation, you can securely share Data Catalog resources across IAM principals, Amazon accounts, Amazon organizations, and organizational units.

For more information about creating Data Catalog resources using Lake Formation, see [Creating Data Catalog tables and databases](#) in the Amazon Lake Formation Developer Guide.

Amazon Athena

Amazon Athena uses the Data Catalog to store and retrieve table metadata for the Amazon S3 data in your Amazon account. The table metadata lets the Athena query engine know how to find, read, and process the data that you want to query.

You can populate the Amazon Glue Data Catalog by using Athena `CREATE TABLE` statements directly. You can manually define and populate the schema and partition metadata in the Data Catalog without needing to run a crawler.

1. In the Athena console, create a database that will store the table metadata in the Data Catalog.
2. Use the `CREATE EXTERNAL TABLE` statement to define the schema of your data source.
3. Use the `PARTITIONED BY` clause to define any partition keys if your data is partitioned.
4. Use the `LOCATION` clause to specify the Amazon S3 path where your actual data files are stored.
5. Run the `CREATE TABLE` statement.

This query creates the table metadata in the Data Catalog based on your defined schema and partitions, without actually crawling the data.

You can query the table in Athena, and it will use the metadata from the Data Catalog to access and query your data files in Amazon S3.

For more information, see [Creating databases and tables](#) in the Amazon Athena User Guide.

Data Catalog settings

The Data Catalog settings contains options to set encryption and permissions options for the Data Catalog in your account.

Data catalog settings

Last updated (UTC)
January 1, 1970 at 00:00:00 

Choose encryption and permission options for your accounts data catalog.

Encryption options

- Metadata encryption**
Enable at-rest encryption for metadata stored in the data catalog.
- Encrypt connection passwords**
When enabled, the password you provide when you create a connection is encrypted with the given KMS key.

Permissions

Add a policy to define fine-grained access control of the data catalog.

1	
---	--

JSON Ln 1, Col 1  Errors: 0  Warnings: 0 

Cancel **Save**

To change the fine-grained access control of the Data Catalog

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose an encryption option.
 - **Metadata encryption** – Select this check box to encrypt the metadata in your Data Catalog. Metadata is encrypted at rest using the Amazon Key Management Service (Amazon KMS) key that you specify. For more information, see [Encrypting your Data Catalog](#).
 - **Encrypt connection passwords** – Select this check box to encrypt passwords in the Amazon Glue connection object when the connection is created or updated. Passwords are encrypted using the Amazon KMS key that you specify. When passwords are returned, they are encrypted. This option is a global setting for all Amazon Glue connections in the Data Catalog. If you clear this check box, previously encrypted passwords remain encrypted using the key that was used when they were created or updated. For more information about Amazon Glue connections, see [Connecting to data](#).

When you enable this option, choose an Amazon KMS key, or choose **Enter a key ARN** and provide the Amazon Resource Name (ARN) for the key. Enter the ARN in the form `arn:aws:kms:region:account-id:key/key-id` . You can also provide the ARN as a key alias, such as `arn:aws:kms:region:account-id:alias/alias-name` .

Important

If this option is selected, any user or role that creates or updates a connection must have `kms:Encrypt` permission on the specified KMS key.

For more information, see [Encrypting connection passwords](#).

3. Choose **Settings**, and then in the **Permissions** editor, add the policy statement to change fine-grained access control of the Data Catalog for your account. Only one policy at a time can be attached to a Data Catalog. You can paste a JSON resource policy into this control. For more information, see [Resource-based policies within Amazon Glue](#).
4. Choose **Save** to update your Data Catalog with any changes you made.

You can also use Amazon Glue API operations to put, get, and delete resource policies. For more information, see [Security APIs in Amazon Glue](#).

Populating and managing transactional tables

[Apache Iceberg](#), [Apache Hudi](#), and Linux Foundation [Delta Lake](#) are open-source table formats designed for handling large-scale data analytics and data lake workloads in Apache Spark.

You can populate Iceberg, Hudi, and Delta Lake tables in the Amazon Glue Data Catalog using the following methods:

- Amazon Glue crawler; – Amazon Glue crawlers can automatically discover and populate Iceberg, Hudi and Delta Lake table metadata in the Data Catalog. For more information, see [Using crawlers to populate the Data Catalog](#).
- Amazon Glue ETL Jobs – You can create ETL jobs to write data to Iceberg, Hudi, and Delta Lake tables and populate their metadata in the Data Catalog. For more information, see [Using data lake frameworks with Amazon Glue ETL jobs](#).
- Amazon Glue console, Amazon Lake Formation console, Amazon CLI or API – You can use the Amazon Glue console, Lake Formation console, or API to create and manage Iceberg table definitions in the Data Catalog.

Topics

- [Creating Apache Iceberg tables](#)
- [Optimizing Iceberg tables](#)
- [Optimizing query performance for Iceberg tables](#)

Creating Apache Iceberg tables

You can create Apache Iceberg tables that use the Apache Parquet data format in the Amazon Glue Data Catalog with data residing in Amazon S3. A table in the Data Catalog is the metadata definition that represents the data in a data store. By default, Amazon Glue creates Iceberg v2 tables. For the difference between v1 and v2 tables, see [Format version changes](#) in the Apache Iceberg documentation.

[Apache Iceberg](#) is an open table format for very large analytic datasets. Iceberg allows for easy changes to your schema, also known as schema evolution, meaning that users can add, rename, or remove columns from a data table without disrupting the underlying data. Iceberg also provides support for data versioning, which allows users to track changes to data overtime. This enables the

time travel feature, which allows users to access and query historical versions of data and analyze changes to the data between updates and deletes.

You can use Amazon Glue or Lake Formation console or the `CreateTable` operation in the Amazon Glue API to create an Iceberg table in the Data Catalog. For more information, see [CreateTable action \(Python: `create_table`\)](#).

When you create an Iceberg table in the Data Catalog, you must specify the table format and metadata file path in Amazon S3 to be able to perform reads and writes.

You can use Lake Formation to secure your Iceberg table using fine-grained access control permissions when you register the Amazon S3 data location with Amazon Lake Formation. For source data in Amazon S3 and metadata that is not registered with Lake Formation, access is determined by IAM permissions policies for Amazon S3 and Amazon Glue actions. For more information, see [Managing permissions](#).

Note

Data Catalog doesn't support creating partitions and adding Iceberg table properties.

Prerequisites

To create Iceberg tables in the Data Catalog, and set up Lake Formation data access permissions, you need to complete the following requirements:

1. Permissions required to create Iceberg tables without the data registered with Lake Formation.

In addition to the permissions required to create a table in the Data Catalog, the table creator requires the following permissions:

- `s3:PutObject` on resource `arn:aws:s3:::{bucketName}`
- `s3:GetObject` on resource `arn:aws:s3:::{bucketName}`
- `s3:DeleteObject` on resource `arn:aws:s3:::{bucketName}`

2. Permissions required to create Iceberg tables with data registered with Lake Formation:

To use Lake Formation to manage and secure the data in your data lake, register your Amazon S3 location that has the data for tables with Lake Formation. This is so that Lake Formation

can vend credentials to Amazon analytical services such as Athena, Redshift Spectrum, and Amazon EMR to access data. For more information on registering an Amazon S3 location, see [Adding an Amazon S3 location to your data lake](#).

A principal who reads and writes the underlying data that is registered with Lake Formation requires the following permissions:

- `lakeformation:GetDataAccess`
- `DATA_LOCATION_ACCESS`

A principal who has data location permissions on a location also has location permissions on all child locations.

For more information on data location permissions, see [Underlying data access control](#) link.

To enable compaction, the service needs to assume an IAM role that has permissions to update tables in the Data Catalog. For details, see [Table optimization prerequisites](#)

Creating an Iceberg table

You can create Iceberg v1 and v2 tables using Amazon Glue or Lake Formation console or Amazon Command Line Interface as documented on this page. You can also create Iceberg tables using the Amazon Glue crawler. For more information, see [Data Catalog and Crawlers](#) in the Amazon Glue Developer Guide.

To create an Iceberg table

Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Under Data Catalog, choose **Tables**, and use the **Create table** button to specify the following attributes:
 - **Table name** – Enter a name for the table. If you're using Athena to access tables, use these [naming tips](#) in the Amazon Athena User Guide.
 - **Database** – Choose an existing database or create a new one.
 - **Description** – The description of the table. You can write a description to help you understand the contents of the table.

- **Table format** – For **Table format**, choose Apache Iceberg.
- **Enable compaction** – Choose **Enable compaction** to compact small Amazon S3 objects in the table into larger objects.
- **IAM role** – To run compaction, the service assumes an IAM role on your behalf. You can choose an IAM role using the drop-down. Ensure that the role has the permissions required to enable compaction.

To learn more about the required permissions, see [Table optimization prerequisites](#).

- **Location** – Specify the path to the folder in Amazon S3 that stores the metadata table. Iceberg needs a metadata file and location in the Data Catalog to be able to perform reads and writes.
- **Schema** – Choose **Add columns** to add columns and data types of the columns. You have the option to create an empty table and update the schema later. Data Catalog supports Hive data types. For more information, see [Hive data types](#).

Iceberg allows you to evolve schema and partition after you create the table. You can use [Athena queries](#) to update the table schema and [Spark queries](#) for updating partitions.

Amazon CLI

```
aws glue create-table \  
  --database-name iceberg-db \  
  --region us-west-2 \  
  --open-table-format-input '{  
    "IcebergInput": {  
      "MetadataOperation": "CREATE",  
      "Version": "2"  
    }  
  }' \  
  --table-input '{"Name":"test-iceberg-input-demo",  
    "TableType": "EXTERNAL_TABLE",  
    "StorageDescriptor":{  
      "Columns":[  
        {"Name":"col1", "Type":"int"},  
        {"Name":"col2", "Type":"int"},  
        {"Name":"col3", "Type":"string"}  
      ],  
      "Location":"s3://DOC_EXAMPLE_BUCKET_ICEBERG/"  
    }  
  }
```

```
}'
```

Optimizing Iceberg tables

Amazon Glue supports multiple table optimization options to enhance the management and performance of Apache Iceberg tables used by the Amazon analytical engines and ETL jobs. These optimizers provide efficient storage utilization, improved query performance, and effective data management. There are three types of table optimizers available in Amazon Glue:

- **Compaction** – Data compaction compacts small data files to reduce storage usage and improve read performance. Data files are merged and rewritten to remove obsolete data and consolidate fragmented data into larger, more efficient files. You can configure compaction to run automatically.

Binpack is the default compaction strategy in Apache Iceberg. It combines smaller data files into larger ones for optimal performance. Compaction also supports sort and Z-order strategies that cluster similar data together. Sort organizes data based on specified columns, improving query performance for filtered operations. Z-order creates sorted datasets that enhance query performance when multiple columns are queried simultaneously. All three compaction strategies - binpack, sort, and Z-order - reduce the amount of data scanned by query engines, thereby lowering query processing costs.

- **Snapshot retention** – Snapshots are timestamped versions of an Iceberg table. Snapshot retention configurations allow customers to enforce how long to retain snapshots and how many snapshots to retain. Configuring a snapshot retention optimizer can help manage storage overhead by removing older, unnecessary snapshots and their associated underlying files.
- **Orphan file deletion** – Orphan files are files that are no longer referenced by the Iceberg table metadata. These files can accumulate over time, especially after operations like table deletions or failed ETL jobs. Enabling orphan file deletion allows Amazon Glue to periodically identify and remove these unnecessary files, freeing up storage.

Catalog-level optimization configuration is available through the Lake Formation console and using the Amazon Glue UpdateCatalog API operation. You can enable or disable compaction, snapshot retention, and orphan file deletion optimizers for individual Iceberg tables in the Data Catalog using the Amazon Glue console, Amazon CLI, or Amazon Glue API operations.

Table optimization prerequisites

The table optimizer assumes the permissions of the Amazon Identity and Access Management (IAM) role that you specify when you enable optimization options (compaction, snapshot retention, and orphan file deletion) for a table. You can either create a single role for all optimizers or create separate roles for each optimizer.

Note

The orphan file deletion optimizer doesn't require the `glue:updateTable` or `s3:putObject` permissions. The snapshot expiration and compaction optimizers require the same set of permissions.

The IAM role must have the permissions to read data and update metadata in the Data Catalog. You can create an IAM role and attach the following inline policies:

- Add the following inline policy that grants Amazon S3 read/write permissions on the location for data that is not registered with Amazon Lake Formation. This policy also includes permissions to update the table in the Data Catalog, and to permit Amazon Glue to add logs in Amazon CloudWatch logs and publish metrics. For source data in Amazon S3 that isn't registered with Lake Formation, access is determined by IAM permissions policies for Amazon S3 and Amazon Glue actions.

In the following inline policies, replace `bucket-name` with your Amazon S3 bucket name, `aws-account-id` and `region` with a valid Amazon account number and Region of the Data Catalog, `database_name` with the name of your database, and `table_name` with the name of the table.

JSON

```
{

orphan-file-deletion/logs:*"
  ]
}
]
}

```

- (Optional) To optimize Iceberg tables with data in Amazon S3 buckets encrypted using [Server-side encryption](#), the compaction role requires permissions to decrypt Amazon S3 objects and generate a new data key to write objects to the encrypted buckets. Add the following policy to the desired Amazon KMS key. We support only bucket-level encryption.

```

{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::<aws-account-id>:role/<optimizer-role-name>"
  },
  "Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey"
  ],
  "Resource": "*"
}

```

- (Optional) For data location registered with Lake Formation, the role used to register the location requires permissions to decrypt Amazon S3 objects and generate a new data key to write objects to the encrypted buckets. For more information, see [Registering an encrypted Amazon S3 location](#).
- (Optional) If the Amazon KMS key is stored in a different Amazon account, you need to include the following permissions to the compaction role.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
      ],
      "Resource": [
        "arn:aws:kms:us-east-1:111122223333:key/key-id"
      ]
    }
  ]
}
```

- The role you use to run compaction must have the `iam:PassRole` permission on the role.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam:111122223333:role/<optimizer-role-name>"
      ]
    }
  ]
}
```

```
}
```

- Add the following trust policy to the role for Amazon Glue service to assume the IAM role to run the compaction process.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

- (Optional) To update the Data Catalog settings to enable catalog-level table optimizations, the IAM role used must have the `glue:UpdateCatalog` permission or Amazon Lake Formation `ALTER CATALOG` permission on the root catalog. You can use `GetCatalog` API to verify the catalog properties.

Catalog-level table optimizers

With a one-time catalog configuration, you can set up automatic optimizers such as compaction, snapshot retention, and orphan file deletion for all new and updated Apache Iceberg tables in the Amazon Glue Data Catalog. Catalog-level optimizer configurations allow you to apply consistent optimizer settings across all tables within a catalog, eliminating the need to configure optimizers individually for each table.

Data lake administrators can configure the table optimizers by selecting the default catalog in the Lake Formation console and enabling optimizers using the `Table optimization` option. When you create new tables or update existing tables in the Data Catalog, the Data Catalog automatically runs the table optimizations to reduce operational burden.

If you have configured optimization at the table level or if you have previously deleted the table optimization settings for a table, those table-specific settings take precedence over the default catalog settings for table optimization. If a configuration parameter is not defined at either the table or catalog level, the Iceberg table property value will be applied. This setting is applicable to snapshot retention and orphan file deletion optimizer.

When enabling catalog-level optimizers, consider the following:

- When you configure optimization settings at the time of catalog creation and subsequently disable the optimizations through an Update Catalog request, the operation will cascade through all the tables within the catalog.
- If you have already configured optimizers for a given table, then the disable operation at the catalog level will not impact this table.
- When you disable optimizers at the catalog level, tables with existing optimizer configurations will maintain their specific settings and remain unaffected by the catalog-level change. However, tables without their own optimizer configurations will inherit the disabled state from the catalog level.
- Since snapshot retention and orphan file deletion optimizers can be schedule-based, updates will introduce a random delay to the start of their schedule. This will cause each optimizer to start at slightly different times, spreading out the load and reducing the likelihood of exceeding service limits.

Topics

- [Enabling catalog-level automatic table optimization](#)
- [Viewing catalog-level optimizations](#)
- [Disabling catalog-level table optimization](#)

Enabling catalog-level automatic table optimization

You can enable the automatic table optimization for all new Apache Iceberg tables in the Data Catalog. After creating the table, you can also explicitly update the table optimization settings manually.

To update the Data Catalog settings to enable catalog-level table optimizations, the IAM role used must have the `glue:UpdateCatalog` permission on the root catalog. You can use `GetCatalog` API to verify the catalog properties.

For the Lake Formation managed tables, the IAM role selected during the catalog optimization configuration requires Lake Formation ALTER, DESCRIBE, INSERT, and DELETE permissions for any new tables or updated tables.

To enable catalog-level optimizers (console)

1. Open the Lake Formation console at <https://console.amazonaws.cn/lakeformation/>.
2. In the navigation pane, choose **Data Catalog**.
3. Select the **Catalogs** tab.
4. Choose the account-level catalog.
5. Choose **Table optimizations**, **Edit** under **Table optimizations** tab. You can also choose **Edit optimizations** from **Actions**.

The screenshot displays the 'Table optimizations' configuration page in the Amazon Lake Formation console. At the top right, there is an 'Actions' button. Below it, the 'Catalog summary' section shows details for a catalog with Name '054881201579', Data encryption '-', IAM role '-', and Catalog ARN 'arn:aws:glue:us-east-1:054881201579:catalog'. Below this, there are tabs for 'Objects', 'Permissions', and 'Table optimizations'. The 'Table optimizations' section is active and contains an 'Edit' button. It is divided into three columns of settings:

- Table statistics:** Manage and edit table statistics. [View pricing](#). Table statistics are currently 'Off'.
- Table optimizations:**
 - Iceberg optimization IAM role:** -
 - Compaction:** Disabled
 - Compaction strategy:** -
 - Snapshot retention:** Disabled
 - Snapshot retention period:** -
 - Number of snapshots to retain:** -
 - Clean expired files:** Disabled
 - Orphan file deletion:** Disabled
 - Orphan file deletion period:** -

6. On the **Table optimization** page, configure the following options:

Optimization options

Table optimization

Compaction

Combine small data files into larger, more efficient files to optimize table performance.

Snapshot retention

Optimize table storage by removing old snapshots from metadata overhead and expiring files that are no longer needed.

Orphan file deletion

Automatically clean up orphan files periodically.

Optimization configuration

Configure Apache Iceberg table optimization to optimize storage and improve query performances. [Learn more](#)

Use default settings

Default settings have been defined to help you get started. You can change them at any time later.

Customize settings

Customize settings for your specific needs.

IAM Role

Configure for all selected optimizers.

Choose an IAM role

View

Create new IAM role

Snapshot retention configuration

Snapshot retention period

Configure how long Apache Iceberg retains historical table snapshots before deleting them.

Use the default retention period of 5 days for snapshots

Specify a custom value in days

Minimum snapshot to retain

Use the default setting of retaining one snapshot

Specify a custom value

Expired snapshots associated files

Delete associated files

Files associated with the expired snapshots will be deleted.

Orphan file deletion configuration

Files under the provided Table Location with a creation time older than this number of days will be deleted if they are no longer referenced by the Apache Iceberg Table metadata.

3

Days

Default is 3 days.

a. Configure **Compaction** settings:

- Enable/disable compaction.
- Choose the IAM role that has the necessary permissions to run the optimizers.

For more information on the permission requirements for the IAM role, see [Table optimization prerequisites](#).

b. Configure **Snapshot retention** settings:

- Enable/disable retention.
- Set snapshot retention period in days - default is 5 days.
- Set number of snapshots to retain - default is 1 snapshot.
- Enable/disable cleaning of expired files.

c. Configure **Orphan file deletion** settings:

- Enable/disable orphan file deletion.
- Set orphan file retention period in days - default is 3 days.

7. Choose **Save**.

Enabling Catalog-Level Optimizers via Amazon CLI

Use the following CLI command to update an existing catalog with optimizer settings:

Example Update catalog with optimizer settings

```
aws glue update-catalog \  
  --name catalog-id \  
  --catalog-input \  
  '{  
    "CatalogId": "111122223333",  
    "CatalogInput": {  
      "CatalogProperties": {  
        "CustomProperties": {  
          "ColumnStatistics.Enabled": "false",  
          "ColumnStatistics.RoleArn": "arn:aws:iam::111122223333:role/service-  
role/stats-role-name"  
        },  
        "IcebergOptimizationProperties": {  
          "RoleArn": "arn:aws:iam::111122223333:role/optimizer-role-name",
```

```
"Compaction": {
  "enabled": "true"
},
"Retention": {
  "enabled": "true",
  "snapshotRetentionPeriodInDays": "10",
  "numberOfSnapshotsToRetain": "5",
  "cleanExpiredFiles": "true"
},
"OrphanFileDeletion": {
  "enabled": "true",
  "orphanFileRetentionPeriodInDays": "3"
}
}
}
}'
```

If you encounter issues with catalog-level optimizers, check the following:

- Ensure the IAM role has the correct permissions as outlined in the Prerequisites section.
- Check CloudWatch logs for any error messages related to optimizer operations.

For more information, see [View available metrics](#) in the *Amazon CloudWatch User Guide*.

- Verify that the catalog settings were successfully applied by checking the catalog configuration.
- For table access failures, check the CloudWatch logs and EventBridge notifications for detailed error information.

Viewing catalog-level optimizations

When catalog-level table optimization is enabled, anytime an Apache Iceberg table is created or updated via the `CreateTable` or `UpdateTable` APIs through Amazon Web Services Management Console, SDK, or Amazon Glue crawler, an equivalent table level setting is created for that table.

After you create or update a table, you can verify the table details to confirm the table optimization. The `Table optimization` shows the `Configuration source` property set as `Catalog`.

Disabling catalog-level table optimization

You can disable table optimization for new tables using the Amazon Lake Formation console, the `glue:UpdateCatalog` API.

To disable the table optimizations at the catalog level

1. Open the Lake Formation console at <https://console.amazonaws.cn/lakeformation/>.
2. On the left navigation bar, choose **Catalogs**.
3. On the **Catalog summary** page, choose **Edit** under **Table optimizations**.
4. On the **Edit optimization** page, unselect the **Optimization options**.
5. Choose **Save**.

Compaction optimization

The Amazon S3 data lakes using open table formats like Apache Iceberg store data as S3 objects. Having thousands of small Amazon S3 objects in a data lake table increases metadata overhead and affects read performance. Amazon Glue Data Catalog provides managed compaction for Iceberg tables, compacting small objects into larger ones for better read performance by Amazon analytics services like Amazon Athena and Amazon EMR, and Amazon Glue ETL jobs. Data Catalog

performs compaction without interfering with concurrent queries and supports compaction only for Parquet format tables.

The table optimizer continuously monitors table partitions and kicks off the compaction process when the threshold is exceeded for the number of files and file sizes.

In the Data Catalog, the compaction process starts when a table or any of its partitions have more than 100 files. Each file must be smaller than 75% of the target file size. The target file size is defined by the `write.target-file-size-bytes` table property, which defaults to 512 MB if not explicitly set.

For limitations, see [Supported formats and limitations for managed data compaction](#).

- [Disabling compaction optimizer](#)

Enabling compaction optimizer

You can use Amazon Glue console, Amazon CLI, or Amazon API to enable compaction for your Apache Iceberg tables in the Amazon Glue Data Catalog. For new tables, you can choose Apache Iceberg as table format and enable compaction when you create the table. Compaction is disabled by default for new tables.

Console

To enable compaction

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/> and sign in as a data lake administrator, the table creator, or a user who has been granted the `glue:UpdateTable` and `lakeformation:GetDataAccess` permissions on the table.
2. In the navigation pane, under **Data Catalog**, choose **Tables**.
3. On the **Tables** page, choose a table in open table format that you want to enable compaction for, then under **Actions** menu, choose **Optimization**, and then choose **Enable**.

You can also enable compaction by selecting the **Table optimization** tab on the **Table details** page. Choose the **Table optimization** tab on the lower section of the page, and choose **Enable compaction**.

The **Enable optimization** option is also available when you create a new Iceberg table in the Data Catalog.

4. On the **Enable optimization** page, choose **Compaction** under **Optimization options**.

Optimization configuration

Configure Apache Iceberg table optimization to optimize storage and improve query performances. [Learn more](#)

[Create Glue network connection](#)

Compaction configuration

Compaction strategy

Choose a compaction strategy [Learn more](#)

- Binpack**
Combines small files into larger files, typically targeting sizes over 100MB, while applying any pending deletes. This is the default and recommended compaction strategy for most use cases.
- Sort**
Organizes data based on specified columns which are sorted hierarchically during compaction, improving query performance for filtered operations. This strategy is recommended when your queries frequently filter on specific columns. To use this strategy, you must first define a sort order in your Iceberg table properties using the 'sort_order' table property.
- Z-Order**
Optimizes data organization by blending multiple attributes into a single scalar value that can be used for sorting, allowing efficient querying across multiple dimensions. This strategy is recommended when you need to query data across multiple dimensions simultaneously. To use this strategy, you must first define a sort order in your Apache Iceberg table properties using the 'sort_order' table property.

Minimum input files

Minimum number of data-files to be present in a partition before compaction will actually compact files.

100

files

Default is 100 files.

Delete file threshold

Minimum number of deletes in a data-file to be eligible for compaction.

1

deletes

Default is 1 delete.

5. Next, select an IAM role from the drop down with the permissions shown in the [Table optimization prerequisites](#) section.

You can also choose **Create a new IAM role** option to create a custom role with the required permissions to run compaction.

Follow the steps below to update an existing IAM role:

- a. To update the permissions policy for the IAM role, in the IAM console, go to the IAM role that is being used for running compaction.
 - b. In the **Add permissions** section, choose Create policy. In the newly opened browser window, create a new policy to use with your role.
 - c. On the Create policy page, choose the JSON tab. Copy the JSON code shown in the Prerequisites into the policy editor field.
6. If you have security policy configurations where the Iceberg table optimizer needs to access Amazon S3 buckets from a specific Virtual Private Cloud (VPC), create an Amazon Glue network connection or use an existing one.

If you don't have an Amazon Glue VPC connection set up already, create a new one by following the steps in the [Creating connections for connectors](#) section using the Amazon Glue console or the Amazon CLI/SDK.

7. Choose a compaction strategy. The available options are:
 - **Binpack** – Binpack is the default compaction strategy in Apache Iceberg. It combines smaller data files into larger ones for optimal performance.
 - **Sort** – Sorting in Apache Iceberg is a data organization technique that clusters information within files based on specified columns, significantly improving query performance by reducing the number of files that need to be processed. You define the sort order in Iceberg's metadata using the sort-order field, and when multiple columns are specified, data is sorted in the sequence the columns appear in the sort order, ensuring records with similar values are stored together within files. The sorting compaction strategy takes the optimization further by sorting data across all files within a partition.
 - **Z-order** – Z-ordering is a way to organize data when you need to sort by multiple columns with equal importance. Unlike traditional sorting that prioritizes one column over others, Z-ordering gives balanced weight to each column, helping your query engine read fewer files when searching for data.

The technique works by weaving together the binary digits of values from different columns. For example, if you have the numbers 3 and 4 from two columns, Z-ordering first converts them to binary (3 becomes 011 and 4 becomes 100), then interleaves these digits to create a new value: 011010. This interleaving creates a pattern that keeps related data physically close together.

Z-ordering is particularly effective for multi-dimensional queries. For example, a customer table Z-ordered by income, state, and zip code can deliver superior performance compared to hierarchical sorting when querying across multiple dimensions. This organization allows queries targeting specific combinations of income and geographic location to quickly locate relevant data while minimizing unnecessary file scans.

8. **Minimum input files** – The number of data files required in a partition before compaction is triggered.
9. **Delete files threshold** – Minimum delete operations required in a data file before it becomes eligible for compaction.
10. Choose **Enable optimization**.

Amazon CLI

The following example shows how to enable compaction. Replace the account ID with a valid Amazon account ID. Replace the database name and table name with actual Iceberg table name and the database name. Replace the `roleArn` with the Amazon Resource Name (ARN) of the IAM role and name of the IAM role that has the required permissions to run compaction. You can replace compaction strategy `sort` with other supported strategies like `z-order` or `binpack`.

order" depending on your requirements.

```
aws glue create-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --table-optimizer-configuration '{  
    "roleArn": "arn:aws:iam::123456789012:role/optimizer_role",  
    "enabled": true,  
    "vpcConfiguration": {"glueConnectionName": "glue_connection_name"},  
    "compactionConfiguration": {  
      "icebergConfiguration": {"strategy": "sort"}  
    }  
  }'
```

```
}  
} '\  
--type compaction
```

Amazon API

Call [CreateTableOptimizer](#) operation to enable compaction for a table.

After you enable compaction, **Table optimization** tab shows the following compaction details once the compaction run is complete:

Start time

The time at which the compaction process started within Data Catalog. The value is a timestamp in UTC time.

End time

The time at which the compaction process ended in Data Catalog. The value is a timestamp in UTC time.

Status

The status of the compaction run. Values are success or fail.

Files compacted

Total number of files compacted.

Bytes compacted

Total number of bytes compacted.

Disabling compaction optimizer

You can disable automatic compaction for a particular Apache Iceberg table using Amazon Glue console or Amazon CLI.

Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.

2. On the left navigation, under **Data Catalog**, choose **Tables**.
3. From the tables list, choose the Iceberg table that you want to disable compaction.
4. Choose the **Table optimization** tab on the lower section of the **Tables details** page.
5. From **Actions**, choose **Disable**, and then choose **Compaction**.
6. Choose **Disable compaction** on the confirmation message. You can re-enable compaction at a later time.

After the you confirm, compaction is disabled and the compaction status for the table turns back to Disabled.

Amazon CLI

In the following example, replace the account ID with a valid Amazon account ID. Replace the database name and table name with actual Iceberg table name and the database name. Replace the `roleArn` with the Amazon Resource Name (ARN) of the IAM role and actual name of the IAM role that has the required permissions to run compaction.

```
aws glue update-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --table-optimizer-configuration  
'{"roleArn":"arn:aws:iam::123456789012:role/optimizer_role", "enabled":'false',  
"vpcConfiguration":{"glueConnectionName":"glue_connection_name"}}'\  
  --type compaction
```

Amazon API

Call [UpdateTableOptimizer](#) operation to disable compaction for a specific table.

Snapshot retention optimization

Apache Iceberg snapshot retention feature allows users to query historical data at specific points in time and revert unwanted modifications to their tables. In the Amazon Glue Data Catalog, snapshot retention configuration controls how long these snapshots (versions of the table data) are kept before being expired and removed. This helps manage storage costs and metadata overhead by automatically removing older snapshots based on a configured retention period or maximum number of snapshots to keep.

You can configure the retention period in days and the maximum number of snapshots to retain for a table. Amazon Glue removes snapshots that are older than the specified retention period from the table metadata, while keeping the most recent snapshots up to the configured limit. After removing old snapshots from the metadata, Amazon Glue deletes the corresponding data and metadata files that are no longer referenced and unique to the expired snapshots. This allows time travel queries only up to the remaining retained snapshots, while reclaiming storage space used by expired snapshot data.

Topics

- [Enabling snapshot retention optimizer](#)
- [Updating snapshot retention optimizer](#)
- [Disabling snapshot retention optimizer](#)

Enabling snapshot retention optimizer

You can use Amazon Glue console, Amazon CLI, or Amazon API to enable snapshot retention optimizers for your Apache Iceberg tables in the Data Catalog. For new tables, you can choose Apache Iceberg as table format and enable snapshot retention optimizer when you create the table. Snapshot retention is disabled by default for new tables.

Console

To enable snapshot retention optimizer

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/> and sign in as a data lake administrator, the table creator, or a user who has been granted the `glue:UpdateTable` and `lakeformation:GetDataAccess` permissions on the table.
2. In the navigation pane, under **Data Catalog**, choose **Tables**.
3. On the **Tables** page, choose an Iceberg table that you want to enable snapshot retention optimizer for, then under **Actions** menu, choose **Enable** under **Optimization**.

You can also enable optimization by selecting the table and opening the **Table details** page. Choose the **Table optimization** tab on the lower section of the page, and choose **Enable snapshot retention**.

4. On the **Enable optimization** page, under **Optimization configuration**, you have two options: **Use default setting** or **Customize settings**. If you choose to use the default settings, Amazon Glue utilizes the properties defined in the Iceberg table configuration to determine

the snapshot retention period and the number of snapshots to be retained. In the absence of this configuration, Amazon Glue retains one snapshot for five days, and deletes files associated with the expired snapshots.

5. Next, choose an IAM role that Amazon Glue can assume on your behalf to run the optimizer. For details about the permissions required for the IAM role, see the [Table optimization prerequisites](#) section.

Follow the steps below to update an existing IAM role:

- a. To update the permissions policy for the IAM role, in the IAM console, go to the IAM role that is being used for running compaction.
 - b. In the Add permissions section, choose Create policy. In the newly opened browser window, create a new policy to use with your role.
 - c. On the Create policy page, choose the JSON tab. Copy the JSON code shown in the Prerequisites into the policy editor field.
6. If you prefer to set the values for the **Snapshot retention configuration** manually, choose **Customize settings**.

Optimization configuration

[Create Glue network connection](#)

Snapshot retention configuration

Snapshot retention period

Configure how long Apache Iceberg retains historical table snapshots before deleting them.

- Use the value specified in Apache Iceberg table configuration
If no value is provided, use the default retention period of 5 days for snapshots.
- Specify a custom value in days

Minimum snapshot to retain

- Use the value specified in Apache Iceberg table configuration
If no value is provided, use the default setting of retaining one snapshot.
- Specify a custom value

Snapshot deletion run rate

Configure the interval in hours between two deletion job runs.

- Use the value specified in Apache Iceberg table configuration
If no value is provided, use the default setting of 24 hours between deletion jobs.
- Specify a custom value in hours

Expired snapshots associated files

- Delete associated files
Files associated with the expired snapshots will be deleted.

7. Choose the box **Apply the selected IAM role to the selected optimizers** option to use a single IAM role for all enabling all optimizers.
8. If you have security policy configurations where the Iceberg table optimizer needs to access Amazon S3 buckets from a specific Virtual Private Cloud (VPC), create an Amazon Glue network connection or use an existing one.

If you don't have an Amazon Glue VPC Connection set up already, create a new one by following the steps in the [Creating connections for connectors](#) section using the Amazon Glue console or the Amazon CLI/SDK.

9. Next, under **Snapshot retention configuration**, either choose to use the values specified in the [Iceberg table configuration](#), or specify custom values for snapshot retention period (history.expire.max-snapshot-age-ms), minimum number of snapshots (history.expire.min-snapshots-to-keep) to retain, and the time in hours between consecutive snapshot deletion job runs.
10. Choose **Delete associated files** to delete underlying files when the table optimizer deletes old snapshots from the table metadata.

If you don't choose this option, when older snapshots are removed from the table metadata, their associated files will remain in the storage as orphaned files.

11. Next, read the caution statement, and choose **I acknowledge** to proceed.

 **Note**

In the Data Catalog, the snapshot retention optimizer honors the lifecycle that is controlled by branch and tag level retention policies. For more information, see [Branching and tagging](#) section in the Iceberg documentation.

12. Review the configuration and choose **Enable optimization**.

Wait a few minutes for the retention optimizer to run and expire old snapshots based on the configuration.

Amazon CLI

To enable snapshot retention for new Iceberg tables in Amazon Glue, you need to create a table optimizer of type `retention` and set the `enabled` field to `true` in the `table-optimizer-configuration`. You can do this using the Amazon CLI command

`create-table-optimizer` or `update-table-optimizer`. Additionally, you need to specify the retention configuration fields like `snapshotRetentionPeriodInDays` and `numberOfSnapshotsToRetain` based on your requirements.

The following example shows how to enable the snapshot retention optimizer. Replace the account ID with a valid Amazon account ID. Replace the database name and table name with actual Iceberg table name and the database name. Replace the `roleArn` with the Amazon Resource Name (ARN) of the IAM role and name of the IAM role that has the required permissions to run the snapshot retention optimizer.

```
aws glue create-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --table-optimizer-configuration \  
  '{"roleArn":"arn:aws:iam::123456789012:role/optimizer_role","enabled":'true',  
  "vpcConfiguration":{  
  "glueConnectionName":"glue_connection_name"}, "retentionConfiguration":  
  {"icebergConfiguration":  
  {"snapshotRetentionPeriodInDays":7,"numberOfSnapshotsToRetain":3,"cleanExpiredFiles":'true'}}  
  --type retention
```

This command creates a retention optimizer for the specified Iceberg table in the given catalog, database, and Region. The `table-optimizer-configuration` specifies the IAM role ARN to use, enables the optimizer, and sets the retention configuration. In this example, it retains snapshots for 7 days, keeps a minimum of 3 snapshots, and cleans expired files.

- `snapshotRetentionPeriodInDays` – The number of days to retain snapshots before expiring them. The default value is 5.
- `numberOfSnapshotsToRetain` – The minimum number of snapshots to keep, even if they are older than the retention period. The default value is 1.
- `cleanExpiredFiles` – A boolean indicating whether to delete expired data files after expiring snapshots. The default value is `true`.

When set to `true`, older snapshots are removed from table metadata, and their underlying files are deleted. If this parameter is set to `false`, older snapshots are removed from table metadata but their underlying files remain in the storage as orphan files.

Amazon API

Call [CreateTableOptimizer](#) operation to enable snapshot retention optimizer for a table.

After you enable compaction, **Table optimization** tab shows the following compaction details (after approximately 15-20 minutes):

Start time

The time at which the snapshot retention optimizer started. The value is a timestamp in UTC time.

Run time

The time shows how long the optimizer takes to complete the task. The value is a timestamp in UTC time.

Status

The status of the optimizer run. Values are success or fail.

Data files deleted

Total number of files deleted.

Manifest files deleted

Total number of manifest files deleted.

Manifest lists deleted

Total number of manifest lists deleted.

Updating snapshot retention optimizer

You can update the existing configuration of an snapshot retention optimizer for a particular Apache Iceberg table using the Amazon Glue console, Amazon CLI, or the UpdateTableOptimizer API.

Console

To update snapshot retention configuration

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.

2. Choose **Data Catalog** and choose **Tables**. From the tables list, choose the Iceberg table you want to update the snapshot retention optimizer configuration.
3. On the lower section of the **Tables details** page, select the **Table optimization** tab, and then choose **Edit**. You can also choose **Edit** under **Optimization** from the **Actions** menu located on the top right corner of the page.
4. On the **Edit optimization** page, make the desired changes.
5. Choose **Save**.

Amazon CLI

To update a snapshot retention optimizer using the Amazon CLI, you can use the following command:

```
aws glue update-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --table-optimizer-configuration  
  '{"roleArn":"arn:aws:iam::123456789012:role/optimizer_role","enabled":'true',  
  "vpcConfiguration":  
  {"glueConnectionName": "glue_connection_name"}, "retentionConfiguration":  
  {"icebergConfiguration":  
  {"snapshotRetentionPeriodInDays": 7, "numberOfSnapshotsToRetain": 3, "cleanExpiredFiles": 'true'}}  
  \  
  --type retention
```

This command updates the retention configuration for the specified table in the given catalog, database, and Region. The key parameters are:

- `snapshotRetentionPeriodInDays` – The number of days to retain snapshots before expiring them. The default value is 1.
- `numberOfSnapshotsToRetain` – The minimum number of snapshots to keep, even if they are older than the retention period. The default value is 5.
- `cleanExpiredFiles` – A boolean indicating whether to delete expired data files after expiring snapshots. The default value is `true`.

When set to true, older snapshots are removed from table metadata, and their underlying files are deleted." If this parameter is set to false, older snapshots are removed from table metadata but their underlying files remain in the storage as orphan files.

API

To update a table optimizer, you can use the `UpdateTableOptimizer` API. This API allows you to update the configuration of an existing table optimizer for compaction, retention, or orphan file removal. The request parameters include:

- `catalogId` (required): The ID of the catalog containing the table
- `databaseName` (optional): The name of the database containing the table
- `tableName` (optional): The name of the table
- `type` (required): The type of table optimizer (compaction, retention, or `orphan_file_deletion`)
- `retentionConfiguration` (required): The updated configuration for the table optimizer, including role ARN, enabled status, retention configuration, and orphan file removal configuration.

Disabling snapshot retention optimizer

You can disable the snapshot retention optimizer for a particular Apache Iceberg table using Amazon Glue console or Amazon CLI.

Console

To disable snapshot retention

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Data Catalog** and choose **Tables**. From the tables list, choose the Iceberg table that you want to disable the optimizer for snapshot retention.
3. On lower section of the **Table details** page, choose **Table optimization** and **Disable, Snapshot retention** under **Actions**.

You can also choose **Disable** under **Optimization** from the **Actions** menu located on top right corner of the page.

4. Choose **Disable** on the confirmation message. You can re-enable the snapshot retention optimizer at a later time.

After the you confirm, snapshot retention optimizer is disabled and the status for snapshot retention turns back to Not enabled.

Amazon CLI

In the following example, replace the account ID with a valid Amazon account ID. Replace the database name and table name with actual Iceberg table name and the database name. Replace the `roleArn` with the Amazon Resource Name (ARN) of the IAM role and actual name of the IAM role that has the required permissions to run the retention optimizer.

```
aws glue update-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --table-optimizer-configuration  
  '{"roleArn":"arn:aws:iam::123456789012:role/optimizer_role", "vpcConfiguration":  
  {"glueConnectionName":"glue_connection_name"}, "enabled":'false'}\  
  --type retention
```

Amazon API

Call [UpdateTableOptimizer](#) operation to disable the snapshot retention optimizer for a specific table.

Deleting orphan files

Amazon Glue Data Catalog allows you to remove orphan files from your Iceberg tables. Orphan files are unreferenced files that exist in your Amazon S3 data source under the specified table location, are not tracked by the Iceberg table metadata, and are older than your configured age limit. These orphan files can accumulate over time due to failure in operations like compaction, partition drops, or table rewrites, and take up unnecessary storage space.

The orphan file deletion optimizer in Amazon Glue scans the table metadata and the actual data files, identifies the orphan files, and deletes them to reclaim storage space. The optimizer only removes files created after the optimizer's creation date that also meet the configured deletion criteria. Files created before or on the optimizer creation date are never deleted.

Orphan file deletion logic

1. Date check – Compares file creation date with optimizer creation date. If file is older than or equal to optimizer creation date, the file is skipped.
2. Optimizer configuration check – If file is newer than optimizer creation date, evaluates the file against the configured age limit. The optimizer deletes the file if it matches the deletion criteria. Skips the file, if it doesn't match the criteria.

You can initiate the orphan file deletion by creating an orphan file deletion table optimizer in the Data Catalog.

Important

By default, orphan file deletion evaluates files across your Amazon Glue table location. While you can configure a sub-prefix to limit the scope of evaluation by using API parameter, you must ensure your table location doesn't contain files from other data sources or tables. If your table location overlaps with other data sources, the service might identify and delete unrelated files as orphans.

Topics

- [Enabling orphan file deletion](#)
- [Updating orphan file deletion optimizer](#)
- [Disabling orphan file deletion](#)

Enabling orphan file deletion

You can use Amazon Glue console, Amazon CLI, or Amazon API to enable orphan file deletion for your Apache Iceberg tables in the Data Catalog. For new tables, you can choose Apache Iceberg as table format and enable orphan file deletion optimizer when you create the table. Snapshot retention is disabled by default for new tables.

Console

To enable orphan file deletion

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/> and sign in as a data lake administrator, the table creator, or a user who has been granted the `glue:UpdateTable` and `lakeformation:GetDataAccess` permissions on the table.
2. In the navigation pane, under **Data Catalog**, choose **Tables**.
3. On the **Tables** page, choose an Iceberg table in that you want to enable orphan file deletion.

Choose the **Table optimization** tab on the lower section of the page, and choose **Enable, Orphan file deletion** from **Actions**.

You can also choose **Enable** under **Optimization** from the **Actions** menu located on the top right corner of the page..

4. On the **Enable optimization** page, choose **Orphan file deletion** under **Optimization options**.
5. If you choose to use **Default settings**, all orphan files will be deleted after 3 days. If you want to keep the orphan files for a specific number of days, choose **Customize settings**.
6. Next, choose an IAM role with the required permissions to delete orphan files.
7. If you have security policy configurations where the Iceberg table optimizer needs to access Amazon S3 buckets from a specific Virtual Private Cloud (VPC), create an Amazon Glue network connection or use an existing one.

If you don't have an Amazon Glue VPC Connection set up already, create a new one by following the steps in the [Creating connections for connectors](#) section using the Amazon Glue console or the Amazon CLI/SDK.

8. If you choose **Customize settings**, enter the number of days to retain the files before deletion under **Orphan file deletion configuration**. You can also specify the interval between two consecutive optimizer runs. The default value is 24 hours.
9. Choose **Enable optimization**.

Amazon CLI

To enable orphan file deletion for an Iceberg table in Amazon Glue, you need to create a table optimizer of type `orphan_file_deletion` and set the `enabled` field to `true`. To create an

orphan file deletion optimizer for an Iceberg table using the Amazon CLI, you can use the following command:

```
aws glue create-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --table-optimizer-configuration \  
  '{"roleArn":"arn:aws:iam::123456789012:role/optimizer_role","enabled":true, \  
  "vpcConfiguration":{ \  
  "glueConnectionName": "glue_connection_name", "orphanFileDeletionConfiguration": \  
  {"icebergConfiguration":{"orphanFileRetentionPeriodInDays":3, "location":'S3 \  
  location'}}}' \  
  --type orphan_file_deletion
```

This command creates an orphan file deletion optimizer for the specified Iceberg table. The key parameters are:

- `roleArn` – the ARN of the IAM role with permissions to access the S3 bucket and Glue resources.
- `enabled` – Set to true to enable the optimizer.
- `orphanFileRetentionPeriodInDays` – The number of days to retain orphan files before deleting them (minimum 1 day).
- `type` – Set to `orphan_file_deletion` to create an orphan file deletion optimizer.

After creating the table optimizer, it will run orphan file deletion periodically (once per day if left enabled). You can check the runs using the `list-table-optimizer-runs` API. The orphan file deletion job will identify and delete files that are not tracked in the Iceberg metadata for the table.

API

Call [CreateTableOptimizer](#) operation to create the orphan file deletion optimizer for a specific table.

Updating orphan file deletion optimizer

You can modify the configuration for the orphan file deletion optimizer, such as changing the retention period for orphan files or the IAM role used by the optimizer using Amazon Glue console, Amazon CLI, or the `UpdateTableOptimizer` operation.

Amazon Web Services Management Console

To update the orphan file deletion optimizer

1. Choose **Data Catalog** and choose **Tables**. From the tables list, choose the table you want to update the orphan file deletion optimizer configuration.
2. On the lower section of the **Tables details** page, choose **Table optimization**, and then choose **Edit**.
3. On the **Edit optimization** page, make the desired changes.
4. Choose **Save**.

Amazon CLI

You can use the `update-table-optimizer` call to update the orphan file deletion optimizer in Amazon Glue, you can use call. This allows you to modify the `OrphanFileDeletionConfiguration` in the `icebergConfiguration` field where you can specify the updated `OrphanFileRetentionPeriodInDays` to set the number of days to retain orphan files, to specify the Iceberg table location to delete orphan files from.

```
aws glue update-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name Iceberg_table \  
  --table-optimizer-configuration \  
  '{"roleArn":"arn:aws:iam::123456789012:role/optimizer_role","enabled":true, \  
  "vpcConfiguration": \  
  {"glueConnectionName":"glue_connection_name"},"orphanFileDeletionConfiguration": \  
  {"icebergConfiguration":{"orphanFileRetentionPeriodInDays":5}}}' \  
  --type orphan_file_deletion
```

API

Call the [UpdateTableOptimizer](#) operation to update the orphan file deletion optimizer for a table.

Disabling orphan file deletion

You can disable orphan file deletion optimizer for a particular Apache Iceberg table using Amazon Glue console or Amazon CLI.

Console

To disable orphan file deletion

1. Choose **Data Catalog** and choose **Tables**. From the tables list, choose the Iceberg table that you want to disable the optimizer for orphan file deletion.
2. On lower section of the **Table details** page, choose **Table optimization** tab.
3. Choose **Actions**, and then choose **Disable , Orphan file deletion**.

You can also choose **Disable** under **Optimization** from the **Actions** menu.

4. Choose **Disable** on the confirmation message. You can re-enable the orphan file deletion optimizer at a later time.

After the you confirm, orphan file deletion optimizer is disabled and the status for orphan file deletion turns back to Not enabled.

Amazon CLI

In the following example, replace the account ID with a valid Amazon account ID. Replace the database name and table name with actual Iceberg table name and the database name. Replace the `roleArn` with the Amazon Resource Name (ARN) of the IAM role and actual name of the IAM role that has the required permissions to disable the optimizer.

```
aws glue update-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --table-optimizer-configuration  
'{"roleArn":"arn:aws:iam::123456789012:role/optimizer_role", "enabled":'false'}'\  
  --type orphan_file_deletion
```

API

Call the [UpdateTableOptimizer](#) operation to disable the snapshot retention optimizer for a specific table.

Viewing optimization details

You can view the optimization status for Apache Iceberg tables in the Amazon Glue console, Amazon CLI, or using Amazon API operations.

Console

To view the optimization status for Iceberg tables (console)

- You can view optimization status for Iceberg tables on the Amazon Glue console by choosing an Iceberg table from the **Tables** list under **Data Catalog**. Under **Table optimization**. Choose the **View all**

Optimization configuration
Configure Apache Iceberg table optimizations to optimize storage and improve query performance.

Compaction history (5686)
Small Amazon S3 objects are automatically compacted into larger objects. View the status of the data compaction run. [Learn more](#)

Thursday, August 22, 2024 at 12:23 AM UTC	Success	Thursday, August 22, 2024 at 12:31 AM UTC	1148	2
Wednesday, August 21, 2024 at 12:23 AM UTC	Success	Wednesday, August 21, 2024 at 12:31 AM UTC	1148	2

Amazon CLI

You can view the optimization details using Amazon CLI.

In the following examples, replace the account ID with a valid Amazon account ID, the database name, and table name with actual Iceberg table name. For type, provide an optimization type. Acceptable values are `compaction`, `retention`, and `orphan-file-deletion`.

- To get the last compaction run details for a table

```
aws get-table-optimizer \
  --catalog-id 123456789012 \
  --database-name iceberg_db \
  --table-name iceberg_table \
```

```
--type compaction
```

- Use the following example to retrieve the history of an optimizer for a specific table.

```
aws list-table-optimizer-runs \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --type compaction
```

- The following example shows how to retrieve the optimization run and configuration details for multiple optimizers. You can specify a maximum of 20 optimizers.

```
aws glue batch-get-table-optimizer \  
  --entries '[{"catalogId":"123456789012", "databaseName":"iceberg_db",  
  "tableName":"iceberg_table", "type":"compaction"}]'
```

API

- Use `GetTableOptimizer` operation to retrieve the last run details of an optimizer.
- Use `ListTableOptimizerRuns` operation to retrieve history of a given optimizer on a specific table. You can specify 20 optimizers in a single API call.
- Use the [BatchGetTableOptimizer](#) operation to retrieve configuration details for multiple optimizers in your account.

Viewing Amazon CloudWatch metrics

After running the table optimizers successfully, the service creates Amazon CloudWatch metrics on the optimization job performance. You can go to the **CloudWatch Metrics** and choose **Metrics, All metrics**. You can filter metrics by the specific namespace (for example Amazon Glue), table name, or database name.

For more information, see [View available metrics](#) in the *Amazon CloudWatch User Guide*.

Compaction

- Number of bytes compacted
- Number of files compacted

- Number of DPU allocated to job
- Duration of job (Hours)

Snapshot retention

- Number of data files deleted
- Number of manifest files deleted
- Number of Manifest lists deleted
- Duration of job (Hours)

Orphan file deletion

- Number of orphan files deleted
- Duration of job (Hours)

Deleting an optimizer

You can delete an optimizer and associated metadata for the table using Amazon CLI or Amazon API operation.

Run the following Amazon CLI command to delete optimization history for a table. You need to specify the optimizer type along with the catalog ID, database name and table name. The acceptable values are: `compaction`, `retention`, and `orphan_file_deletion`.

```
aws glue delete-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --type compaction
```

Use `DeleteTableOptimizer` operation to delete an optimizer for a table.

Considerations and limitations

This section includes things to consider when using table optimizers within the Amazon Glue Data Catalog.

Supported formats and limitations for managed data compaction

Data compaction supports a variety of data types and compression formats for reading and writing data, including reading data from encrypted tables.

Concurrency Control:

Apache Iceberg supports optimistic concurrency control, allowing multiple writers to perform operations simultaneously. Conflicts are detected and resolved at commit time. When working with streaming pipelines, configure appropriate retry settings through table properties and compaction settings to handle concurrent writes effectively. For detailed guidance, refer to the Amazon Big Data Blog on managing concurrent writes in Iceberg tables. see <https://aws.amazon.com/blogs/big-data/manage-concurrent-write-conflicts-in-apache-iceberg-on-the-aws-glue-data-catalog/>

Compaction Retries:

When compaction operations fail four consecutive times, Amazon Glue catalog table optimization automatically suspends the optimizer to prevent unnecessary compute resource consumption. First investigate the logs and try to understand why compaction is repeatedly failing. To resume compaction optimization, you can re-enable the optimizer through the Amazon Glue console or API.

Data compaction supports:

- **Encryption** – Data compaction only supports default Amazon S3 encryption (SSE-S3) and server-side KMS encryption (SSE-KMS).
- **Compaction strategies** -- Binpack, sort, and Z-order sorting
- You can run compaction from the account where Data Catalog resides when the Amazon S3 bucket that stores the underlying data is in another account. To do this, the compaction role requires access to the Amazon S3 bucket.

Data compaction currently doesn't support:

- **Compaction on cross-account tables** – You can't run compaction on cross-account tables.
- **Compaction on cross-Region tables** – You can't run compaction on cross-Region tables.
- **Enabling compaction on resource links**
- **Tables in Amazon S3 Express One Zone storage class** – You can't run compaction on S3 Express One Zone Iceberg Tables.

- **Z-order compaction strategy doesn't support the following data types :**
 - Decimal
 - TimestampWithoutZone

Considerations for snapshot retention and orphan file deletion optimizers

The following considerations apply to the snapshot retention and the orphan file deletion optimizers.

- The snapshot retention and orphan file deletion processes have a maximum limit of deleting 1,000,000 files per run. When deleting expired snapshots, if the number of eligible files for deletion surpasses 1,000,000, any remaining files beyond that threshold will continue to exist in the table storage as orphan files.
- Snapshots will be preserved by the snapshot retention optimizer only when both criteria are satisfied: the minimum number of snapshots to keep and the specified retention period.
- The snapshot retention optimizer deletes expired snapshot metadata from Apache Iceberg, preventing time travel queries for expired snapshots and optionally deleting associated data files.
- Orphan file deletion optimizer deletes orphaned data and metadata files that are no longer referenced by Iceberg metadata if their creation time is before the orphan file deletion retention period from the time of optimizer run.
- Apache Iceberg facilitates version control through branches and tags, which are named pointers to specific snapshot states. Each branch and tag follows its own independent life-cycle, governed by retention policies defined at their respective levels. The Amazon Glue Data Catalog optimizers take these life cycle policies into account, ensuring adherence to the specified retention rules. Branch and tag-level retention policies take precedence over the optimizer configurations.

For more information, see [Branching and Tagging](#) in Apache Iceberg documentation.

- Snapshot retention and orphan file deletion optimizers will delete files eligible for clean-up as per configured parameters. Enhance your control over file deletion by implementing S3 versioning and life-cycle policies on the appropriate buckets.

For detailed instructions on setting up versioning and creating life cycle rules, see <https://docs.amazonaws.cn/AmazonS3/latest/userguide/Versioning.html>.

- For proper orphan file determination, ensure that the provided table location and any sub-paths don't overlap with or contain data from any other tables or data sources. If paths overlap, you risk unrecoverable data loss from unintended deletion of files.

Debugging `OversizedAllocationException` exception

To resolve an `OversizedAllocationException` exception:

- Reduce the batch size of the vectorized reader and check. The default batch size is 5000. This is controlled in the `read.parquet.vectorization.batch-size`.
 - If this doesn't work even after multiple variations, turn off vectorization. This is controlled in the `read.parquet.vectorization.enabled`.
 - If this doesn't work even after multiple variations, turn off vectorization. This is controlled in the `read.parquet.vectorization.enabled`.

Supported Regions for table optimizers

The table optimization features (compaction, snapshot retention, and orphan file deletion) for Amazon Glue Data Catalog are available in the following Amazon Web Services Regions:

- Asia Pacific (Tokyo)
- Asia Pacific (Seoul)
- Asia Pacific (Mumbai)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Jakarta)
- Canada (Central)
- Europe (Ireland)
- Europe (London)
- Europe (Frankfurt)
- Europe (Stockholm)
- US East (N. Virginia)
- US East (Ohio)

- US West (Oregon)
- South America (São Paulo)

Optimizing query performance for Iceberg tables

Apache Iceberg is a high-performance open table format for huge analytic datasets. Amazon Glue supports calculating and updating number of distinct values (NDVs) for each column in Iceberg tables. These statistics can facilitate better query optimization, data management, and performance efficiency for data engineers and scientists working with large-scale datasets.

Amazon Glue estimates the number of distinct values in each column of the Iceberg table and store them in [Puffin](#) files on Amazon S3 associated with Iceberg table snapshots. Puffin is an Iceberg file format designed to store metadata like indexes, statistics, and sketches. Storing sketches in Puffin files tied to snapshots ensures transactional consistency and freshness of the NDV statistics.

You can configure to run column statistics generation task using Amazon Glue console or Amazon CLI. When you initiate the process, Amazon Glue starts a Spark job in the background and updates the Amazon Glue table metadata in the Data Catalog. You can view column statistics using Amazon Glue console or Amazon CLI or by calling the [GetColumnStatisticsForTable](#) API operation.

Note

If you're using Amazon Lake Formation permissions to control access to the table, the role assumed by the column statistics task requires full table access to generate statistics.

Topics

- [Prerequisites for generating column statistics](#)
- [Generating column statistics for Iceberg tables](#)
- [See also](#)

Prerequisites for generating column statistics

To generate or update column statistics for Iceberg tables, the statistics generation task assumes an Amazon Identity and Access Management (IAM) role on your behalf. Based on the permissions

granted to the role, the column statistics generation task can read the data from the Amazon S3 data store.

When you configure the column statistics generation task, Amazon Glue allows you to create a role that includes the `AWSGlueServiceRole` Amazon managed policy plus the required inline policy for the specified data source.

If you specify an existing role for generating column statistics, ensure that it includes the `AWSGlueServiceRole` policy or equivalent (or a scoped down version of this policy), and the required inline policies.

For more information about the required permissions, see [Prerequisites for generating column statistics](#).

Generating column statistics for Iceberg tables

Follow these steps to configure a schedule for generating statistics in the Data Catalog using Amazon Glue console or Amazon CLI or the or run the `StartColumnStatisticsTaskRun` operation.

To generate column statistics

1. Sign in to the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose **Tables** under Data Catalog .
3. Choose an Iceberg table from the list.
4. Choose **Column statistics, Generate on demand**, under **Actions** menu.

You can also choose **Generate statistics** button under **Column statistics** tab in the lower section of the **Tables** page.

5. On the **Generate statistics** page, provide the statistics generation details. Follow steps 6-11 in the [Generating column statistics on a schedule](#) section to configure a schedule for statistics generation for Iceberg tables.

You can also choose to generate column statistics on-demand by followin the instructions in the [Generating column statistics on demand](#)

Note

Sampling option is not available for Iceberg tables.

Amazon Glue calculates the number of distinct values for each column of the Iceberg table to a new Puffin file committed to the specified snapshot ID in your Amazon S3 location.

Managing the Data Catalog

The Amazon Glue Data Catalog is a central metadata repository that stores structural and operational metadata for your Amazon S3 data sets. Managing the Data Catalog effectively is crucial for maintaining data quality, performance, security, and governance.

By understanding and applying these Data Catalog management practices, you can ensure your metadata remains accurate, performant, secure, and well-governed as your data landscape evolves.

This section covers the following aspects of Data Catalog management:

- *Updating table schema and partitions* As your data evolves, you may need to update the table schema or partition structure defined in the Data Catalog. For more information on how to make these updates programmatically using the Amazon Glue ETL, see [Updating the schema, and adding new partitions in the Data Catalog using Amazon Glue ETL jobs](#).
- *Managing column statistics:* Accurate column statistics help optimize query plans and improve performance. For more information on how to generate, update, and manage column statistics, see [Optimizing query performance using column statistics](#).
- *Encrypting the Data Catalog* To protect sensitive metadata, you can encrypt your Data Catalog using Amazon Key Management Service (Amazon KMS). This section explains how to enable and manage encryption for your Data Catalog.
- *Securing the Data Catalog with Amazon Lake Formation* Lake Formation provides a comprehensive approach to data lake security and access control. You can use Lake Formation to secure and govern access to your Data Catalog and underlying data.

Topics

Updating the schema, and adding new partitions in the Data Catalog using Amazon Glue ETL jobs

Your extract, transform, and load (ETL) job might create new table partitions in the target data store. Your dataset schema can evolve and diverge from the Amazon Glue Data Catalog schema over time. Amazon Glue ETL jobs now provide several features that you can use within your ETL script to update your schema and partitions in the Data Catalog. These features allow you to see the results of your ETL work in the Data Catalog, without having to rerun the crawler.

New partitions

If you want to view the new partitions in the Amazon Glue Data Catalog, you can do one of the following:

- When the job finishes, rerun the crawler, and view the new partitions on the console when the crawler finishes.
- When the job finishes, view the new partitions on the console right away, without having to rerun the crawler. You can enable this feature by adding a few lines of code to your ETL script, as shown in the following examples. The code uses the `enableUpdateCatalog` argument to indicate that the Data Catalog is to be updated during the job run as the new partitions are created.

Method 1

Pass `enableUpdateCatalog` and `partitionKeys` in an options argument.

Python

```
additionalOptions = {"enableUpdateCatalog": True}
```

```

additionalOptions["partitionKeys"] = ["region", "year", "month", "day"]

sink = glueContext.write_dynamic_frame_from_catalog(frame=last_transform,
  database=<target_db_name>,

  table_name=<target_table_name>, transformation_ctx="write_sink",

  additional_options=additionalOptions)

```

Scala

```

val options = JsonOptions(Map(
  "path" -> <S3_output_path>,
  "partitionKeys" -> Seq("region", "year", "month", "day"),
  "enableUpdateCatalog" -> true))
val sink = glueContext.getCatalogSink(
  database = <target_db_name>,
  tableName = <target_table_name>,
  additionalOptions = options)sink.writeDynamicFrame(df)

```

Method 2

Pass `enableUpdateCatalog` and `partitionKeys` in `getSink()`, and call `setCatalogInfo()` on the `DataSink` object.

Python

```

sink = glueContext.getSink(
  connection_type="s3",
  path="<S3_output_path>",
  enableUpdateCatalog=True,
  partitionKeys=["region", "year", "month", "day"])
sink.setFormat("json")
sink.setCatalogInfo(catalogDatabase=<target_db_name>,
  catalogTableName=<target_table_name>)
sink.writeFrame(last_transform)

```

Scala

```

val options = JsonOptions(
  Map("path" -> <S3_output_path>,
    "partitionKeys" -> Seq("region", "year", "month", "day"),

```

```
    "enableUpdateCatalog" -> true))
val sink = glueContext.getSink("s3", options).withFormat("json")
sink.setCatalogInfo(<target_db_name>, <target_table_name>)
sink.writeDynamicFrame(df)
```

Now, you can create new catalog tables, update existing tables with modified schema, and add new table partitions in the Data Catalog using an Amazon Glue ETL job itself, without the need to re-run crawlers.

Updating table schema

If you want to overwrite the Data Catalog table's schema you can do one of the following:

- When the job finishes, rerun the crawler and make sure your crawler is configured to update the table definition as well. View the new partitions on the console along with any schema updates, when the crawler finishes. For more information, see [Configuring a Crawler Using the API](#).
- When the job finishes, view the modified schema on the console right away, without having to rerun the crawler. You can enable this feature by adding a few lines of code to your ETL script, as shown in the following examples. The code uses `enableUpdateCatalog` set to `true`, and also `updateBehavior` set to `UPDATE_IN_DATABASE`, which indicates to overwrite the schema and add new partitions in the Data Catalog during the job run.

Python

```
additionalOptions = {
    "enableUpdateCatalog": True,
    "updateBehavior": "UPDATE_IN_DATABASE"}
additionalOptions["partitionKeys"] = ["partition_key0", "partition_key1"]

sink = glueContext.write_dynamic_frame_from_catalog(frame=last_transform,
    database=<dst_db_name>,
    table_name=<dst_tbl_name>, transformation_ctx="write_sink",
    additional_options=additionalOptions)
job.commit()
```

Scala

```
val options = JsonOptions(Map(
    "path" -> outputPath,
```

```

    "partitionKeys" -> Seq("partition_0", "partition_1"),
    "enableUpdateCatalog" -> true))
val sink = glueContext.getCatalogSink(database = nameSpace, tableName = tableName,
    additionalOptions = options)
sink.writeDynamicFrame(df)

```

You can also set the `updateBehavior` value to `LOG` if you want to prevent your table schema from being overwritten, but still want to add the new partitions. The default value of `updateBehavior` is `UPDATE_IN_DATABASE`, so if you don't explicitly define it, then the table schema will be overwritten.

If `enableUpdateCatalog` is not set to `true`, regardless of whichever option selected for `updateBehavior`, the ETL job will not update the table in the Data Catalog.

Creating new tables

You can also use the same options to create a new table in the Data Catalog. You can specify the database and new table name using `setCatalogInfo`.

Python

```

sink = glueContext.getSink(connection_type="s3", path="s3://path/to/data",
    enableUpdateCatalog=True, updateBehavior="UPDATE_IN_DATABASE",
    partitionKeys=["partition_key0", "partition_key1"])
sink.setFormat("<format>")
sink.setCatalogInfo(catalogDatabase=<dst_db_name>, catalogTableName=<dst_tbl_name>)
sink.writeFrame(last_transform)

```

Scala

```

val options = JsonOptions(Map(
    "path" -> outputPath,
    "partitionKeys" -> Seq("<partition_1>", "<partition_2>"),
    "enableUpdateCatalog" -> true,
    "updateBehavior" -> "UPDATE_IN_DATABASE"))
val sink = glueContext.getSink(connectionType = "s3", connectionOptions =
    options).withFormat("<format>")
sink.setCatalogInfo(catalogDatabase = "<dst_db_name>", catalogTableName =
    "<dst_tbl_name>")
sink.writeDynamicFrame(df)

```

Restrictions

Take note of the following restrictions:

- Only Amazon Simple Storage Service (Amazon S3) targets are supported.
- The `enableUpdateCatalog` feature is not supported for governed tables.
- Only the following formats are supported: `json`, `csv`, `avro`, and `parquet`.
- To create or update tables with the `parquet` classification, you must utilize the Amazon Glue optimized `parquet` writer for `DynamicFrames`. This can be achieved with one of the following:
 - If you're updating an existing table in the catalog with `parquet` classification, the table must have the `"useGlueParquetWriter"` table property set to `true` before you update it. You can set this property via the Amazon Glue APIs/SDK, via the console or via an Athena DDL statement.

The screenshot shows the Amazon Glue console interface for editing a table. The left sidebar contains navigation options like 'Getting started', 'Data Catalog tables', and 'Data Integration and ETL'. The main content area is titled 'Edit table' and is divided into three sections: 'Table details', 'Serde parameters', and 'Table properties'. The 'Table properties' section contains a table with the following data:

Key	Value	Remove
skip.header.line.count	1	Remove
has_encrypted_data	false	Remove
columnsOrdered	true	Remove
areColumnsQuoted	false	Remove
delimiter	,	Remove
classification	csv	Remove
typeOfData	file	Remove
Enter a unique key	Enter a value	Remove

At the bottom of the 'Table properties' section, there is an 'Add' button highlighted with a red rectangle. The 'Add' button is located below the input fields for the new property.

Once the catalog table property is set, you can use the following snippet of code to update the catalog table with the new data:

```
glueContext.write_dynamic_frame.from_catalog(
    frame=frameToWrite,
    database="dbName",
    table_name="tableName",
    additional_options={
        "enableUpdateCatalog": True,
        "updateBehavior": "UPDATE_IN_DATABASE"
    }
)
```

- If the table doesn't already exist within catalog, you can utilize the `getSink()` method in your script with `connection_type="s3"` to add the table and its partitions to the catalog, along with writing the data to Amazon S3. Provide the appropriate `partitionKeys` and `compression` for your workflow.

```
s3sink = glueContext.getSink(
    path="s3://bucket/folder/",
    connection_type="s3",
    updateBehavior="UPDATE_IN_DATABASE",
    partitionKeys=[],
    compression="snappy",
    enableUpdateCatalog=True
)

s3sink.setCatalogInfo(
    catalogDatabase="dbName", catalogTableName="tableName"
)

s3sink.setFormat("parquet", useGlueParquetWriter=True)
s3sink.writeFrame(frameToWrite)
```

- The `glueparquet` format value is a legacy method of enabling the Amazon Glue parquet writer.
- When the `updateBehavior` is set to `LOG`, new partitions will be added only if the `DynamicFrame` schema is equivalent to or contains a subset of the columns defined in the Data Catalog table's schema.
- Schema updates are not supported for non-partitioned tables (not using the "partitionKeys" option).

- Your `partitionKeys` must be equivalent, and in the same order, between your parameter passed in your ETL script and the `partitionKeys` in your Data Catalog table schema.
- This feature currently does not yet support updating/creating tables in which the updating schemas are nested (for example, arrays inside of structs).

For more information, see [the section called "Amazon Glue for Spark"](#).

Working with MongoDB connections in ETL jobs

You can create a connection for MongoDB and then use that connection in your Amazon Glue job. For more information, see [the section called "MongoDB connections"](#) in the Amazon Glue programming guide. The `connection url`, `username` and `password` are stored in the MongoDB connection. Other options can be specified in your ETL job script using the `additionalOptions` parameter of `glueContext.getCatalogSource`. The other options can include:

- `database`: (Required) The MongoDB database to read from.
- `collection`: (Required) The MongoDB collection to read from.

By placing the `database` and `collection` information inside the ETL job script, you can use the same connection for in multiple jobs.

1. Create an Amazon Glue Data Catalog connection for the MongoDB data source. See ["connectionType": "mongodb"](#) for a description of the connection parameters. You can create the connection using the console, APIs or CLI.
2. Create a database in the Amazon Glue Data Catalog to store the table definitions for your MongoDB data. See [Creating databases](#) for more information.
3. Create a crawler that crawls the data in the MongoDB using the information in the connection to connect to the MongoDB. The crawler creates the tables in the Amazon Glue Data Catalog that describe the tables in the MongoDB database that you use in your job. See [Using crawlers to populate the Data Catalog](#) for more information.
4. Create a job with a custom script. You can create the job using the console, APIs or CLI. For more information, see [Adding Jobs in Amazon Glue](#).
5. Choose the data targets for your job. The tables that represent the data target can be defined in your Data Catalog, or your job can create the target tables when it runs. You choose a target location when you author the job. If the target requires a connection, the connection is also

referenced in your job. If your job requires multiple data targets, you can add them later by editing the script.

6. Customize the job-processing environment by providing arguments for your job and generated script.

Here is an example of creating a `DynamicFrame` from the MongoDB database based on the table structure defined in the Data Catalog. The code uses `additionalOptions` to provide the additional data source information:

Scala

```
val resultFrame: DynamicFrame = glueContext.getCatalogSource(  
    database = catalogDB,  
    tableName = catalogTable,  
    additionalOptions = JsonOptions(Map("database" -> DATABASE_NAME,  
        "collection" -> COLLECTION_NAME))  
).getDynamicFrame()
```

Python

```
glue_context.create_dynamic_frame_from_catalog(  
    database = catalogDB,  
    table_name = catalogTable,  
    additional_options = {"database": "database_name",  
        "collection": "collection_name"})
```

7. Run the job, either on-demand or through a trigger.

Optimizing query performance using column statistics

You can compute column-level statistics for Amazon Glue Data Catalog tables in data formats such as Parquet, ORC, JSON, ION, CSV, and XML without setting up additional data pipelines. Column statistics help you to understand data profiles by getting insights about values within a column.

Data Catalog supports generating statistics for column values such as minimum value, maximum value, total null values, total distinct values, average length of values, and total occurrences of true values. Amazon analytical services such as Amazon Redshift and Amazon Athena can use these column statistics to generate query execution plans, and choose the optimal plan that improves query performance.

There are three scenarios for generating column statistics:

Auto

Amazon Glue supports automatic column statistics generation at the catalog-level so that it can automatically generate statistics for new tables in the Amazon Glue Data Catalog.

Scheduled

Amazon Glue supports scheduling column statistics generation so that it can be run automatically on a recurring schedule.

With scheduled statistics computation, the column statistics task updates the overall table-level statistics, such as min, max, and avg with the new statistics, providing query engines with accurate and up-to-date statistics to optimize query execution.

On-demand

Use this option to generate column statistics on-demand whenever needed. This is useful for ad-hoc analysis or when statistics need to be computed immediately.

You can configure to run column statistics generation task using Amazon Glue console, Amazon CLI, and Amazon Glue API operations. When you initiate the process, Amazon Glue starts a Spark job in the background and updates the Amazon Glue table metadata in the Data Catalog. You can view column statistics using Amazon Glue console or Amazon CLI or by calling the [GetColumnStatisticsForTable](#) API operation.

Note

If you're using Lake Formation permissions to control access to the table, the role assumed by the column statistics task requires full table access to generate statistics.

Topics

- [Prerequisites for generating column statistics](#)
- [Automatic column statistics generation](#)
- [Generating column statistics on a schedule](#)
- [Generating column statistics on demand](#)
- [Viewing column statistics](#)

- [Viewing column statistics task runs](#)
- [Stopping column statistics task run](#)
- [Deleting column statistics](#)
- [Considerations and limitations](#)

Prerequisites for generating column statistics

To generate or update column statistics, the statistics generation task assumes an Amazon Identity and Access Management (IAM) role on your behalf. Based on the permissions granted to the role, the column statistics generation task can read the data from the Amazon S3 data store.

When you configure the column statistics generation task, Amazon Glue allows you to create a role that includes the `AWSGlueServiceRole` Amazon managed policy plus the required inline policy for the specified data source.

If you specify an existing role for generating column statistics, ensure that it includes the `AWSGlueServiceRole` policy or equivalent (or a scoped down version of this policy), plus the required inline policies. Follow these steps to create a new IAM role:

Note

To generate statistics for tables managed by Lake Formation, the IAM role used to generate statistics requires full table access.

When you configure the column statistics generation task, Amazon Glue allows you to create a role that includes the `AWSGlueServiceRole` Amazon managed policy plus the required inline policy for the specified data source. You can also create a role and attach the the permissions listed in the policy below, and add that role to the column statistics generation task.

To create an IAM role for generating column statistics

1. To create an IAM role, see [Create an IAM role for Amazon Glue](#).
2. To update an existing role, in the IAM console, go to the IAM role that is being used by the generate column statistics process.
3. In the **Add permissions** section, choose **Attach policies**. In the newly opened browser window, choose `AWSGlueServiceRole` Amazon managed policy.

4. You also need to include permissions to read data from the Amazon S3 data location.

In the **Add permissions** section, choose **Create policy**. In the newly opened browser window, create a new policy to use with your role.

5. In the **Create policy** page, choose the **JSON** tab. Copy the following JSON code into the policy editor field.

 **Note**

In the following policies, replace account ID with a valid Amazon Web Services account, and replace region with the Region of the table, and bucket-name with the Amazon S3 bucket name.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3BucketAccess",
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/*",
        "arn:aws:s3:::amzn-s3-demo-bucket"
      ]
    }
  ]
}
```

6. (Optional) If you're using Lake Formation permissions to provide access to your data, the IAM role requires `lakeformation:GetDataAccess` permissions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "LakeFormationDataAccess",
      "Effect": "Allow",
      "Action": "lakeformation:GetDataAccess",
      "Resource": [
        "*"
      ]
    }
  ]
}
```

If the Amazon S3 data location is registered with Lake Formation, and the IAM role assumed by the column statistics generation task doesn't have `IAM_ALLOWED_PRINCIPALS` group permissions granted on the table, the role requires Lake Formation ALTER and DESCRIBE permissions on the table. The role used for registering the Amazon S3 bucket requires Lake Formation INSERT and DELETE permissions on the table.

If the Amazon S3 data location is not registered with Lake Formation, and the IAM role doesn't have `IAM_ALLOWED_PRINCIPALS` group permissions granted on the table, the role requires Lake Formation ALTER, DESCRIBE, INSERT and DELETE permissions on the table.

7. If you've enabled the catalog-level `Automatic statistics generation` option, the IAM role must have the `glue:UpdateCatalog` permission or the Lake Formation ALTER CATALOG permission on the default Data Catalog. You can use the `GetCatalog` operation to verify the catalog properties.
8. (Optional) The column statistics generation task that writes encrypted Amazon CloudWatch Logs requires the following permissions in the key policy.

JSON

```
{
  "Version": "2012-10-17",
```

```

"Statement": [
  {
    "Sid": "CWLogsKmsPermissions",
    "Effect": "Allow",
    "Action": [
      "logs:CreateLogGroup",
      "logs:CreateLogStream",
      "logs:PutLogEvents",
      "logs:AssociateKmsKey"
    ],
    "Resource": [
      "arn:aws:logs:us-east-1:111122223333:log-group:/aws-glue:*"
    ]
  },
  {
    "Sid": "KmsPermissions",
    "Effect": "Allow",
    "Action": [
      "kms:GenerateDataKey",
      "kms:Decrypt",
      "kms:Encrypt"
    ],
    "Resource": [
      "arn:aws:kms:us-east-1:111122223333:key/arn of key used for ETL cloudwatch encryption"
    ],
    "Condition": {
      "StringEquals": {
        "kms:ViaService": [
          "glue.us-east-1.amazonaws.com"
        ]
      }
    }
  }
]
}

```

- The role you use to run column statistics must have the `iam:PassRole` permission on the role.

JSON

```
{
```

```

"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "iam:PassRole"
    ],
    "Resource": [
      "arn:aws:iam:111122223333:role/columnstats-role-name"
    ]
  }
]
}

```

10. When you create an IAM role for generating column statistics, that role must also have the following trust policy that enables the service to assume the role.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "TrustPolicy",
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}

```

Automatic column statistics generation

Automatic generation of column statistics allows you to schedule and automatically compute statistics on new tables in the Amazon Glue Data Catalog. When you enable automatic statistics generation, the Data Catalog discovers new tables with specific data formats such as Parquet, JSON, CSV, XML, ORC, ION, and Apache Iceberg, along with their individual bucket paths. With a one-time catalog configuration, the Data Catalog generates statistics for these tables.

Data lake administrators can configure the statistics generation by selecting the default catalog in the Lake Formation console, and enabling table statistics using the `Optimization` configuration option. When you create new tables or update existing tables in the Data Catalog, the Data Catalog collects the number of distinct values (NDVs) for Apache Iceberg tables, and additional statistics such as the number of nulls, maximum, minimum, and average length for other supported file formats on a weekly basis.

If you have configured statistics generation at the table-level or if you have previously deleted the statistics generation settings for a table, those table-specific settings take precedence over the default catalog settings for automatic column statistics generation.

Automatic statistics generation task analyzes 50% of records in the tables to calculate statistics. Automatic column statistics generation ensures that the Data Catalog maintains weekly metrics that can be used by query engines like Amazon Athena and Amazon Redshift Spectrum for improved query performance and potential cost savings. It allows scheduling statistics generation using Amazon Glue APIs or the console, providing an automated process without manual intervention.

Topics

- [Enabling catalog-level automatic statistics generation](#)
- [Viewing automated table-level settings](#)
- [Disabling catalog-level column statistics generation](#)

Enabling catalog-level automatic statistics generation

You can enable the automatic column statistics generation for all new Apache Iceberg tables and tables in non-OTF table (Parquet, JSON, CSV, XML, ORC, ION) formats in the Data Catalog. After creating the table, you can also explicitly update the column statistics settings manually.

To update the Data Catalog settings to enable catalog-level, the IAM role used must have the `glue:UpdateCatalog` permission or Amazon Lake Formation `ALTER CATALOG` permission on the root catalog. You can use `GetCatalog` API to verify the catalog properties.

Amazon Web Services Management Console

To enable the automatic column statistics generation at the account-level

1. Open the Lake Formation console at <https://console.amazonaws.cn/lakeformation/>.

- On the left navigation bar, choose **Catalogs**.
- On the **Catalog summary** page, choose **Edit** under **Optimization configuration**.

The screenshot shows the Amazon Glue 'Catalog summary' page. At the top, there's a 'Catalog summary' card with the following details: Name (489977581737), Data encryption (-), IAM role (-), and Catalog ARN (arn:aws:glue:us-east-2:[:redacted]:catalog). Below this card are tabs for 'Objects', 'Permissions', and 'Table optimizations'. The 'Table optimizations' tab is active, showing 'Table statistics' as 'On'. An 'Actions' menu is open on the right, with 'Edit' selected under the 'Optimization configuration' section.

- On the **Table optimization configuration** page, choose the **Enable automatic statistics generation for the tables of the catalog** option.

Edit optimization configuration

The screenshot shows the 'Edit optimization configuration' page. Under the 'Table statistics' section, the checkbox 'Enable automatic statistics generation for the tables of the catalog' is checked. Below this, the 'IAM role' section has a dropdown menu with 'AWSGlueServiceRole-crawler-test-role' selected and a 'View' button next to it. There is also a 'Create new IAM role' button.

- Choose an existing IAM role or create a new one that has the necessary permissions to run the column statistics task.
- Choose **Submit**.

Amazon CLI

You can also enable catalog-level statistics collection through the Amazon CLI. To configure table-level statistics collection using Amazon CLI, run the following command:

```
aws glue update-catalog --cli-input-json '{
  "name": "123456789012",
  "catalogInput": {
    "description": "Updating root catalog with role arn",
    "catalogProperties": {
```

```
        "customProperties": {
            "ColumnStatistics.RoleArn": "arn:aws:iam::"123456789012":role/
service-role/AWSGlueServiceRole",
            "ColumnStatistics.Enabled": "true"
        }
    }
}'
```

The above command calls Amazon Glue's `UpdateCatalog` operation, which takes in a `CatalogProperties` structure with the following key-value pairs for catalog-level statistics generation:

- `ColumnStatistics.RoleArn` – IAM role ARN to be used for all tasks triggered for Catalog-level statistics generation
- `ColumnStatistics.Enabled` – Boolean indicating whether the catalog-level settings is enabled or disabled

Viewing automated table-level settings

When catalog-level statistics collection is enabled, anytime an Apache Hive table or Apache Iceberg table is created or updated via the `CreateTable` or `UpdateTable` APIs through Amazon Web Services Management Console, SDK, or Amazon Glue crawler, an equivalent table level setting is created for that table.

Tables with automatic statistics generation enabled must follow one of following properties:

- Use an `InputSerdeLibrary` that begins with `org.apache.hadoop` and `TableType` equals `EXTERNAL_TABLE`
- Use an `InputSerdeLibrary` that begins with `com.amazon.ion` and `TableType` equals `EXTERNAL_TABLE`
- Contain `table_type: "ICEBERG"` in it's parameters structure.

After you create or update a table, you can verify the table details to confirm the statistics generation. The `Statistics generation` summary shows the `Schedule` property set as `AUTO` and `Statistics configuration` value is `Inherited from catalog`. Any table setting with the following setting would be automatically triggered by Glue internally.

Disabling catalog-level column statistics generation

You can disable automatic column statistics generation for new tables using the Amazon Lake Formation console, the `glue:UpdateCatalogSettings` API, or the `glue>DeleteColumnStatisticsTaskSettings` API.

To disable the automatic column statistics generation at the account-level

1. Open the Lake Formation console at <https://console.amazonaws.cn/lakeformation/>.
2. On the left navigation bar, choose **Catalogs**.
3. On the **Catalog summary** page, choose **Edit** under **Optimization configuration**.
4. On the **Table optimization configuration** page, unselect the **Enable automatic statistics generation for the tables of the catalog** option.
5. Choose **Submit**.

Generating column statistics on a schedule

Follow these steps to configure a schedule for generating column statistics in the Amazon Glue Data Catalog using the Amazon Glue console, the Amazon CLI, or the [CreateColumnStatisticsTaskSettings](#) operation.

Console

To generate column statistics using the console

1. Sign in to the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose Data Catalog tables.
3. Choose a table from the list.
4. Choose **Column statistics** tab in the lower section of the **Tables** page.
5. You can also choose **Generate on schedule** under **Column statistics** from **Actions**.
6. On the **Generate statistics on schedule** page, configure a recurring schedule for running the column statistics task by choosing the frequency and start time. You can choose the frequency to be hourly, daily, weekly, or define a cron expression to specify the schedule.

A cron expression is a string representing a schedule pattern, consisting of 6 fields separated by spaces: * * * * * <minute> <hour> <day of month> <month> <day of week> <year> For example, to run a task every day at midnight, the cron expression would be: 0 0 * * ? *

For more information, see [Cron expressions](#).

► **Advanced configuration - optional**

[Cancel](#) Generate statistics

7. Next, choose the column option to generate statistics.
 - **All columns** – Choose this option to generate statistics for all columns in the table.
 - **Selected columns** – Choose this option to generate statistics for specific columns. You can select the columns from the drop-down list.
8. Choose an IAM role or create an existing role that has permissions to generate statistics. Amazon Glue assumes this role to generate column statistics.

A quicker approach is to let the Amazon Glue console to create a role for you. The role that it creates is specifically for generating column statistics, and includes the `AWSGlueServiceRole` Amazon managed policy plus the required inline policy for the specified data source.

If you specify an existing role for generating column statistics, ensure that it includes the `AWSGlueServiceRole` policy or equivalent (or a scoped down version of this policy), plus the required inline policies.

9. (Optional) Next, choose a security configuration to enable at-rest encryption for logs.
10. (Optional) You can choose a sample size by indicating only a specific percent of rows from the table to generate statistics. The default is all rows. Use the up and down arrows to increase or decrease the percent value.

We recommend to include all rows in the table to compute accurate statistics. Use sample rows to generate column statistics only when approximate values are acceptable.

11. Choose **Generate statistics** to run the column statistics generation task.

Amazon CLI

You can use the following Amazon CLI example to create a column statistics generation schedule. The database-name, table-name, and role are required parameters, and optional parameters are schedule, column-name-list, catalog-id, sample-size, and security-configuration.

```
aws glue create-column-statistics-task-settings \  
  --database-name 'database_name' \  
  --table-name table_name \  
  --role 'arn:aws:iam::123456789012:role/stats-role' \  
  --schedule 'cron(0 0-5 14 * * ?)' \  
  --column-name-list 'col-1' \  
  --catalog-id '123456789012' \  
  --sample-size '10.0' \  
  --security-configuration 'test-security'
```

You can generate column statistics also by calling the [StartColumnStatisticsTaskRun](#) operation.

Managing the schedule for column statistics generation

You can manage the scheduling operations such as updating, starting, stopping, and deleting schedules for the column statistics generation in Amazon Glue. You can use Amazon Glue console, Amazon CLI, or [Amazon Glue column statistics API operations](#) to perform these tasks.

Topics

- [Updating the column statistics generation schedule](#)
- [Stopping the schedule for column statistics generation](#)
- [Resuming the schedule for column statistics generation](#)
- [Deleting column statistics generation schedule](#)

Updating the column statistics generation schedule

You can update the schedule to trigger the column statistics generation task after it has been created. You can use the Amazon Glue console, Amazon CLI, or run the [UpdateColumnStatisticsTaskSettings](#) operation to update the schedule for a table. You can modify the parameters of an existing schedule, such as the schedule type (on-demand, or scheduled) and other optional parameters.

Amazon Web Services Management Console

To update the settings for a column statistics generation task

1. Sign in to the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose the table that you want to update from the tables list.
3. In the lower section of the table details page, choose **Column statistics**.
4. Under **Actions**, choose **Edit** to update the schedule.
5. Make the desired changes to the schedule, and choose **Save**.

Amazon CLI

If you are not using Amazon Glue's statistics generation feature in the console, you can manually update the schedule using the `update-column-statistics-task-settings` command. The following example shows how to update column statistics using Amazon CLI.

```
aws glue update-column-statistics-task-settings \  
  --database-name 'database_name' \  
  --table-name 'table_name' \  
  --role arn:aws:iam::123456789012:role/stats_role \  
  --schedule 'cron(0 0-5 16 * * ?)' \  
  --column-name-list 'col-1' \  
  --sample-size '20.0' \  
  --catalog-id '123456789012' \  
  --table-id 'table-id'
```

```
--security-configuration 'test-security'
```

Stopping the schedule for column statistics generation

If you no longer need the incremental statistics, you can stop the scheduled generation to save resources and costs. Pausing the schedule doesn't impact the previously generated statistics. You can resume the schedule at your convenience.

Amazon Web Services Management Console

To stop the schedule for a column statistics generation task

1. On Amazon Glue console, choose **Tables** under Data Catalog.
2. Select a table with column statistics.
3. On the **Table details** page, choose **Column statistics**.
4. Under **Actions**, choose **Scheduled generation, Pause**.
5. Choose **Pause** to confirm.

Amazon CLI

To stop a column statistics task run schedule using the Amazon CLI, you can use the following command:

```
aws glue stop-column-statistics-task-run-schedule \  
  --database-name 'database_name' \  
  --table-name 'table_name'
```

Replace the `database_name` and the `table_name` with the actual names of the database and table for which you want to stop the column statistics task run schedule.

Resuming the schedule for column statistics generation

If you've paused the statistics generation schedule, Amazon Glue allows you to resume the schedule at your convenience. You can resume the schedule using the Amazon Glue console, Amazon CLI, or the [StartColumnStatisticsTaskRunSchedule](#) operation.

Amazon Web Services Management Console

To resume the schedule for column statistics generation

1. On Amazon Glue console, choose **Tables** under Data Catalog.
2. Select a table with column statistics.
3. On the **Table details** page, choose **Column statistics**.
4. Under **Actions**, choose **Scheduled generation**, and choose **Resume**.
5. Choose **Resume** to confirm.

Amazon CLI

Replace the `database_name` and the `table_name` with the actual names of the database and table for which you want to stop the column statistics task run schedule.

```
aws glue start-column-statistics-task-run-schedule \  
  --database-name 'database_name' \  
  --table-name 'table_name'
```

Deleting column statistics generation schedule

While maintaining up-to-date statistics is generally recommended for optimal query performance, there are specific use cases where removing the automatic generation schedule might be beneficial.

- If the data remains relatively static, the existing column statistics may remain accurate for an extended period, reducing the need for frequent updates. Deleting the schedule can prevent unnecessary resource consumption and overhead associated with regenerating statistics on unchanging data.
- When manual control over statistics generation is preferred. By deleting the automatic schedule, administrators can selectively update column statistics at specific intervals or after significant data changes, aligning the process with their maintenance strategies and resource allocation needs.

Amazon Web Services Management Console

To delete the schedule for column statistics generation

1. On Amazon Glue console, choose **Tables** under Data Catalog.
2. Select a table with column statistics.
3. On the **Table details** page, choose **Column statistics**.
4. Under **Actions**, choose **Scheduled generation, Delete**.
5. Choose **Delete** to confirm.

Amazon CLI

Replace the `database_name` and the `table_name` with the actual names of the database and table for which you want to stop the column statistics task run schedule.

You can delete column statistics schedule using the [DeleteColumnStatisticsTaskSettings](#) API operation or Amazon CLI. The following example shows how to delete the schedule for generating column statistics using Amazon Command Line Interface (Amazon CLI).

```
aws glue delete-column-statistics-task-settings \  
  --database-name 'database_name' \  
  --table-name 'table_name'
```

Generating column statistics on demand

You can run the column statistics task for the Amazon Glue Data Catalog tables task on-demand without a set schedule. This option is useful for ad-hoc analysis or when statistics need to be computed immediately.

Follow these steps to generate column statistics on demand for the Data Catalog tables using Amazon Glue console or Amazon CLI.

Amazon Web Services Management Console

To generate column statistics using the console

1. Sign in to the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. Choose Data Catalog tables.

3. Choose a table from the list.
4. Choose **Generate statistics** under **Actions** menu.

You can also choose **Generate**, **Generate on demand** option under **Column statistics** tab in the lower section of the **Table** page.

5. Follow steps 7 - 11 in the [Generating column statistics on a schedule](#) to generate column statistics for the table.
6. On the **Generate statistics** page, specify the following options:

Generate statistics on demand Info

Generate column statistics for the table to improve query performance and potentially save costs. [View pricing](#)

Column options

All columns
Generate statistics for all columns.

Selected columns
Choose the columns to generate statistics.

IAM Role

Column statistics task requires permissions to read Data Catalog tables and underlying data in the S3 bucket.

IAM role

Create new IAM role

Use an existing IAM role

Existing IAM role

[View](#)

▼ Advanced configuration - optional

Security configuration

Choose a security configuration to enable at-rest encryption on the logs pushed to CloudWatch.

Sample rows

The percentage of rows to sample.

%

Between 0 and 100. Leave blank if using all rows.

Cancel Generate statistics

- **All columns** – Choose this option to generate statistics for all columns in the table.
- **Selected columns** – Choose this option to generate statistics for specific columns. You can select the columns from the drop-down list.
- **IAM role** – Choose **Create a new IAM role** that has the required permission policies to run the column statistics generation task. Choose **View** permission details to review the policy statement. You can also select an IAM role from the list. For more information about the required permissions, see [Prerequisites for generating column statistics](#).

Amazon Glue assumes the permissions of the role that you specify to generate statistics.

For more information about providing roles for Amazon Glue, see [Identity-based policies for Amazon Glue](#).

- (Optional) Next, choose a security configuration to enable at-rest encryption for logs.
- **Sample rows** – Choose only a specific percent of rows from the table to generate statistics. The default is all rows. Use the up and down arrows to increase or decrease the percent value.

 **Note**

We recommend to include all rows in the table to compute accurate statistics. Use sample rows to generate column statistics only when approximate values are acceptable.

Choose **Generate statistics** to run the task.

Amazon CLI

This command will trigger an column statistics task run for the specified table. You need to provide the database name, table name, an IAM role with permissions to generate statistics, and optionally provide column names and a sample size percentage for the statistics computation.

```
aws glue start-column-statistics-task-run \  
  --database-name 'database_name' \  
  --table-name 'table_name' \  
  --role 'arn:aws:iam::123456789012:role/stats-role' \  
  --column-name 'col1', 'col2' \  
  --sample-size 10.0
```

This command will start a task to generate column statistics for the specified table.

Updating column statistics on demand

Maintaining up-to-date column statistics is crucial for the query optimizer to generate efficient execution plans, ensuring improved query performance, reduced resource consumption, and better

overall system performance. This process is particularly important after significant data changes, such as bulk loads or extensive modifications, which can render existing statistics obsolete.

You need to explicitly run the **Generate statistics** task from the Amazon Glue console to refresh the column statistics. Data Catalog doesn't automatically refresh the statistics.

If you are not using Amazon Glue's statistics generation feature in the console, you can manually update column statistics using the [UpdateColumnStatisticsForTable](#) API operation or Amazon CLI. The following example shows how to update column statistics using Amazon CLI.

```
aws glue update-column-statistics-for-table --cli-input-json:

{
  "CatalogId": "111122223333",
  "DatabaseName": "database_name",
  "TableName": "table_name",
  "ColumnStatisticsList": [
    {
      "ColumnName": "col1",
      "ColumnType": "Boolean",
      "AnalyzedTime": "1970-01-01T00:00:00",
      "StatisticsData": {
        "Type": "BOOLEAN",
        "BooleanColumnStatisticsData": {
          "NumberOfTrues": 5,
          "NumberOfFalses": 5,
          "NumberOfNulls": 0
        }
      }
    }
  ]
}
```

Viewing column statistics

After generating the statistics successfully, Data Catalog stores this information for the cost-based optimizers in Amazon Athena and Amazon Redshift to make optimal choices when running queries. The statistics varies based on the type of the column.

Amazon Web Services Management Console

To view column statistics for a table

- After running column statistics task, the **Column statistics** tab on the **Table details** page shows the statistics for the table.

The screenshot shows the AWS Glue console interface for a table named 'pentest_orders_xml'. The 'Column statistics' tab is active, displaying a table with 9 columns of statistics. The table includes columns for Column name, Last updated (UTC), Average length, Distinct values, Max length, Null values, Max value, Min value, True values, and False values. The data is as follows:

Column name	Last updated (UTC)	Average length	Distinct values	Max length	Null values	Max value	Min value	True values	False values
o_clerk	October 25, 2023 at 19:14:	15.00	919	15	-	-	-	-	-
o_comment	October 25, 2023 at 19:14:	88.38	3156	124559	-	-	-	-	-
o_custkey	October 25, 2023 at 19:14:	-	919	-	-	1499	1	-	-
o_order-priority	October 25, 2023 at 19:14:	8.45	5	15	-	-	-	-	-
o_orderdate	October 25, 2023 at 19:14:	10.00	1790	10	-	-	-	-	-
o_orderkey	October 25, 2023 at 19:14:	-	3098	-	-	12451	1	-	-
o_orderstatus	October 25, 2023 at 19:14:	1.00	3	1	-	-	-	-	-
o_ship-priority	October 25, 2023 at 19:14:	-	1	-	-	-	-	-	-
o_totalprice	October 25, 2023 at 19:14:	-	3062	-	-	422359.65	974.04	-	-

The following statistics are available:

- Column name:** Column name used to generate statistics
- Last updated:** Data and time when the statistics were generated
- Average length:** Average length of values in the column
- Distinct values:** Total number of distinct values in the column. We estimate the number of distinct values in a column with 5% relative error.
- Max value:** The largest value in the column.
- Min value:** The smallest value in the column.
- Max length:** The length of the highest value in the column.
- Null values:** The total number of null values in the column.
- True values:** The total number of true values in the column.
- False values:** The total number of false values in the column.

- **numFiles**: The total number of files in the table. This value is available under the **Advanced properties** tab.

Amazon CLI

The following example shows how to retrieve column statistics using Amazon CLI.

```
aws glue get-column-statistics-for-table \
  --database-name database_name \
  --table-name table_name \
  --column-names <column_name>
```

You can also view the column statistics using the [GetColumnStatisticsForTable](#) API operation.

Viewing column statistics task runs

After you run a column statistics task, you can explore the task run details for a table using Amazon Glue console, Amazon CLI or using [GetColumnStatisticsTaskRuns](#) operation.

Console

To view column statistics task run details

1. On Amazon Glue console, choose **Tables** under Data Catalog.
2. Select a table with column statistics.
3. On the **Table details** page, choose **Column statistics**.
4. Choose **View runs**.

You can see information about all runs associated with the specified table.

The screenshot shows the Amazon Glue console interface for viewing column statistics task runs. The breadcrumb navigation is 'AWS Glue > Tables > path1 > All column statistics runs'. The main heading is 'All runs (1)'. Below the heading, there is a search bar labeled 'Filter data' and a refresh button. The table below shows the details of the task run.

Run ID	Status	Start time (UTC)	End time (UTC)	Duration	Column selection	Row sampling
f6a7b304-ad59-49d1-9:	Running	November 16, 2023 at 00:21:44	-	-	All columns	100%

Amazon CLI

In the following example, replace values for `DatabaseName` and `TableName` with the actual database and table name.

```
aws glue get-column-statistics-task-runs --input-cli-json file://input.json
{
  "DatabaseName": "database_name",
  "TableName": "table_name"
}
```

Stopping column statistics task run

You can stop a column statistics task run for a table using Amazon Glue console, Amazon CLI or using [StopColumnStatisticsTaskRun](#) operation.

Console

To stop a column statistics task run

1. On Amazon Glue console, choose **Tables** under Data Catalog.
2. Select the table with the column statistics task run is in progress.
3. On the **Table details** page, choose **Column statistics**.
4. Choose **Stop**.

If you stop the task before the run is complete, column statistics won't be generated for the table.

Amazon CLI

In the following example, replace values for `DatabaseName` and `TableName` with the actual database and table name.

```
aws glue stop-column-statistics-task-run --input-cli-json file://input.json
{
  "DatabaseName": "database_name",
  "TableName": "table_name"
}
```

Deleting column statistics

You can delete column statistics using the [DeleteColumnStatisticsForTable](#) API operation or Amazon CLI. The following example shows how to delete column statistics using Amazon Command Line Interface (Amazon CLI).

```
aws glue delete-column-statistics-for-table \  
  --database-name 'database_name' \  
  --table-name 'table_name' \  
  --column-name 'column_name'
```

Considerations and limitations

The following considerations and limitations apply to generating column statistics.

Considerations

- Using sampling to generate statistics reduces run time, but can generate inaccurate statistics.
- Data Catalog doesn't store different versions of the statistics.
- You can only run one statistics generation task at a time per table.
- If a table is encrypted using customer Amazon KMS key registered with Data Catalog, Amazon Glue uses the same key to encrypt statistics.

Column statistics task supports generating statistics:

- When the IAM role has full table permissions (IAM or Lake Formation).
- When the IAM role has permissions on the table using Lake Formation hybrid access mode.

Column statistics task doesn't support generating statistics for:

- Tables with Lake Formation cell-based access control
- Transactional data lakes - Linux foundation Delta Lake, Apache Hudi
- Tables in federated databases - Hive metastore, Amazon Redshift datashares

- Nested columns, arrays, and struct data types.
- Table that is shared with you from another account

Encrypting your Data Catalog

You can protect your metadata stored in the Amazon Glue Data Catalog at rest using encryption keys managed by Amazon Key Management Service (Amazon KMS). You can enable Data Catalog encryption for new Data Catalog, by using the **Data Catalog settings**. You can enable or disable encryption for existing Data Catalog as needed. When enabled, Amazon Glue encrypts all new metadata written to the catalog, while existing metadata remains unencrypted.

For detailed information about encrypting your Data Catalog, see [Encrypting your Data Catalog](#).

Securing your Data Catalog using Lake Formation

Amazon Lake Formation is a service that makes it easier to set up a secure data lake in Amazon. It provides a central place to create and securely manage your data lakes by defining fine-grained access control permissions. Lake Formation uses the Data Catalog to store and retrieve metadata about your data lake, such as table definitions, schema information, and data access control settings.

You can register your Amazon S3 data location of the metadata table or database with Lake Formation and use it to define metadata-level permissions on the Data Catalog resources. You can also use Lake Formation to manage storage access permissions on the underlying data stored in Amazon S3 on behalf of integrated analytical engines.

For more information see [What is Amazon Lake Formation?](#)

Working with Amazon Glue Data Catalog views in Amazon Glue

You can create and manage views in the Amazon Glue Data Catalog, commonly known as Amazon Glue Data Catalog views. These views are useful because they support multiple SQL query engines, allowing you to access the same view across different Amazon services, such as Amazon Athena, Amazon Redshift, and Amazon Glue. You can use views based on Apache Iceberg, Apache Hudi, and Delta Lake.

By creating a view in the Data Catalog, you can use resource grants and tag-based access controls in Amazon Lake Formation to grant access to it. Using this method of access control, you don't

have to configure additional access to the tables referenced when creating the view. This method of granting permissions is called definer semantics, and these views are called definer views. For more information about access control in Amazon Lake Formation, see [Granting and revoking permissions on Data Catalog resources](#) in the Amazon Lake Formation Developer Guide.

Data Catalog views are useful for the following use cases:

- **Granular access control** – You can create a view that restricts data access based on the permissions the user needs. For example, you can use views in the Data Catalog to prevent employees who don't work in the HR department from seeing personally identifiable information (PII).
- **Complete view definition** – By applying filters on your view in the Data Catalog, you ensure that data records available in the view are always complete.
- **Enhanced security** – The query definition used to create the view must be complete, making Data Catalog views less susceptible to SQL commands from malicious actors.
- **Simple data sharing** – Share data with other Amazon accounts without moving data, using cross-account data sharing in Amazon Lake Formation.

Creating a Data Catalog view

You can create Data Catalog views using the Amazon CLI and Amazon Glue ETL scripts using Spark SQL. The syntax for creating a Data Catalog view includes specifying the view type as `MULTI DIALECT` and the `SECURITY` predicate as `DEFINER`, indicating a definer view.

Example SQL statement to create a Data Catalog view:

```
CREATE PROTECTED MULTI DIALECT VIEW database_name.catalog_view SECURITY DEFINER
AS SELECT order_date, sum(totalprice) AS price
FROM source_table
GROUP BY order_date;
```

After creating a Data Catalog view, you can use an IAM role with the Amazon Lake Formation `SELECT` permission on the view to query it from services like Amazon Athena, Amazon Redshift, or Amazon Glue ETL jobs. You don't need to grant access to the underlying tables referenced in the view.

For more information on creating and configuring Data Catalog views, see [Building Amazon Glue Data Catalog views](#) in the Amazon Lake Formation Developer Guide.

Supported view operations

The following command fragments show you various ways to work with Data Catalog views:

CREATE VIEW

Creates a data-catalog view. The following is a sample that shows creating a view from an existing table:

```
CREATE PROTECTED MULTI DIALECT VIEW catalog_view
SECURITY DEFINER AS SELECT * FROM my_catalog.my_database.source_table
```

ALTER VIEW

Available syntax:

```
ALTER VIEW view_name [FORCE] ADD DIALECT AS query
ALTER VIEW view_name [FORCE] UPDATE DIALECT AS query
ALTER VIEW view_name DROP DIALECT
```

You can use the `FORCE ADD DIALECT` option to force update the schema and sub objects as per the new engine dialect. Note that doing this can result in query errors if you don't also use `FORCE` to update other engine dialects. The following shows a sample:

```
ALTER VIEW catalog_view FORCE ADD DIALECT AS
SELECT order_date, sum(totalprice) AS price FROM source_table GROUP BY orderdate;
```

The following shows how to alter a view in order to update the dialect:

```
ALTER VIEW catalog_view UPDATE DIALECT AS
SELECT count(*) FROM my_catalog.my_database.source_table;
```

DESCRIBE VIEW

Available syntax for describing a view:

`SHOW COLUMNS {FROM|IN} view_name [{FROM|IN} database_name]` – If the user has the required Amazon Glue and Amazon Lake Formation permissions to describe the view, they can list the columns. The following shows a couple sample commands for showing columns:

```
SHOW COLUMNS FROM my_database.source_table;
SHOW COLUMNS IN my_database.source_table;
```

DESCRIBE view_name – If the user has the required Amazon Glue and Amazon Lake Formation permissions to describe the view, they can list the columns in the view along with its metadata.

DROP VIEW

Available syntax:

```
DROP VIEW [ IF EXISTS ] view_name
```

The following sample shows a DROP statement that tests if a view exists prior to dropping it:

```
DROP VIEW IF EXISTS catalog_view;
```

SHOW CREATE VIEW view_name – Shows the SQL statement that creates the specified view. The following is a sample that shows creating a data-catalog view:

```
SHOW CREATE TABLE my_database.catalog_view;CREATE PROTECTED MULTI DIALECT VIEW
my_catalog.my_database.catalog_view (
  net_profit,
  customer_id,
  item_id,
  sold_date)
TBLPROPERTIES (
  'transient_lastDdlTime' = '1736267222')
SECURITY DEFINER AS SELECT * FROM
my_database.store_sales_partitioned_1f WHERE customer_id IN (SELECT customer_id from
source_table limit 10)
```

SHOW VIEWS

List all views in the catalog, such as regular views, multi-dialect views (MDV), and MDV without Spark dialect. Available syntax is the following:

```
SHOW VIEWS [{ FROM | IN } database_name] [LIKE regex_pattern]:
```

The following shows a sample command to show views:

```
SHOW VIEWS IN marketing_analytics LIKE 'catalog_view*';
```

For more information about creating and configuring data-catalog views, see [Building Amazon Glue Data Catalog views](#) in the Amazon Lake Formation Developer Guide.

Querying a Data Catalog view

After creating a Data Catalog view, you can query the view. The IAM role configured in your Amazon Glue jobs must have the Lake Formation **SELECT** permission on the Data Catalog view. You don't need to grant access to the underlying tables referenced in the view.

Once you have everything set up, you can query your view. For example, you can run the following query to access a view.

```
SELECT * from my_database.catalog_view LIMIT 10;
```

Limitations

Consider the following limitations when you use Data Catalog views.

- You can only create Data Catalog views with Amazon Glue 5.0 and above.
- The Data Catalog view definer must have SELECT access to the underlying base tables accessed by the view. Creating the Data Catalog view fails if a specific base table has any Lake Formation filters imposed on the definer role.
- Base tables must not have the IAMAllowedPrincipals data lake permission in Amazon Lake Formation. If present, the error **Multi Dialect views may only reference tables without IAMAllowedPrincipals permissions occurs**.
- The table's Amazon S3 location must be registered as a Amazon Lake Formation data lake location. If the table isn't registered, the error Multi Dialect views may only reference Amazon Lake Formation managed tables occurs. For information about how to register Amazon Amazon S3 locations in Amazon Lake Formation, see [Registering an Amazon S3 location](#) in the Amazon Lake Formation Developer Guide.
- You can only create PROTECTED Data Catalog views. UNPROTECTED views aren't supported.
- You can't reference tables in another Amazon account in a Data Catalog view definition. You also can't reference a table in the same account that's in a separate region.
- To share data across an account or region, the entire view must be shared cross account and cross region, using Amazon Lake Formation resource links.

- User-defined functions (UDFs) aren't supported.
- You can't reference other views in Data Catalog views.

Accessing the Data Catalog

You can use the Amazon Glue Data Catalog (Data Catalog) to discover and understand your data. Data Catalog provides a consistent way to maintain schema definitions, data types, locations, and other metadata. You can access the Data Catalog using the following methods:

- Amazon Glue console – You can access and manage the Data Catalog through the Amazon Glue console, a web-based user interface. The console allows you to browse and search for databases, tables, and their associated metadata, as well as create, update, and delete metadata definitions.
- Amazon Glue crawler – Crawlers are programs that automatically scan your data sources and populate the Data Catalog with metadata. You can create and run crawlers to discover and catalog data from various sources like Amazon S3, Amazon RDS, Amazon DynamoDB, Amazon CloudWatch, and JDBC-compliant relational databases such as MySQL, and PostgreSQL as well as several non-Amazon sources such as Snowflake and Google BigQuery.
- Amazon Glue APIs – You can access the Data Catalog programmatically using the Amazon Glue APIs. These APIs allow you to interact with the Data Catalog programmatically, enabling automation and integration with other applications and services.
- Amazon Command Line Interface (Amazon CLI) – You can use the Amazon CLI to access and manage the Data Catalog from the command line. The CLI provides commands for creating, updating, and deleting metadata definitions, as well as querying and retrieving metadata information.
- Integration with other Amazon services – The Data Catalog integrates with various other Amazon services, allowing you to access and utilize the metadata stored in the catalog. For example, you can use Amazon Athena to query data sources using the metadata in the Data Catalog, and use Amazon Lake Formation to manage data access and governance for the Data Catalog resources.

Topics

- [Connecting to the Data Catalog using Amazon Glue Iceberg REST endpoint](#)
- [Connecting to the Data Catalog using Amazon Glue Iceberg REST extension endpoint](#)
- [Amazon Glue REST APIs for Apache Iceberg specifications](#)
- [Connecting to Data Catalog from a standalone Spark application](#)

- [Data mapping between Amazon Redshift and Apache Iceberg](#)
- [Considerations and limitations when using Amazon Glue Iceberg REST Catalog APIs](#)

Connecting to the Data Catalog using Amazon Glue Iceberg REST endpoint

Amazon Glue's Iceberg REST endpoint supports API operations specified in the Apache Iceberg REST specification. Using an Iceberg REST client, you can connect your application running on an analytics engine to the REST catalog hosted in the Data Catalog.

The endpoint supports both Apache Iceberg table specifications - v1 and v2, defaulting to v2. When using the Iceberg table v1 specification, you must specify v1 in the API call. Using the API operation, you can access Iceberg tables stored in both Amazon S3 object storage and Amazon S3 Table storage.

Endpoint configuration

You can access the Amazon Glue Iceberg REST catalog using the service endpoint. Refer to the [Amazon Glue service endpoints reference guide](#) for the region-specific endpoint. For example, when connecting to Amazon Glue in the us-east-1 Region, you need to configure the endpoint URI property as follows:

```
Endpoint : https://glue.us-east-1.amazonaws.com/iceberg
```

Additional configuration properties – When using Iceberg client to connect an analytics engine like Spark to the service endpoint, you are required to specify the following application configuration properties:

```
catalog_name = "mydatacatalog"
aws_account_id = "123456789012"
aws_region = "us-east-1"
spark = SparkSession.builder \
  ... \
  .config("spark.sql.defaultCatalog", catalog_name) \
  .config(f"spark.sql.catalog.{catalog_name}",
"org.apache.iceberg.spark.SparkCatalog") \
  .config(f"spark.sql.catalog.{catalog_name}.type", "rest") \
  .config(f"spark.sql.catalog.{catalog_name}.uri", "https://glue.
{aws_region}.amazonaws.com/iceberg") \
```

```
.config(f"spark.sql.catalog.{catalog_name}.warehouse", "{aws_account_id}") \  
.config(f"spark.sql.catalog.{catalog_name}.rest.sigv4-enabled", "true") \  
.config(f"spark.sql.catalog.{catalog_name}.rest.signing-name", "glue") \  
  
.config("spark.sql.extensions", "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \  
.getOrCreate()
```

Amazon Glue Iceberg endpoint <https://glue.us-east-1.amazonaws.com/iceberg> supports the following Iceberg REST APIs:

- GetConfig
- ListNamespaces
- CreateNamespace
- LoadNamespaceMetadata
- UpdateNamespaceProperties
- DeleteNamespace
- ListTables
- CreateTable
- LoadTable
- TableExists
- UpdateTable
- DeleteTable

Prefix and catalog path parameters

Iceberg REST catalog APIs have a free-form prefix in their request URLs. For example, the `ListNamespaces` API call uses the `GET/v1/{prefix}/namespaces` URL format. Amazon Glue prefix always follows the `/catalogs/{catalog}` structure to ensure that the REST path aligns the Amazon Glue multi-catalog hierarchy. The `{catalog}` path parameter can be derived based on the following rules:

Access pattern	Glue catalog ID Style	Prefix Style	Example default catalog ID	Example REST route
Access the default catalog in current account	not required	:	not applicable	GET /v1/catalogs/:/namespaces
Access the default catalog in a specific account	accountID	accountID	111122223333	GET /v1/catalogs/111122223333/namespaces
Access a nested catalog in current account	catalog1/catalog2	catalog1/catalog2	rmscatalog1:db1	GET /v1/catalogs/rmscatalog1:db1/namespaces
Access a nested catalog in a specific account	accountID:catalog1/catalog2	accountID:catalog1/catalog2	123456789012/rmscatalog1:db1	GET /v1/catalogs/123456789012:rmscatalog1:db1/namespaces

This catalog ID to prefix mapping is required only when you directly call the REST APIs. When you are working with the Amazon Glue Iceberg REST catalog APIs through an engine, you need to specify the Amazon Glue catalog ID in the warehouse parameter for your Iceberg REST catalog API setting or in the `glue.id` parameter for your Amazon Glue extensions API setting. For example, see how you can use it with EMR Spark in [Use an Iceberg cluster with Spark](#).

Namespace path parameter

Namespaces in Iceberg REST catalog APIs path can have multiple levels. However, Amazon Glue only supports single-level namespaces. To access a namespace in a multi-level catalog hierarchy, you can connect to a multi-level catalog above the namespace to reference the namespace. This allows any query engine that supports the 3-part notation of `catalog.namespace.table`

to access objects in Amazon Glue's multi-level catalog hierarchy without compatibility issues compared to using the multi-level namespace.

Connecting to the Data Catalog using Amazon Glue Iceberg REST extension endpoint

Amazon Glue Iceberg REST extension endpoint provides additional APIs, which are not present in the Apache Iceberg REST specification, and provides server-side scan planning capabilities. These additional APIs are used when you access tables stored in Amazon Redshift managed storage. The endpoint is accessible from an application using Apache Iceberg Amazon Glue Data Catalog extensions.

Endpoint configuration – A catalog with tables in the Redshift managed storage is accessible using the service endpoint. Refer to the [Amazon Glue service endpoints reference guide](#) for the region-specific endpoint. For example, when connecting to Amazon Glue in the us-east-1 Region, you need to configure the endpoint URI property as follows:

```
Endpoint : https://glue.us-east-1.amazonaws.com/extensions
```

```
catalog_name = "myredshiftcatalog"
aws_account_id = "123456789012"
aws_region = "us-east-1"
spark = SparkSession.builder \
    .config("spark.sql.defaultCatalog", catalog_name) \
    .config(f"spark.sql.catalog.{catalog_name}",
"org.apache.iceberg.spark.SparkCatalog") \
    .config(f"spark.sql.catalog.{catalog_name}.type", "glue") \
    .config(f"spark.sql.catalog.{catalog_name}.glue.id",
"{123456789012}:redshiftnamespacecatalog/redshiftdb") \

    .config("spark.sql.extensions", "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions") \
    .getOrCreate()
```

Amazon Glue REST APIs for Apache Iceberg specifications

This section contains specifications about the Amazon Glue Iceberg REST catalog and Amazon Glue extension APIs, and considerations when using these APIs.

API requests to the Amazon Glue Data Catalog endpoints are authenticated using Amazon Signature Version 4 (SigV4). See [Amazon Signature Version 4 for API requests](#) section to learn more about Amazon SigV4.

When accessing the Amazon Glue service endpoint, and Amazon Glue metadata, the application assumes an IAM role which requires `glue:getCatalog` IAM action.

Access to the Data Catalog, and its objects can be managed using IAM, Lake Formation, or Lake Formation hybrid mode permissions.

Federated catalogs in the Data Catalog have Lake Formation registered data locations. Lake Formation works with the Data Catalog to provide database-style permissions to manage user access to Data Catalog objects.

You can use IAM, Amazon Lake Formation, or Lake Formation hybrid mode permissions to manage access to the default Data Catalog and its objects.

To create, insert, or delete data in Lake Formation managed objects, you must set up specific permissions for the IAM user or role.

- `CREATE_CATALOG` – Required to create catalogs
- `CREATE_DATABASE` – Required to create databases
- `CREATE_TABLE` – Required to create tables
- `DELETE` – Required to delete data from a table
- `DESCRIBE` – Required to read metadata
- `DROP` – Required to drop/delete a table or database
- `INSERT` – Needed when the principal needs to insert data into a table
- `SELECT` – Needed when the principal needs to select data from a table

For more information, see [Lake Formation permissions reference](#) in the Amazon Lake Formation Developer Guide.

GetConfig

General information

Operation name	GetConfig
-----------------------	-----------

Type	Iceberg REST Catalog API
REST path	GET /iceberg/v1/config
IAM action	glue:GetCatalog
Lake Formation permissions	Not applicable
CloudTrail event	glue:GetCatalog
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L67

Considerations and limitations

- The warehouse query parameter must be set to the Amazon Glue catalog ID. If not set, the root catalog in the current account is used to return the response. For more information, see [the section called “Prefix and catalog path parameters”](#).

GetCatalog

General information

Operation name	GetCatalog
Type	Amazon Glue extension API
REST path	GET/extensions/v1/catalogs/{catalog}
IAM action	glue:GetCatalog
Lake Formation permissions	DESCRIBE
CloudTrail event	glue:GetCatalog
Open API definition	https://github.com/aws-labs/glue-extensions-for-iceberg/blob/main/glue-extensions-api.yaml#L40

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.

ListNamespaces

General information

Operation name	ListNamespaces
Type	Iceberg REST Catalog API
REST path	GET/iceberg/v1/catalogs/{catalog}/namespaces
IAM action	glue:GetDatabase
Lake Formation permissions	ALL, DESCRIBE, SELECT
CloudTrail event	glue:GetDatabase
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L205

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- Only namespaces of the next level is displayed. To list namespaces in deeper levels, specify the nested catalog ID in the catalog path parameter.

CreateNamespace

General information

Operation name	CreateNamespace
Type	Iceberg REST Catalog API

REST path	POST/iceberg/v1/catalogs/{catalog}/namespaces
IAM action	glue:CreateDatabase
Lake Formation permissions	ALL, DESCRIBE, SELECT
CloudTrail event	glue:CreateDatabase
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L256

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- Only single level namespace can be created. To create a multi-level namespace, you must iteratively create each level, and connect to the level using the catalog path parameter.

StartCreateNamespaceTransaction

General information

Operation name	StartCreateNamespaceTransaction
Type	Amazon Glue extensions API
REST path	POST/extensions/v1/catalogs/{catalog}/namespaces
IAM action	glue:CreateDatabase
Lake Formation permissions	ALL, DESCRIBE, SELECT
CloudTrail event	glue:CreateDatabase
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L256

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can create only single-level namespace. To create a multi-level namespaces, you must iteratively create each level, and connect to the level using the catalog path parameter.
- The API is asynchronous, and returns a transaction ID that that you can use for tracking using the CheckTransactionStatus API call.
- You can call this API, only if the GetCatalog API call contains the parameter use-extensions=true in the response.

LoadNamespaceMetadata

General information

Operation name	LoadNamespaceMetadata
Type	Iceberg REST Catalog API
REST path	GET/iceberg/v1/catalogs/{catalog}/namespaces/{ns}
IAM action	glue:GetDatabase
Lake Formation permissions	ALL, DESCRIBE, SELECT
CloudTrail event	glue:GetDatabase
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L302

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.

UpdateNamespaceProperties

General information

Operation name	UpdateNamespaceProperties
Type	Iceberg REST Catalog API
REST path	POST /iceberg/v1/catalogs/{catalog}/namespaces/{ns}/properties
IAM action	glue:UpdateDatabase
Lake Formation permissions	ALL, ALTER
CloudTrail event	glue:UpdateDatabase
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L400

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST path parameter. For more information, see the [the section called “Namespace path parameter”](#) section.

DeleteNamespace

General information

Operation name	DeleteNamespace
Type	Iceberg REST Catalog API
REST path	DELETE/iceberg/v1/catalogs/{catalog}/namespaces/{ns}
IAM action	glue>DeleteDatabase

Lake Formation permissions	ALL, DROP
CloudTrail event	glue>DeleteDatabase
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L365

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.
- If there are objects in the database, the operation will fail.
- The API is asynchronous, and returns a transaction ID that that you can use for tracking using the CheckTransactionStatus API call.
- The API can only be used if the GetCatalog API call indicates use-extensions=true in response.

StartDeleteNamespaceTransaction

General information

Operation name	StartDeleteNamespaceTransaction
Type	Amazon Glue extensions API
REST path	DELETE /extensions/v1/catalogs/{catalog}/namespces/{ns}
IAM action	glue>DeleteDatabase
Lake Formation permissions	ALL, DROP
CloudTrail event	glue>DeleteDatabase
Open API definition	https://github.com/aws-labs/glue-extensions-for-iceberg/blob/main/glue-extensions-api.yaml#L85

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify a only single-level namespace in the REST Path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.
- If there are objects in the database, the operation will fail.
- The API is asynchronous, and returns a transaction ID that that you can use for tracking using the CheckTransactionStatus API call.
- The API can only be used if the GetCatalog API call indicates use-extensions=true in response.

ListTables

General information

Operation name	ListTables
Type	Iceberg REST Catalog API
REST path	GET /iceberg/v1/catalogs/{catalog}/namespaces/{ns}/tables
IAM action	glue:GetTables
Lake Formation permissions	ALL, SELECT, DESCRIBE
CloudTrail event	glue:GetTables
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L463

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.

- All tables including non-Iceberg tables will be listed. To determine if a table can be loaded as an Iceberg table or not, call `LoadTable` operation.

CreateTable

General information

Operation name	CreateTable
Type	Iceberg REST Catalog API
REST path	GET /iceberg/v1/catalogs/{catalog}/namespaces/{ns}/tables
IAM action	glue:CreateTable
Lake Formation permissions	ALL, CREATE_TABLE
CloudTrail event	glue:CreateTable
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L497

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more information, see the [the section called “Namespace path parameter”](#) section.
- `CreateTable` with staging is not supported. If the `stageCreate` query parameter is specified, the operation will fail. This means operation like `CREATE TABLE AS SELECT` is not supported, and you can use a combination of `CREATE TABLE` and `INSERT INTO` as a workaround.
- The `CreateTable` API operation doesn't support the option `state-create = TRUE`.

StartCreateTableTransaction

General information

Operation name	CreateTable
Type	Amazon Glue extensions API
REST path	POST/extensions/v1/catalogs/{catalog}/namespaces/{ns}/tables
IAM action	glue:CreateTable
Lake Formation permissions	ALL, CREATE_TABLE
CloudTrail event	glue:CreateTable
Open API definition	https://github.com/awslabs/glue-extensions-for-iceberg/blob/main/glue-extensions-api.yaml#L107

Considerations and limitations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.
- CreateTable with staging is not supported. If the stageCreate query parameter is specified, the operation will fail. This means operation like CREATE TABLE AS SELECT is not supported, and user should use a combination of CREATE TABLE and INSERT INTO to workaround.
- The API is asynchronous, and returns a transaction ID that that you can use for tracking using the CheckTransactionStatus API call.
- The API can only be used if the GetCatalog API call indicates use-extensions=true in response.

LoadTable

General information

Operation name	LoadTable
Type	Iceberg REST Catalog API
REST path	GET /iceberg/v1/catalogs/{catalog}/namespaces/{ns}/tables/{table}
IAM action	glue:GetTable
Lake Formation permissions	ALL, SELECT, DESCRIBE
CloudTrail event	glue:GetTable
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L616

Considerations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single level namespace in the REST Path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.
- CreateTable with staging is not supported. If the stageCreate query parameter is specified, the operation will fail. This means operation like CREATE TABLE AS SELECT is not supported, and user should use a combination of CREATE TABLE and INSERT INTO to workaround.
- The API is asynchronous, and returns a transaction ID that that you can use for tracking using the CheckTransactionStatus API call.
- The API can only be used if the GetCatalog API call indicates use-extensions=true in response.

ExtendedLoadTable

General information

Operation name	LoadTable
Type	Amazon Glue extensions API
REST path	GET /extensions/v1/catalogs/{catalog}/namespaces/{ns}/tables/{table}
IAM action	glue:GetTable
Lake Formation permissions	ALL, SELECT, DESCRIBE
CloudTrail event	glue:GetTable
Open API definition	https://github.com/awslabs/glue-extensions-for-iceberg/blob/main/glue-extensions-api.yaml#L134

Considerations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.
- Only all mode is supported for snapshots query parameter.
- Compared to LoadTable API, the ExtendedLoadTable API differs in the following ways:
 - Doesn't strictly enforce that all the fields to be available.
 - provides the following additional parameters in the config field of the response:

Additional parameters

Config key	Description
aws.server-side-capabilitie s.scan-planning	Indicates if the table can be scanned using the PreparePI an table and PlanTable APIs.

Config key	Description
aws.server-side-capabilities.data-commit	Indicates if the table can be committed using the StartUpdateTable transaction.
aws.glue.staging.location	Used for server side scan planning or data commit, a service-managed staging location that can be used for engine to write temporary data files
aws.glue.staging.access-key-id	Used for server side scan planning or data commit, a part of the temporary Amazon credentials to access the service-managed staging location
aws.glue.staging.secret-access-key	Used for server side scan planning or data commit, a part of the temporary Amazon credentials to access the service-managed staging location.
aws.glue.staging.session-token	Used for server side scan planning or data commit, a part of the temporary Amazon credentials to access the service-managed staging location.
aws.glue.staging.expiration-ms	Used for server side scan planning or data commit, expiration time of the credentials to access the service-managed staging. location.
aws.glue.staging.data-transfer-role-arn	Used for server side scan planning or data commit, an IAM role that can be assumed to access the service-managed staging location.

PreplanTable

General information

Operation name	PreplanTable
Type	Amazon Glue extensions API
REST path	POST /extensions/v1/catalogs/{catalog}/namespaces/{ns}/tables/{table}/preplan

IAM action	glue:GetTable
Lake Formation permissions	ALL, SELECT, DESCRIBE
CloudTrail event	glue:GetTable
Open API definition	https://github.com/aws-labs/glue-extensions-for-iceberg/blob/main/glue-extensions-api.yaml#L211

Considerations

- The catalog path parameter should follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more information, see the [the section called “Namespace path parameter”](#) section.
- Caller of this API should always determine if there are remaining results to fetch based on the page token. A response with empty page item but a pagination token is possible if the server side is still processing but is not able to produce any result in the given response time.
- You can use this API only if the ExtendedLoadTable API response contains `aws.server-side-capabilities.scan-planning=true`.

PlanTable

General information

Operation name	PlanTable
Type	Amazon Glue extensions API
REST path	POST /extensions/v1/catalogs/{catalog}/namespaces/{ns}/tables/{table}/plan
IAM action	glue:GetTable
Lake Formation permissions	ALL, SELECT, DESCRIBE
CloudTrail event	glue:GetTable

Open API definition	https://github.com/awslabs/glue-extensions-for-iceberg/blob/main/glue-extensions-api.yaml#L243
---------------------	---

Considerations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.
- Caller of this API should always determine if there are remaining results to fetch based on the page token. A response with empty page item but a pagination token is possible if the server side is still processing but is not able to produce any result in the given response time.
- You can use this API only if the ExtendedLoadTable API response contains `aws.server-side-capabilities.scan-planning=true`.

TableExists

General information

Operation name	TableExists
Type	Iceberg REST Catalog API
REST path	HEAD/iceberg/v1/catalogs/{catalog}/namespaces/{ns}/tables/{table}
IAM action	glue:GetTable
Lake Formation permissions	ALL, SELECT, DESCRIBE
CloudTrail event	glue:GetTable
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L833

Considerations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.

UpdateTable

General information

Operation name	UpdateTable
Type	Iceberg REST Catalog API
REST path	POST /iceberg/v1/catalogs/{catalog}/namespaces/{ns}/tables/{table}
IAM action	glue:UpdateTable
Lake Formation permissions	ALL, ALTER
CloudTrail event	glue:UpdateTable
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L677

Considerations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.

StartUpdateTableTransaction

General information

Operation name	StartUpdateTableTransaction
----------------	-----------------------------

Type	Amazon Glue extension API
REST path	POST/extensions/v1/catalogs/{catalog}/namespaces/{ns}/tables/{table}
IAM action	glue:UpdateTable
Lake Formation permissions	ALL, ALTER
CloudTrail event	glue:UpdateTable
Open API definition	https://github.com/awslabs/glue-extensions-for-iceberg/blob/main/glue-extensions-api.yaml#L154

Considerations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more information, see the [the section called “Namespace path parameter”](#) section.
- The API is asynchronous, and returns a transaction ID that that you can use for tracking using the `CheckTransactionStatus` API call.
- A `RenamTable` operation can also be performed through this API. When that happens, the caller must also have `glue:CreateTable` or LakeFormation `CREATE_TABLE` permission for the table to be renamed to.
- You can use this API only if the `ExtendedLoadTable` API response contains `aws.server-side-capabilities.scan-planning=true`.

DeleteTable

General information

Operation name	DeleteTable
Type	Iceberg REST Catalog API

REST path	DELETE/iceberg/v1/catalogs/{catalog}/namespaces/{ns}/tables/{table}
IAM action	glue:DeleteTable
Lake Formation permissions	ALL, DROP
CloudTrail event	glue:DeleteTable
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L793

Considerations

- The catalog path parameter should follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more in formation, see the [the section called “Namespace path parameter”](#) section.
- DeleteTable API operation supports a purge option. When purge is set to true, the table data is deleted, otherwise data is not deleted. For tables in Amazon S3, the operation does not delete table data. The operation fails when table is stored in Amazon S3, and `purge = TRUE`, .

For tables stored in Amazon Redshift managed storage, the operation will delete table data, similar to DROP TABLE behavior in Amazon Redshift. The operation fails when table is stored in Amazon Redshift and `purge = FALSE`.

- `purgeRequest=true` is not supported.

StartDeleteTableTransaction

General information

Operation name	StartDeleteTableTransaction
Type	Amazon Glue extensions API
REST path	DELETE /extensions/v1/catalogs/{catalog}/namespaces/{ns}/tables/{table}

IAM action	glue:DeleteTable
Lake Formation permissions	ALL, DROP
CloudTrail event	glue:DeleteTable
Open API definition	https://github.com/apache/iceberg/blob/apache-iceberg-1.6.1/open-api/rest-catalog-open-api.yaml#L793

Considerations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.
- You can specify only a single-level namespace in the REST Path parameter. For more information, see the [the section called “Namespace path parameter”](#) section.
- `purgeRequest=false` is not supported.
- The API is asynchronous, and returns a transaction ID that can be tracked through `CheckTransactionStatus`.

CheckTransactionStatus

General information

Operation name	CheckTransactionStatus
Type	Amazon Glue extensions API
REST path	POST/extensions/v1/transactions/status
IAM action	The same permission as the action that initiates the transaction
Lake Formation permissions	The same permission as the action that initiates the transaction
Open API definition	https://github.com/aws-labs/glue-extensions-for-iceberg/blob/main/glue-extensions-api.yaml#L273

Considerations

- The catalog path parameter must follow the style described in the [the section called “Prefix and catalog path parameters”](#) section.

Connecting to Data Catalog from a standalone Spark application

You can connect to the Data Catalog from a stand application using an Apache Iceberg connector.

1. Create an IAM role for Spark application.
2. Connect to Amazon Glue Iceberg Rest endpoint using Iceberg connector.

```
# configure your application. Refer to https://docs.aws.amazon.com/cli/latest/
userguide/cli-configure-envvars.html for best practices on configuring environment
variables.
export AWS_ACCESS_KEY_ID=$(aws configure get appUser.aws_access_key_id)
export AWS_SECRET_ACCESS_KEY=$(aws configure get appUser.aws_secret_access_key)
export AWS_SESSION_TOKEN=$(aws configure get appUser.aws_secret_token)

export AWS_REGION=us-east-1
export REGION=us-east-1
export AWS_ACCOUNT_ID = {specify your aws account id here}

~/spark-3.5.3-bin-hadoop3/bin/spark-shell \
  --packages org.apache.iceberg:iceberg-spark-runtime-3.4_2.12:1.6.0 \
  --conf
"spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions"
\
  --conf "spark.sql.defaultCatalog=spark_catalog" \
  --conf "spark.sql.catalog.spark_catalog=org.apache.iceberg.spark.SparkCatalog" \
  --conf "spark.sql.catalog.spark_catalog.type=rest" \
  --conf "spark.sql.catalog.spark_catalog.uri=https://glue.us-east-1.amazonaws.com/
iceberg" \
  --conf "spark.sql.catalog.spark_catalog.warehouse = {AWS_ACCOUNT_ID}" \
  --conf "spark.sql.catalog.spark_catalog.rest.sigv4-enabled=true" \
  --conf "spark.sql.catalog.spark_catalog.rest.signing-name=glue" \
  --conf "spark.sql.catalog.spark_catalog.rest.signing-region=us-east-1" \
  --conf "spark.sql.catalog.spark_catalog.io-
impl=org.apache.iceberg.aws.s3.S3FileIO" \
  --conf
"spark.hadoop.fs.s3a.aws.credentials.provider=org.apache.hadoop.fs.s3a.SimpleAWSCredentialsProvider"
```

3. Query data in the Data Catalog.

```
spark.sql("create database myicebergdb").show()
spark.sql("""CREATE TABLE myicebergdb.mytbl (name string) USING iceberg location
's3://bucket_name/mytbl'""")
spark.sql("insert into myicebergdb.mytbl values('demo') ").show()
```

Data mapping between Amazon Redshift and Apache Iceberg

Redshift and Iceberg support various data types. The following compatibility matrix outlines the support and limitations when mapping data between these two data systems. Please refer to [Amazon Redshift Data Types](#) and [Apache Iceberg Table Specifications](#) for more details on supported data types in respective data systems.

Redshift data type	Aliases	Iceberg data type
SMALLINT	INT2	int
INTEGER	INT, INT4	int
BIGINT	INT8	long
DECIMAL	NUMERIC	decimal
REAL	FLOAT4	float
REAL	FLOAT4	float
DOUBLE PRECISION	FLOAT8, FLOAT	double
CHAR	CHARACTER, NCHAR	string
VARCHAR	CHARACTER VARYING, NVARCHAR	string
BPCHAR		string

Redshift data type	Aliases	Iceberg data type
TEXT		string
DATE		date
TIME	TIME WITHOUT TIMEZONE	time
TIME	TIME WITH TIMEZONE	not supported
TIMESTAMP	TIMESTAMP WITHOUT TIMEZONE	TIMESTAMP
TIMESTAMPZ	TIMESTAMP WITH TIMEZONE	TIMESTAMPZ
INTERVAL YEAR TO MONTH		Not supported
INTERVAL DAY TO SECOND		Not supported
BOOLEAN	BOOL	bool
HLLSKETCH		Not supported
SUPER		Not supported
VARBYTE	VARBINARY, BINARY VARYING	binary
GEOMETRY		Not supported
GEOGRAPHY		Not supported

Considerations and limitations when using Amazon Glue Iceberg REST Catalog APIs

Following are the considerations and limitations when using the Apache Iceberg REST Catalog Data Definition Language (DDL) operation behavior.

Considerations

- **RenameTable API behavior** – The `RenameTable` operation is supported in tables in Amazon Redshift but not in Amazon S3.
- **DDL operations for namespaces and tables in Amazon Redshift** – Create, Update, Delete operations for namespaces and tables in Amazon Redshift are asynchronous operations because they are dependent on when Amazon Redshift managed workgroup is available and whether a conflicting DDL and DML transaction is in progress and operation has to wait for lock and then attempt to commit changes.

Limitations

- View APIs in the Apache Iceberg REST specification are not supported in Amazon Glue Iceberg REST Catalog.

Amazon Glue Data Catalog best practices

This section covers best practices for effectively managing and utilizing the Amazon Glue Data Catalog. It emphasizes practices such as efficient crawler usage, metadata organization, security, performance optimization, automation, data governance, and integration with other Amazon services.

- **Use crawlers effectively** – Run crawlers regularly to keep the Data Catalog up-to-date with changes in your data sources. Use incremental crawls for frequently changing data sources to improve performance. Configure crawlers to automatically add new partitions or update schemas when changes are detected.
- **Organize and name metadata tables** – Establish a consistent naming convention for databases and tables in the Data Catalog. Group related data sources into logical databases or folders for better organization. Use descriptive names that convey the purpose and content of each table.
- **Manage schemas effectively** – Take advantage of the schema inference capabilities of Amazon Glue crawlers. Review and update schema changes before applying them to avoid breaking downstream applications. Use schema evolution features to handle schema changes gracefully.
- **Secure the Data Catalog** – Enable data encryption at rest and in transit for the Data Catalog. Implement fine-grained access control policies to restrict access to sensitive data. Regularly audit and review Data Catalog permissions and activity logs.

- **Integrate with other Amazon services Data Catalog** Use the Data Catalog as a centralized metadata layer for services like Amazon Athena, Redshift Spectrum, and Amazon Lake Formation. Leverage Amazon Glue ETL jobs to transform and load data into various data stores while maintaining metadata in the Data Catalog.
- **Monitor and optimize performance Data Catalog** Monitor the performance of crawlers and ETL jobs using Amazon CloudWatch metrics. Partition large datasets in the Data Catalog to improve query performance. Implement performance optimizations for frequently accessed metadata.
- **Stay updated with Amazon Glue documentation and best practices Data Catalog** Regularly check the Amazon Glue documentation and Amazon Glue resources for the latest updates, best practices, and recommendations. Attend Amazon Glue webinars, workshops, and other events to learn from experts and stay informed about new features and capabilities.

Monitoring Data Catalog usage metrics in Amazon CloudWatch

Amazon Glue Data Catalog usage metrics are now available with Amazon CloudWatch, simplifying the monitoring and understanding of resource utilization in your Data Catalog. You now have immediate visibility into your Glue Catalog API usage of catalogs, databases, tables, partitions, and connections, making it easier to maintain oversight of your Data Catalog.

Overview of Data Catalog metrics

Amazon Glue Data Catalog automatically publishes usage metrics to Amazon CloudWatch. With CloudWatch metrics integration, you can track critical performance indicators every minute, including:

- Table requests
- Partition indexes created
- Connections updated
- Statistics updated

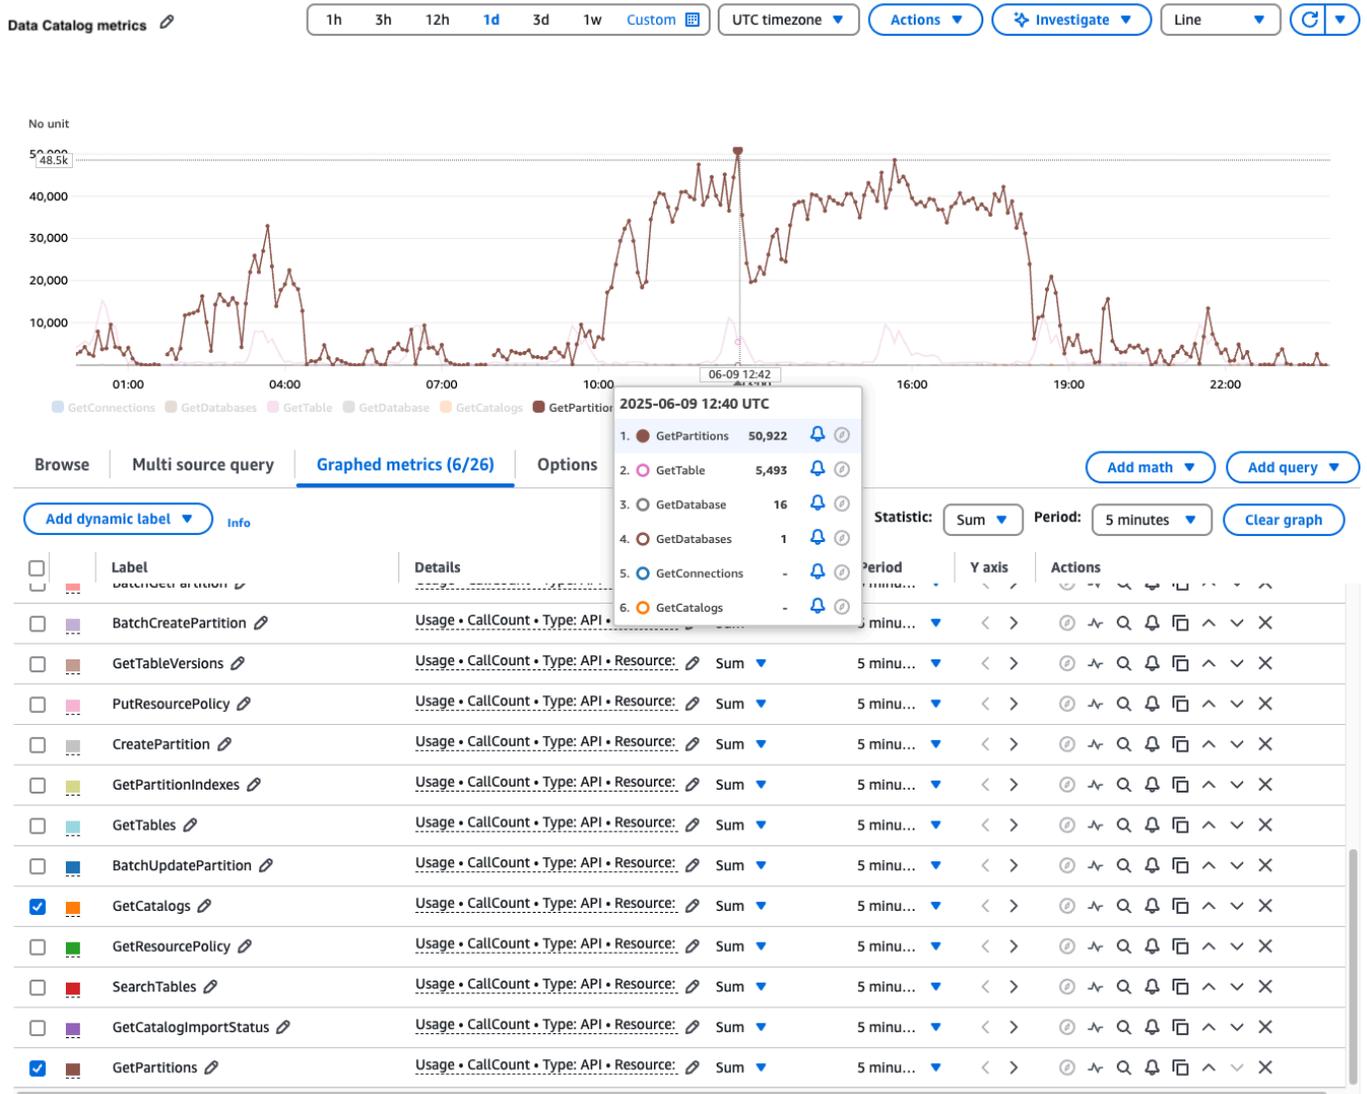

These metrics help you identify bottlenecks, detect anomalies, and make data-driven decisions to improve overall data catalog reliability. You can also set up CloudWatch alarms to receive notifications when metrics exceed specified thresholds, allowing for proactive management of your deployment.

Adding metrics to your CloudWatch dashboard

You can create custom dashboards to monitor your Amazon Glue Data Catalog resources and set up alarms to be notified of any unusual activity.

You can add Data Catalog metrics to your CloudWatch dashboard by following these steps:

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. In the navigation pane, choose **Metrics**.
3. Choose **All metrics**.
4. Choose **Usage>By Amazon resource**.
5. Filter by **Glue** to see available metrics.
6. Select the metrics you want to add to your dashboard.
7. Add metrics for catalogs, databases, tables, partitions, and connections to your CloudWatch graph.

You can configure custom alarms that trigger automatically when API usage exceeds your defined thresholds to identify abnormalities in your data catalog usage.

For detailed instructions on setting up alarms, see [Creating a Metrics Insights CloudWatch alarm](#).

Amazon Glue Schema registry

Note

Amazon Glue Schema Registry is not supported in the following Regions in the Amazon Glue console: Asia Pacific (Jakarta), Europe (Zurich) and Middle East (UAE).

The Amazon Glue Schema registry allows you to centrally discover, control, and evolve data stream schemas. A *schema* defines the structure and format of a data record. With Amazon Glue Schema registry, you can manage and enforce schemas on your data streaming applications using convenient integrations with Apache Kafka, [Amazon Managed Streaming for Apache Kafka](#), [Amazon Kinesis Data Streams](#), [Amazon Managed Service for Apache Flink](#), and [Amazon Lambda](#).

The Schema registry supports AVRO (v1.11.4) data format, JSON Data format with [JSON Schema format](#) for the schema (specifications Draft-04, Draft-06, and Draft-07) with JSON schema validation using the [Everit library](#), Protocol Buffers (Protobuf) versions proto2 and proto3 without support for extensions or groups, and Java language support, with other data formats and languages to come. Supported features include compatibility, schema sourcing via metadata, auto-registration of schemas, IAM compatibility, and optional ZLIB compression to reduce storage and data transfer. The Schema registry is serverless and free to use.

Using a schema as a data format contract between producers and consumers leads to improved data governance, higher quality data, and enables data consumers to be resilient to compatible upstream changes.

The Schema registry allows disparate systems to share a schema for serialization and de-serialization. For example, assume you have a producer and consumer of data. The producer knows the schema when it publishes the data. The Schema Registry supplies a serializer and deserializer for certain systems such as Amazon MSK or Apache Kafka.

For more information, see [How the schema registry works](#).

Topics

- [Schemas](#)
- [Registries](#)
- [Schema versioning and compatibility](#)
- [Open source Serde libraries](#)
- [Quotas of the Schema Registry](#)
- [How the schema registry works](#)
- [Getting started with schema registry](#)

Schemas

A *schema* defines the structure and format of a data record. A schema is a versioned specification for reliable data publication, consumption, or storage.

In this example schema for Avro, the format and structure are defined by the layout and field names, and the format of the field names is defined by the data types (e.g., `string`, `int`).

```
{
  "type": "record",
  "namespace": "ABC_Organization",
  "name": "Employee",
  "fields": [
    {
      "name": "Name",
      "type": "string"
    },
    {
      "name": "Age",
      "type": "int"
    },
    {
      "name": "address",
      "type": {
        "type": "record",
        "name": "addressRecord",
        "fields": [
          {
            "name": "street",
            "type": "string"
          },
          {
            "name": "zipcode",
            "type": "int"
          }
        ]
      }
    }
  ]
}
```

In this example JSON schema draft-07 for JSON, the format is defined by the [JSON Schema organization](#).

```
{
  "$id": "https://example.com/person.schema.json",
  "$schema": "http://json-schema.org/draft-07/schema#",
  "title": "Person",
  "type": "object",
  "properties": {
    "firstName": {
      "type": "string",
      "description": "The person's first name."
    },
    "lastName": {
      "type": "string",
      "description": "The person's last name."
    },
    "age": {
      "description": "Age in years which must be equal to or greater than zero.",
      "type": "integer",
      "minimum": 0
    }
  }
}
```

In this example for Protobuf, the format is defined by the [version 2 of the Protocol Buffers language \(proto2\)](#).

```
syntax = "proto2";

package tutorial;

option java_multiple_files = true;
option java_package = "com.example.tutorial.protos";
option java_outer_classname = "AddressBookProtos";

message Person {
  optional string name = 1;
  optional int32 id = 2;
  optional string email = 3;

  enum PhoneType {
    MOBILE = 0;
```

```
    HOME = 1;
    WORK = 2;
}

message PhoneNumber {
    optional string number = 1;
    optional PhoneType type = 2 [default = HOME];
}

repeated PhoneNumber phones = 4;
}

message AddressBook {
    repeated Person people = 1;
}
```

Registries

A *registry* is a logical container of schemas. Registries allow you to organize your schemas, as well as manage access control for your applications. A registry has an Amazon Resource Name (ARN) to allow you to organize and set different access permissions to schema operations within the registry.

You may use the default registry or create as many new registries as necessary.

Amazon Glue Schema Registry Hierarchy

- RegistryName: [string]
 - RegistryArn: [Amazon ARN]
 - CreatedTime: [timestamp]
 - UpdatedTime: [timestamp]
- SchemaName: [string]
 - SchemaArn: [Amazon ARN]
 - DataFormat: [Avro, Json, or Protobuf]
 - Compatibility: [eg. BACKWARD, BACKWARD_ALL, FORWARD, FORWARD_ALL, FULL, FULL_ALL, NONE, DISABLED]
 - Status: [eg. PENDING, AVAILABLE, DELETING]
 - SchemaCheckpoint: [integer]

- CreatedTime: [timestamp]
 - UpdatedTime: [timestamp]
-
- SchemaVersion: [string]
 - SchemaVersionNumber: [integer]
 - Status: [eg. PENDING, AVAILABLE, DELETING, FAILURE]
 - SchemaDefinition: [string, Value: JSON]
 - CreatedTime: [timestamp]
-
- SchemaVersionMetadata: [list]
 - MetadataKey: [string]
 - MetadataInfo
 - MetadataValue: [string]
 - CreatedTime: [timestamp]

Schema versioning and compatibility

Each schema can have multiple versions. Versioning is governed by a compatibility rule that is applied on a schema. Requests to register new schema versions are checked against this rule by the Schema Registry before they can succeed.

A schema version that is marked as a checkpoint is used to determine the compatibility of registering new versions of a schema. When a schema first gets created the default checkpoint will be the first version. As the schema evolves with more versions, you can use the CLI/SDK to change the checkpoint to a version of a schema using the UpdateSchema API that adheres to a set of constraints. In the console, editing the schema definition or compatibility mode will change the checkpoint to the latest version by default.

Compatibility modes allow you to control how schemas can or cannot evolve over time. These modes form the contract between applications producing and consuming data. When a new version of a schema is submitted to the registry, the compatibility rule applied to the schema name is used to determine if the new version can be accepted. There are 8 compatibility modes: NONE, DISABLED, BACKWARD, BACKWARD_ALL, FORWARD, FORWARD_ALL, FULL, FULL_ALL.

In the Avro data format, fields may be optional or required. An optional field is one in which the Type includes null. Required fields do not have null as the Type.

In the Protobuf data format, fields can be optional (including repeated) or required in proto2 syntax, while all fields are optional (including repeated) in proto3 syntax. All compatibility rules are determined based on the understanding of the Protocol Buffers specifications as well as the guidance from the [Google Protocol Buffers documentation](#).

- *NONE*: No compatibility mode applies. You can use this choice in development scenarios or if you do not know the compatibility modes that you want to apply to schemas. Any new version added will be accepted without undergoing a compatibility check.
- *DISABLED*: This compatibility choice prevents versioning for a particular schema. No new versions can be added.
- *BACKWARD*: This compatibility choice is recommended because it allows consumers to read both the current and the previous schema version. You can use this choice to check compatibility against the previous schema version when you delete fields or add optional fields. A typical use case for BACKWARD is when your application has been created for the most recent schema.

AVRO

For example, assume you have a schema defined by first name (required), last name (required), email (required), and phone number (optional).

If your next schema version removes the required email field, this would successfully register. BACKWARD compatibility requires consumers to be able to read the current and previous schema version. Your consumers will be able to read the new schema as the extra email field from old messages is ignored.

If you have a proposed new schema version that adds a required field, for example, zip code, this would not successfully register with BACKWARD compatibility. Your consumers on the new version would not be able to read old messages before the schema change, as they are missing the required zip code field. However, if the zip code field was set as optional in the new schema, then the proposed version would successfully register as consumers can read the old schema without the optional zip code field.

JSON

For example, assume you have a schema version defined by first name (optional), last name (optional), email (optional) and phone number (optional).

If your next schema version adds the optional phone number property, this would successfully register as long as the original schema version does not allow any additional properties

by setting the `additionalProperties` field to `false`. BACKWARD compatibility requires consumers to be able to read the current and previous schema version. Your consumers will be able to read data produced with the original schema where phone number property does not exist.

If you have a proposed new schema version that adds the optional phone number property, this would not successfully register with BACKWARD compatibility when the original schema version sets the `additionalProperties` field to `true`, namely allowing any additional property. Your consumers on the new version would not be able to read old messages before the schema change, as they cannot read data with phone number property in a different type, for example string instead of number.

PROTOBUF

For example, assume you have a schema version defined by a Message Person with `first name` (required), `last name` (required), `email` (required), and `phone number` (optional) fields under `proto2` syntax.

Similar to AVRO scenarios, if your next schema version removes the required `email` field, this would successfully register. BACKWARD compatibility requires consumers to be able to read the current and previous schema version. Your consumers will be able to read the new schema as the extra `email` field from old messages is ignored.

If you have a proposed new schema version that adds a required field, for example, `zip code`, this would not successfully register with BACKWARD compatibility. Your consumers on the new version would not be able to read old messages before the schema change, as they are missing the required `zip code` field. However, if the `zip code` field was set as optional in the new schema, then the proposed version would successfully register as consumers can read the old schema without the optional `zip code` field.

In case of a gRPC use case, adding new RPC service or RPC method is a backward compatible change. For example, assume you have a schema version defined by an RPC service `MyService` with two RPC methods `Foo` and `Bar`.

If your next schema version adds a new RPC method called `Baz`, this would successfully register. Your consumers will be able to read data produced with the original schema according to BACKWARD compatibility since the newly added RPC method `Baz` is optional.

If you have a proposed new schema version that removes the existing RPC method Foo, this would not successfully register with BACKWARD compatibility. Your consumers on the new version would not be able to read old messages before the schema change, as they cannot understand and read data with the non-existent RPC method Foo in a gRPC application.

- *BACKWARD_ALL*: This compatibility choice allows consumers to read both the current and all previous schema versions. You can use this choice to check compatibility against all previous schema versions when you delete fields or add optional fields.
- *FORWARD*: This compatibility choice allows consumers to read both the current and the subsequent schema versions, but not necessarily later versions. You can use this choice to check compatibility against the last schema version when you add fields or delete optional fields. A typical use case for FORWARD is when your application has been created for a previous schema and should be able to process a more recent schema.

AVRO

For example, assume you have a schema version defined by first name (required), last name (required), email (optional).

If you have a new schema version that adds a required field, e.g. phone number, this would successfully register. FORWARD compatibility requires consumers to be able to read data produced with the new schema by using the previous version.

If you have a proposed schema version that deletes the required first name field, this would not successfully register with FORWARD compatibility. Your consumers on the prior version would not be able to read the proposed schemas as they are missing the required first name field. However, if the first name field was originally optional, then the proposed new schema would successfully register as the consumers can read data based on the new schema that doesn't have the optional first name field.

JSON

For example, assume you have a schema version defined by first name (optional), last name (optional), email (optional) and phone number (optional).

If you have a new schema version that removes the optional phone number property, this would successfully register as long as the new schema version does not allow any additional properties by setting the `additionalProperties` field to false. FORWARD compatibility

requires consumers to be able to read data produced with the new schema by using the previous version.

If you have a proposed schema version that deletes the optional phone number property, this would not successfully register with FORWARD compatibility when the new schema version sets the `additionalProperties` field to true, namely allowing any additional property. Your consumers on the prior version would not be able to read the proposed schemas as they could have phone number property in a different type, for example string instead of number.

PROTOBUF

For example, assume you have a schema version defined by a Message Person with `first name` (required), `last name` (required), `email` (optional) fields under proto2 syntax.

Similar to AVRO scenarios, if you have a new schema version that adds a required field, e.g. `phone number`, this would successfully register. FORWARD compatibility requires consumers to be able to read data produced with the new schema by using the previous version.

If you have a proposed schema version that deletes the required `first name` field, this would not successfully register with FORWARD compatibility. Your consumers on the prior version would not be able to read the proposed schemas as they are missing the required `first name` field. However, if the `first name` field was originally optional, then the proposed new schema would successfully register as the consumers can read data based on the new schema that doesn't have the optional `first name` field.

In case of a gRPC use case, removing an RPC service or RPC method is a forward-compatible change. For example, assume you have a schema version defined by an RPC service `MyService` with two RPC methods `Foo` and `Bar`.

If your next schema version deletes the existing RPC method named `Foo`, this would successfully register according to FORWARD compatibility as the consumers can read data produced with the new schema by using the previous version. If you have a proposed new schema version that adds an RPC method `Baz`, this would not successfully register with FORWARD compatibility. Your consumers on the prior version would not be able to read the proposed schemas as they are missing the RPC method `Baz`.

- **FORWARD_ALL**: This compatibility choice allows consumers to read data written by producers of any new registered schema. You can use this choice when you need to add fields or delete optional fields, and check compatibility against all previous schema versions.

- *FULL*: This compatibility choice allows consumers to read data written by producers using the previous or next version of the schema, but not earlier or later versions. You can use this choice to check compatibility against the last schema version when you add or remove optional fields.
- *FULL_ALL*: This compatibility choice allows consumers to read data written by producers using all previous schema versions. You can use this choice to check compatibility against all previous schema versions when you add or remove optional fields.

Open source Serde libraries

Amazon provides open-source Serde libraries as a framework for serializing and deserializing data. The open source design of these libraries allows common open-source applications and frameworks to support these libraries in their projects.

For more details on how the Serde libraries work, see [How the schema registry works](#).

Quotas of the Schema Registry

Quotas, also referred to as limits in Amazon, are the maximum values for the resources, actions, and items in your Amazon account. The following are soft limits for the Schema Registry in Amazon Glue.

Schema version metadata key-value pairs

You can have up to 10 key-value pairs per SchemaVersion per Amazon Region.

You can view or set the key-value metadata pairs using the [QuerySchemaVersionMetadata action \(Python: `query_schema_version_metadata`\)](#) or [PutSchemaVersionMetadata action \(Python: `put_schema_version_metadata`\)](#) APIs.

The following are hard limits for the Schema Registry in Amazon Glue.

Registries

You can have up to 100 registries per Amazon Region for this account.

SchemaVersion

You can have up to 10000 schema versions per Amazon Region for this account.

Each new schema creates a new schema version, so you can theoretically have up to 10000 schemas per account per region, if each schema has only one version.

Schema payloads

There is a size limit of 170KB for schema payloads.

How the schema registry works

This section describes how the serialization and deserialization processes in schema registry work.

1. Register a schema: If the schema doesn't already exist in the registry, the schema can be registered with a schema name equal to the name of the destination (e.g., `test_topic`, `test_stream`, `prod_firehose`) or the producer can provide a custom name for the schema. Producers can also add key-value pairs to the schema as metadata, such as `source: msk_kafka_topic_A`, or apply Amazon tags to schemas on schema creation. Once a schema is registered the Schema Registry returns the schema version ID to the serializer. If the schema exists but the serializer is using a new version that doesn't exist, the Schema Registry will check the schema reference a compatibility rule to ensure the new version is compatible before registering it as a new version.

There are two methods of registering a schema: manual registration and auto-registration. You can register a schema manually via the Amazon Glue console or CLI/SDK.

When auto-registration is turned on in the serializer settings, automatic registration of the schema will be performed. If `REGISTRY_NAME` is not provided in the producer configurations, then auto-registration will register the new schema version under the default registry (default-registry). See [Installing SerDe Libraries](#) for information on specifying the auto-registration property.

2. Serializer validates data records against the schema: When the application producing data has registered its schema, the Schema Registry serializer validates the record being produced by the application is structured with the fields and data types matching a registered schema. If the schema of the record does not match a registered schema, the serializer will return an exception and the application will fail to deliver the record to the destination.

If no schema exists and if the schema name is not provided via the producer configurations, then the schema is created with the same name as the topic name (if Apache Kafka or Amazon MSK) or stream name (if Kinesis Data Streams).

Every record has a schema definition and data. The schema definition is queried against the existing schemas and versions in the Schema Registry.

By default, producers cache schema definitions and schema version IDs of registered schemas. If a record's schema version definition does not match what's available in cache, the producer will attempt to validate the schema with the Schema Registry. If the schema version is valid, then its version ID and definition will be cached locally on the producer.

You can adjust the default cache period (24 hours) within the optional producer properties in step #3 of [Installing SerDe Libraries](#).

3. **Serialize and deliver records:** If the record complies with the schema, the serializer decorates each record with the schema version ID, serializes the record based on the data format selected (AVRO, JSON, Protobuf, or other formats coming soon), compresses the record (optional producer configuration), and delivers it to the destination.
4. **Consumers deserialize the data:** Consumers reading this data use the Schema Registry deserializer library that parses the schema version ID from the record payload.
5. **Deserializer may request the schema from the Schema Registry:** If this is the first time the deserializer has seen records with a particular schema version ID, using the schema version ID the deserializer will request the schema from the Schema Registry and cache the schema locally on the consumer. If the Schema Registry cannot deserialize the record, the consumer can log the data from the record and move on, or halt the application.
6. **The deserializer uses the schema to deserialize the record:** When the deserializer retrieves the schema version ID from the Schema Registry, the deserializer decompresses the record (if record sent by producer is compressed) and uses the schema to deserialize the record. The application now processes the record.

Note

Encryption: Your clients communicate with the Schema Registry via API calls which encrypt data in-transit using TLS encryption over HTTPS. Schemas stored in the Schema Registry are always encrypted at rest using a service-managed Amazon Key Management Service (Amazon KMS) key.

Note

User Authorization: The Schema Registry supports identity-based IAM policies.

Getting started with schema registry

The following sections provide an overview and walk you through setting up and using Schema Registry. For information about schema registry concepts and components, see [Amazon Glue Schema registry](#).

Topics

- [Installing SerDe Libraries](#)
- [Integrating with Amazon Glue Schema Registry](#)
- [Migration from a third-party schema registry to Amazon Glue Schema Registry](#)

Installing SerDe Libraries

The SerDe libraries provide a framework for serializing and deserializing data.

You will install the open source serializer for your applications producing data (collectively the "serializers"). The serializer handles serialization, compression, and the interaction with the Schema Registry. The serializer automatically extracts the schema from a record being written to a Schema Registry compatible destination, such as Amazon MSK. Likewise, you will install the open source deserializer on your applications consuming data.

Java Implementation

Note

Prerequisites: Before completing the following steps, you will need to have a Amazon Managed Streaming for Apache Kafka (Amazon MSK) or Apache Kafka cluster running. Your producers and consumers need to be running on Java 8 or above.

To install the libraries on producers and consumers:

1. Inside both the producers' and consumers' pom.xml files, add this dependency via the code below:

```
<dependency>
  <groupId>software.amazon.glue</groupId>
```

```
<artifactId>schema-registry-serde</artifactId>
<version>1.1.5</version>
</dependency>
```

Alternatively, you can clone the [Amazon Glue Schema Registry Github repository](#).

2. Setup your producers with these required properties:

```
props.put(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
StringSerializer.class.getName()); // Can replace StringSerializer.class.getName()
with any other key serializer that you may use
props.put(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
GlueSchemaRegistryKafkaSerializer.class.getName());
props.put(AWSSchemaRegistryConstants.AWS_REGION, "us-east-2");
properties.put(AWSSchemaRegistryConstants.DATA_FORMAT, "JSON"); // OR "AVRO"
```

If there are no existing schemas, then auto-registration needs to be turned on (next step). If you do have a schema that you would like to apply, then replace "my-schema" with your schema name. Also the "registry-name" has to be provided if schema auto-registration is off. If the schema is created under the "default-registry" then registry name can be omitted.

3. (Optional) Set any of these optional producer properties. For detailed property descriptions, see [the ReadMe file](#).

```
props.put(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING, "true"); // If
not passed, uses "false"
props.put(AWSSchemaRegistryConstants.SCHEMA_NAME, "my-schema"); // If not passed,
uses transport name (topic name in case of Kafka, or stream name in case of Kinesis
Data Streams)
props.put(AWSSchemaRegistryConstants.REGISTRY_NAME, "my-registry"); // If not passed,
uses "default-registry"
props.put(AWSSchemaRegistryConstants.CACHE_TIME_TO_LIVE_MILLIS, "86400000"); // If
not passed, uses 86400000 (24 Hours)
props.put(AWSSchemaRegistryConstants.CACHE_SIZE, "10"); // default value is 200
props.put(AWSSchemaRegistryConstants.COMPATIBILITY_SETTING, Compatibility.FULL); //
Pass a compatibility mode. If not passed, uses Compatibility.BACKWARD
props.put(AWSSchemaRegistryConstants.DESCRPTION, "This registry is used for several
purposes."); // If not passed, constructs a description
props.put(AWSSchemaRegistryConstants.COMPRESSION_TYPE,
AWSSchemaRegistryConstants.COMPRESSION.ZLIB); // If not passed, records are sent
uncompressed
```

Auto-registration registers the schema version under the default registry ("default-registry"). If a SCHEMA_NAME is not specified in the previous step, then the topic name is inferred as SCHEMA_NAME.

See [Schema versioning and compatibility](#) for more information on compatibility modes.

4. Setup your consumers with these required properties:

```
props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
    StringDeserializer.class.getName());
props.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
    GlueSchemaRegistryKafkaDeserializer.class.getName());
props.put(AWSSchemaRegistryConstants.AWS_REGION, "us-east-2"); // Pass an Amazon Web
    Services Region
props.put(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
    AvroRecordType.GENERIC_RECORD.getName()); // Only required for AVRO data format
```

5. (Optional) Set these optional consumer properties. For detailed property descriptions, see [the ReadMe file](#).

```
properties.put(AWSSchemaRegistryConstants.CACHE_TIME_TO_LIVE_MILLIS, "86400000"); //
    If not passed, uses 86400000
props.put(AWSSchemaRegistryConstants.CACHE_SIZE, "10"); // default value is 200
props.put(AWSSchemaRegistryConstants.SECONDARY_DESERIALIZER,
    "com.amazonaws.services.schemaregistry.deserializers.external.ThirdPartyDeserializer"); //
    For migration fall back scenario
```

C# Implementation

Note

Prerequisites: Before completing the following steps, you will need to have a Amazon Managed Streaming for Apache Kafka (Amazon MSK) or Apache Kafka cluster running. Your producers and consumers need to be running on .NET 8.0 or above.

Installation

For C# applications, install the Amazon Glue Schema Registry SerDe NuGet package using one of the following methods:

.NET CLI:

Use the following command to install the package:

```
dotnet add package Aws.Glue.SchemaRegistry --version 1.0.0-<rid>
```

where <rid> could be 1.0.0-linux-x64, 1.0.0-linux-musl-x64 or 1.0.0-linux-arm64

PackageReference (in your .csproj file):

Add the following to your project file:

```
<PackageReference Include="Aws.Glue.SchemaRegistry" Version="1.0.0-<rid>" />
```

where <rid> could be 1.0.0-linux-x64, 1.0.0-linux-musl-x64 or 1.0.0-linux-arm64

Configuration File Setup

Create a configuration properties file (e.g., gsr-config.properties) with the required settings:

Minimal Configuration:

The following shows a minimal configuration example:

```
region=us-east-1
registry.name=default-registry
dataFormat=AVRO
schemaAutoRegistrationEnabled=true
```

Using C# Glue Schema client library for Kafka SerDes

Sample serializer usage:

The following example shows how to use the serializer:

```
private static readonly string PROTOBUF_CONFIG_PATH = "<PATH_TO_CONFIG_FILE>";
var protobufSerializer = new GlueSchemaRegistryKafkaSerializer(PROTOBUF_CONFIG_PATH);
var serialized = protobufSerializer.Serialize(message, message.Descriptor.FullName);
// send serialized bytes to Kafka using producer.Produce(serialized)
```

Sample deserializer usage:

The following example shows how to use the deserializer:

```
private static readonly string PROTOBUF_CONFIG_PATH = "<PATH_TO_CONFIG_FILE>";
var dataConfig = new GlueSchemaRegistryDataFormatConfiguration(
    new Dictionary<string, dynamic>
    {
        {
            GlueSchemaRegistryConstants.ProtobufMessageDescriptor, message.Descriptor
        }
    }
);
var protobufDeserializer = new
    GlueSchemaRegistryKafkaDeserializer(PROTOBUF_CONFIG_PATH, dataConfig);

// read message from Kafka using serialized = consumer.Consume()
var deserializedObject = protobufDeserializer.Deserialize(message.Descriptor.FullName,
    serialized);
```

Using C# Glue Schema client library with KafkaFlow for SerDes

Sample serializer usage:

The following example shows how to configure KafkaFlow with the serializer:

```
services.AddKafka(kafka => kafka
    .UseConsoleLog()
    .AddCluster(cluster => cluster
        .WithBrokers(new[] { "localhost:9092" })
        .AddProducer<CustomerProducer>(producer => producer
            .DefaultTopic("customer-events")
            .AddMiddlewares(m => m

        .AddSerializer<GlueSchemaRegistryKafkaFlowProtobufSerializer<Customer>>(
            () => new
                GlueSchemaRegistryKafkaFlowProtobufSerializer<Customer>("config/gsr-
                    config.properties")
            )
        )
    )
);
```

Sample deserializer usage:

The following example shows how to configure KafkaFlow with the deserializer:

```
.AddConsumer(consumer => consumer
    .Topic("customer-events")
    .WithGroupId("customer-group")
    .WithBufferSize(100)
    .WithWorkersCount(10)
    .AddMiddlewares(middlewares => middlewares
        .AddDeserializer<GlueSchemaRegistryKafkaFlowProtobufDeserializer<Customer>>(
            () => new
                GlueSchemaRegistryKafkaFlowProtobufDeserializer<Customer>("config/gsr-
                    config.properties")
            )
        .AddTypedHandlers(h => h.AddHandler<CustomerHandler>())
    )
)
```

Optional Producer Properties

You can extend your configuration file with additional optional properties:

```
# Auto-registration (if not passed, uses "false")
schemaAutoRegistrationEnabled=true

# Schema name (if not passed, uses topic name)
schema.name=my-schema

# Registry name (if not passed, uses "default-registry")
registry.name=my-registry

# Cache settings
cacheTimeToLiveMillis=86400000
cacheSize=200

# Compatibility mode (if not passed, uses BACKWARD)
compatibility=FULL

# Registry description
description=This registry is used for several purposes.

# Compression (if not passed, records are sent uncompressed)
```

```
compressionType=ZLIB
```

Supported Data Formats

Both Java and C# implementations support the same data formats:

- *AVRO*: Apache Avro binary format
- *JSON*: JSON Schema format
- *PROTOBUF*: Protocol Buffers format

Notes

- To get started with the library, please visit <https://www.nuget.org/packages/AWS.Glue.SchemaRegistry>
- Source code is available at: <https://github.com/awslabs/aws-glue-schema-registry>

Creating a registry

You may use the default registry or create as many new registries as necessary using the Amazon Glue APIs or Amazon Glue console.

Amazon Glue APIs

You can use these steps to perform this task using the Amazon Glue APIs.

To use the Amazon CLI for the Amazon Glue Schema Registry APIs, make sure to update your Amazon CLI to the latest version.

To add a new registry, use the [CreateRegistry action \(Python: create_registry\)](#) API. Specify `RegistryName` as the name of the registry to be created, with a max length of 255, containing only letters, numbers, hyphens, underscores, dollar signs, or hash marks.

Specify a `Description` as a string not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

Optionally, specify one or more `Tags` for your registry, as a map array of key-value pairs.

```
aws glue create-registry --registry-name registryName1 --description description
```

When your registry is created it is assigned an Amazon Resource Name (ARN), which you can view in the `RegistryArn` of the API response. Now that you've created a registry, create one or more schemas for that registry.

Amazon Glue console

To add a new registry in the Amazon Glue console:

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose **Add registry**.
4. Enter a **Registry name** for the registry, consisting of letters, numbers, hyphens, or underscores. This name cannot be changed.
5. Enter a **Description** (optional) for the registry.
6. Optionally, apply one or more tags to your registry. Choose **Add new tag** and specify a **Tag key** and optionally a **Tag value**.
7. Choose **Add registry**.

Schema registries > Add registry

Add a new schema registry

Add a schema registry to store one or multiple new related schemas.

Registry name
Name can't be changed post creation.

Only letters (A-Z), numbers (0-9), hyphens (-), underscores (_), dollar signs (\$), or hash marks (#) allowed. 255 characters maximum.

Description - optional

2048 characters maximum.

Registry tags - optional
No tags defined.

You can add up to 50 more tags.

When your registry is created it is assigned an Amazon Resource Name (ARN), which you can view by choosing the registry from the list in **Schema registries**. Now that you've created a registry, create one or more schemas for that registry.

Dealing with a specific record (JAVA POJO) for JSON

You can use a plain old Java object (POJO) and pass the object as a record. This is similar to the notion of a specific record in AVRO. The [mbknor-jackson-jsonschema](#) can generate a JSON schema for the POJO passed. This library can also inject additional information in the JSON schema.

The Amazon Glue Schema Registry library uses the injected "className" field in schema to provide a fully classified class name. The "className" field is used by the deserializer to deserialize into an object of that class.

Example class :

```
@JsonSchemaDescription("This is a car")
@JsonSchemaTitle("Simple Car Schema")
```

```
@Builder
@AllArgsConstructor
@EqualsAndHashCode
// Fully qualified class name to be added to an additionally injected property
// called className for deserializer to determine which class to deserialize
// the bytes into
@JsonSchemaInject(
    strings = {@JsonSchemaString(path = "className",
        value =
            "com.amazonaws.services.schemaregistry.integrationtests.generators.Car")}
)
// List of annotations to help infer JSON Schema are defined by https://github.com/
mbknor/mbknor-jackson-jsonSchema
public class Car {
    @JsonProperty(required = true)
    private String make;

    @JsonProperty(required = true)
    private String model;

    @JsonSchemaDefault("true")
    @JsonProperty
    public boolean used;

    @JsonSchemaInject(ints = {@JsonSchemaInt(path = "multipleOf", value = 1000)})
    @Max(200000)
    @JsonProperty
    private int miles;

    @Min(2000)
    @JsonProperty
    private int year;

    @JsonProperty
    private Date purchaseDate;

    @JsonProperty
    @JsonFormat(shape = JsonFormat.Shape.NUMBER)
    private Date listedDate;

    @JsonProperty
    private String[] owners;

    @JsonProperty
```

```
private Collection<Float> serviceChecks;

// Empty constructor is required by Jackson to deserialize bytes
// into an Object of this class
public Car() {}
}
```

Creating a schema

You can create a schema using the Amazon Glue APIs or the Amazon Glue console.

Amazon Glue APIs

You can use these steps to perform this task using the Amazon Glue APIs.

To add a new schema, use the [CreateSchema action \(Python: create_schema\)](#) API.

Specify a `RegistryId` structure to indicate a registry for the schema. Or, omit the `RegistryId` to use the default registry.

Specify a `SchemaName` consisting of letters, numbers, hyphens, or underscores, and `DataFormat` as **AVRO** or **JSON**. `DataFormat` once set on a schema is not changeable.

Specify a `Compatibility` mode:

- *Backward (recommended)* — Consumer can read both current and previous version.
- *Backward all* — Consumer can read current and all previous versions.
- *Forward* — Consumer can read both current and subsequent version.
- *Forward all* — Consumer can read both current and all subsequent versions.
- *Full* — Combination of Backward and Forward.
- *Full all* — Combination of Backward all and Forward all.
- *None* — No compatibility checks are performed.
- *Disabled* — Prevent any versioning for this schema.

Optionally, specify `Tags` for your schema.

Specify a `SchemaDefinition` to define the schema in Avro, JSON, or Protobuf data format. See the examples.

For Avro data format:

```
aws glue create-schema --registry-id RegistryName="registryName1" --schema-name
testschema --compatibility NONE --data-format AVRO --schema-definition "{\"type\":
\"record\", \"name\": \"r1\", \"fields\": [ {\"name\": \"f1\", \"type\": \"int\"},
{\"name\": \"f2\", \"type\": \"string\"} ]}"
```

```
aws glue create-schema --registry-id RegistryArn="arn:aws:glue:us-
east-2:901234567890:registry/registryName1" --schema-name testschema --compatibility
NONE --data-format AVRO --schema-definition "{\"type\": \"record\", \"name\": \"r1\",
\"fields\": [ {\"name\": \"f1\", \"type\": \"int\"}, {\"name\": \"f2\", \"type\":
\"string\"} ]}"
```

For JSON data format:

```
aws glue create-schema --registry-id RegistryName="registryName" --schema-name
testSchemaJson --compatibility NONE --data-format JSON --schema-definition "{\"$schema
\": \"http://json-schema.org/draft-07/schema#\", \"type\": \"object\", \"properties\":
{\"f1\": {\"type\": \"string\"}}}"
```

```
aws glue create-schema --registry-id RegistryArn="arn:aws:glue:us-
east-2:901234567890:registry/registryName" --schema-name testSchemaJson --compatibility
NONE --data-format JSON --schema-definition "{\"$schema\": \"http://json-schema.org/
draft-07/schema#\", \"type\": \"object\", \"properties\": {\"f1\": {\"type\": \"string\"}}}"
```

For Protobuf data format:

```
aws glue create-schema --registry-id RegistryName="registryName" --schema-name
testSchemaProtobuf --compatibility NONE --data-format PROTOBUF --schema-definition
"syntax = \"proto2\";package org.test;message Basic { optional int32 basic = 1;}"
```

```
aws glue create-schema --registry-id RegistryArn="arn:aws:glue:us-
east-2:901234567890:registry/registryName" --schema-name testSchemaProtobuf
--compatibility NONE --data-format PROTOBUF --schema-definition "syntax =
\"proto2\";package org.test;message Basic { optional int32 basic = 1;}"
```

Amazon Glue console

To add a new schema using the Amazon Glue console:

1. Sign in to the Amazon Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schemas**.
3. Choose **Add schema**.
4. Enter a **Schema name**, consisting of letters, numbers, hyphens, underscores, dollar signs, or hashmarks. This name cannot be changed.
5. Choose the **Registry** where the schema will be stored from the drop-down menu. The parent registry cannot be changed post-creation.
6. Leave the **Data format** as *Apache Avro* or *JSON*. This format applies to all versions of this schema.
7. Choose a **Compatibility mode**.
 - *Backward (recommended)* — receiver can read both current and previous versions.
 - *Backward All* — receiver can read current and all previous versions.
 - *Forward* — sender can write both current and previous versions.
 - *Forward All* — sender can write current and all previous versions.
 - *Full* — combination of Backward and Forward.
 - *Full All* — combination of Backward All and Forward All.
 - *None* — no compatibility checks performed.
 - *Disabled* — prevent any versioning for this schema.
8. Enter an optional **Description** for the registry of up to 250 characters.

The screenshot shows the 'Add a new schema' page in the Amazon Glue console. The left sidebar contains navigation links for various Glue services. The main content area is titled 'Add a new schema' and includes the following sections:

- Schema name:** A text input field with a placeholder 'Enter a schema name...'. Below it, a note states: 'Only letters (A-Z), numbers (0-9), hyphens (-), underscores (_), dollar signs (\$), or hash marks (#) allowed. 255 characters maximum.'
- Registry:** A dropdown menu with a placeholder 'Select a registry...'. To the right are a refresh icon and an 'Add new registry' button.
- Data format:** A dropdown menu currently showing 'Apache Avro'. A note below states: 'Glue schemas only support Apache Avro for now, which offers the compatibility options below. [Learn more](#)'.
- Compatibility mode:** A dropdown menu currently showing 'Backward (default) - consumer can read both current and previous version'. Below this is a blue information box with an 'i' icon and the text: 'Backward compatibility [Learn more](#). This compatibility choice allows consumers to read both the current and the previous schema version. This means that for instance, a new schema version cannot drop data fields or change the type of these fields, so they can't be read by consumers using the previous version.'
- Description - optional:** A text area with a placeholder 'Enter a schema description...'. Below it, a note states: '2048 characters maximum.'

9. Optionally, apply one or more tags to your schema. Choose **Add new tag** and specify a **Tag key** and optionally a **Tag value**.

10. In the **First schema version** box, enter or paste your initial schema. .

For Avro format, see [Working with Avro data format](#)

For JSON format, see [Working with JSON data format](#)

11. Optionally, choose **Add metadata** to add version metadata to annotate or classify your schema version.

12. Choose **Create schema and version**.

Resources

Schema tags - optional

No tags defined.

Add new tag

You can add up to 50 more tags.

First schema version

Please specify the initial definition of your schema below, so that it can be used in your applications or within Amazon Glue. You may change your schema definition by registering new versions at any point later. Please enter Apache Avro schema below. [Learn more](#)

1

Version metadata - optional

No metadata key-value pairs.

Add metadata

You can add 10 more metadata key-value pairs.

Cancel Create schema and version

The schema is created and appears in the list under **Schemas**.

Working with Avro data format

Avro provides data serialization and data exchange services. Avro stores the data definition in JSON format making it easy to read and interpret. The data itself is stored in binary format.

For information on defining an Apache Avro schema, see the [Apache Avro specification](#).

Working with JSON data format

Data can be serialized with JSON format. [JSON Schema format](#) defines the standard for JSON Schema format.

Updating a schema or registry

Once created you can edit your schemas, schema versions, or registry.

Updating a registry

You can update a registry using the Amazon Glue APIs or the Amazon Glue console. The name of an existing registry cannot be edited. You can edit the description for a registry.

Amazon Glue APIs

To update an existing registry, use the [UpdateRegistry action \(Python: update_registry\)](#) API.

Specify a `RegistryId` structure to indicate the registry that you want to update. Pass a `Description` to change the description for a registry.

```
aws glue update-registry --description updatedDescription --registry-id
RegistryArn="arn:aws:glue:us-east-2:901234567890:registry/registryName1"
```

Amazon Glue console

To update a registry using the Amazon Glue console:

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose a registry from the the list of registries, by checking its box.
4. In the **Action** menu, choose **Edit registry**.

Updating a schema

You can update the description or compatibility setting for a schema.

To update an existing schema, use the [UpdateSchema action \(Python: `update_schema`\)](#) API.

Specify a `SchemaId` structure to indicate the schema that you want to update. One of `VersionNumber` or `Compatibility` has to be provided.

Code example 11:

```
aws glue update-schema --description testDescription --schema-id
  SchemaName="testSchema1",RegistryName="registryName1" --schema-version-number
  LatestVersion=true --compatibility NONE
```

```
aws glue update-schema --description testDescription --schema-id
  SchemaArn="arn:aws:glue:us-east-2:901234567890:schema/registryName1/testSchema1" --
  schema-version-number LatestVersion=true --compatibility NONE
```

Adding a schema version

When you add a schema version, you will need to compare the versions to make sure the new schema will be accepted.

To add a new version to an existing schema, use the [RegisterSchemaVersion action \(Python: `register_schema_version`\)](#) API.

Specify a `SchemaId` structure to indicate the schema for which you want to add a version, and a `SchemaDefinition` to define the schema.

Code example 12:

```
aws glue register-schema-version --schema-definition '{"type": "record", "name":
  "r1", "fields": [ {"name": "f1", "type": "int"}, {"name": "f2", "type
  ": "string"} ]}' --schema-id SchemaArn="arn:aws:glue:us-east-1:901234567890:schema/
  registryName/testschema"
```

```
aws glue register-schema-version --schema-definition '{"type": "record", "name":
  "r1", "fields": [ {"name": "f1", "type": "int"}, {"name": "f2", "type
  ": "string"} ]}' --schema-id SchemaName="testschema",RegistryName="testregistry"
```

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schemas**.
3. Choose the schema from the the list of schemas, by checking its box.
4. Choose one or more schemas from the list, by checking the boxes.
5. In the **Action** menu, choose **Register new version**.
6. In the **New version** box, enter or paste your new schema.
7. Choose **Compare with previous version** to see differences with the previous schema version.
8. Optionally, choose **Add metadata** to add version metadata to annotate or classify your schema version. Enter **Key** and optional **Value**.
9. Choose **Register version**.

Schemas > test-1 > Register version

Register a new schema version

Register version 4 to your schema.

Schema name	test-1
Data format	Apache Avro
Compatibility mode	Backward compatibility
Schema tags	No tags defined.

New Version 4

This is a copy of version 1's schema definition. A schema definition not associated with any existing schema versions must be defined in order to register a new schema version.

```

1  {
2    "type": "record",
3    "name": "r0",
4    "fields": [
5      {
6        "name": "f1",
7        "type": "int"
8      }
9    ]
10 }

```

[Compare with previous version](#)

Version metadata - optional

No metadata key-value pairs.

[Add metadata](#)

You can add 10 more metadata key-value pairs.

[Cancel](#) [Register version](#)

The schema(s) version appears in the list of versions. If the version changed the compatibility mode, the version will be marked as a checkpoint.

Example of a schema version comparison

When you choose to **Compare with previous version**, you will see the previous and new versions displayed together. Changed information will be highlighted as follows:

- **Yellow:** indicates changed information.

- *Green*: indicates content added in the latest version.
- *Red*: indicates content removed in the latest version.

You can also compare against earlier versions.

Schema version comparison

Schema test-1 Compatibility Mode Backward compatibility

Version 1 (latest a... Version 4 (new)

```

1 {
2   "type": "record",
3-  "name": "r0",
4   "fields": [
5     {
6       "name": "f1",
7       "type": "int"
8     }
9   ]
10 }

```

```

1 {
2   "type": "record",
3+  "name": "user.record",
4+  "aliases": "userInfo",
5   "fields": [
6     {
7       "name": "f1",
8       "type": "int"
9     }
10  ]
11 }

```

Deleting a schema or registry

Deleting a schema, a schema version, or a registry are permanent actions that cannot be undone.

Deleting a schema

You may want to delete a schema when it will no longer be used within a registry, using the Amazon Web Services Management Console, or the [DeleteSchema action \(Python: delete_schema\)](#) API.

Deleting one or more schemas is a permanent action that cannot be undone. Make sure that the schema or schemas are no longer needed.

To delete a schema from the registry, call the [DeleteSchema action \(Python: delete_schema\)](#) API, specifying the SchemaId structure to identify the schema.

For example:

```
aws glue delete-schema --schema-id SchemaArn="arn:aws:glue:us-east-2:901234567890:schema/registryName1/schemaname"
```

```
aws glue delete-schema --schema-id SchemaName="TestSchema6-deleteschemabyname",RegistryName="default-registry"
```

Amazon Glue console

To delete a schema from the Amazon Glue console:

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose the registry that contains your schema from the the list of registries.
4. Choose one or more schemas from the list, by checking the boxes.
5. In the **Action** menu, choose **Delete schema**.
6. Enter the text **Dele**te in the field to confirm deletion.
7. Choose **Delete**.

The schema(s) you specified are deleted from the registry.

Deleting a schema version

As schemas accumulate in the registry, you may want to delete unwanted schema versions using the Amazon Web Services Management Console, or the [DeleteSchemaVersions action \(Python: delete_schema_versions\)](#) API. Deleting one or more schema versions is a permanent action that cannot be undone. Make sure that the schema versions are no longer needed.

When deleting schema versions, take note of the following constraints:

- You cannot delete a check-pointed version.
- The range of contiguous versions cannot be more than 25.
- The latest schema version must not be in a pending state.

Specify the `SchemaId` structure to identify the schema, and specify `Versions` as a range of versions to delete. For more information on specifying a version or range of versions, see [DeleteRegistry action \(Python: delete_registry\)](#). The schema versions you specified are deleted from the registry.

Calling the [ListSchemaVersions action \(Python: list_schema_versions\)](#) API after this call will list the status of the deleted versions.

For example:

```
aws glue delete-schema-versions --schema-id
  SchemaName="TestSchema6",RegistryName="default-registry" --versions "1-1"
```

```
aws glue delete-schema-versions --schema-id SchemaArn="arn:aws:glue:us-
east-2:901234567890:schema/default-registry/TestSchema6-NON-Existent" --versions "1-1"
```

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose the registry that contains your schema from the the list of registries.
4. Choose one or more schemas from the list, by checking the boxes.
5. In the **Action** menu, choose **Delete schema**.
6. Enter the text **Dele**te in the field to confirm deletion.
7. Choose **Delete**.

The schema versions you specified are deleted from the registry.

Deleting a registry

You may want to delete a registry when the schemas it contains should no longer be organized under that registry. You will need to reassign those schemas to another registry.

Deleting one or more registries is a permanent action that cannot be undone. Make sure that the registry or registries no longer needed.

The default registry can be deleted using the Amazon CLI.

Amazon Glue API

To delete the entire registry including the schema and all of its versions, call the [DeleteRegistry action \(Python: delete_registry\)](#) API. Specify a RegistryId structure to identify the registry.

For example:

```
aws glue delete-registry --registry-id RegistryArn="arn:aws:glue:us-east-2:901234567890:registry/registryName1"
```

```
aws glue delete-registry --registry-id RegistryName="TestRegistry-deletebyname"
```

To get the status of the delete operation, you can call the GetRegistry API after the asynchronous call.

Amazon Glue console

To delete a registry from the Amazon Glue console:

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose a registry from the list, by checking a box.
4. In the **Action** menu, choose **Delete registry**.
5. Enter the text **Dele**te in the field to confirm deletion.
6. Choose **Delete**.

The registries you selected are deleted from Amazon Glue.

IAM examples for serializers

Note

Amazon managed policies grant necessary permissions for common use cases. For information on using managed policies to manage the schema registry, see [Amazon managed \(predefined\) policies for Amazon Glue](#).

For serializers, you should create a minimal policy similar to that below to give you the ability to find the schemaVersionId for a given schema definition. Note, you should have read permissions

on the registry in order to read the schemas in the registry. You can limit the registries that can be read by using the `Resource` clause.

Code example 13:

```
{
  "Sid" : "GetSchemaByDefinition",
  "Effect" : "Allow",
  "Action" :
  [
    "glue:GetSchemaByDefinition"
  ],
  "Resource" : ["arn:aws:glue:us-east-2:012345678:registry/registryname-1",
                "arn:aws:glue:us-east-2:012345678:schema/registryname-1/
schemaname-1",
                "arn:aws:glue:us-east-2:012345678:schema/registryname-1/
schemaname-2"
               ]
}
```

Further, you can also allow producers to create new schemas and versions by including the following extra methods. Note, you should be able to inspect the registry in order to add/remove/evolve the schemas inside it. You can limit the registries that can be inspected by using the `Resource` clause.

Code example 14:

```
{
  "Sid" : "RegisterSchemaWithMetadata",
  "Effect" : "Allow",
  "Action" :
  [
    "glue:GetSchemaByDefinition",
    "glue:CreateSchema",
    "glue:RegisterSchemaVersion",
    "glue:PutSchemaVersionMetadata",
  ],
  "Resource" : ["arn:aws-cn:glue:aws-region:123456789012:registry/registryname-1",
                "arn:aws-cn:glue:aws-region:123456789012:schema/registryname-1/
schemaname-1",
                "arn:aws-cn:glue:aws-region:123456789012:schema/registryname-1/
schemaname-2"
               ]
}
```

```
}
```

IAM examples for deserializers

For deserializers (consumer side), you should create a policy similar to that below to allow the deserializer to fetch the schema from the Schema Registry for deserialization. Note, you should be able to inspect the registry in order to fetch the schemas inside it.

Code example 15:

```
{
  "Sid" : "GetSchemaVersion",
  "Effect" : "Allow",
  "Action" :
  [
    "glue:GetSchemaVersion"
  ],
  "Resource" : ["*"]
}
```

Private connectivity using Amazon PrivateLink

You can use Amazon PrivateLink to connect your data producer's VPC to Amazon Glue by defining an interface VPC endpoint for Amazon Glue. When you use a VPC interface endpoint, communication between your VPC and Amazon Glue is conducted entirely within the Amazon network. For more information, see [Using Amazon Glue with VPC Endpoints](#).

Accessing Amazon CloudWatch metrics

Amazon CloudWatch metrics are available as part of CloudWatch's free tier. You can access these metrics in the CloudWatch console. API-Level metrics include CreateSchema (Success and Latency), GetSchemaByDefinition, (Success and Latency), GetSchemaVersion (Success and Latency), RegisterSchemaVersion (Success and Latency), PutSchemaVersionMetadata (Success and Latency). Resource-level metrics include Registry.ThrottledByLimit, SchemaVersion.ThrottledByLimit, SchemaVersion.Size.

Sample Amazon CloudFormation template for schema registry

The following is a sample template for creating Schema Registry resources in Amazon CloudFormation. To create this stack in your account, copy the above template into a file `SampleTemplate.yaml`, and run the following command:

```
aws cloudformation create-stack --stack-name ABCSchemaRegistryStack --template-body
  "'cat SampleTemplate.yaml'"
```

This example uses `AWS::Glue::Registry` to create a registry, `AWS::Glue::Schema` to create a schema, `AWS::Glue::SchemaVersion` to create a schema version, and `AWS::Glue::SchemaVersionMetadata` to populate schema version metadata.

```
Description: "A sample CloudFormation template for creating Schema Registry resources."
```

```
Resources:
```

```

Integrating with Amazon Glue Schema Registry

These sections describe integrations with Amazon Glue schema registry. The examples in these sections show a schema with AVRO data format. For more examples, including schemas with JSON data format, see the integration tests and ReadMe information in the [Amazon Glue Schema Registry open source repository](#).

Topics

- [Use case: Connecting Schema Registry to Amazon MSK or Apache Kafka](#)
- [Use case: Integrating Amazon Kinesis Data Streams with the Amazon Glue Schema Registry](#)
- [Use case: Amazon Managed Service for Apache Flink](#)
- [Use Case: Integration with Amazon Lambda](#)
- [Use case: Amazon Glue Data Catalog](#)
- [Use case: Amazon Glue streaming](#)
- [Use case: Apache Kafka Streams](#)

Use case: Connecting Schema Registry to Amazon MSK or Apache Kafka

Let's assume you are writing data to an Apache Kafka topic, and you can follow these steps to get started.

1. Create an Amazon Managed Streaming for Apache Kafka (Amazon MSK) or Apache Kafka cluster with at least one topic. If creating an Amazon MSK cluster, you can use the Amazon Web Services Management Console. Follow these instructions: [Getting Started Using Amazon MSK](#) in the *Amazon Managed Streaming for Apache Kafka Developer Guide*.
2. Follow the [Installing SerDe Libraries](#) step above.

3. To create schema registries, schemas, or schema versions, follow the instructions under the [Getting started with schema registry](#) section of this document.
4. Start your producers and consumers to use the Schema Registry to write and read records to/from the Amazon MSK or Apache Kafka topic. Example producer and consumer code can be found in [the ReadMe file](#) from the Serde libraries. The Schema Registry library on the producer will automatically serialize the record and decorate the record with a schema version ID.
5. If the schema of this record has been inputted, or if auto-registration is turned on, then the schema will have been registered in the Schema Registry.
6. The consumer reading from the Amazon MSK or Apache Kafka topic, using the Amazon Glue Schema Registry library, will automatically lookup the schema from the Schema Registry.

Use case: Integrating Amazon Kinesis Data Streams with the Amazon Glue Schema Registry

This integration requires that you have an existing Amazon Kinesis data stream. For more information, see [Getting Started with Amazon Kinesis Data Streams](#) in the *Amazon Kinesis Data Streams Developer Guide*.

There are two ways that you can interact with data in a Kinesis data stream.

- Through the Kinesis Producer Library (KPL) and Kinesis Client Library (KCL) libraries in Java. Multi-language support is not provided.
- Through the `PutRecords`, `PutRecord`, and `GetRecords` Kinesis Data Streams APIs available in the Amazon SDK for Java.

If you currently use the KPL/KCL libraries, we recommend continuing to use that method. There are updated KCL and KPL versions with Schema Registry integrated, as shown in the examples. Otherwise, you can use the sample code to leverage the Amazon Glue Schema Registry if using the KDS APIs directly.

Schema Registry integration is only available with KPL v0.14.2 or later and with KCL v2.3 or later. Schema Registry integration with JSON data format is available with KPL v0.14.8 or later and with KCL v2.3.6 or later.

Interacting with Data Using Kinesis SDK V2

This section describes interacting with Kinesis using Kinesis SDK V2

```
// Example JSON Record, you can construct a AVRO record also
```

```
private static final JsonDataWithSchema record =
    JsonDataWithSchema.builder(schemaString, payloadString);
private static final DataFormat dataFormat = DataFormat.JSON;

//Configurations for Schema Registry
GlueSchemaRegistryConfiguration gsrConfig = new GlueSchemaRegistryConfiguration("us-
east-1");

GlueSchemaRegistrySerializer glueSchemaRegistrySerializer =
    new GlueSchemaRegistrySerializerImpl(awsCredentialsProvider, gsrConfig);
GlueSchemaRegistryDataFormatSerializer dataFormatSerializer =
    new GlueSchemaRegistrySerializerFactory().getInstance(dataFormat, gsrConfig);

Schema gsrSchema =
    new Schema(dataFormatSerializer.getSchemaDefinition(record), dataFormat.name(),
    "MySchema");

byte[] serializedBytes = dataFormatSerializer.serialize(record);

byte[] gsrEncodedBytes = glueSchemaRegistrySerializer.encode(streamName, gsrSchema,
    serializedBytes);

PutRecordRequest putRecordRequest = PutRecordRequest.builder()
    .streamName(streamName)
    .partitionKey("partitionKey")
    .data(SdkBytes.fromByteArray(gsrEncodedBytes))
    .build();
shardId = kinesisClient.putRecord(putRecordRequest)
    .get()
    .shardId();

GlueSchemaRegistryDeserializer glueSchemaRegistryDeserializer = new
    GlueSchemaRegistryDeserializerImpl(awsCredentialsProvider, gsrConfig);

GlueSchemaRegistryDataFormatDeserializer gsrDataFormatDeserializer =
    glueSchemaRegistryDeserializerFactory.getInstance(dataFormat, gsrConfig);

GetShardIteratorRequest getShardIteratorRequest = GetShardIteratorRequest.builder()
    .streamName(streamName)
    .shardId(shardId)
    .shardIteratorType(ShardIteratorType.TRIM_HORIZON)
    .build();

String shardIterator = kinesisClient.getShardIterator(getShardIteratorRequest)
```

```

        .get()
        .shardIterator();

GetRecordsRequest getRecordRequest = GetRecordsRequest.builder()
    .shardIterator(shardIterator)
    .build();
GetRecordsResponse recordsResponse = kinesisClient.getRecords(getRecordRequest)
    .get();

List<Object> consumerRecords = new ArrayList<>();
List<Record> recordsFromKinesis = recordsResponse.records();

for (int i = 0; i < recordsFromKinesis.size(); i++) {
    byte[] consumedBytes = recordsFromKinesis.get(i)
        .data()
        .asByteArray();

    Schema gsrSchema = glueSchemaRegistryDeserializer.getSchema(consumedBytes);
    Object decodedRecord =
gsrDataFormatDeserializer.deserialize(ByteBuffer.wrap(consumedBytes),

gsrSchema.getSchemaDefinition());
    consumerRecords.add(decodedRecord);
}

```

Interacting with data using the KPL/KCL libraries

This section describes integrating Kinesis Data Streams with Schema Registry using the KPL/KCL libraries. For more information on using KPL/KCL, see [Developing Producers Using the Amazon Kinesis Producer Library](#) in the *Amazon Kinesis Data Streams Developer Guide*.

Setting up the Schema Registry in KPL

1. Define the schema definition for the data, data format and schema name authored in the Amazon Glue Schema Registry.
2. Optionally configure the `GlueSchemaRegistryConfiguration` object.
3. Pass the schema object to the `addUserRecord` API.

```

private static final String SCHEMA_DEFINITION = "{\"namespace\": \"example.avro\", \"n\"
+ \" \"type\": \"record\", \"n\"
+ \" \"name\": \"User\", \"n\"
+ \" \"fields\": [\"n\"

```

```
+ " {"name": "name", "type": "string"},\n"+ " {"name": "favorite_number", "type": ["int", "null"]},\n"+ " {"name": "favorite_color", "type": ["string", "null"]}\n"+ " ]\n"+ "}";

KinesisProducerConfiguration config = new KinesisProducerConfiguration();
config.setRegion("us-west-1")

//[Optional] configuration for Schema Registry.

GlueSchemaRegistryConfiguration schemaRegistryConfig =
new GlueSchemaRegistryConfiguration("us-west-1");

schemaRegistryConfig.setCompression(true);

config.setGlueSchemaRegistryConfiguration(schemaRegistryConfig);

///Optional configuration ends.

final KinesisProducer producer =
    new KinesisProducer(config);

final ByteBuffer data = getDataToSend();

com.amazonaws.services.schemaregistry.common.Schema gsrSchema =
new Schema(SCHEMA_DEFINITION, DataFormat.AVRO.toString(), "demoSchema");

ListenableFuture<UserRecordResult> f = producer.addUserRecord(
    config.getStreamName(), TIMESTAMP, Utils.randomExplicitHashKey(), data, gsrSchema);

private static ByteBuffer getDataToSend() {
    org.apache.avro.Schema avroSchema =
        new org.apache.avro.Schema.Parser().parse(SCHEMA_DEFINITION);

    GenericRecord user = new GenericData.Record(avroSchema);
    user.put("name", "Emily");
    user.put("favorite_number", 32);
    user.put("favorite_color", "green");

    ByteArrayOutputStream outBytes = new ByteArrayOutputStream();
    Encoder encoder = EncoderFactory.get().directBinaryEncoder(outBytes, null);
    new GenericDatumWriter<>(avroSchema).write(user, encoder);
    encoder.flush();
}
```

```
    return ByteBuffer.wrap(outBytes.toByteArray());  
}
```

Setting up the Kinesis client library

You will develop your Kinesis Client Library consumer in Java. For more information, see [Developing a Kinesis Client Library Consumer in Java](#) in the *Amazon Kinesis Data Streams Developer Guide*.

1. Create an instance of `GlueSchemaRegistryDeserializer` by passing a `GlueSchemaRegistryConfiguration` object.
2. Pass the `GlueSchemaRegistryDeserializer` to `retrievalConfig.glueSchemaRegistryDeserializer`.
3. Access the schema of incoming messages by calling `kinesisClientRecord.getSchema()`.

```
GlueSchemaRegistryConfiguration schemaRegistryConfig =  
    new GlueSchemaRegistryConfiguration(this.region.toString());  
  
GlueSchemaRegistryDeserializer glueSchemaRegistryDeserializer =  
    new  
GlueSchemaRegistryDeserializerImpl(DefaultCredentialsProvider.builder().build(),  
schemaRegistryConfig);  
  
RetrievalConfig retrievalConfig =  
    configsBuilder.retrievalConfig().retrievalSpecificConfig(new  
    PollingConfig(streamName, kinesisClient));  
retrievalConfig.glueSchemaRegistryDeserializer(glueSchemaRegistryDeserializer);  
  
Scheduler scheduler = new Scheduler(  
    configsBuilder.checkpointConfig(),  
    configsBuilder.coordinatorConfig(),  
    configsBuilder.leaseManagementConfig(),  
    configsBuilder.lifecycleConfig(),  
    configsBuilder.metricsConfig(),  
    configsBuilder.processorConfig(),  
    retrievalConfig  
);  
  
public void processRecords(ProcessRecordsInput processRecordsInput) {  
    MDC.put(SHARD_ID_MDC_KEY, shardId);  
    try {
```

```

        log.info("Processing {} record(s)",
            processRecordsInput.records().size());
        processRecordsInput.records()
            .forEach(
                r ->
                    log.info("Processed record pk: {} -- Seq: {} : data {} with
schema: {}",
                        r.partitionKey(),
r.sequenceNumber(), recordToAvroObj(r).toString(), r.getSchema()));
            } catch (Throwable t) {
                log.error("Caught throwable while processing records. Aborting.");
                Runtime.getRuntime().halt(1);
            } finally {
                MDC.remove(SHARD_ID_MDC_KEY);
            }
    }

    private GenericRecord recordToAvroObj(KinesisClientRecord r) {
        byte[] data = new byte[r.data().remaining()];
        r.data().get(data, 0, data.length);
        org.apache.avro.Schema schema = new
org.apache.avro.Schema.Parser().parse(r.schema().getSchemaDefinition());
        DatumReader datumReader = new GenericDatumReader<>(schema);

        BinaryDecoder binaryDecoder = DecoderFactory.get().binaryDecoder(data, 0,
data.length, null);
        return (GenericRecord) datumReader.read(null, binaryDecoder);
    }
}

```

Interacting with data using the Kinesis Data Streams APIs

This section describes integrating Kinesis Data Streams with Schema Registry using the Kinesis Data Streams APIs.

1. Update these Maven dependencies:

```

<dependencyManagement>
  <dependencies>
    <dependency>
      <groupId>com.amazonaws</groupId>
      <artifactId>aws-java-sdk-bom</artifactId>
      <version>1.11.884</version>

```

```

        <type>pom</type>
        <scope>import</scope>
    </dependency>
</dependencies>
</dependencyManagement>

<dependencies>
    <dependency>
        <groupId>com.amazonaws</groupId>
        <artifactId>aws-java-sdk-kinesis</artifactId>
    </dependency>

    <dependency>
        <groupId>software.amazon.glue</groupId>
        <artifactId>schema-registry-serde</artifactId>
        <version>1.1.5</version>
    </dependency>

    <dependency>
        <groupId>com.fasterxml.jackson.dataformat</groupId>
        <artifactId>jackson-dataformat-cbor</artifactId>
        <version>2.11.3</version>
    </dependency>
</dependencies>

```

2. In the producer, add schema header information using the PutRecords or PutRecord API in Kinesis Data Streams.

```

//The following lines add a Schema Header to the record
    com.amazonaws.services.schemaregistry.common.Schema awsSchema =
        new com.amazonaws.services.schemaregistry.common.Schema(schemaDefinition,
DataFormat.AVRO.name(),
            schemaName);
    GlueSchemaRegistrySerializerImpl glueSchemaRegistrySerializer =
        new
GlueSchemaRegistrySerializerImpl(DefaultCredentialsProvider.builder().build(), new
GlueSchemaRegistryConfiguration(getConfigs()));
    byte[] recordWithSchemaHeader =
        glueSchemaRegistrySerializer.encode(streamName, awsSchema,
recordAsBytes);

```

3. In the producer, use the PutRecords or PutRecord API to put the record into the data stream.

4. In the consumer, remove the schema record from the header, and serialize an Avro schema record.

```
//The following lines remove Schema Header from record
    GlueSchemaRegistryDeserializerImpl glueSchemaRegistryDeserializer =
        new
GlueSchemaRegistryDeserializerImpl(DefaultCredentialsProvider.builder().build(),
getConfigs());
    byte[] recordWithSchemaHeaderBytes = new
byte[recordWithSchemaHeader.remaining()];
    recordWithSchemaHeader.get(recordWithSchemaHeaderBytes, 0,
recordWithSchemaHeaderBytes.length);
    com.amazonaws.services.schemaregistry.common.Schema awsSchema =
        glueSchemaRegistryDeserializer.getSchema(recordWithSchemaHeaderBytes);
    byte[] record =
glueSchemaRegistryDeserializer.getData(recordWithSchemaHeaderBytes);

//The following lines serialize an AVRO schema record
if (DataFormat.AVRO.name().equals(awsSchema.getDataFormat())) {
    Schema avroSchema = new
org.apache.avro.Schema.Parser().parse(awsSchema.getSchemaDefinition());
    Object genericRecord = convertBytesToRecord(avroSchema, record);
    System.out.println(genericRecord);
}
```

Interacting with data using the Kinesis Data Streams APIs

The following is example code for using the PutRecords and GetRecords APIs.

```
//Full sample code
import
com.amazonaws.services.schemaregistry.deserializers.GlueSchemaRegistryDeserializerImpl;
import
com.amazonaws.services.schemaregistry.serializers.GlueSchemaRegistrySerializerImpl;
import com.amazonaws.services.schemaregistry.utils.AVROUtils;
import com.amazonaws.services.schemaregistry.utils.AWSSchemaRegistryConstants;
import org.apache.avro.Schema;
import org.apache.avro.generic.GenericData;
import org.apache.avro.generic.GenericDatumReader;
import org.apache.avro.generic.GenericDatumWriter;
import org.apache.avro.generic.GenericRecord;
import org.apache.avro.io.Decoder;
```

```
import org.apache.avro.io.DecoderFactory;
import org.apache.avro.io.Encoder;
import org.apache.avro.io.EncoderFactory;
import software.amazon.awssdk.auth.credentials.DefaultCredentialsProvider;
import software.amazon.awssdk.services.glue.model.DataFormat;

import java.io.ByteArrayOutputStream;
import java.io.File;
import java.io.IOException;
import java.nio.ByteBuffer;
import java.util.Collections;
import java.util.HashMap;
import java.util.Map;

public class PutAndGetExampleWithEncodedData {
    static final String regionName = "us-east-2";
    static final String streamName = "testStream1";
    static final String schemaName = "User-Topic";
    static final String AVRO_USER_SCHEMA_FILE = "src/main/resources/user.avsc";
    KinesisApi kinesisApi = new KinesisApi();

    void runSampleForPutRecord() throws IOException {
        Object testRecord = getTestRecord();
        byte[] recordAsBytes = convertRecordToBytes(testRecord);
        String schemaDefinition =
AVROUtils.getInstance().getSchemaDefinition(testRecord);

        //The following lines add a Schema Header to a record
        com.amazonaws.services.schemaregistry.common.Schema awsSchema =
            new com.amazonaws.services.schemaregistry.common.Schema(schemaDefinition,
DataFormat.AVRO.name(),
                schemaName);
        GlueSchemaRegistrySerializerImpl glueSchemaRegistrySerializer =
            new
GlueSchemaRegistrySerializerImpl(DefaultCredentialsProvider.builder().build(), new

        configs.setMetadata(getMetadata());
        return configs;
    }

    private Object getTestRecord() throws IOException {
        GenericRecord genericRecord;
        Schema.Parser parser = new Schema.Parser();
        Schema avroSchema = parser.parse(new File(AVRO_USER_SCHEMA_FILE));

        genericRecord = new GenericData.Record(avroSchema);
        genericRecord.put("name", "testName");
        genericRecord.put("favorite_number", 99);
        genericRecord.put("favorite_color", "red");

        return genericRecord;
    }
}
```

```
}
```

Use case: Amazon Managed Service for Apache Flink

Apache Flink is a popular open source framework and distributed processing engine for stateful computations over unbounded and bounded data streams. Amazon Managed Service for Apache Flink is a fully managed Amazon service that enables you to build and manage Apache Flink applications to process streaming data.

Open source Apache Flink provides a number of sources and sinks. For example, predefined data sources include reading from files, directories, and sockets, and ingesting data from collections and iterators. Apache Flink DataStream Connectors provide code for Apache Flink to interface with various third-party systems, such as Apache Kafka or Kinesis as sources and/or sinks.

For more information, see [Amazon Kinesis Data Analytics Developer Guide](#).

Apache Flink Kafka connector

Apache Flink provides an Apache Kafka data stream connector for reading data from and writing data to Kafka topics with exactly-once guarantees. Flink's Kafka consumer, `FlinkKafkaConsumer`, provides access to read from one or more Kafka topics. Apache Flink's Kafka Producer, `FlinkKafkaProducer`, allows writing a stream of records to one or more Kafka topics. For more information, see [Apache Kafka Connector](#).

Apache Flink Kinesis streams Connector

The Kinesis data stream connector provides access to Amazon Kinesis Data Streams. The `FlinkKinesisConsumer` is an exactly-once parallel streaming data source that subscribes to multiple Kinesis streams within the same Amazon service region, and can transparently handle re-sharding of streams while the job is running. Each subtask of the consumer is responsible for fetching data records from multiple Kinesis shards. The number of shards fetched by each subtask will change as shards are closed and created by Kinesis. The `FlinkKinesisProducer` uses Kinesis Producer Library (KPL) to put data from an Apache Flink stream into a Kinesis stream. For more information, see [Amazon Kinesis Streams Connector](#).

For more information, see the [Amazon Glue Schema Github repository](#).

Integrating with Apache Flink

The SerDes library provided with Schema Registry integrates with Apache Flink. To work with Apache Flink, you are required to implement

[SerializationSchema](#) and [DeserializationSchema](#) interfaces called `GlueSchemaRegistryAvroSerializationSchema` and `GlueSchemaRegistryAvroDeserializationSchema`, which you can plug into Apache Flink connectors.

Adding an Amazon Glue Schema Registry dependency into the Apache Flink application

To set up the integration dependencies to Amazon Glue Schema Registry in the Apache Flink application:

1. Add the dependency to the `pom.xml` file.

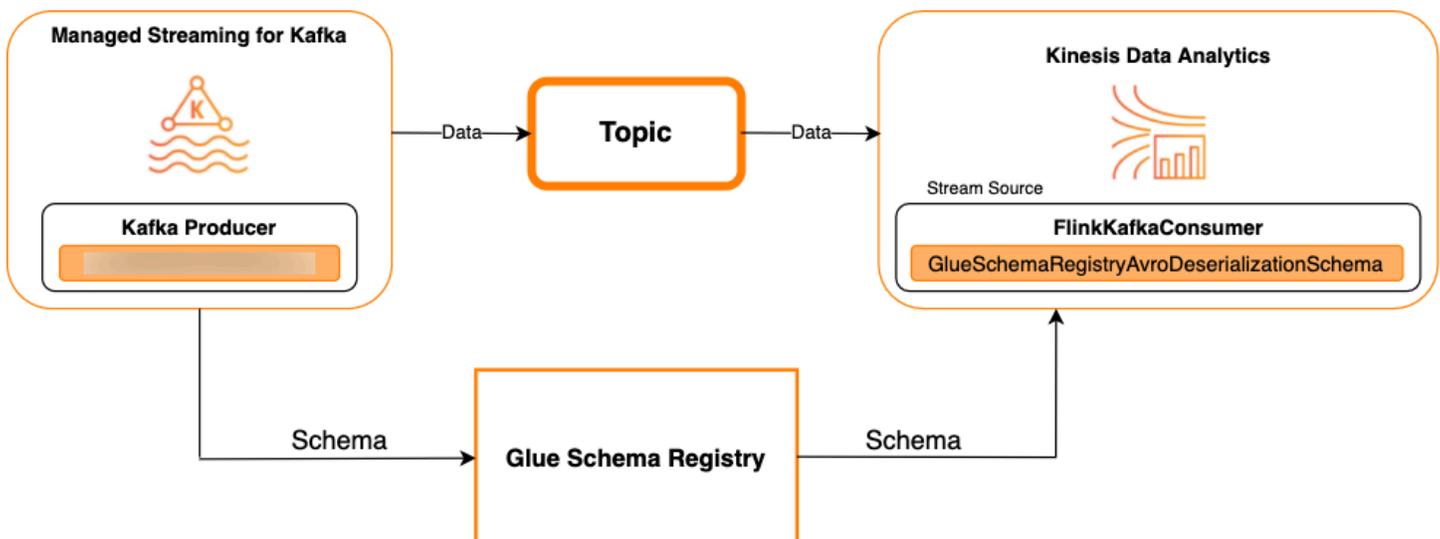

```
<dependency>
  <groupId>software.amazon.glue</groupId>
  <artifactId>schema-registry-flink-serde</artifactId>
  <version>1.0.0</version>
</dependency>
```

Integrating Kafka or Amazon MSK with Apache Flink

You can use Managed Service for Apache Flink for Apache Flink, with Kafka as a source or Kafka as a sink.

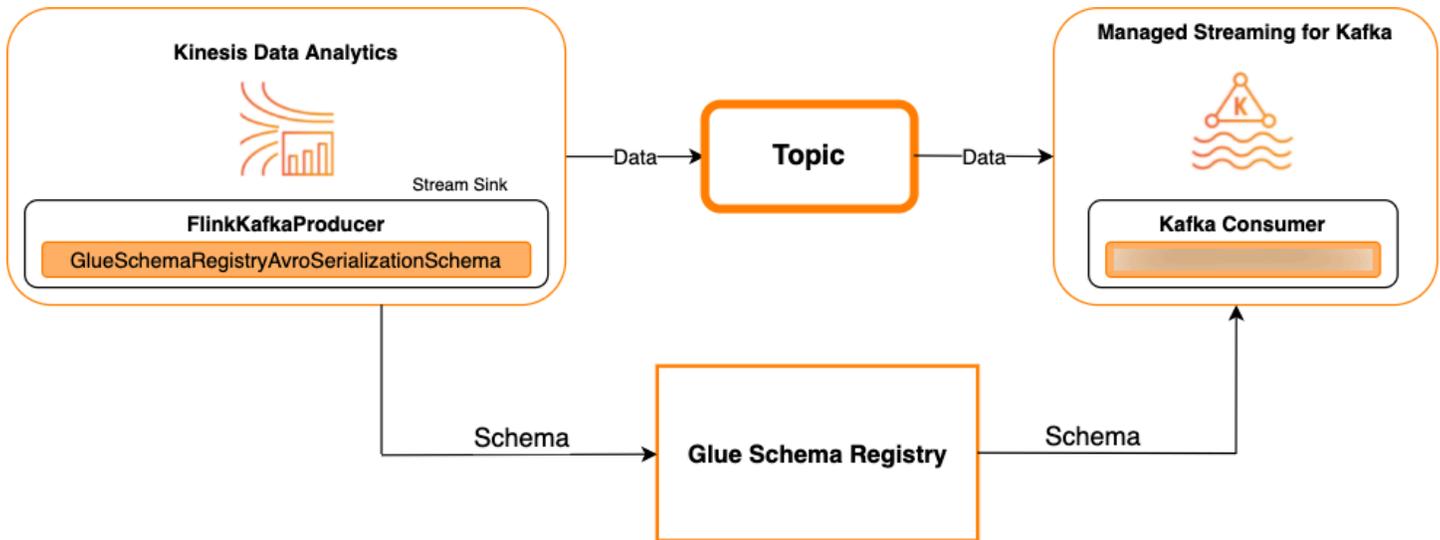

Kafka as a source

The following diagram shows integrating Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kafka as a source.

Kafka as a sink

The following diagram shows integrating Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kafka as a sink.

To integrate Kafka (or Amazon MSK) with Managed Service for Apache Flink for Apache Flink, with Kafka as a source or Kafka as a sink, make the code changes below. Add the bolded code blocks to your respective code in the analogous sections.

If Kafka is the source, then use the deserializer code (block 2). If Kafka is the sink, use the serializer code (block 3).

```

StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();

String topic = "topic";
Properties properties = new Properties();
properties.setProperty("bootstrap.servers", "localhost:9092");
properties.setProperty("group.id", "test");

// block 1
Map<String, Object> configs = new HashMap<>();
configs.put(AWSSchemaRegistryConstants.AWS_REGION, "aws-region");
configs.put(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING, true);
configs.put(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
    AvroRecordType.GENERIC_RECORD.getName());

FlinkKafkaConsumer<GenericRecord> consumer = new FlinkKafkaConsumer<>(
    topic,
    // block 2
  
```

```
GlueSchemaRegistryAvroDeserializationSchema.forGeneric(schema, configs),
properties);
```

```
FlinkKafkaProducer<GenericRecord> producer = new FlinkKafkaProducer<>(
    topic,
    // block 3
    GlueSchemaRegistryAvroSerializationSchema.forGeneric(schema, topic, configs),
    properties);
```

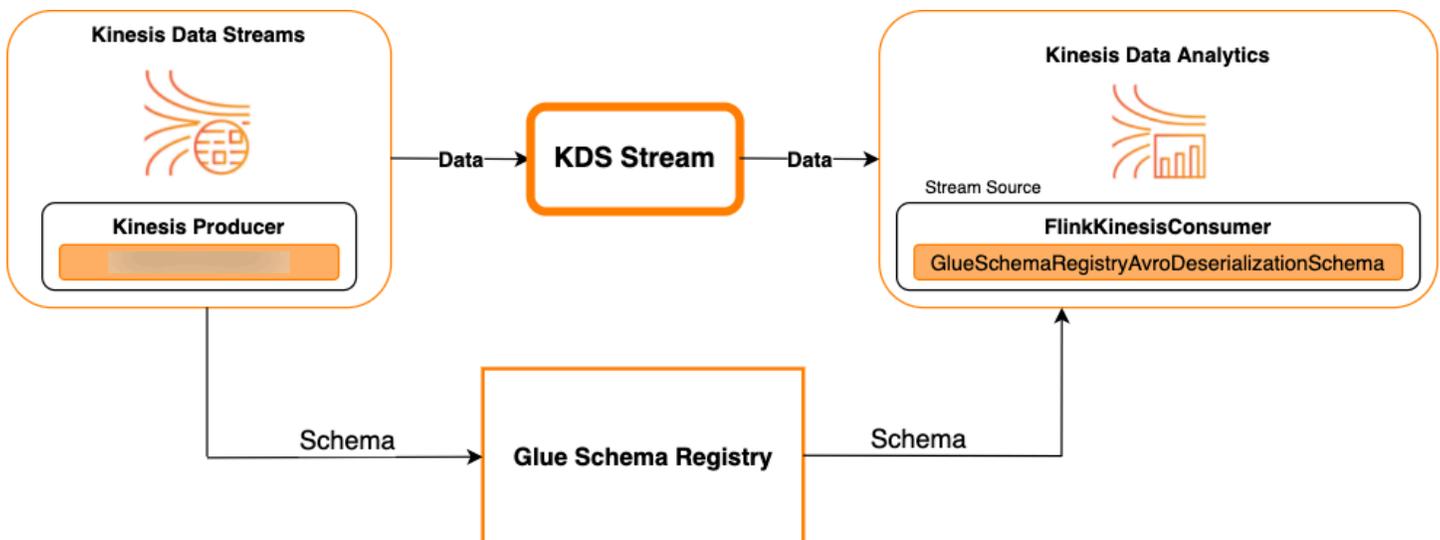

```
DataStream<GenericRecord> stream = env.addSource(consumer);
stream.addSink(producer);
env.execute();
```

Integrating Kinesis Data Streams with Apache Flink

You can use Managed Service for Apache Flink for Apache Flink with Kinesis Data Streams as a source or a sink.

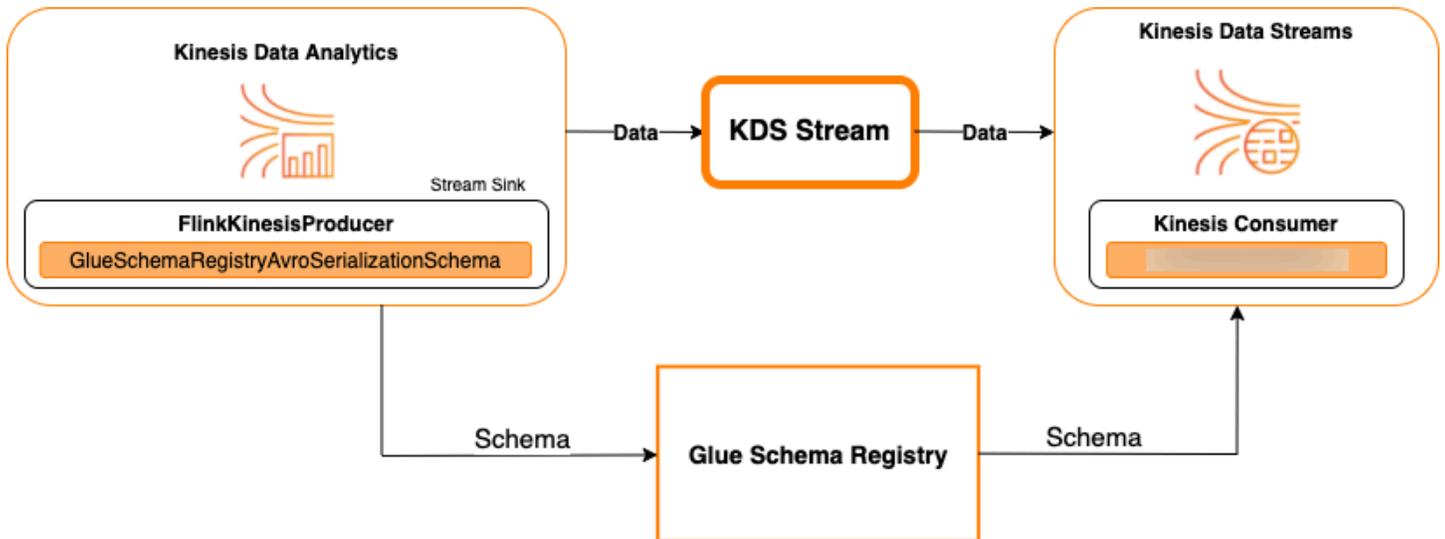

Kinesis Data Streams as a source

The following diagram shows integrating Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kinesis Data Streams as a source.

Kinesis Data Streams as a sink

The following diagram shows integrating Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kinesis Data Streams as a sink.

To integrate Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kinesis Data Streams as a source or Kinesis Data Streams as a sink, make the code changes below. Add the bolded code blocks to your respective code in the analogous sections.

If Kinesis Data Streams is the source, use the deserializer code (block 2). If Kinesis Data Streams is the sink, use the serializer code (block 3).

```

StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();

String streamName = "stream";
Properties consumerConfig = new Properties();
consumerConfig.put(AWSConfigConstants.AWS_REGION, "aws-region");
consumerConfig.put(AWSConfigConstants.AWS_ACCESS_KEY_ID, "aws_access_key_id");
consumerConfig.put(AWSConfigConstants.AWS_SECRET_ACCESS_KEY, "aws_secret_access_key");
consumerConfig.put(ConsumerConfigConstants.STREAM_INITIAL_POSITION, "LATEST");

// block 1
Map<String, Object> configs = new HashMap<>();
configs.put(AWSSchemaRegistryConstants.AWS_REGION, "aws-region");
configs.put(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING, true);
configs.put(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
AvroRecordType.GENERIC_RECORD.getName());

FlinkKinesisConsumer<GenericRecord> consumer = new FlinkKinesisConsumer<>(
    streamName,
    // block 2
GlueSchemaRegistryAvroDeserializationSchema.forGeneric(schema, configs),
    properties);
  
```

```
FlinkKinesisProducer<GenericRecord> producer = new FlinkKinesisProducer<>(  
    // block 3  
    GlueSchemaRegistryAvroSerializationSchema.forGeneric(schema, topic, configs),  
    properties);  
producer.setDefaultStream(streamName);  
producer.setDefaultPartition("0");  
  
DataStream<GenericRecord> stream = env.addSource(consumer);  
stream.addSink(producer);  
env.execute();
```

Use Case: Integration with Amazon Lambda

To use an Amazon Lambda function as an Apache Kafka/Amazon MSK consumer and deserialize Avro-encoded messages using Amazon Glue Schema Registry, visit the [MSK Labs page](#).

Use case: Amazon Glue Data Catalog

Amazon Glue tables support schemas that you can specify manually or by reference to the Amazon Glue Schema Registry. The Schema Registry integrates with the Data Catalog to allow you to optionally use schemas stored in the Schema Registry when creating or updating Amazon Glue tables or partitions in the Data Catalog. To identify a schema definition in the Schema Registry, at a minimum, you need to know the ARN of the schema it is part of. A schema version of a schema, which contains a schema definition, can be referenced by its UUID or version number. There is always one schema version, the "latest" version, that can be looked up without knowing its version number or UUID.

When calling the `CreateTable` or `UpdateTable` operations, you will pass a `TableInput` structure that contains a `StorageDescriptor`, which may have a `SchemaReference` to an existing schema in the Schema Registry. Similarly, when you call the `GetTable` or `GetPartition` APIs, the response may contain the schema and the `SchemaReference`. When a table or partition was created using a schema references, the Data Catalog will try to fetch the schema for this schema reference. In case it is unable to find the schema in the Schema Registry, it returns an empty schema in the `GetTable` response; otherwise the response will have both the schema and schema reference.

You can also perform the actions from the Amazon Glue console.

To perform these operations and create, update, or view the schema information, you must give an IAM role to the calling user that provides permissions for the `GetSchemaVersion` API.

Adding a table or updating the schema for a table

Adding a new table from an existing schema binds the table to a specific schema version. Once new schema versions get registered, you can update this table definition from the View table page in the Amazon Glue console or using the [UpdateTable action \(Python: update_table\)](#) API.

Adding a table from an existing schema

You can create an Amazon Glue table from a schema version in the registry using the Amazon Glue console or CreateTable API.

Amazon Glue API

When calling the CreateTable API, you will pass a TableInput that contains a StorageDescriptor which has a SchemaReference to an existing schema in the Schema Registry.

Amazon Glue console

To create a table from the Amazon Glue console:

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Tables**.
3. In the **Add Tables** menu, choose **Add table from existing schema**.
4. Configure the table properties and data store per the Amazon Glue Developer Guide.
5. In the **Choose a Glue schema** page, select the **Registry** where the schema resides.
6. Choose the **Schema name** and select the **Version** of the schema to apply.
7. Review the schema preview, and choose **Next**.
8. Review and create the table.

The schema and version applied to the table appears in the **Glue schema** column in the list of tables. You can view the table to see more details.

Updating the schema for a table

When a new schema version becomes available, you may want to update a table's schema using the [UpdateTable action \(Python: update_table\)](#) API or the Amazon Glue console.

⚠ Important

When updating the schema for an existing table that has an Amazon Glue schema specified manually, the new schema referenced in the Schema Registry may be incompatible. This can result in your jobs failing.

Amazon Glue API

When calling the `UpdateTable` API, you will pass a `TableInput` that contains a `StorageDescriptor` which has a `SchemaReference` to an existing schema in the Schema Registry.

Amazon Glue console

To update the schema for a table from the Amazon Glue console:

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Tables**.
3. View the table from the list of tables.
4. Click **Update schema** in the box that informs you about a new version.
5. Review the differences between the current and new schema.
6. Choose **Show all schema differences** to see more details.
7. Choose **Save table** to accept the new version.

Use case: Amazon Glue streaming

Amazon Glue streaming consumes data from streaming sources and perform ETL operations before writing to an output sink. Input streaming source can be specified using a Data Table or directly by specifying the source configuration.

Amazon Glue streaming supports a Data Catalog table for the streaming source created with the schema present in the Amazon Glue Schema Registry. You can create a schema in the Amazon Glue Schema Registry and create an Amazon Glue table with a streaming source using this schema. This Amazon Glue table can be used as an input to an Amazon Glue streaming job for deserializing data in the input stream.

One point to note here is when the schema in the Amazon Glue Schema Registry changes, you need to restart the Amazon Glue streaming job needs to reflect the changes in the schema.

Use case: Apache Kafka Streams

The Apache Kafka Streams API is a client library for processing and analyzing data stored in Apache Kafka. This section describes the integration of Apache Kafka Streams with Amazon Glue Schema Registry, which allows you to manage and enforce schemas on your data streaming applications. For more information on Apache Kafka Streams, see [Apache Kafka Streams](#).

Integrating with the SerDes Libraries

There is a `GlueSchemaRegistryKafkaStreamsSerde` class that you can configure a Streams application with.

Kafka Streams application example code

To use the Amazon Glue Schema Registry within an Apache Kafka Streams application:

1. Configure the Kafka Streams application.

```
final Properties props = new Properties();
    props.put(StreamsConfig.APPLICATION_ID_CONFIG, "avro-streams");
    props.put(StreamsConfig.BOOTSTRAP_SERVERS_CONFIG, "localhost:9092");
    props.put(StreamsConfig.CACHE_MAX_BYTES_BUFFERING_CONFIG, 0);
    props.put(StreamsConfig.DEFAULT_KEY_SERDE_CLASS_CONFIG,
Serdes.String().getClass().getName());
    props.put(StreamsConfig.DEFAULT_VALUE_SERDE_CLASS_CONFIG,
AWSKafkaAvroSerDe.class.getName());
    props.put(ConsumerConfig.AUTO_OFFSET_RESET_CONFIG, "earliest");

    props.put(AWSSchemaRegistryConstants.AWS_REGION, "aws-region");
    props.put(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING, true);
    props.put(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
AvroRecordType.GENERIC_RECORD.getName());
    props.put(AWSSchemaRegistryConstants.DATA_FORMAT, DataFormat.AVRO.name());
```

2. Create a stream from the topic avro-input.

```
StreamsBuilder builder = new StreamsBuilder();
final KStream<String, GenericRecord> source = builder.stream("avro-input");
```

3. Process the data records (the example filters out those records whose value of `favorite_color` is pink or where the value of `amount` is 15).

```
final KStream<String, GenericRecord> result = source
    .filter((key, value) -
    > !"pink".equals(String.valueOf(value.get("favorite_color"))));
    .filter((key, value) -> !"15.0".equals(String.valueOf(value.get("amount"))));
```

4. Write the results back to the topic `avro-output`.

```
result.to("avro-output");
```

5. Start the Apache Kafka Streams application.

```
KafkaStreams streams = new KafkaStreams(builder.build(), props);
streams.start();
```

Implementation results

These results show the filtering process of records that were filtered out in step 3 as a `favorite_color` of "pink" or value of "15.0".

Records before filtering:

```
{"name": "Sansa", "favorite_number": 99, "favorite_color": "white"}
{"name": "Harry", "favorite_number": 10, "favorite_color": "black"}
{"name": "Hermione", "favorite_number": 1, "favorite_color": "red"}
{"name": "Ron", "favorite_number": 0, "favorite_color": "pink"}
{"name": "Jay", "favorite_number": 0, "favorite_color": "pink"}

{"id": "commute_1", "amount": 3.5}
{"id": "grocery_1", "amount": 25.5}
{"id": "entertainment_1", "amount": 19.2}
{"id": "entertainment_2", "amount": 105}
{"id": "commute_1", "amount": 15}
```

Records after filtering:

```

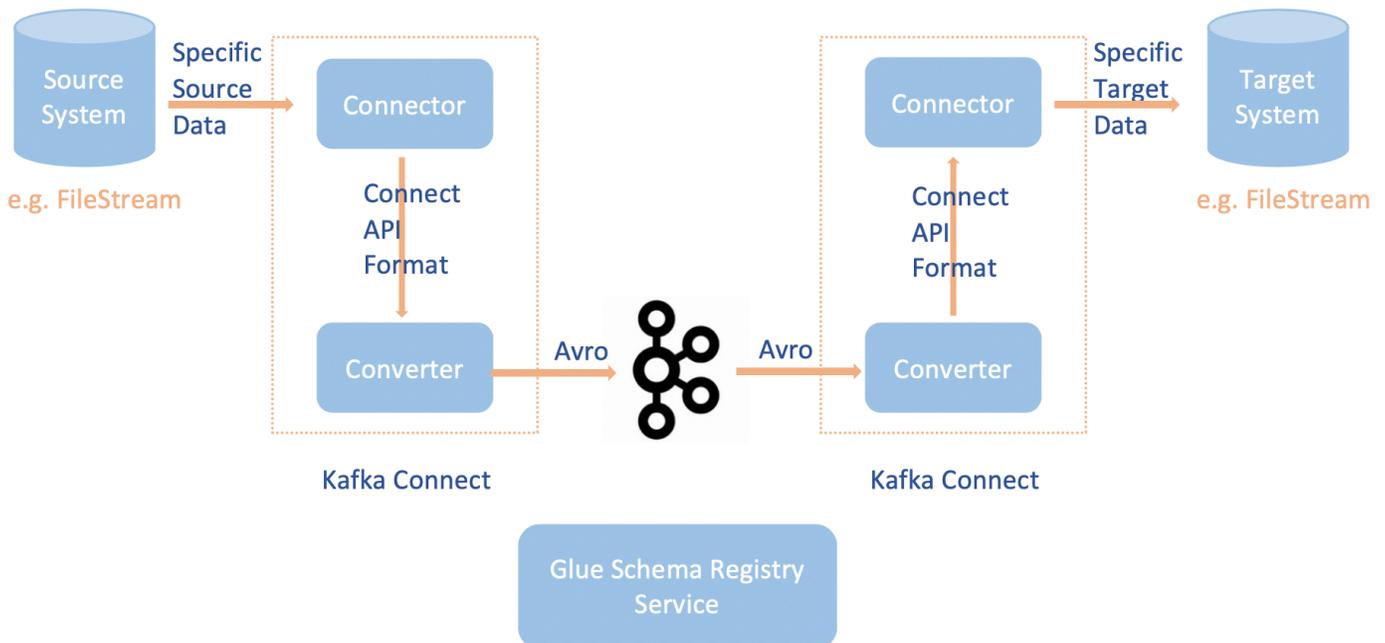

{"name": "Sansa", "favorite_number": 99, "favorite_color": "white"}
{"name": "Harry", "favorite_number": 10, "favorite_color": "black"}
{"name": "Hermione", "favorite_number": 1, "favorite_color": "red"}
{"name": "Ron", "favorite_number": 0, "favorite_color": "pink"}

{"id": "commute_1", "amount": 3.5}
{"id": "grocery_1", "amount": 25.5}
{"id": "entertainment_1", "amount": 19.2}
{"id": "entertainment_2", "amount": 105}

```

Use case: Apache Kafka Connect

The integration of Apache Kafka Connect with the Amazon Glue Schema Registry enables you to get schema information from connectors. The Apache Kafka converters specify the format of data within Apache Kafka and how to translate it into Apache Kafka Connect data. Every Apache Kafka Connect user will need to configure these converters based on the format they want their data in when loaded from or stored into Apache Kafka. In this way, you can define your own converters to translate Apache Kafka Connect data into the type used in the Amazon Glue Schema Registry (for example: Avro) and utilize our serializer to register its schema and do serialization. Then converters are also able to use our deserializer to deserialize data received from Apache Kafka and convert it back into Apache Kafka Connect data. An example workflow diagram is given below.

1. Install the `aws-glue-schema-registry` project by cloning the [Github repository for the Amazon Glue Schema Registry](#).

```
git clone git@github.com:aws-labs/aws-glue-schema-registry.git
cd aws-glue-schema-registry
mvn clean install
mvn dependency:copy-dependencies
```

2. If you plan on using Apache Kafka Connect in *Standalone* mode, update **`connect-standalone.properties`** using the instructions below for this step. If you plan on using Apache Kafka Connect in *Distributed* mode, update **`connect-avro-distributed.properties`** using the same instructions.
 - a. Add these properties also to the Apache Kafka connect properties file:

```
key.converter.region=aws-region
value.converter.region=aws-region
key.converter.schemaAutoRegistrationEnabled=true
value.converter.schemaAutoRegistrationEnabled=true
key.converter.avroRecordType=GENERIC_RECORD
value.converter.avroRecordType=GENERIC_RECORD
```

- b. Add the command below to the **Launch mode** section under **`kafka-run-class.sh`**:

```
-cp $CLASSPATH:"<your Amazon GlueSchema Registry base directory>/target/dependency/*"
```

3. Add the command below to the **Launch mode** section under **`kafka-run-class.sh`**

```
-cp $CLASSPATH:"<your Amazon GlueSchema Registry base directory>/target/dependency/*"
```

It should look like this:

```
# Launch mode
if [ "$DAEMON_MODE" = "xtrue" ]; then
  nohup "$JAVA" $KAFKA_HEAP_OPTS $KAFKA_JVM_PERFORMANCE_OPTS $KAFKA_GC_LOG_OPTS
  $KAFKA_JMX_OPTS $KAFKA_LOG4J_OPTS -cp $CLASSPATH:"/Users/johndoe/aws-glue-schema-
  registry/target/dependency/*" $KAFKA_OPTS "$@" > "$CONSOLE_OUTPUT_FILE" 2>&1 < /dev/
  null &
else
```

```
exec "$JAVA" $KAFKA_HEAP_OPTS $KAFKA_JVM_PERFORMANCE_OPTS $KAFKA_GC_LOG_OPTS
$KAFKA_JMX_OPTS $KAFKA_LOG4J_OPTS -cp $CLASSPATH:"/Users/johndoe/aws-glue-schema-
registry/target/dependency/*" $KAFKA_OPTS "$@"
fi
```

4. If using bash, run the below commands to set-up your CLASSPATH in your bash_profile. For any other shell, update the environment accordingly.

```
echo 'export GSR_LIB_BASE_DIR=<>' >> ~/.bash_profile
echo 'export GSR_LIB_VERSION=1.0.0' >> ~/.bash_profile
echo 'export KAFKA_HOME=<your Apache Kafka installation directory>' >> ~/.bash_profile
echo 'export CLASSPATH=$CLASSPATH:$GSR_LIB_BASE_DIR/avro-kafkaconnect-converter/
target/schema-registry-kafkaconnect-converter-$GSR_LIB_VERSION.jar:$GSR_LIB_BASE_DIR/
common/target/schema-registry-common-$GSR_LIB_VERSION.jar:$GSR_LIB_BASE_DIR/
avro-serializer-deserializer/target/schema-registry-serde-$GSR_LIB_VERSION.jar'
>> ~/.bash_profile
source ~/.bash_profile
```

5. (Optional) If you want to test with a simple file source, then clone the file source connector.

```
git clone https://github.com/mmolimar/kafka-connect-fs.git
cd kafka-connect-fs/
```

- a. Under the source connector configuration, edit the data format to Avro, file reader to AvroFileReader and update an example Avro object from the file path you are reading from. For example:

```
vim config/kafka-connect-fs.properties
```

```
fs.uris=<path to a sample avro object>
policy.regex=^.*\.avro$
file_reader.class=com.github.mmolimar.kafka.connect.fs.file.reader.AvroFileReader
```

- b. Install the source connector.

```
mvn clean package
echo "export CLASSPATH=\$CLASSPATH:\\"$(find target/ -type f -name '*.jar'| grep
'\-package' | tr '\n' ':')\\"" >> ~/.bash_profile
source ~/.bash_profile
```

- c. Update the sink properties under *<your Apache Kafka installation directory>/config/connect-file-sink.properties* update the topic name and out file name.

```
file=<output file full path>
topics=<my topic>
```

6. Start the Source Connector (in this example it is a file source connector).

```
$KAFKA_HOME/bin/connect-standalone.sh $KAFKA_HOME/config/connect-standalone.properties config/kafka-connect-fs.properties
```

7. Run the Sink Connector (in this example it is a file sink connector).

```
$KAFKA_HOME/bin/connect-standalone.sh $KAFKA_HOME/config/connect-standalone.properties $KAFKA_HOME/config/connect-file-sink.properties
```

For an example Kafka Connect usage, look at the `run-local-tests.sh` script under `integration-tests` folder in the [Github repository for the Amazon Glue Schema Registry](#).

Migration from a third-party schema registry to Amazon Glue Schema Registry

The migration from a third-party schema registry to the Amazon Glue Schema Registry has a dependency on the existing, current third-party schema registry. If there are records in an Apache Kafka topic which were sent using a third-party schema registry, consumers need the third-party schema registry to deserialize those records. The `AWSKafkaAvroDeserializer` provides the ability to specify a secondary deserializer class which points to the third-party deserializer and is used to deserialize those records.

There are two criteria for retirement of a third-party schema. First, retirement can occur only after records in Apache Kafka topics using the 3rd party schema registry are either no longer required by and for any consumers. Second, retirement can occur by aging out of the Apache Kafka topics, depending on the retention period specified for those topics. Note that if you have topics which have infinite retention, you can still migrate to the Amazon Glue Schema Registry but you will not be able to retire the third-party schema registry. As a workaround, you can use an application or Mirror Maker 2 to read from the current topic and produce to a new topic with the Amazon Glue Schema Registry.

To migrate from a third-party schema registry to the Amazon Glue Schema Registry:

1. Create a registry in the Amazon Glue Schema Registry, or use the default registry.
2. Stop the consumer. Modify it to include Amazon Glue Schema Registry as the primary deserializer, and the third-party schema registry as the secondary.
 - Set the consumer properties. In this example, the `secondary_deserializer` is set to a different deserializer. The behavior is as follows: the consumer retrieves records from Amazon MSK and first tries to use the `AWSKafkaAvroDeserializer`. If it is unable to read the magic byte that contains the Avro Schema ID for the Amazon Glue Schema Registry schema, the `AWSKafkaAvroDeserializer` then tries to use the deserializer class provided in the `secondary_deserializer`. The properties specific to the secondary deserializer also need to be provided in the consumer properties, such as the `schema_registry_url_config` and `specific_avro_reader_config`, as shown below.

```
consumerProps.setProperty(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
    StringDeserializer.class.getName());
consumerProps.setProperty(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
    AWKafkaAvroDeserializer.class.getName());
consumerProps.setProperty(AWSSchemaRegistryConstants.AWS_REGION,
    KafkaClickstreamConsumer.gsrRegion);
consumerProps.setProperty(AWSSchemaRegistryConstants.SECONDARY_DESERIALIZER,
    KafkaAvroDeserializer.class.getName());
consumerProps.setProperty(KafkaAvroDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
    "URL for third-party schema registry");
consumerProps.setProperty(KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG,
    "true");
```

3. Restart the consumer.
4. Stop the producer and point the producer to the Amazon Glue Schema Registry.
 - a. Set the producer properties. In this example, the producer will use the default-registry and auto register schema versions.

```
producerProps.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
    StringSerializer.class.getName());
producerProps.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
    AWKafkaAvroSerializer.class.getName());
producerProps.setProperty(AWSSchemaRegistryConstants.AWS_REGION, "us-east-2");
producerProps.setProperty(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
    AvroRecordType.SPECIFIC_RECORD.getName());
```

```
producerProps.setProperty(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING,  
"true");
```

5. (Optional) Manually move existing schemas and schema versions from the current third-party schema registry to the Amazon Glue Schema Registry, either to the default-registry in Amazon Glue Schema Registry or to a specific non-default registry in Amazon Glue Schema Registry. This can be done by exporting schemas from the third-party schema registries in JSON format and creating new schemas in Amazon Glue Schema Registry using the Amazon Web Services Management Console or the Amazon CLI.

This step may be important if you need to enable compatibility checks with previous schema versions for newly created schema versions using the Amazon CLI and the Amazon Web Services Management Console, or when producers send messages with a new schema with auto-registration of schema versions turned on.

6. Start the producer.

Connecting to data

An Amazon Glue *connection* is a Data Catalog object that stores login credentials, URI strings, virtual private cloud (VPC) information, and more for a particular data store. Amazon Glue crawlers, jobs, and development endpoints use connections in order to access certain types of data stores. You can use connections for both sources and targets, and reuse the same connection across multiple crawler or extract, transform, and load (ETL) jobs.

The latest version of the Amazon Glue connections schema provides a unified way to manage data connections across Amazon services and applications, such as Amazon Glue, Amazon Athena, and Amazon SageMaker AI Unified Studio.

Overview of using connectors and connections

A *connection* contains the properties that are required to connect to a particular data store. When you create a connection, it is stored in the Amazon Glue Data Catalog. You choose a connector, and then create a connection based on that connector.

You can subscribe to connectors for non-natively supported data stores in Amazon Web Services Marketplace, and then use those connectors when you're creating connections. Developers can also create their own connectors, and you can use them when creating connections.

Note

Connections created using custom or Amazon Web Services Marketplace connectors in Amazon Glue Studio appear in the Amazon Glue console with type set to UNKNOWN.

The following steps describe the overall process of using connectors in Amazon Glue Studio:

1. Subscribe to a connector in Amazon Web Services Marketplace, or develop your own connector and upload it to Amazon Glue Studio. For more information, see [Adding connectors to Amazon Glue Studio](#).
2. Review the connector usage information. You can find this information on the **Usage** tab on the connector product page. For example, if you click the **Usage** tab on this product page, [Amazon Glue Connector for Google BigQuery](#), you can see in the **Additional Resources** section a link to a blog about using this connector.

3. Create a connection. You choose which connector to use and provide additional information for the connection, such as login credentials, URI strings, and virtual private cloud (VPC) information. For more information, see [Creating connections for connectors](#).
4. Create an IAM role for your job. The job assumes the permissions of the IAM role that you specify when you create it. This IAM role must have the necessary permissions to authenticate with, extract data from, and write data to your data stores.
5. Create an ETL job and configure the data source properties for your ETL job. Provide the connection options and authentication information as instructed by the custom connector provider. For more information, see [Authoring jobs with custom connectors](#).
6. Customize your ETL job by adding transforms or additional data stores, as described in [Starting visual ETL jobs in Amazon Glue Studio](#).
7. If using a connector for the data target, configure the data target properties for your ETL job. Provide the connection options and authentication information as instructed by the custom connector provider. For more information, see [the section called "Authoring jobs with custom connectors"](#).
8. Customize the job run environment by configuring job properties, as described in [Modify the job properties](#).
9. Run the job.

Unified connections

Amazon recently introduced a new feature called "SageMaker LakeHouse Connections" or "Amazon Glue Unified Connections." This feature allows you to create connections that can be used by multiple Amazon services, such as Amazon Glue and Amazon Athena. When you create a data source in Amazon Athena, you'll notice a section that refers to Amazon Glue connection inputs. In this case, Amazon Athena will create a Amazon Glue connection for you, including any Amazon Athena-specific properties in the `AthenaProperties` section of the connection.

On the other hand, if you create a connection directly in Amazon Glue, you'll only be prompted to enter properties specific to Amazon Glue and Apache Spark, which will be stored in the `ConnectionProperties` and `SparkProperties` sections of the connection.

Both of these scenarios result in the creation of a "unified connection," but the connections created in Amazon Athena are only configured for use within Amazon Athena, while the connections created in Amazon Glue are only configured for use within Amazon Glue. However, it's possible to

update these connections with the missing properties (either Amazon Athena or Spark properties) so that they can be used by both services. Amazon SageMaker AI Unified Studio takes care of this automatically by filling in all necessary properties (`ConnectionProperties` , `AthenaProperties` , and `SparkProperties`) on the Amazon Glue connection, ensuring that the connection can be used by both Amazon Glue and Amazon Athena.

It's important to note that although we refer to these as "unified connections," the connections created in Amazon Glue or Amazon Athena individually are not truly unified unless they are properly configured for use by both services. Only the connections created through SageMaker Unified Studio are truly unified and usable by multiple services out of the box.

Additionally, connections created in Amazon Glue are not visible in Amazon Athena because Amazon Athena displays data sources, which include a reference to a Amazon Glue connection but are not the Amazon Glue connection itself. Similarly, connections created in Amazon Athena are not visible in Amazon Glue Studio because Amazon Glue Studio filters out any connection that hasn't been configured with the necessary settings for Amazon Glue.

Amazon Glue Studio creates unified connections by default. In the Amazon Glue console, you can see the version of the connection in the connections table on the connections page, on the connections detail page, and the connections table in the job details page.

The connection version is visible on Connection details:

Postgresql connection v2

None ▾ ↻

Current connections

These are the connections currently associated with the job.

Name	Type	VPC	Subnet	Security Groups	Version
<p>No connections</p> <p>No connections attached.</p>					

With version 2 connections, you have the following expanded data connectivity capabilities:

- **Connection type discovery:** Support for creating connections using standardized templates. Amazon Glue automatically discovers the connection types accessible by you and the required and optional inputs for a given connection type.
- **Reusability:** Connection definitions that are reusable across Amazon data processing engines and tools like Amazon Glue, Amazon Athena, and Amazon SageMaker AI. Connections now contain `AthenaProperties`, `SparkProperties`, `PythonProperties` which allow to specify compute environment/service specific connection properties in addition to the common properties stored in `ConnectionProperties`. Athena now creates Connections in Amazon Glue by specifying Athena specific properties in the `AthenaProperties` property map.
- **Data preview:** Ability to browse metadata and preview data from connected sources.
- **Connector metadata:** Reusable connections may be used in order to discover table metadata.
- **Service linked secrets:** Users may provide necessary OAuth, basic or custom authentication credentials in the `CreateConnection` request. The `CreateConnection` API creates a Service Linked Secret in your account and stores the credentials on your behalf.

Supported authentication types

Unified connections supports the following authentication types:

- **BASIC** – Most database connection types and existing Amazon Glue connection types support basic authentication, which is a username and password. Previously, the naming of the keys in `SecretsManager` were connector specific and, for example, may have been `user`, `username`, `userName`, `opensearch.net.http.auth.user`, etc. This is where unified connections standardized basic authentication connection types on `USERNAME` and `PASSWORD` keys.
- **OAUTH2** – The majority of newly launched SaaS connection types support OAuth2 protocol.
- **CUSTOM** – A few connection types have some other authentication mechanism such as Google BigQuery where users are expected to provide the JSON which they get from Google BigQuery.

Considerations

When you create a unified connection for data sources, consider the following differences:

- When creating a unified connection via Amazon Glue Studio, user credentials are stored in Amazon Secrets Manager instead of the connection itself. This means jobs now need access to Secrets Manager.

- If jobs run in a VPC, they require either a VPC endpoint or NAT gateway to access Amazon Secrets Manager and Secure Token Service (STS), which incurs additional costs.
- For certain data sources (Redshift, SQL Server, MySQL, Oracle, PostgreSQL), creating a unified connection via Amazon Glue Studio requires access to Amazon STS and Amazon Secrets Manager. This is necessary to establish a secure connection and retrieve the required credentials for accessing these data sources within your Virtual Private Cloud (VPC).
- Creating a unified connection via Amazon Glue Studio requires an IAM role with permissions to access Amazon Secrets Manager and manage VPC resources (if using a VPC):
 - `secretsmanager:GetSecretValue`
 - `secretsmanager:PutSecretValue`
 - `secretsmanager:DescribeSecret`
 - `ec2:CreateNetworkInterface`
 - `ec2>DeleteNetworkInterface`
 - `ec2:DescribeNetworkInterfaces`
 - `ec2:DescribeSubnets`

Available connections

Amazon Glue supports the following connection types:

- Amazon Aurora (supported if the native JDBC driver is being used. Not all driver features can be leveraged)
- Amazon DocumentDB
- Amazon DynamoDB
- Amazon OpenSearch Service, for use with Amazon Glue for Spark.
- Amazon Redshift
- Azure Cosmos, for use of Azure Cosmos DB for NoSQL with Amazon Glue ETL jobs
- Azure SQL, for use with Amazon Glue for Spark.
- Google BigQuery, for use with Amazon Glue for Spark.
- JDBC
- Kafka
- Microsoft Dynamics 365 CRM

- MongoDB
- MongoDB Atlas
- Pipedrive
- Salesforce
- SAP HANA, for use with Amazon Glue for Spark.
- SAP OData
- Snowflake, for use with Amazon Glue for Spark.
- Teradata Vantage, when using Amazon Glue for Spark.
- Vertica, for use with Amazon Glue for Spark.
- Various Amazon Relational Database Service (Amazon RDS) offerings.
- Network (designates a connection to a data source that is in an Amazon Virtual Private Cloud (Amazon VPC))

With Amazon Glue Studio, you can also create a connection for a *connector*. A connector is an optional code package that assists with accessing data stores in Amazon Glue Studio. For more information, see [Using connectors and connections with Amazon Glue Studio](#)

For information about how to connect to on-premises databases, see [How to access and analyze on-premises data stores using Amazon Glue](#) at the Amazon Big Data Blog website.

To create a connection with VPC configuration while using a custom IAM role, it must have the following VPC access actions:

- secretsmanager:GetSecretValue
- secretsmanager:PutSecretValue
- secretsmanager:DescribeSecret
- ec2:CreateNetworkInterface
- ec2>DeleteNetworkInterface
- ec2:DescribeNetworkInterfaces
- ec2:DescribeSubnets

Limitations

- You can't edit connections through the Amazon Glue console if you created a v2 connection using Amazon Glue APIs:
 - Amazon DocumentDB
 - Amazon Aurora
 - MariaDB
 - MongoDB Atlas
 - MongoDB

REST API Connections

Amazon Glue connectors cover a wide range of data sources both Amazon and external. However, there may be proprietary systems or emerging platforms that native Amazon Glue connectors do not support. The Amazon Glue REST connector provides a mechanism to configure a customized connector for any data source that has a REST-based API which then works the same way as natively supported Amazon Glue connectors. This capability minimizes the need to build custom libraries or ETL scripts to access these data sources.

To enable the REST API connector, Amazon Glue has introduced a new Amazon resource - **Connection Type**. The following operations can be used to manage connectivity to REST API-based data sources:

- **RegisterConnectionType** - Registers a Connection Type in Amazon Glue based on the configuration provided. For request structure, See [RegisterConnectionType](#).
- **DeleteConnectionType** - Deletes a Connection Type configuration in Amazon Glue. See [DeleteConnectionType](#).
- **DescribeConnectionType** - Returns full details of the supported options for a given connection type in Amazon Glue. See [DescribeConnectionType](#).
- **ListConnectionTypes** - Returns list of connection types with high-level details of what is supported for each Amazon Glue connection type. See [ListConnectionTypes](#).

Creating a REST connection type in Amazon Glue

To create a REST connection type, use the Amazon CLI, Amazon SDK or Amazon API to invoke the RegisterConnectionType API. Configuration details are provided based on the REST API being connected to.

Note

REST connections cannot be created using Amazon Glue console

Pre-Requirement

Before attempting to configure your Amazon Glue REST API connector, you need to familiarize yourself with the internal workings of the REST API. It helps if you have the REST API documentation for the data source and a tool for inspecting the request/ response structure.

The following properties of the REST API should be identified:

- Authentication mechanism used for calls made to the REST endpoint. Amazon Glue REST API connectors support: **basic authentication, OAuth2 - ClientCredentials, OAuth2 - Authorization Code, OAuth2 - JWT and custom authentication.**
- Entities (data objects) that you can transfer through the REST endpoint and related metadata (such as field names and data types).
- The HTTP request and response structure. This structure includes the HTTP method, endpoint URL, headers, query parameters, and the format of the request body and response payload.
- The pagination scheme. Amazon Glue REST API connectors support two pagination schemes: `cursor`-based and `offset`-based pagination.

RegisterConnectionType

Registers a ConnectionType in Amazon Glue based on the configuration provided. The ConnectionType resource is a new Amazon Glue resource that stores details about how requests and responses are interpreted by the data source. Today, only the REST protocol is supported. It encapsulates details about the REST API source such as:

- **Connection properties** - Defines BaseUrl to connect to REST API and any additional request parameters needed to take input during Amazon Glue CreateConnection.

- **Authentication configuration** - Defines how requests to the REST API are authenticated. This configuration is used when creating an Amazon Glue Connection for the Connection Type.
- **REST configuration** - Defines HTTP request and response configuration to read data from REST API source. The following properties need to be configured at either the **Global** or **Entity** level:
 - **Request method** - Defines the REST HTTP Method.
 - **Response configuration** - Defines how the API response should be interpreted (including Records or Error locations in the body).
 - **Pagination configuration** - Defines the strategy that the REST API uses for paginating the resulting records and how the pagination properties are to be sent/ retrieved.
 - **Validation endpoint configuration** - Defines the endpoint to be called to validate an Amazon Glue connection.
 - **Entity configurations** - Defines the REST entities that the connector supports and their schema.

RegisterConnectionType Request Syntax

See [RegisterConnectionType](#)

Once a REST API connection type has been registered, it is ready to be used to create connections to the configured data source. Refer to [Connecting to REST APIs](#) for detailed instructions.

Amazon Glue connection properties

This topic includes information about properties for Amazon Glue connections.

Topics

- [Required connection properties](#)
- [Amazon Glue JDBC connection properties](#)
- [Amazon Glue MongoDB and MongoDB Atlas connection properties](#)
- [Salesforce connection properties](#)
- [Snowflake connection](#)
- [Vertica connection](#)
- [SAP HANA connection](#)
- [Azure SQL connection](#)

- [Teradata Vantage connection](#)
- [OpenSearch Service connection](#)
- [Azure Cosmos connection](#)
- [Amazon Glue SSL connection properties](#)
- [Apache Kafka connection properties for client authentication](#)
- [Google BigQuery connection](#)
- [Vertica connection](#)

Required connection properties

When you define a connection on the Amazon Glue console, you must provide values for the following properties:

Connection name

Enter a unique name for your connection.

Connection type

Choose **JDBC** or one of the specific connection types.

For details about the JDBC connection type, see [the section called "JDBC connection properties"](#)

Choose **Network** to connect to a data source within an Amazon Virtual Private Cloud environment (Amazon VPC).

Depending on the type that you choose, the Amazon Glue console displays other required fields. For example, if you choose **Amazon RDS**, you must then choose the database engine.

Require SSL connection

When you select this option, Amazon Glue must verify that the connection to the data store is connected over a trusted Secure Sockets Layer (SSL).

For more information, including additional options that are available when you select this option, see [the section called "SSL connection properties"](#).

Select MSK cluster (Amazon managed streaming for Apache Kafka (MSK) only)

Specifies an MSK cluster from another Amazon account.

Kafka bootstrap server URLs (Kafka only)

Specifies a comma-separated list of bootstrap server URLs. Include the port number.

For example: b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094, b-2.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094, b-3.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094

Amazon Glue JDBC connection properties

Amazon Glue Studio now creates unified connections for MySQL, Oracle, PostgreSQL, Redshift, and SQL Server data sources, which requires additional steps for accessing Secrets Manager and VPC resources, which may incur extra costs. You can access these connections in Amazon Glue Studio by choosing the connection name for the respective connection.

For more information, see [Considerations](#).

Amazon Glue can connect to the following data stores through a JDBC connection:

- Amazon Redshift
- Amazon Aurora
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL
- Snowflake, when using Amazon Glue crawlers.
- Aurora (supported if the native JDBC driver is being used. Not all driver features can be leveraged)
- Amazon RDS for MariaDB

Important

Currently, an ETL job can use JDBC connections within only one subnet. If you have multiple data stores in a job, they must be on the same subnet, or accessible from the subnet.

If you choose to bring in your own JDBC driver versions for Amazon Glue crawlers, your crawlers will consume resources in Amazon Glue jobs and Amazon S3 to ensure your

provided drivers are run in your environment. The additional usage of resources will be reflected in your account. Additionally, providing your own JDBC driver does not mean that the crawler is able to leverage all of the driver's features. Drivers are limited to the properties described in [Defining connections in the Data Catalog](#).

The following are additional properties for the JDBC connection type.

JDBC URL

Enter the URL for your JDBC data store. For most database engines, this field is in the following format. In this format, replace *protocol*, *host*, *port*, and *db_name* with your own information.

```
jdbc:protocol:://host:port/db_name
```

Depending on the database engine, a different JDBC URL format might be required. This format can have slightly different use of the colon (:) and slash (/) or different keywords to specify databases.

For JDBC to connect to the data store, a *db_name* in the data store is required. The *db_name* is used to establish a network connection with the supplied username and password. When connected, Amazon Glue can access other databases in the data store to run a crawler or run an ETL job.

The following JDBC URL examples show the syntax for several database engines.

- To connect to an Amazon Redshift cluster data store with a dev database:

```
jdbc:redshift://xxx.us-east-1.redshift.amazonaws.com:8192/dev
```

- To connect to an Amazon RDS for MySQL data store with an employee database:

```
jdbc:mysql://xxx-cluster.cluster-xxx.us-east-1.rds.amazonaws.com:3306/  
employee
```

- To connect to an Amazon RDS for PostgreSQL data store with an employee database:

```
jdbc:postgresql://xxx-cluster.cluster-xxx.us-  
east-1.rds.amazonaws.com:5432/employee
```

- To connect to an Amazon RDS for Oracle data store with an employee service name:

```
jdbc:oracle:thin://@xxx-cluster.cluster-xxx.us-
east-1.rds.amazonaws.com:1521/employee
```

The syntax for Amazon RDS for Oracle can follow the following patterns. In these patterns, replace *host*, *port*, *service_name*, and *SID* with your own information.

- `jdbc:oracle:thin://@host:port/service_name`
- `jdbc:oracle:thin://@host:port:SID`
- To connect to an Amazon RDS for Microsoft SQL Server data store with an employee database:

```
jdbc:sqlserver://xxx-cluster.cluster-xxx.us-
east-1.rds.amazonaws.com:1433;databaseName=employee
```

The syntax for Amazon RDS for SQL Server can follow the following patterns. In these patterns, replace *server_name*, *port*, and *db_name* with your own information.

- `jdbc:sqlserver://server_name:port;database=db_name`
- `jdbc:sqlserver://server_name:port;databaseName=db_name`
- To connect to an Amazon Aurora PostgreSQL instance of the employee database, specify the endpoint for the database instance, the port, and the database name:

```
jdbc:postgresql://employee_instance_1.xxxxxxxxxxxxxx.us-
east-2.rds.amazonaws.com:5432/employee
```

- To connect to an Amazon RDS for MariaDB data store with an employee database, specify the endpoint for the database instance, the port, and the database name:

```
jdbc:mysql://xxx-cluster.cluster-xxx.aws-
region.rds.amazonaws.com:3306/employee
```

⚠ Warning

Snowflake JDBC connections are supported only by Amazon Glue crawlers. When using the Snowflake connector in Amazon Glue jobs, use the Snowflake connection type.

To connect to a Snowflake instance of the sample database, specify the endpoint for the snowflake instance, the user, the database name, and the role name. You can optionally add the warehouse parameter.

```
jdbc:snowflake://account_name.snowflakecomputing.com/?  
user=user_name&db=sample&role=role_name&warehouse=warehouse_name
```

Important

For Snowflake connections over JDBC, the order of parameters in the URL is enforced and must be ordered as user, db, role_name, and warehouse.

- To connect to a Snowflake instance of the sample database with Amazon private link, specify the snowflake JDBC URL as follows:

```
jdbc:snowflake://account_name.region.privatelink.snowflakecomputing.com/?  
user=user_name&db=sample&role=role_name&warehouse=warehouse_name
```

Username

Note

We recommend that you use an Amazon secret to store connection credentials instead of supplying your user name and password directly. For more information, see [Storing connection credentials in Amazon Secrets Manager](#).

Provide a user name that has permission to access the JDBC data store.

Password

Enter the password for the user name that has access permission to the JDBC data store.

Port

Enter the port used in the JDBC URL to connect to an Amazon RDS Oracle instance. This field is only shown when **Require SSL connection** is selected for an Amazon RDS Oracle instance.

VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The Amazon Glue console lists all VPCs for the current Region.

Important

When working over a JDBC connection which is hosted off of Amazon, such as with data from Snowflake, your VPC should have a NAT gateway which splits traffic into public and private subnets. The public subnet is used for connection to the external source, and the internal subnet is used for processing by Amazon Glue. For information on configuring your Amazon VPC for external connections, read [Connect to the internet or other networks using NAT devices](#) and [Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from Amazon Glue](#).

Subnet

Choose the subnet within the VPC that contains your data store. The Amazon Glue console lists all subnets for the data store in your VPC.

Security groups

Choose the security groups that are associated with your data store. Amazon Glue requires one or more security groups with an inbound source rule that allows Amazon Glue to connect. The Amazon Glue console lists all security groups that are granted inbound access to your VPC. Amazon Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

JDBC Driver Class name - optional

Provide the custom JDBC driver class name:

- Postgres – org.postgresql.Driver
- MySQL – com.mysql.jdbc.Driver, com.mysql.cj.jdbc.Driver
- Redshift – com.amazon.redshift.jdbc.Driver, com.amazon.redshift.jdbc42.Driver
-

Oracle – oracle.jdbc.driver.OracleDriver

- SQL Server – com.microsoft.sqlserver.jdbc.SQLServerDriver

JDBC Driver S3 Path - optional

Provide the Amazon S3 location to the custom JDBC driver. This is an absolute path to a .jar file. If you want to provide your own JDBC drivers to connect to your data sources for your crawler-supported databases,

you can specify values for parameters

`customJdbcDriverS3Path` and `customJdbcDriverClassName`.

Using a JDBC driver supplied by a customer is limited to the required [Required connection properties](#).

Amazon Glue MongoDB and MongoDB Atlas connection properties

The following are additional properties for the MongoDB or MongoDB Atlas connection type.

MongoDB URL

Enter the URL for your MongoDB or MongoDB Atlas data store:

- For MongoDB: `mongodb://host:port/database`. The host can be a hostname, IP address, or UNIX domain socket. If the connection string doesn't specify a port, it uses the default MongoDB port, 27017.
- For MongoDB Atlas: `mongodb+srv://server.example.com/database`. The host can be a hostname that follows corresponds to a DNS SRV record. The SRV format does not require a port and will use the default MongoDB port, 27017.

Username

Note

We recommend that you use an Amazon secret to store connection credentials instead of supplying your user name and password directly. For more information, see [Storing connection credentials in Amazon Secrets Manager](#).

Provide a user name that has permission to access the JDBC data store.

Password

Enter the password for the user name that has access permission to the MongoDB or MongoDB Atlas data store.

Salesforce connection properties

The following are additional properties for the Salesforce connection type.

- **ENTITY_NAME(String)** - (Required) Used for Read/Write. The name of your Object in Salesforce.
- **API_VERSION(String)** - (Required) Used for Read/Write. Salesforce Rest API version you want to use.
- **SELECTED_FIELDS(List<String>)** - Default: empty(SELECT *). Used for Read. Columns you want to select for the object.
- **FILTER_PREDICATE(String)** - Default: empty. Used for Read. It should be in the Spark SQL format.
- **QUERY(String)** - Default: empty. Used for Read. Full Spark SQL query.
- **PARTITION_FIELD(String)** - Used for Read. Field to be used to partition query.
- **LOWER_BOUND(String)**- Used for Read. An inclusive lower bound value of the chosen partition field.
- **UPPER_BOUND(String)** - Used for Read. An exclusive upper bound value of the chosen partition field.
- **NUM_PARTITIONS(Integer)** - Default: 1. Used for Read. Number of partitions for read.
- **IMPORT_DELETED_RECORDS(String)** - Default: FALSE. Used for read. To get the delete records while querying.
- **WRITE_OPERATION(String)** - Default: INSERT. Used for write. Value should be INSERT, UPDATE, UPSERT, DELETE.
- **ID_FIELD_NAMES(String)** - Default : null. Used only for UPSERT.

Snowflake connection

The following properties are used to set up a Snowflake connection used in Amazon Glue ETL jobs. When crawling Snowflake, use a JDBC connection.

Snowflake URL

The URL of your Snowflake endpoint. For more information about Snowflake endpoint URLs, see [Connecting to Your Accounts](#) in the Snowflake documentation.

Amazon Secret

The **Secret name** of a secret in Amazon Secrets Manager. Amazon Glue will connect to Snowflake using the `sfUser` and `sfPassword` keys of your secret.

Snowflake role (optional)

A Snowflake security role Amazon Glue will use when connecting.

Use the following properties when configuring a connection to a Snowflake endpoint hosted in Amazon VPC using Amazon PrivateLink.

VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The Amazon Glue console lists all VPCs for the current Region.

Subnet

Choose the subnet within the VPC that contains your data store. The Amazon Glue console lists all subnets for the data store in your VPC.

Security groups

Choose the security groups that are associated with your data store. Amazon Glue requires one or more security groups with an inbound source rule that allows Amazon Glue to connect. The Amazon Glue console lists all security groups that are granted inbound access to your VPC. Amazon Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

Vertica connection

Use the following properties to set up a Vertica connection for Amazon Glue ETL jobs.

Vertica Host

The hostname of your Vertica installation.

Vertica Port

The port your Vertica installation is available through.

Amazon Secret

The **Secret name** of a secret in Amazon Secrets Manager. Amazon Glue will connect to Vertica using the keys of your secret.

Use the following properties when configuring a connection to a Vertica endpoint hosted in Amazon VPC.

VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The Amazon Glue console lists all VPCs for the current Region.

Subnet

Choose the subnet within the VPC that contains your data store. The Amazon Glue console lists all subnets for the data store in your VPC.

Security groups

Choose the security groups that are associated with your data store. Amazon Glue requires one or more security groups with an inbound source rule that allows Amazon Glue to connect. The Amazon Glue console lists all security groups that are granted inbound access to your VPC. Amazon Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

SAP HANA connection

Use the following properties to set up a SAP HANA connection for Amazon Glue ETL jobs.

SAP HANA URL

A SAP JDBC URL.

SAP HANA JDBC URLs are in the form

`jdbc:sap://saphanaHostname:saphanaPort?databaseName=saphanaDBname,ParameterName`

Amazon Glue requires the following JDBC URL parameters:

- `databaseName` – A default database in SAP HANA to connect to.

Amazon Secret

The **Secret name** of a secret in Amazon Secrets Manager. Amazon Glue will connect to SAP HANA using the keys of your secret.

Use the following properties when configuring a connection to a SAP HANA endpoint hosted in Amazon VPC:

VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The Amazon Glue console lists all VPCs for the current Region.

Subnet

Choose the subnet within the VPC that contains your data store. The Amazon Glue console lists all subnets for the data store in your VPC.

Security groups

Choose the security groups that are associated with your data store. Amazon Glue requires one or more security groups with an inbound source rule that allows Amazon Glue to connect. The Amazon Glue console lists all security groups that are granted inbound access to your VPC. Amazon Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

Azure SQL connection

Use the following properties to set up a Azure SQL connection for Amazon Glue ETL jobs.

Azure SQL URL

The JDBC URL of an Azure SQL endpoint.

The URL must be in the following format:

```
jdbc:sqlserver://databaseServerName:databasePort;databaseName=azuresqlDBname;
```

Amazon Glue requires the following URL properties:

- `databaseName` – A default database in Azure SQL to connect to.

For more information about JDBC URLs for Azure SQL Managed Instances, see the [Microsoft documentation](#).

Amazon Secret

The **Secret name** of a secret in Amazon Secrets Manager. Amazon Glue will connect to Azure SQL using the keys of your secret.

Teradata Vantage connection

Use the following properties to set up a Teradata Vantage connection for Amazon Glue ETL jobs.

Teradata URL

To connect to a Teradata instance specify the hostname for the database instance and relevant Teradata parameters:

```
jdbc:teradata://teradataHostname/ParameterName=ParameterValue,ParameterName=Pa
```

Amazon Glue supports the following JDBC URL parameters:

- DATABASE_NAME – A default database in Teradata to connect to.
- DBS_PORT – Specifies the Teradata port, if nonstandard.

Amazon Secret

The **Secret name** of a secret in Amazon Secrets Manager. Amazon Glue will connect to Teradata Vantage using the keys of your secret.

Use the following properties when configuring a connection to a Teradata Vantage endpoint hosted in Amazon VPC:

VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The Amazon Glue console lists all VPCs for the current Region.

Subnet

Choose the subnet within the VPC that contains your data store. The Amazon Glue console lists all subnets for the data store in your VPC.

Security groups

Choose the security groups that are associated with your data store. Amazon Glue requires one or more security groups with an inbound source rule that allows Amazon Glue to connect.

The Amazon Glue console lists all security groups that are granted inbound access to your VPC. Amazon Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

OpenSearch Service connection

Use the following properties to set up a OpenSearch Service connection for Amazon Glue ETL jobs.

Domain endpoint

An Amazon OpenSearch Service domain endpoint will have the following default form, `https://search-domainName-unstructuredIdContent.region.es.amazonaws.com`. For more information on identifying your domain endpoint, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

Port

The port open on the endpoint.

Amazon Secret

The **Secret name** of a secret in Amazon Secrets Manager. Amazon Glue will connect to OpenSearch Service using the keys of your secret.

Use the following properties when configuring a connection to a OpenSearch Service endpoint hosted in Amazon VPC:

VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The Amazon Glue console lists all VPCs for the current Region.

Subnet

Choose the subnet within the VPC that contains your data store. The Amazon Glue console lists all subnets for the data store in your VPC.

Security groups

Choose the security groups that are associated with your data store. Amazon Glue requires one or more security groups with an inbound source rule that allows Amazon Glue to connect. The Amazon Glue console lists all security groups that are granted inbound access to your

VPC. Amazon Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

Azure Cosmos connection

Use the following properties to set up a Azure Cosmos connection for Amazon Glue ETL jobs.

Azure Cosmos DB Account Endpoint URI

The endpoint used to connect to Azure Cosmos. For more information, see [the Azure documentation](#).

Amazon Secret

The **Secret name** of a secret in Amazon Secrets Manager. Amazon Glue will connect to Azure Cosmos using the keys of your secret.

Amazon Glue SSL connection properties

The following are details about the **Require SSL connection** property.

If you do not require SSL connection, Amazon Glue ignores failures when it uses SSL to encrypt a connection to the data store. See the documentation for your data store for configuration instructions. When you select this option, the job run, crawler, or ETL statements in a development endpoint fail when Amazon Glue cannot connect.

Note

Snowflake supports an SSL connection by default, so this property is not applicable for Snowflake.

This option is validated on the Amazon Glue client side. For JDBC connections, Amazon Glue only connects over SSL with certificate and host name validation. SSL connection support is available for:

- Oracle Database
- Microsoft SQL Server

- PostgreSQL
- Amazon Redshift
- MySQL (Amazon RDS instances only)
- Amazon Aurora MySQL (Amazon RDS instances only)
- Amazon Aurora PostgreSQL (Amazon RDS instances only)
- Kafka, which includes Amazon Managed Streaming for Apache Kafka
- MongoDB

Note

To enable an **Amazon RDS Oracle** data store to use **Require SSL connection**, you must create and attach an option group to the Oracle instance.

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Add an **Option group** to the Amazon RDS Oracle instance. For more information about how to add an option group on the Amazon RDS console, see [Creating an Option Group](#)
3. Add an **Option** to the option group for **SSL**. The **Port** you specify for SSL is later used when you create an Amazon Glue JDBC connection URL for the Amazon RDS Oracle instance. For more information about how to add an option on the Amazon RDS console, see [Adding an Option to an Option Group](#) in the *Amazon RDS User Guide*. For more information about the Oracle SSL option, see [Oracle SSL](#) in the *Amazon RDS User Guide*.
4. On the Amazon Glue console, create a connection to the Amazon RDS Oracle instance. In the connection definition, select **Require SSL connection**. When requested, enter the **Port** that you used in the Amazon RDS Oracle SSL option.

The following additional optional properties are available when **Require SSL connection** is selected for a connection:

Custom JDBC certificate in S3

If you have a certificate that you are currently using for SSL communication with your on-premises or cloud databases, you can use that certificate for SSL connections to Amazon Glue data sources or targets. Enter an Amazon Simple Storage Service (Amazon S3) location that contains a custom root certificate. Amazon Glue uses this certificate to establish an SSL

connection to the database. Amazon Glue handles only X.509 certificates. The certificate must be DER-encoded and supplied in base64 encoding PEM format.

If this field is left blank, the default certificate is used.

Custom JDBC certificate string

Enter certificate information specific to your JDBC database. This string is used for domain matching or distinguished name (DN) matching. For Oracle Database, this string maps to the `SSL_SERVER_CERT_DN` parameter in the security section of the `tnsnames.ora` file. For Microsoft SQL Server, this string is used as `hostNameInCertificate`.

The following is an example for the Oracle Database `SSL_SERVER_CERT_DN` parameter.

```
cn=sales,cn=OracleContext,dc=us,dc=example,dc=com
```

Kafka private CA certificate location

If you have a certificate that you are currently using for SSL communication with your Kafka data store, you can use that certificate with your Amazon Glue connection. This option is required for Kafka data stores, and optional for Amazon Managed Streaming for Apache Kafka data stores. Enter an Amazon Simple Storage Service (Amazon S3) location that contains a custom root certificate. Amazon Glue uses this certificate to establish an SSL connection to the Kafka data store. Amazon Glue handles only X.509 certificates. The certificate must be DER-encoded and supplied in base64 encoding PEM format.

Skip certificate validation

Select the **Skip certificate validation** check box to skip validation of the custom certificate by Amazon Glue. If you choose to validate, Amazon Glue validates the signature algorithm and subject public key algorithm for the certificate. If the certificate fails validation, any ETL job or crawler that uses the connection fails.

The only permitted signature algorithms are `SHA256withRSA`, `SHA384withRSA`, or `SHA512withRSA`. For the subject public key algorithm, the key length must be at least 2048.

Kafka client keystore location

The Amazon S3 location of the client keystore file for Kafka client side authentication. Path must be in the form `s3://bucket/prefix/filename.jks`. It must end with the file name and `.jks` extension.

Kafka client keystore password (optional)

The password to access the provided keystore.

Kafka client key password (optional)

A keystore can consist of multiple keys, so this is the password to access the client key to be used with the Kafka server side key.

Apache Kafka connection properties for client authentication

Amazon Glue supports the Simple Authentication and Security Layer (SASL) framework for authentication when you create an Apache Kafka connection. The SASL framework supports various mechanisms of authentication, and Amazon Glue offers the SCRAM (user name and password), GSSAPI (Kerberos protocol), and PLAIN protocols.

Use Amazon Glue Studio to configure one of the following client authentication methods. For more information, see [Creating connections for connectors](#) in the Amazon Glue Studio user guide.

- None - No authentication. This is useful if creating a connection for testing purposes.
- SASL/SCRAM-SHA-512 - Choosing this authentication method will allow you to specify authentication credentials. There are two options available:
 - Use Amazon Secrets Manager (recommended) - if you select this option, you can store your user name and password in Amazon Secrets Manager and let Amazon Glue access them when needed. Specify the secret that stores the SSL or SASL authentication credentials. For more information, see [Storing connection credentials in Amazon Secrets Manager](#).
 - Provide a user name and password directly.
- SASL/GSSAPI (Kerberos) - if you select this option, you can select the location of the keytab file, krb5.conf file and enter the Kerberos principal name and Kerberos service name. The locations for the keytab file and krb5.conf file must be in an Amazon S3 location. Since MSK does not yet support SASL/GSSAPI, this option is only available for customer managed Apache Kafka clusters. For more information, see [MIT Kerberos Documentation: Keytab](#).
- SASL/PLAIN - choose this authentication method to specify authentication credentials. There are two options available:
 - Use Amazon Secrets Manager (recommended) - if you select this option, you can store your credentials in Amazon Secrets Manager and let Amazon Glue access the information when needed. Specify the secret that stores the SSL or SASL authentication credentials.

- Provide username and password directly.
- SSL Client Authentication - if you select this option, you can select the location of the Kafka client keystore by browsing Amazon S3. Optionally, you can enter the Kafka client keystore password and Kafka client key password.

Google BigQuery connection

The following properties are used to set up a Google BigQuery connection used in Amazon Glue ETL jobs. For more information, see [the section called “BigQuery connections”](#).

Amazon Secret

The **Secret name** of a secret in Amazon Secrets Manager. Amazon Glue ETL jobs will connect to Google BigQuery using the `credentials` key of your secret.

Vertica connection

The following properties are used to set up a Vertica connection used in Amazon Glue ETL jobs. For more information, see [the section called “Vertica connections”](#).

Storing connection credentials in Amazon Secrets Manager

We recommend that you use Amazon Secrets Manager to supply connection credentials for your data store. Using Secrets Manager this way lets Amazon Glue access your secret at runtime for ETL jobs and crawler runs, and helps keep your credentials secure.

Prerequisites

To use Secrets Manager with Amazon Glue, you must grant your [IAM role for Amazon Glue](#) permission to retrieve secret values. The Amazon managed policy `AWSGlueServiceRole` doesn't include Amazon Secrets Manager permissions. For example IAM policies, see [Example: Permission to retrieve secret values](#) in the *Amazon Secrets Manager User Guide*.

Depending on your network setup, you might also need to create a VPC endpoint to establish a private connection between your VPC and Secrets Manager. For more information, see [Using an Amazon Secrets Manager VPC endpoint](#).

To create a secret for Amazon Glue

1. Follow the instructions in [Create and manage secrets](#) in the *Amazon Secrets Manager User Guide*. The following example JSON shows how to specify your credentials in the **Plaintext** tab when you create a secret for Amazon Glue.

```
{
  "username": "EXAMPLE-USERNAME",
  "password": "EXAMPLE-PASSWORD"
}
```

2. Associate your secret with a connection using the Amazon Glue Studio interface. For detailed instructions, see [Creating connections for connectors](#) in the *Amazon Glue Studio User Guide*.

Adding an Amazon Glue connection

You can connect to data sources in Amazon Glue for Spark programmatically. For more information, see [Connection types and options for ETL in Amazon Glue for Spark](#)

You can also use the Amazon Glue console to add, edit, delete, and test connections. For information about Amazon Glue connections, see [Connecting to data](#).

Connecting to Amazon Redshift in Amazon Glue Studio

Note

You can use Amazon Glue for Spark to read from and write to tables in Amazon Redshift databases outside of Amazon Glue Studio. To configure Amazon Redshift with Amazon Glue jobs programmatically, see [Redshift connections](#).

Amazon Glue provides built-in support for Amazon Redshift. Amazon Glue Studio provides a visual interface to connect to Amazon Redshift, author data integration jobs, and run them on Amazon Glue Studio serverless Spark runtime.

Topics

- [Creating an Amazon Redshift connection](#)
- [Creating a Amazon Redshift source node](#)
- [Creating an Amazon Redshift target node](#)
- [Advanced options](#)

Creating an Amazon Redshift connection

Permissions needed

Additional permissions are need to use Amazon Redshift clusters and Amazon Redshift serverless environments. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

- redshift:DescribeClusters
- redshift-serverless:ListWorkgroups
- redshift-serverless:ListNamespaces

Overview

When adding an Amazon Redshift connection, you can choose an existing Amazon Redshift connection or create a new connection when adding a **Data source - Redshift** node in Amazon Glue Studio.

Amazon Glue supports both Amazon Redshift clusters and Amazon Redshift serverless environments. When you create a connection, Amazon Redshift serverless environments display the **serverless** label next to the connection option.

For more information on how to create a Amazon Redshift connection, see [Moving data to and from Amazon Redshift](#).

Creating a Amazon Redshift source node

Permissions needed

Amazon Glue Studio jobs using Amazon Redshift data sources require additional permissions. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

The following permissions are needed in order to use an Amazon Redshift connection.

- redshift-data:ListSchemas
- redshift-data:ListTables
- redshift-data:DescribeTable
- redshift-data:ExecuteStatement
- redshift-data:DescribeStatement
- redshift-data:GetStatementResult

Adding an Amazon Redshift data source

To add a Data Source – Amazon Redshift node:

1. Choose the Amazon Redshift access type:
 - Direct data connection (recommended) – choose this option if you want to access your Amazon Redshift data directly. This is the recommended option and also the default.

- Data Catalog tables – choose this option if you have Data Catalog tables that you want to use.
2. If you choose Direct data connection, choose the connection for your Amazon Redshift data source. This assumes that the connection already exists and you can select from existing connections. If you need to create a connection, choose **Create Redshift connection**. For more information, see [Overview of using connectors and connections](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**. Information about the connection are visible, including URL, security groups, subnet, availability zone, description, and created (UTC) and last updated (UTC) timestamps.

3. Choose a Amazon Redshift source option:
 - **Choose a single table** – this is the table that contains the data you want to access from a single Amazon Redshift table.
 - **Enter custom query** – allows you to access a dataset from multiple Amazon Redshift tables based on your custom query.
4. If you chose a single table, choose the Amazon Redshift schema. The list of available schema to choose from is determined by the selected table.

Or, choose **Enter custom query**. Choose this option to access a custom dataset from multiple Amazon Redshift tables. When you choose this option, enter the Amazon Redshift query.

When connecting to an Amazon Redshift serverless environment, add the following permission to the custom query:

```
GRANT SELECT ON ALL TABLES IN <schema> TO PUBLIC
```

You can choose **Infer schema** to read the schema based on the query that you entered. You can also choose **Open Redshift query editor** to enter a Amazon Redshift query. For more information, see [Querying a database using the query editor](#).

5. In **Performance and security**, choose the Amazon S3 staging directory and IAM role.
 - **Amazon S3 staging directory** – choose the Amazon S3 location for temporarily staging data.
 - **IAM role** – choose the IAM role that can write to the Amazon S3 location you selected.

6. In **Custom Redshift paramters - optional**, enter the parameter and value.

Creating an Amazon Redshift target node

Permissions needed

Amazon Glue Studio jobs using Amazon Redshift data target require additional permissions. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

The following permissions are needed in order to use an Amazon Redshift connection.

- redshift-data:ListSchemas
- redshift-data:ListTables

Adding an Amazon Redshift target node

To create a a Amazon Redshift target node:

1. Choose an existing Amazon Redshift table as the target, or enter a new table name.
2. When you use the **Data target - Redshift** target node, you can choose from the following options:
 - **APPEND** – If a table already exists, dump all the new data into the table as an insert. If the table doesn't exist, create it and then insert all new data.

Additionally, check the box if you want to update (UPSERT) existing records in the target table. The table must exist first, otherwise the operation will fail.

- **MERGE** – Amazon Glue will update or append data to your target table based on the conditions you specify.

Note

To use the merge action in Amazon Glue, you must enable Amazon Redshift merge functionality. For instructions on how to enable merge for your Amazon Redshift instance, see [MERGE \(preview\)](#).

Choose options:

- **Choose keys and simple actions** – choose the columns to be used as matching keys between the source data and your target data set.

Specify the following options when matched:

- Update record in your target data set with data from source.
- Delete record in your target data set.

Specify the following options when not matched:

- Insert source data as a new row into your target data set.
- Do nothing.
- **Enter custom MERGE statement** – You can then choose **Validate Merge statement** to verify that the statement is valid or invalid.
- **TRUNCATE** – If a table already exists, truncate the table data by first clearing the contents of the target table. If truncate is successful, then insert all data. If the table doesn't exist, create the table and insert all data. If truncate is not successful, the operation will fail.
- **DROP** – If a table already exists, delete the table metadata and data. If deletion is successful, then insert all data. If the table doesn't exist, create the table and insert all data. If drop is not successful, the operation will fail.
- **CREATE** – Create a new table with the default name. If table name already exist, create a new table with a name postfix of `job_datetime` to the name for uniqueness. This will insert all the data into the new table. If the table exists, the final table name will have the postfix appended. If the table doesn't exist, a table will be created. In either case, a new table will be created.

Advanced options

See [Using the Amazon Redshift Spark connector on Amazon Glue](#).

Connecting to Azure Cosmos DB in Amazon Glue Studio

Amazon Glue provides built-in support for Azure Cosmos DB. Amazon Glue Studio provides a visual interface to connect to Azure Cosmos DB for NoSQL, author data integration jobs, and run them on the Amazon Glue Studio serverless Spark runtime.

Topics

- [Creating a Azure Cosmos DB connection](#)
- [Creating a Azure Cosmos DB source node](#)
- [Creating a Azure Cosmos DB target node](#)
- [Advanced options](#)

Creating a Azure Cosmos DB connection

Prerequisites:

- In Azure, you will need to identify or generate an Azure Cosmos DB Key for use by Amazon Glue, `cosmosKey`. For more information, see [Secure access to data in Azure Cosmos DB](#) in the Azure documentation.

To configure a connection to Azure Cosmos DB:

1. In Amazon Secrets Manager, create a secret using your Azure Cosmos DB Key. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, `secretName` for the next step.
 - When selecting **Key/value pairs**, create a pair for the key `spark.cosmos.accountKey` with the value `cosmosKey`.
2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, `connectionName`, for future use in Amazon Glue.
 - When selecting a **Connection type**, select Azure Cosmos DB.
 - When selecting an **Amazon Secret**, provide `secretName`.

Creating a Azure Cosmos DB source node

Prerequisites needed

- A Amazon Glue Azure Cosmos DB connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called “Creating a Azure Cosmos DB connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Azure Cosmos DB for NoSQL container you would like to read from. You will need identification information for the container.

An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.

Adding a Azure Cosmos DB data source

To add a Data source – Azure Cosmos DB node:

1. Choose the connection for your Azure Cosmos DB data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Azure Cosmos DB connection**. For more information see the previous section, [the section called “Creating a Azure Cosmos DB connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose **Cosmos DB Database Name** – provide the name of the database you want to read from, *cosmosDBName*.
3. Choose **Azure Cosmos DB Container** – provide the name of the container you want to read from, *cosmosContainerName*.
4. Optionally, choose **Azure Cosmos DB Custom Query** – provide a SQL SELECT query to retrieve specific information from Azure Cosmos DB.
5. In **Custom Azure Cosmos properties**, enter parameters and values as needed.

Creating a Azure Cosmos DB target node

Prerequisites needed

- A Amazon Glue Azure Cosmos DB connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called “Creating a Azure Cosmos DB connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Azure Cosmos DB table you would like to write to. You will need identification information for the container. **You must create the container before calling the connection method.**

An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.

Adding a Azure Cosmos DB data target

To add a Data target – Azure Cosmos DB node:

1. Choose the connection for your Azure Cosmos DB data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Azure Cosmos DB connection**. For more information see the previous section, [the section called “Creating a Azure Cosmos DB connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose **Cosmos DB Database Name** – provide the name of the database you want to read from, *cosmosDBName*.
3. Choose **Azure Cosmos DB Container** – provide the name of the container you want to read from, *cosmosContainerName*.
4. In **Custom Azure Cosmos properties**, enter parameters and values as needed.

Advanced options

You can provide advanced options when creating a Azure Cosmos DB node. These options are the same as those available when programming Amazon Glue for Spark scripts.

See [the section called “Azure Cosmos DB connections”](#).

Connecting to Azure SQL in Amazon Glue Studio

Amazon Glue provides built-in support for Azure SQL. Amazon Glue Studio provides a visual interface to connect to Azure SQL, author data integration jobs, and run them on the Amazon Glue Studio serverless Spark runtime.

Topics

- [Creating a Azure SQL connection](#)
- [Creating a Azure SQL source node](#)
- [Creating a Azure SQL target node](#)
- [Advanced options](#)

Creating a Azure SQL connection

To connect to Azure SQL from Amazon Glue, you will need to create and store your Azure SQL credentials in a Amazon Secrets Manager secret, then associate that secret with a Azure SQL Amazon Glue connection.

To configure a connection to Azure SQL:

1. In Amazon Secrets Manager, create a secret using your Azure SQL credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key user with the value *azuresqlUsername*.
 - When selecting **Key/value pairs**, create a pair for the key password with the value *azuresqlPassword*.
2. In the Amazon Glue console, create a connection by following the steps in [the section called “Adding an Amazon Glue connection”](#). After creating the connection, keep the connection name, *connectionName*, for future use in Amazon Glue.
 - When selecting a **Connection type**, select Azure SQL.
 - When providing **Azure SQL URL**, provide a JDBC endpoint URL.

The URL must be in the following format:

```
jdbc:sqlserver://databaseServerName:databasePort;databaseName=azuresqlDBName
```

Amazon Glue requires the following URL properties:

- `databaseName` – A default database in Azure SQL to connect to.

For more information about JDBC URLs for Azure SQL Managed Instances, see the [Microsoft documentation](#).

- When selecting an **Amazon Secret**, provide *secretName*.

Creating a Azure SQL source node

Prerequisites needed

- A Amazon Glue Azure SQL connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called “Creating a Azure SQL connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Azure SQL table you would like to read from, *tableName*.

An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in *connectionName*, schema and table name through the `dbtable`.

Adding a Azure SQL data source

To add a Data source – Azure SQL node:

1. Choose the connection for your Azure SQL data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Azure SQL connection**. For more information see the previous section, [the section called “Creating a Azure SQL connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **Azure SQL Source** option:

- **Choose a single table** – access all data from a single table.
 - **Enter custom query** – access a dataset from multiple tables based on your custom query.
3. If you chose a single table, enter *tableName*.

If you chose **Enter custom query**, enter a TransactSQL SELECT query.
 4. In **Custom Azure SQL properties**, enter parameters and values as needed.

Creating a Azure SQL target node

Prerequisites needed

- A Amazon Glue Azure SQL connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called “Creating a Azure SQL connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Azure SQL table you would like to write to, *tableName*.

An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in *connectionName*, schema and table name through the *dbtable*.

Adding a Azure SQL data target

To add a Data target – Azure SQL node:

1. Choose the connection for your Azure SQL data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Azure SQL connection**. For more information see the previous section, [the section called “Creating a Azure SQL connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Configure **Table name** by providing *tableName*.
3. In **Custom Azure SQL properties**, enter parameters and values as needed.

Advanced options

You can provide advanced options when creating a Azure SQL node. These options are the same as those available when programming Amazon Glue for Spark scripts.

See [the section called "Azure SQL connections"](#).

Connecting to Google BigQuery in Amazon Glue Studio

Note

You can use Amazon Glue for Spark to read from and write to tables in Google BigQuery in Amazon Glue 4.0 and later versions. To configure Google BigQuery with Amazon Glue jobs programmatically, see [BigQuery connections](#).

Amazon Glue Studio provides a visual interface to connect to BigQuery, author data integration jobs, and run them on the Amazon Glue Studio serverless Spark runtime.

When creating a connection to Google BigQuery in Amazon Glue Studio, a unified connection is created. For more information, see [Considerations](#).

Instead of creating a secret with the credentials in a specific format, {"credentials": "base64 encoded JSON"}, now with unified connection to Google BigQuery, you can create a secret which directly includes the JSON from Google BigQuery: {"type": "service-account", ...}.

Topics

- [Creating a BigQuery connection](#)
- [Creating a BigQuery source node](#)
- [Creating a BigQuery target node](#)
- [Advanced options](#)

Creating a BigQuery connection

To connect to Google BigQuery from Amazon Glue, you will need to create and store your Google Cloud Platform credentials in a Amazon Secrets Manager secret, then associate that secret with a Google BigQuery Amazon Glue connection.

To configure a connection to BigQuery:

1. In Google Cloud Platform, create and identify relevant resources:
 - Create or identify a GCP project containing BigQuery tables you would like to connect to.
 - Enable the BigQuery API. For more information, see [Use the BigQuery Storage Read API to read table data](#).
2. In Google Cloud Platform, create and export service account credentials:

You can use the BigQuery credentials wizard to expedite this step: [Create credentials](#).

To create a service account in GCP, follow the tutorial available in [Create service accounts](#).

- When selecting **project**, select the project containing your BigQuery table.
- When selecting GCP IAM roles for your service account, add or create a role that would grant appropriate permissions to run BigQuery jobs to read, write or create BigQuery tables.

To create credentials for your service account, follow the tutorial available in [Create a service account key](#).

- When selecting key type, select **JSON**.

You should now have downloaded a JSON file with credentials for your service account. It should look similar to the following:

```
{
  "type": "service_account",
  "project_id": "*****",
  "private_key_id": "*****",
  "private_key": "*****",
  "client_email": "*****",
  "client_id": "*****",
  "auth_uri": "https://accounts.google.com/o/oauth2/auth",
```

```
"token_uri": "https://oauth2.googleapis.com/token",
"auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
"client_x509_cert_url": "*****",
"universe_domain": "googleapis.com"
}
```

3. In Amazon Secrets Manager, create a secret using your downloaded credentials file. You can choose the **Plaintext** tab and paste the JSON formatted file content. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
4. In the Amazon Glue Data Catalog, create a connection by following the steps in <https://docs.amazonaws.cn/glue/latest/dg/console-connections.html>. After creating the connection, keep the connection name, *connectionName*, for the next step.
 - When selecting a **Connection type**, select Google BigQuery.
 - When selecting an **Amazon Secret**, provide *secretName*.
5. Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.
6. In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection**.

Creating a BigQuery source node

Prerequisites needed

- A BigQuery type Amazon Glue Data Catalog connection
- An Amazon Secrets Manager secret for your Google BigQuery credentials, used by the connection.
- Appropriate permissions on your job to read the secret used by the connection.
- The name and dataset of the table and corresponding Google Cloud project you would like to read.

Adding a BigQuery data source

To add a Data source – BigQuery node:

1. Choose the connection for your BigQuery data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create BigQuery connection**. For more information, see [Overview of using connectors and connections](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Identify what BigQuery data you would like to read, then choose a **BigQuery Source** option
 - Choose a single table – allows you to pull all data from a table.
 - Enter a custom query – allows you to customize which data is retrieved by providing a query.
3. Describe the data you would like to read

(Required) set **Parent Project** to the project containing your table, or a billing parent project, if relevant.

If you chose a single table, set **Table** to the name of a Google BigQuery table in the following format: [dataset].[table]

If you chose a query, provide it to **Query**. In your query, refer to tables with their fully qualified table name, in the format: [project].[dataset].[tableName].

4. Provide BigQuery properties

If you chose a single table, you do not need to provide additional properties.

If you chose a query, you must provide the following **Custom Google BigQuery properties**:

- Set `viewsEnabled` to true.
- Set `materializationDataset` to a dataset. The GCP principal authenticated by the credentials provided through the Amazon Glue connection must be able to create tables in this dataset.

Creating a BigQuery target node

Prerequisites needed

- A BigQuery type Amazon Glue Data Catalog connection
- An Amazon Secrets Manager secret for your Google BigQuery credentials, used by the connection.
- Appropriate permissions on your job to read the secret used by the connection.
- The name and dataset of the table and corresponding Google Cloud project you would like to write to.

Adding a BigQuery data target

To add a Data target – BigQuery node:

1. Choose the connection for your BigQuery data target. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create BigQuery connection**. For more information, see [Overview of using connectors and connections](#) .

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Identify what BigQuery table you would like to write to, then choose a **Write method**.
 - Direct – writes to BigQuery directly using the BigQuery Storage Write API.
 - Indirect – writes to Google Cloud Storage, then copies to BigQuery.

If you would like to write indirectly, provide a destination GCS location with **Temporary GCS bucket**. You will need to provide additional configuration in your Amazon Glue connection. For more information, see [Using indirect write with Google BigQuery](#).

3. Describe the data you would like to read

(Required) set **Parent Project** to the project containing your table, or a billing parent project, if relevant.

If you chose a single table, set **Table** to the name of a Google BigQuery table in the following format: [dataset].[table]

Advanced options

You can provide advanced options when creating a BigQuery node. These options are the same as those available when programming Amazon Glue for Spark scripts.

See [BigQuery connection option reference](#) in the Amazon Glue developer guide.

Connecting to Microsoft Dynamics 365 CRM

Microsoft Dynamics 365 is a product line of enterprise resource planning and customer relationship management intelligent business applications.

Topics

- [Amazon Glue support for Microsoft Dynamics 365](#)
- [Policies containing the API operations for creating and using connections](#)
- [Configuring Microsoft Dynamics 365 CRM](#)
- [Configuring Microsoft Dynamics 365 CRM connections](#)
- [Reading from Microsoft Dynamics 365 CRM entities](#)
- [Microsoft Dynamics 365 CRM connection option reference](#)
- [Limitations](#)

Amazon Glue support for Microsoft Dynamics 365

Amazon Glue supports Microsoft Dynamics 365 as follows:

Supported as a source?

Yes. You can use Amazon Glue ETL jobs to query data from Microsoft Dynamics 365.

Supported as a target?

No.

Supported Microsoft Dynamics 365 CRM API versions

v9.2.

Policies containing the API operations for creating and using connections

The following sample policy describes the required Amazon permissions for creating and using connections. If you are creating a new role, create a policy that contains the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:ListConnectionTypes",
        "glue:DescribeConnectionType",
        "glue:RefreshOAuth2Tokens",
        "glue:ListEntities",
        "glue:DescribeEntity"
      ],
      "Resource": "*"
    }
  ]
}
```

You can also use the following managed IAM policies to allow access:

- [AWSGlueServiceRole](#) – Grants access to resources that various Amazon Glue processes require to run on your behalf. These resources include Amazon Glue, Amazon S3, IAM, CloudWatch Logs, and Amazon EC2. If you follow the naming convention for resources specified in this policy, Amazon Glue processes have the required permissions. This policy is typically attached to roles specified when defining crawlers, jobs, and development endpoints.
- [AWSGlueConsoleFullAccess](#) – Grants full access to Amazon Glue resources when an identity that the policy is attached to uses the Amazon Management Console. If you follow the naming convention for resources specified in this policy, users have full console capabilities. This policy is typically attached to users of the Amazon Glue console.

Configuring Microsoft Dynamics 365 CRM

Before you can use Amazon Glue to transfer data from Microsoft Dynamics 365 CRM, you must meet these requirements:

Minimum requirements

- You have a Microsoft Dynamics 365 CRM developer account with ClientId and Secret.
- Your Microsoft Dynamics 365 CRM account has API access with a valid license.

If you meet these requirements, you're ready to connect Amazon Glue to your Microsoft Dynamics 365 CRM account. For typical connections, you don't need do anything else in Microsoft Dynamics 365 CRM.

Configuring Microsoft Dynamics 365 CRM connections

AUTHORIZATION_CODE Grant Type

- This grant type is considered “three-legged” OAuth as it relies on redirecting users to the third party authorization server to authenticate the user. It is used when creating connections via the Amazon Glue Console. The Amazon Glue Console will redirect the user to Microsoft Dynamics 365 CRM where the user must login and allow Amazon Glue the requested permissions to access their Microsoft Dynamics 365 CRM instance.
- Users may opt to create their own connected app in Microsoft Dynamics 365 CRM and provide their own client id and client secret when creating connections through the Amazon Glue Console. In this scenario, they will still be redirected to Microsoft Dynamics 365 CRM to login and authorize Amazon Glue to access their resources.
- This grant type results in a refresh token and access token. The access token is short lived, and may be refreshed automatically without user interaction using the refresh token.
- For public Microsoft Dynamics 365 CRM documentation on creating a connected app for Authorization Code OAuth flow, see | Microsoft Learn. [Microsoft App Registration](#).

Microsoft Dynamics 365 CRM supports OAuth2.0 authentication.

To configure a Microsoft Dynamics 365 CRM connection:

1. In Amazon Secrets Manager, create a secret with the following details. It is required to create a secret for each connection in Amazon Glue.

- For AuthorizationCode grant type:

For customer managed connected app - Secret should contain the connected app Client Secret with `USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET` as key.

2. In Amazon Glue Studio, create a connection under **Data Connections** by following the steps below:

- When selecting a **Data Source**, select Microsoft Dynamics 365 CRM.
- Select the **INSTANCE_URL** of the Microsoft Dynamics 365 CRM instance you want to connect to.
- Select the IAM role that Amazon Glue can assume and has permissions for following actions:
JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:DescribeSecret",
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutSecretValue",
        "ec2:CreateNetworkInterface",
        "ec2:DescribeNetworkInterfaces",
        "ec2>DeleteNetworkInterface"
      ],
      "Resource": "*"
    }
  ]
}
```

- Select **Token URL** and **Authorization Code URL** to access your Microsoft Dynamics 365 CRM workspace.
 - Provide **User Managed Client Application ClientId** of your Microsoft Dynamics 365 CRM app.
 - Select the `secretName` which you want to use for this connection in Amazon Glue to put the tokens.
 - Select the network options if you want to use your network.
3. Grant the IAM role associated with your Amazon Glue job permission to read `secretName`.
Choose **Next**.

- In your Amazon Glue job configuration, provide `connectionName` as an **Additional network connection**.

Reading from Microsoft Dynamics 365 CRM entities

Prerequisites

- A Microsoft Dynamics 365 CRM object you would like to read from. You will need the object name such as contacts or accounts. The following table shows the supported entities.

Supported entities

Entity	Can be Filtered	Supports Limit	Supports Order By	Supports Select *	Supports Partitioning
Dynamic entity	Yes	Yes	Yes	Yes	Yes

Example

```

dynamics365_read = glueContext.create_dynamic_frame.from_options(
    connection_type="microsoftdynamics365crm",
    connection_options={
        "connectionName": "connectionName",
        "ENTITY_NAME": "dynamic_entity",
        "API_VERSION": "v9.2",
        "INSTANCE_URL": "https://{tenantID}.api.crm.dynamics.com"
    }

```

Microsoft Dynamics 365 CRM Entity and Field Details

Entities with dynamic metadata:

Microsoft Dynamics 365 CRM provides endpoints to fetch metadata dynamically. Therefore, for dynamic entities, the operator support is captured at datatype level.

Entity	Data Type	Supported Operators
Dynamic entity	DateTime	=, <, <=, >, >=, BETWEEN
	Date	=, <, <=, >, >=
	String	=, !=
	Double	=, <, <=, >, >=
	Integer	=, <, <=, >, >=
	Decimal	=, <, <=, >, >=
	Long	=, <, <=, >, >=
	BigInteger	=, <, <=, >, >=
	List	NA
	Struct	NA
	Map	NA

Partitioning queries

Microsoft Dynamics 365 CRM supports only field based partitioning.

Additional spark options `PARTITION_FIELD`, `LOWER_BOUND`, `UPPER_BOUND`, `NUM_PARTITIONS` can be provided if you want to utilize concurrency in Spark. With these parameters, the original query would be split into `NUM_PARTITIONS` number of sub-queries that can be executed by spark tasks concurrently.

- `PARTITION_FIELD`: the name of the field to be used to partition query.
- `LOWER_BOUND`: an inclusive lower bound value of the chosen partition field.

For Datetime, we accept the Spark timestamp format used in Spark SQL queries. Example of valid values: "2024-01-30T06:47:51.000Z".

- `UPPER_BOUND`: an exclusive upper bound value of the chosen partition field.

- NUM_PARTITIONS: number of partitions.

Entity wise partitioning field support details are captured in below table:

Entity Name	Partitioning Fields	Data Type
Dynamic Entity (Standard entity)	Dynamic DateTime fields which are queryable	createdon, modifiedon
Dynamic Entity (Custom entity)	createdon, modifiedon	createdon, modifiedon

Example

```
dynamics365_read = glueContext.create_dynamic_frame.from_options(
    connection_type="microsoftynamics365crm",
    connection_options={
        "connectionName": "connectionName",
        "ENTITY_NAME": "dynamic_entity",
        "API_VERSION": "v9.2",
        "instanceUrl": "https://{tenantID}.api.crm.dynamics.com"
        "PARTITION_FIELD": "createdon"
        "LOWER_BOUND": "2024-01-30T06:47:51.000Z"
        "UPPER_BOUND": "2024-06-30T06:47:51.000Z"
        "NUM_PARTITIONS": "10"
    }
}
```

Microsoft Dynamics 365 CRM connection option reference

The following are connection options for Microsoft Dynamics 365 CRM:

- ENTITY_NAME(String) - (Required) Used for Read. The name of your object in Microsoft Dynamics 365 CRM.
- API_VERSION(String) - (Required) Used for Read. Microsoft Dynamics 365 CRM Rest API version you want to use.
- SELECTED_FIELDS(List<String>) - Default: empty(SELECT *). Used for Read. Columns you want to select for the object.

- `FILTER_PREDICATE(String)` - Default: empty. Used for Read. It should be in the Spark SQL format.
- `QUERY(String)` - Default: empty. Used for Read. Full Spark SQL query.
- `INSTANCE_URL(String)` - (Required) A valid Microsoft Dynamics 365 CRM Instance URL with the format: `https://{tenantID}.api.crm.dynamics.com`
- `NUM_PARTITIONS(Integer)` - Default: 1. Used for Read. Number of partitions for read.
- `PARTITION_FIELD(String)` - Used for Read. Field to be used to partition query.
- `LOWER_BOUND(String)`- Used for Read. An inclusive lower bound value of the chosen partition field. Example: `2024-01-30T06:47:51.000Z`.
- `UPPER_BOUND(String)` - Used for Read. An exclusive upper bound value of the chosen partition field. Example: `2024-06-30T06:47:51.000Z`.

Limitations

The following are limitations for the Microsoft Dynamics 365 CRM connector:

- In Microsoft Dynamics 365 CRM, record based partitioning is not supported as it does not support an offset parameter, and thus record based partitioning cannot be supported.
- Pagination is set at a maximum of 500 records per page to avoid Internal Server exceptions from SaaS due to a combination of data size and rate limitations.
 - [SaaS documentation on pagination](#)
 - [SaaS documentation on rate limits](#)
- Microsoft Dynamics 365 CRM supports `order by` on only parent fields for all entities. `order by` is not supported on sub-fields.
 - Both ASC and DESC directions are supported.
 - `order by` on multiple fields is supported.
- Filtering on "createddatetime" field of the `aadusers` standard entity is throwing a bad request error from SaaS even though it supports filtration. There is no specific identification of any other entity having a similar issue due to the dynamic nature of the metadata and neither is the root cause known. Hence, it cannot be handled.
- Complex object types, such as Struct, List, and Map do not support filtration.
- Many fields that can be retrieved from a response have `isRetrievable` marked as `false` in dynamic metadata response. In order to avoid data loss, `isRetrievable` is set to `true` for all fields.

- Field based partitioning will be supported on all entities when it adheres to the following criteria:
 - DateTime queryable fields should be present in standard entities or created on and modified on fields (system-generated) in custom entities.
 - There is no exclusive identification of system generated fields or the nullable property from any SaaS metadata APIs, however it is a general practice that only the fields available by default, are filterable and non-nullable. Therefore, the above criterion of field selection is considered null safe and if it is filterable, it will be eligible for partitioning.

Connecting to MongoDB in Amazon Glue Studio

Amazon Glue provides built-in support for MongoDB. Amazon Glue Studio provides a visual interface to connect to MongoDB, author data integration jobs, and run them on the Amazon Glue Studio serverless Spark runtime.

Topics

- [Creating a MongoDB connection](#)
- [Creating a MongoDB source node](#)
- [Creating a MongoDB target node](#)
- [Advanced options](#)

Creating a MongoDB connection

Prerequisites:

- If your MongoDB instance is in an Amazon VPC, configure Amazon VPC to allow your Amazon Glue job to communicate with the MongoDB instance without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that Amazon Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your MongoDB instance and this location. Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

To configure a connection to MongoDB:

1. Optionally, in Amazon Secrets Manager, create a secret using your MongoDB credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

- When selecting **Key/value pairs**, create a pair for the key username with the value *mongodbUser*.

When selecting **Key/value pairs**, create a pair for the key password with the value *mongodbPass*.

2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in Amazon Glue.

- When selecting a **Connection type**, select **MongoDB** or **MongoDB Atlas**.
- When selecting **MongoDB URL** or **MongoDB Atlas URL**, provide the hostname of your MongoDB instance.

A MongoDB URL is provided in the format
mongodb://mongoHost:mongoPort/mongoDBname.

A MongoDB Atlas URL is provided in the format *mongodb+srv://mongoHost:mongoPort/mongoDBname*.

Providing the default database for the connection, *mongoDBname* is optional.

- If you chose to create an Secrets Manager secret, choose the Amazon Secrets Manager **Credential type**.

Then, in **Amazon Secret** provide *secretName*.

- If you choose to provide **Username and password**, provide *mongodbUser* and *mongodbPass*.

3. In the following situations, you may require additional configuration:

- For MongoDB instances hosted on Amazon in an Amazon VPC

- You will need to provide Amazon VPC connection information to the Amazon Glue connection that defines your MongoDB security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a Amazon Glue MongoDB connection, you will need to perform the following steps before running your Amazon Glue job:

- When working with Amazon Glue jobs in the visual editor, you must provide Amazon VPC connection information for your job to connect to MongoDB. Identify a suitable location in Amazon VPC and provide it to your Amazon Glue MongoDB connection.
- If you chose to create an Secrets Manager secret, grant the IAM role associated with your Amazon Glue job permission to read *secretName*.

Creating a MongoDB source node

Prerequisites needed

- A Amazon Glue MongoDB connection, as described in the previous section, [the section called “Creating a MongoDB connection”](#).
- If you chose to create an Secrets Manager secret, appropriate permissions on your job to read the secret used by the connection.
- A MongoDB collection you would like to read from. You will need identification information for the collection.

A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.

Adding a MongoDB data source

To add a Data source – MongoDB node:

1. Choose the connection for your MongoDB data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create MongoDB connection**. For more information see the previous section, [the section called “Creating a MongoDB connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **Database**. Enter *mongodbName*.
3. Choose a **Collection**. Enter *mongodbCollection*.
4. Choose your **Partitioner**, **Partition size (MB)** and **Partition key**. For more information about partition parameters, see [the section called "'connectionType': 'mongodb' as source"](#).
5. In **Custom MongoDB properties**, enter parameters and values as needed.

Creating a MongoDB target node

Prerequisites needed

- A Amazon Glue MongoDB connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called "Creating a MongoDB connection"](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A MongoDB table you would like to write to, *tableName*.

Adding a MongoDB data target

To add a Data target – MongoDB node:

1. Choose the connection for your MongoDB data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create MongoDB connection**. For more information see the previous section, [the section called "Creating a MongoDB connection"](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **Database**. Enter *mongodbName*.
3. Choose a **Collection**. Enter *mongodbCollection*.
4. Choose your **Partitioner**, **Partition size (MB)** and **Partition key**. For more information about partition parameters, see [the section called "'connectionType': 'mongodb' as source"](#).
5. Choose **Retry Writes** if desired.
6. In **Custom MongoDB properties**, enter parameters and values as needed.

Advanced options

You can provide advanced options when creating a MongoDB node. These options are the same as those available when programming Amazon Glue for Spark scripts.

See [the section called “MongoDB connection”](#).

Connecting to OpenSearch Service in Amazon Glue Studio

Amazon Glue provides built-in support for Amazon OpenSearch Service. Amazon Glue Studio provides a visual interface to connect to Amazon OpenSearch Service, author data integration jobs, and run them on the Amazon Glue Studio serverless Spark runtime. This feature is not compatible with OpenSearch Service serverless.

Amazon Glue Studio creates a unified connection for Amazon OpenSearch Service. For more information, see [Considerations](#).

Topics

- [Creating a OpenSearch Service connection](#)
- [Creating a OpenSearch Service source node](#)
- [Creating a OpenSearch Service target node](#)
- [Advanced options](#)

Creating a OpenSearch Service connection

Prerequisites:

- Identify the domain endpoint, *aosEndpoint* and port, *aosPort* you would like to read from, or create the resource by following instructions in the Amazon OpenSearch Service documentation. For more information on creating a domain, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

An Amazon OpenSearch Service domain endpoint will have the following default form, `https://search-domainName-unstructuredIdContent.region.es.amazonaws.com`. For more information on identifying your domain endpoint, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

Identify or generate HTTP basic authentication credentials, *aosUser* and *aosPassword* for your domain.

To configure a connection to OpenSearch Service:

1. In Amazon Secrets Manager, create a secret using your OpenSearch Service credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key USERNAME with the value *aosUser*.
 - When selecting **Key/value pairs**, create a pair for the key PASSWORD with the value *aosPassword*.
2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in Amazon Glue.
 - When selecting a **Connection type**, select OpenSearch Service.
 - When selecting a Domain endpoint, provide *aosEndpoint*.
 - When selecting a port, provide *aosPort*.
 - When selecting an **Amazon Secret**, provide *secretName*.

Creating a OpenSearch Service source node

Prerequisites needed

- A Amazon Glue OpenSearch Service connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called "Creating a OpenSearch Service connection"](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A OpenSearch Service index you would like to read from, *aosIndex*.

Adding a OpenSearch Service data source

To add a Data source – OpenSearch Service node:

1. Choose the connection for your OpenSearch Service data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create**

OpenSearch Service connection. For more information see the previous section, [the section called “Creating a OpenSearch Service connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Provide **Index**, the index you would like to read.
3. Optionally, provide **Query**, an OpenSearch query to deliver more specific results. For more information about writing OpenSearch queries, consult [the section called “Read from OpenSearch Service”](#).
4. In **Custom OpenSearch Service properties**, enter parameters and values as needed.

Creating a OpenSearch Service target node

Prerequisites needed

- A Amazon Glue OpenSearch Service connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called “Creating a OpenSearch Service connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A OpenSearch Service index you would like to write to, *aosIndex*.

Adding a OpenSearch Service data target

To add a Data target – OpenSearch Service node:

1. Choose the connection for your OpenSearch Service data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create OpenSearch Service connection**. For more information see the previous section, [the section called “Creating a OpenSearch Service connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Provide **Index**, the index you would like to read.
3. In **Custom OpenSearch Service properties**, enter parameters and values as needed.

Advanced options

You can provide advanced options when creating an OpenSearch Service node. These options are the same as those available when programming Amazon Glue for Spark scripts.

See [the section called “OpenSearch Service connections”](#).

Connecting to a REST API

Amazon Glue allows you to configure an Amazon Glue ConnectionType that can be used to connect Amazon Glue to any REST API-based data source. This can be used as a data source in your ETL Jobs. You can run these jobs to transfer data between the REST API-based data source and Amazon services or other supported applications.

Topics

- [Amazon Glue support for REST API](#)
- [Policies containing the API operations for registering connection types and creating/using connections](#)
- [Configuring a REST API ConnectionType](#)
- [Configuring a REST API connection](#)
- [Tutorial: Creating a REST API ConnectionType and Connection](#)
- [Limitations](#)

Amazon Glue support for REST API

Amazon Glue supports REST API as follows:

Supported as a source?

Yes. You can use Amazon Glue ETL jobs to query data from a REST API-based data source.

Supported as a target?

No.

Policies containing the API operations for registering connection types and creating/using connections

The following sample IAM policy describes the required permissions for registering, creating, managing and using the REST API connections within Amazon Glue ETL jobs. If you are creating a new role, create a policy that contains the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:RegisterConnectionType",
        "glue:ListConnectionTypes",
        "glue:DescribeConnectionType",
        "glue:CreateConnection",
        "glue:RefreshOAuth2Tokens",
        "glue:ListEntities",
        "glue:DescribeEntity"
      ],
      "Resource": "*"
    }
  ]
}
```

You can also use the following IAM policies to allow access:

- [AWSGlueServiceRole](#) – Grants access to resources that various Amazon Glue processes require to run on your behalf. These resources include Amazon Glue, Amazon S3, IAM, CloudWatch Logs, and Amazon EC2. If you follow the naming convention for resources specified in this policy, Amazon Glue processes have the required permissions. This policy is typically attached to roles specified when defining crawlers, jobs, and development endpoints.
- [AWSGlueConsoleFullAccess](#) – Grants full access to Amazon Glue resources when an identity that the policy is attached to uses the Amazon Management Console. If you follow the naming convention for resources specified in this policy, users have full console capabilities. This policy is typically attached to users of the Amazon Glue console.

If providing Network Options when creating a REST API connection, the following actions must also be included in the IAM role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:DescribeSecret",
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutSecretValue",
        "ec2:CreateNetworkInterface",
        "ec2:DescribeNetworkInterfaces",
        "ec2>DeleteNetworkInterface"
      ],
      "Resource": "*"
    }
  ]
}
```

Configuring a REST API ConnectionType

Before you can use Amazon Glue to transfer data from the REST API-based data source, you must meet these requirements:

Minimum requirements

The following are the minimum requirements:

- You have configured and registered an Amazon Glue REST API connection type. See [Connecting to REST APIs](#).
- If using OAuth2 Client Credentials, Authorization Code or JWT, configure the client app accordingly.

If you meet these requirements, you're ready to connect Amazon Glue to your REST API-based data source. Typically, no further configurations are needed on the REST API side.

Configuring a REST API connection

In order to configure an Amazon Glue REST API connector, you need to configure an Amazon Glue connection type. This connection type contains details about the properties of how the REST data source operates and interprets things like authentication, requests, responses, pagination, validations, and entities/ metadata. For a comprehensive list of the required properties for an

Amazon Glue REST connection type, see the [RegisterConnectionType](#) API and the steps for [Connecting to REST APIs](#).

When creating the REST API connector, the following policy is needed to allow relevant actions:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:RegisterConnectionType",
        "glue:ListConnectionTypes",
        "glue:DescribeConnectionType",
        "glue:CreateConnection",
        "secretsmanager:DescribeSecret",
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutSecretValue",
        "ec2:CreateNetworkInterface",
        "ec2:DescribeNetworkInterfaces",
        "ec2>DeleteNetworkInterface"
      ],
      "Resource": "*"
    }
  ]
}
```

Tutorial: Creating a REST API ConnectionType and Connection

Connecting to the Foo REST API

We will create an Amazon Glue REST API ConnectionType and a corresponding Amazon Glue connection for the Foo REST API. This API has the following properties (which can be retrieved from REST API documentation).

- **Instance URL:** <https://foo.cloud.com/rest/v1>.
- **Authentication type:** OAuth2 (Client Credentials).
- **REST method:** GET.
- **Pagination type:** Offset with properties "limit" and "offset" placed in query parameter of request.
- **Supported entities:**

- **Bar:** relative path [/bar.json].
- **Baz:** relative path [/baz.json].

Once all the details are obtained, we can begin creating the Amazon Glue connection to the Foo REST API.

To create a REST API connection:

1. Create the REST API connection type in Amazon Glue by calling the RegisterConnectionType API using Amazon API, CLI, or SDK. This will create a new ConnectionType resource in Amazon Glue.

```
{
  "ConnectionType": "REST-FOO-CONNECTOR",
  "IntegrationType": "REST",
  "Description": "AWS Glue Connection Type for the FOO REST API",
  "ConnectionProperties": {
    "Url": {
      "Name": "Url",
      "Required": true,
      "DefaultValue": "https://foo.cloud.com/rest/v1",
      "PropertyType": "USER_INPUT"
    }
  },
  "ConnectorAuthenticationConfiguration": {
    "AuthenticationTypes": ["OAUTH2"],
    "OAuth2Properties": {
      "OAuth2GrantType": "CLIENT_CREDENTIALS"
    }
  },
  "RestConfiguration": {
    "GlobalSourceConfiguration": {
      "RequestMethod": "GET",
      "ResponseConfiguration": {
        "ResultPath": "$.result",
        "ErrorPath": "$.error.message"
      }
    },
    "PaginationConfiguration": {
      "OffsetConfiguration": {
        "OffsetParameter": {
          "Key": "offset",
          "PropertyLocation": "QUERY_PARAM"
        }
      }
    }
  }
}
```

```
        "LimitParameter": {
            "Key": "limit",
            "PropertyLocation": "QUERY_PARAM",
            "DefaultValue": "50"
        }
    },
    "ValidationEndpointConfiguration": {
        "RequestMethod": "GET",
        "RequestPath": "/bar.json?offset=1&limit=10"
    },
    "EntityConfigurations": {
        "bar": {
            "SourceConfiguration": {
                "RequestMethod": "GET",
                "RequestPath": "/bar.json",
                "ResponseConfiguration": {
                    "ResultPath": "$.result",
                    "ErrorPath": "$.error.message"
                }
            },
            "Schema": {
                "name": {
                    "Name": "name",
                    "FieldDataType": "STRING"
                },
                "description": {
                    "Name": "description",
                    "FieldDataType": "STRING"
                },
                "id": {
                    "Name": "id",
                    "FieldDataType": "STRING"
                },
                "status": {
                    "Name": "status",
                    "FieldDataType": "STRING"
                }
            }
        }
    }
}
```

```
}

```

2. In Amazon Secrets Manager, create a secret. The Secret should contain the connected app Consumer Secret with `USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET` as key.

 **Note**

You must create a secret per connection in Amazon Glue

3. Create the Amazon Glue connection by calling the `CreateConnection` API using the Amazon API, CLI, or SDK.
 - a. Reference the REST connection type name from Step 1 as the `ConnectionType`.
 - b. Provide the `InstanceUrl` and any other `ConnectionProperties` that were defined during the Amazon Glue `ConnectionType` registration process.
 - c. Choose from the configured `AuthenticationTypes`. The REST API Foo uses `OAuth2` with the `ClientCredentials` grant type.
 - d. Provide the **SecretArn** and other **AuthenticationProperties** that are configured. For example, we have configured `OAuth2` as the `AuthenticationType` so we will set the `OAuth2Properties` in the `CreateConnectionInput`. This will require properties like `OAuth2GrantType`, `TokenUrl`, and `OAuth2ClientApplication`.
4. Make the `CreateConnection` request which will create the Amazon Glue connection.

```
{
  "ConnectionInput": {
    "Name": "ConnectionFooREST",
    "ConnectionType": "REST-FOO-CONNECTOR",
    "ConnectionProperties": {},
    "ValidateCredentials": true,
    "AuthenticationConfiguration": {
      "AuthenticationType": "OAUTH2",
      "SecretArn":
"arn:aws:secretsmanager:<region>:<accountId>:secret:<secretId>",
      "OAuth2Properties": {
        "OAuth2GrantType": "CLIENT_CREDENTIALS",
        "TokenUrl": "https://foo.cloud.com/oauth/token",
        "OAuth2ClientApplication": {
          "UserManagedClientApplicationClientId": "your-managed-client-id"
        }
      }
    }
  }
}
```

```
}  
  }  
}
```

Limitations

The following are limitations for the REST API connector

- REST API connector is only available through the Amazon API, CLI, or SDK. You cannot configure REST connectors through the console.
- The Amazon Glue REST ConnectionType can only be configured to READ data from the REST API-based data source. The connection can only be used as a SOURCE in Amazon Glue ETL jobs.
- Filtering and partitioning is not supported.
- Field selection is not supported.

Connecting to Salesforce

Salesforce provides customer relationship management (CRM) software that help you with sales, customer service, e-commerce, and more. If you're a Salesforce user, you can connect Amazon Glue to your Salesforce account. Then, you can use Salesforce as a data source or destination in your ETL Jobs. Run these jobs to transfer data between Salesforce and Amazon services or other supported applications.

Topics

- [Amazon Glue support for Salesforce](#)
- [Policies containing the API operations for creating and using connections](#)
- [Configuring Salesforce](#)
- [Apply System Admin profile](#)
- [Configuring Salesforce connections](#)
- [Reading from Salesforce](#)
- [Writing to Salesforce](#)
- [Salesforce connection options](#)
- [Limitations for the Salesforce connector](#)
- [Set up the Authorization Code flow for Salesforce](#)

- [Set up the JWT bearer OAuth flow for Salesforce](#)

Amazon Glue support for Salesforce

Amazon Glue supports Salesforce as follows:

Supported as a source?

Yes. You can use Amazon Glue ETL jobs to query data from Salesforce.

Supported as a target?

Yes. You can use Amazon Glue ETL jobs to write records into Salesforce.

Supported Salesforce API versions

The following Salesforce API versions are supported

- v58.0
- v59.0
- v60.0

Policies containing the API operations for creating and using connections

The following sample IAM policy describes the required permissions for creating, managing and using Salesforce connections within Amazon Glue ETL jobs. If you are creating a new role, create a policy that contains the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:DescribeSecret",
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutSecretValue",
        "glue:ListConnectionTypes",
        "glue:DescribeConnectionType",
```

```

        "glue:RefreshOAuth2Tokens",
        "glue:ListEntities",
        "glue:DescribeEntity"
    ],
    "Resource": "*"
}
]
}

```

You can also use the following IAM policies to allow access:

- [AWSGlueServiceRole](#) – Grants access to resources that various Amazon Glue processes require to run on your behalf. These resources include Amazon Glue, Amazon S3, IAM, CloudWatch Logs, and Amazon EC2. If you follow the naming convention for resources specified in this policy, Amazon Glue processes have the required permissions. This policy is typically attached to roles specified when defining crawlers, jobs, and development endpoints.
- [AWSGlueConsoleFullAccess](#) – Grants full access to Amazon Glue resources when an identity that the policy is attached to uses the Amazon Management Console. If you follow the naming convention for resources specified in this policy, users have full console capabilities. This policy is typically attached to users of the Amazon Glue console.

If providing Network Options when creating a Salesforce connection, the following actions must also be included in the IAM role:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:DescribeNetworkInterfaces",
        "ec2>DeleteNetworkInterface"
      ],
      "Resource": "*"
    }
  ]
}

```

```
}
```

For Zero-ETL Salesforce connections, see [Zero-ETL prerequisites](#).

For Zero-ETL Salesforce connections, see [Zero-ETL prerequisites](#).

Configuring Salesforce

Before you can use Amazon Glue to transfer data to or from Salesforce, you must meet these requirements:

Minimum requirements

The following are minimum requirements:

- You have a Salesforce account.
- Your Salesforce account is enabled for API access. API access is enabled by default for the Enterprise, Unlimited, Developer, and Performance editions.

If you meet these requirements, you're ready to connect Amazon Glue to your Salesforce account. Amazon Glue handles the remaining requirements with the Amazon managed connected app.

The Amazon managed connected app for Salesforce

The Amazon managed connected app helps you create a Salesforce connection in fewer steps. In Salesforce, a connected app is a framework that authorizes external applications, like Amazon Glue, to access your Salesforce data using OAuth 2.0. To use the Amazon managed connected app, create a Salesforce connection by using the Amazon Glue console. When you configure the connection, set the **OAuth grant type** to **Authorization code** and leave the box checked for **Use Amazon managed client application**.

When saving the connection, you will be redirected to Salesforce to login and approve Amazon Glue access to your Salesforce account.

Apply System Admin profile

In Salesforce, follow the steps to apply the System Admin profile:

1. In Salesforce, navigate to **Settings > Connected Apps > Connected Apps OAuth Usage**.
2. In the list of connected apps, find Amazon Glue and choose **Install**. If needed, choose **Unblock**.

3. Navigate to **Settings > Manage Connected Apps** then choose **Amazon Glue**. Under OAuth Policies, choose **Admin approved users are pre-authorized** and select the **System Admin** profile. This action restricts access to Amazon Glue only to users with the System Admin profile.

Apply System Admin profile

In Salesforce, follow the steps to apply the System Admin profile:

1. In Salesforce, navigate to **Settings > Connected Apps > Connected Apps OAuth Usage**.
2. In the list of connected apps, find Amazon Glue and choose **Install**. If needed, choose **Unblock**.
3. Navigate to **Settings > Manage Connected Apps** then choose **Amazon Glue**. Under OAuth Policies, choose **Admin approved users are pre-authorized** and select the **System Admin** profile. This action restricts access to Amazon Glue only to users with the System Admin profile.

Configuring Salesforce connections

To configure a Salesforce connection:

1. In Amazon Secrets Manager, create a secret with the following details:
 - a. For the JWT_TOKEN grant type - the secret should contain the JWT_TOKEN key with its value.
 - b. For the AuthorizationCode grant type:
 - i. For an Amazon Managed connected app, an empty secret or a secret with some temporary value must be provided.
 - ii. For a customer managed connected app, the secret should contain the connected app Consumer Secret with USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET as the key.
 - c. Note: You must create a secret for your connection in Amazon Glue.
2. In Amazon Glue Glue Studio, create a connection under **Data Connections** by following the steps below:
 - a. When selecting a **Connection type**, select Salesforce.
 - b. Provide the INSTANCE_URL of the Salesforce instance you want to connect to.
 - c. Provide the Salesforce environment.

- d. Select the Amazon IAM role which Amazon Glue can assume and has permissions for following actions:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:DescribeSecret",
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutSecretValue",
        "ec2:CreateNetworkInterface",
        "ec2:DescribeNetworkInterfaces",
        "ec2>DeleteNetworkInterface"
      ],
      "Resource": "*"
    }
  ]
}
```

- e. Select the OAuth2 grant type which you want to use for the connections. The grant type determines how Amazon Glue communicates with Salesforce to request access to your data. Your choice affects the requirements that you must meet before you create the connection. You can choose either of these types:

- **JWT_BEARER Grant Type:** This grant type works well for automation scenarios as it allows a JSON Web Token (JWT) to be created up front with the permissions of a particular user in the Salesforce instance. The creator has control over how long the JWT is valid for. Amazon Glue is able to use the JWT to obtain an access token which is used to call Salesforce APIs.

This flow requires that the user has created a connected app in their Salesforce instance which enables issuing JWT-based access tokens for users.

For information on creating a connected app for the JWT bearer OAuth flow, see [OAuth 2.0 JWT bearer flow for server-to-server integration](#). To set up the JWT bearer flow with the Salesforce connected app, see [Set up the JWT bearer OAuth flow for Salesforce](#).

- **AUTHORIZATION_CODE Grant Type:** This grant type is considered a "three-legged" OAuth as it relies on redirecting users to the third-party authorization server to authenticate the

user. It is used when creating connections via the Amazon Glue console. The user creating a connection may by default rely on an Amazon Glue connected app (Amazon Glue managed client application) where they do not need to provide any OAuth related information except for their Salesforce instance URL. The Amazon Glue console will redirect the user to Salesforce where the user must login and allow Amazon Glue the requested permissions to access their Salesforce instance.

Users may still opt to create their own connected app in Salesforce and provide their own client ID and client secret when creating connections through the Amazon Glue console. In this scenario, they will still be redirected to Salesforce to login and authorize Amazon Glue to access their resources.

This grant type results in a refresh token and access token. The access token is short lived, and may be refreshed automatically without user interaction using the refresh token.

For information on creating a connected app for the Authorization Code OAuth flow, see [the section called "Set up the Authorization Code flow for Salesforce"](#).

- f. Select the `secretName` which you want to use for this connection in Amazon Glue to store the OAuth 2.0 tokens.
 - g. Select the network options if you want to use your network.
3. Grant the IAM role associated with your Amazon Glue job permission to read `secretName`.
 4. If providing network options, also grant the IAM role the following permissions:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:DescribeNetworkInterfaces",
        "ec2>DeleteNetworkInterface"
      ],
      "Resource": "*"
    }
  ]
}
```

Configuring Salesforce connections with the Amazon CLI

You can create Salesforce connections using the Amazon CLI:

```
aws glue create-connection --connection-input \
"{\"Name\": \"salesforce-conn1\", \"ConnectionType\": \"SALESFORCE\",
\"ConnectionProperties\": {\"ROLE_ARN\": \"arn:aws:iam::123456789012:role/glue-role\",
\"INSTANCE_URL\": \"https://example.my.salesforce.com\"}, \"ValidateCredentials\": true,
\"AuthenticationConfiguration\": {\"AuthenticationType\": \"OAUTH2\", \"SecretArn\":
\"arn:aws:secretsmanager:us-east-1:123456789012:secret:salesforce-conn1-secret-IAMcdk
\", \"OAuth2Properties\": {\"OAuth2GrantType\": \"JWT_BEARER\", \"TokenUrl\": \"https://
login.salesforce.com/services/oauth2/token\"}}}" \
--endpoint-url https://glue.us-east-1.amazonaws.com \
--region us-east-1
```

Reading from Salesforce

Prerequisite

A Salesforce sObject you would like to read from. You will need the object name such as Account or Case or Opportunity.

Example:

```
salesforce_read = glueContext.create_dynamic_frame.from_options(
    connection_type="salesforce",
    connection_options={
        "connectionName": "connectionName",
        "ENTITY_NAME": "Account",
        "API_VERSION": "v60.0"
    }
)
```

Partitioning queries

You can provide the additional Spark options `PARTITION_FIELD`, `LOWER_BOUND`, `UPPER_BOUND`, and `NUM_PARTITIONS` if you want to utilize concurrency in Spark. With these parameters, the original query would be split into `NUM_PARTITIONS` number of sub-queries that can be executed by Spark tasks concurrently.

- `PARTITION_FIELD`: the name of the field to be used to partition the query.

- **LOWER_BOUND**: an **inclusive** lower bound value of the chosen partition field.

For Date or Timestamp fields, the connector accepts the Spark timestamp format used in Spark SQL queries.

Examples of valid values:

```
"TIMESTAMP \"1707256978123\""
```

```
"TIMESTAMP '2018-01-01 00:00:00.000 UTC'"
```

```
"TIMESTAMP \"2018-01-01 00:00:00 Pacific/Tahiti\""
```

```
"TIMESTAMP \"2018-01-01 00:00:00\""
```

```
"TIMESTAMP \"-123456789\" Pacific/Tahiti"
```

```
"TIMESTAMP \"1702600882\""
```

- **UPPER_BOUND**: an **exclusive** upper bound value of the chosen partition field.
- **NUM_PARTITIONS**: the number of partitions.
- **TRANSFER_MODE**: supports two modes: SYNC and ASYNC. Default is SYNC. When set to ASYNC, Bulk API 2.0 Query will be utilized for processing.

Example:

```
salesforce_read = glueContext.create_dynamic_frame.from_options(
    connection_type="salesforce",
    connection_options={
        "connectionName": "connectionName",
        "ENTITY_NAME": "Account",
        "API_VERSION": "v60.0",
        "PARTITION_FIELD": "SystemModstamp",
        "LOWER_BOUND": "TIMESTAMP '2021-01-01 00:00:00 Pacific/Tahiti'",
        "UPPER_BOUND": "TIMESTAMP '2023-01-10 00:00:00 Pacific/Tahiti'",
        "NUM_PARTITIONS": "10",
        "TRANSFER_MODE": "ASYNC"
    }
)
```

FILTER_PREDICATE option

FILTER_PREDICATE: It is an optional parameter. This option is used for query filter.

Examples of **FILTER_PREDICATE**:

Case 1: FILTER_PREDICATE with single criterion**Examples:**

```
LastModifiedDate >= TIMESTAMP '2025-04-01 00:00:00 Pacific/Tahiti'
```

```
LastModifiedDate <= TIMESTAMP "2025-04-01 00:00:00"
```

```
LastModifiedDate >= TIMESTAMP '2018-01-01 00:00:00.000 UTC'
```

```
LastModifiedDate <= TIMESTAMP "-123456789 Pacific/Tahiti"
```

```
LastModifiedDate <= TIMESTAMP "1702600882"
```

Case 2: FILTER_PREDICATE with multiple criteria**Examples:**

```
LastModifiedDate >= TIMESTAMP '2025-04-01 00:00:00 Pacific/Tahiti' AND Id =  
"0012w00001CotGiAAJ"
```

```
LastModifiedDate >= TIMESTAMP "1702600882" AND Id = "001gL000002i26MQAQ"
```

Case 3: FILTER_PREDICATE single criterion with LIMIT**Examples:**

```
LastModifiedDate >= TIMESTAMP "1702600882" LIMIT 2
```

Case 4: FILTER_PREDICATE with LIMIT**Examples:**

```
LIMIT 2
```

Writing to Salesforce

Prerequisites

A Salesforce sObject you would like to write to. You will need the object name such as Account or Case or Opportunity.

The Salesforce connector supports four write operations:

- INSERT
- UPSERT
- UPDATE
- DELETE

When using the UPSERT write operation, the ID_FIELD_NAMES option must be provided to specify the external ID field for the records.

You can also add connection options:

- **TRANSFER_MODE:** Supports two modes: SYNC and ASYNC. Default is SYNC. When set to ASYNC, Bulk API 2.0 Ingest will be utilized for processing.
- **FAIL_ON_FIRST_ERROR:** The default value is FALSE, which means the Amazon Glue job will continue processing all the data even if there are some failed write records. When set to TRUE, the Amazon Glue job will fail if there are any failed write records, and it will not continue processing.

Example

```
salesforce_write = glueContext.write_dynamic_frame.from_options(  
    frame=frameToWrite,  
    connection_type="salesforce",  
    connection_options={  
        "connectionName": "connectionName",  
        "ENTITY_NAME": "Account",  
        "API_VERSION": "v60.0",  
        "WRITE_OPERATION": "INSERT",  
        "TRANSFER_MODE": "ASYNC",  
        "FAIL_ON_FIRST_ERROR": "true"  
    }  
)
```

Salesforce connection options

The following connection options are supported for the Salesforce connector:

- **ENTITY_NAME(String)** - (Required) Used for Read/Write. The name of your Object in Salesforce.
- **API_VERSION(String)** - (Required) Used for Read/Write. Salesforce Rest API version you want to use.
- **SELECTED_FIELDS(List<String>)** - Default: empty(SELECT *). Used for Read. Columns you want to select for the object.
- **FILTER_PREDICATE(String)** - Default: empty. Used for Read. It should be in the Spark SQL format.

When providing a filter predicate, only the AND operator is supported. Other operators such as OR and IN are not currently supported.

- **QUERY(String)** - Default: empty. Used for Read. Full Spark SQL query.
- **PARTITION_FIELD(String)** - Used for Read. Field to be used to partition query.

- LOWER_BOUND(String)- Used for Read. An inclusive lower bound value of the chosen partition field.
- UPPER_BOUND(String) - Used for Read. An exclusive upper bound value of the chosen partition field.
- NUM_PARTITIONS(Integer) - Default: 1. Used for Read. Number of partitions for read.
- IMPORT_DELETED_RECORDS(String) - Default: FALSE. Used for read. To get the delete records while querying.
- WRITE_OPERATION(String) - Default: INSERT. Used for write. Value should be INSERT, UPDATE, UPSERT, DELETE.
- ID_FIELD_NAMES(String) - Default : null. Required for UPDATE and UPSERT.

Limitations for the Salesforce connector

The following are limitations for the Salesforce connector:

- We only support Spark SQL and Salesforce SOQL is not supported.
- Job bookmarks are not supported.
- Salesforce field names are case sensitive. When writing to Salesforce, data must match the casing of the fields defined within Salesforce.

Set up the Authorization Code flow for Salesforce

Refer to Salesforce public documentation for enabling the OAuth 2.0 Authorization Code flow.

To configure the connected app:

1. Activate the **Enable OAuth Settings** checkbox.
2. In the **Callback URL** text field, enter one or more redirect URLs for Amazon Glue.

Redirect URLs have the following format:

`https://region.console.aws.amazon.com/gluestudio/oauth`

In this URL, *region* is the code for the Amazon Region where you use Amazon Glue to transfer data from Salesforce. For example, the code for the US East (N. Virginia) Region is `us-east-1`. For that Region, the URL is the following:

<https://us-east-1.console.aws.amazon.com/gluestudio/oauth>

For the Amazon Regions that Amazon Glue supports, and their codes, see [Amazon Glue endpoints and quotas](#) in the *Amazon General Reference*.

3. Activate the **Require Secret for Web Server Flow** checkbox.
4. In the **Available OAuth Scopes** list, add the following scopes:
 - Manage user data via APIs (api)
 - Access custom permissions (custom_permissions)
 - Access the identity URL service (id, profile, email, address, phone)
 - Access unique user identifiers (openid)
 - Perform requests at any time (refresh_token, offline_access)
5. Set the refresh token policy for the connected app to **Refresh token is valid until revoked**. Otherwise, your jobs will fail when your refresh token expires. For more information on how to check and edit the refresh token policy, see [Manage OAuth Access Policies for a Connected App](#) in the Salesforce documentation.

Set up the JWT bearer OAuth flow for Salesforce

Refer to Salesforce public documentation for enabling server-to-server integration with [OAuth 2.0 JSON Web Tokens](#).

Once you have created a JWT and configured the connected app appropriately in Salesforce, you can create a new Salesforce connection with the `JWT_TOKEN` key set in your Secrets Manager Secret. Set the OAuth grant type to **JWT Bearer Token** when creating the connection.

Connecting to SAP HANA in Amazon Glue Studio

Amazon Glue provides built-in support for SAP HANA. Amazon Glue Studio provides a visual interface to connect to SAP HANA, author data integration jobs, and run them on the Amazon Glue Studio serverless Spark runtime.

Amazon Glue Studio creates a unified connection for SAP HANA. For more information, see [Considerations](#).

Topics

- [Creating a SAP HANA connection](#)

- [Creating a SAP HANA source node](#)
- [Creating a SAP HANA target node](#)
- [Advanced options](#)

Creating a SAP HANA connection

To connect to SAP HANA from Amazon Glue, you will need to create and store your SAP HANA credentials in a Amazon Secrets Manager secret, then associate that secret with a SAP HANA Amazon Glue connection. You will need to configure network connectivity between your SAP HANA service and Amazon Glue.

Prerequisites:

- If your SAP HANA service is in an Amazon VPC, configure Amazon VPC to allow your Amazon Glue job to communicate with the SAP HANA service without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that Amazon Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your SAP HANA endpoint and this location. Your job will need to establish a TCP connection with your SAP HANA JDBC port. For more information about SAP HANA ports, see the [SAP HANA documentation](#). Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

To configure a connection to SAP HANA:

1. In Amazon Secrets Manager, create a secret using your SAP HANA credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key `username/USERNAME` with the value *saphanaUsername*.
 - When selecting **Key/value pairs**, create a pair for the key `password/PASSWORD` with the value *saphanaPassword*.

2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in Amazon Glue.
 - When selecting a **Connection type**, select SAP HANA.
 - When providing **SAP HANA URL**, provide the URL for your instance.

SAP HANA JDBC URLs are in the form

```
jdbc:sap://saphanaHostname:saphanaPort?databaseName=saphanaDBname,Parameter
```

Amazon Glue requires the following JDBC URL parameters:

- *databaseName* – A default database in SAP HANA to connect to.
- When selecting an **Amazon Secret**, provide *secretName*.

After creating a Amazon Glue SAP HANA connection, you will need to perform the following steps before running your Amazon Glue job:

- Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.

Creating a SAP HANA source node

Prerequisites needed

- An Amazon Glue SAP HANA connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called "Creating a SAP HANA connection"](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A SAP HANA table you would like to read from, *tableName*, or query *targetQuery*.

A table can be specified with a SAP HANA table name and schema name, in the form *schemaName.tableName*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *tableIdentifier*. Note that the database is provided as a JDBC URL parameter in *connectionName*.

Adding a SAP HANA data source

To add a Data source – SAP HANA node:

1. Choose the connection for your SAP HANA data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create SAP HANA connection**. For more information see the previous section, [the section called “Creating a SAP HANA connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **SAP HANA Source** option:
 - **Choose a single table** – access all data from a single table.
 - **Enter custom query** – access a dataset from multiple tables based on your custom query.
3. If you chose a single table, enter *tableName*.

If you chose **Enter custom query**, enter a SQL SELECT query.
4. In **Custom SAP HANA properties**, enter parameters and values as needed.

Creating a SAP HANA target node

Prerequisites needed

- A Amazon Glue SAP HANA connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called “Creating a SAP HANA connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A SAP HANA table you would like to write to, *tableName*.

A table can be specified with a SAP HANA table name and schema name, in the form *schemaName.tableName*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *tableIdentifier*. Note that the database is provided as a JDBC URL parameter in *connectionName*.

Adding a SAP HANA data target

To add a Data target – SAP HANA node:

1. Choose the connection for your SAP HANA data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create SAP HANA connection**. For more information see the previous section, [the section called “Creating a SAP HANA connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Configure **Table name** by providing *tableName*.
3. In **Custom Teradata properties**, enter parameters and values as needed.

Advanced options

You can provide advanced options when creating a SAP HANA node. These options are the same as those available when programming Amazon Glue for Spark scripts.

See [the section called “SAP HANA connections”](#).

Connecting to SAP OData

SAP OData is a standard Web protocol used for querying and updating data present in SAP using ABAP (Advanced Business Application Programming), applying and building on Web technologies such as HTTP to provide access to information from a variety of external applications, platforms and devices. With the product, you can access everything you need to help you seamlessly integrate with your SAP system, application, or data.

Topics

- [Amazon Glue support for SAP OData](#)
- [Create connections](#)
- [Creating SAP OData job](#)
- [Writing to SAP OData](#)
- [Using the SAP OData state management script](#)
- [Partitioning for Non ODP entities](#)

- [SAP OData connection options](#)
- [SAP OData entity and field details](#)

Amazon Glue support for SAP OData

Amazon Glue supports SAP OData as follows:

Supported as a source?

Yes. You can use Amazon Glue ETL jobs to query data from SAP OData.

Supported as a target?

Yes. You can use Amazon Glue ETL jobs to write records into SAP OData.

Supported SAP OData API versions

The following SAP OData API versions are supported:

- 2.0

Supported sources

The following sources are supported:

- ODP (Operational Data Provisioning) Sources:
 - BW Extractors (DataSources)
 - CDS Views
 - SLT
- Non-ODP Sources, for example:
 - CDS View Services
 - RFC-based Services
 - Custom ABAP Services

Supported SAP Components

The following are minimum requirements:

- You must enable catalog service for service discovery.
 - Configure operational data provisioning (ODP) data sources for extraction in the SAP Gateway of your SAP system.
 - **OData V2.0:** Enable the OData V2.0 catalog service(s) in your SAP Gateway via transaction /IWFND/MAINT_SERVICE.
 - Enable OData V2.0 services in your SAP Gateway via transaction /IWFND/MAINT_SERVICE.
 - Your SAP OData service must support client side pagination/query options such as \$top and \$skip. It must also support system query option \$count.
 - You must provide the required authorization for the user in SAP to discover the services and extract data using SAP OData services. Refer to the security documentation provided by SAP.
- If you want to use OAuth 2.0 as an authorization mechanism, you must enable OAuth 2.0 for the OData service and register the OAuth client per SAP documentation.
- To generate an OData service based on ODP data sources, SAP Gateway Foundation must be installed locally in your ERP/BW stack or in a hub configuration.
 - For your ERP/BW applications, the SAP NetWeaver AS ABAP stack must be at 7.50 SP02 or above.
 - For the hub system (SAP Gateway), the SAP NetWeaver AS ABAP of the hub system must be 7.50 SP01 or above for remote hub setup.
- For non-ODP sources, your SAP NetWeaver stack version must be 7.40 SP02 or above.

Supported Authentication Methods

The following authentication methods are supported:

- Basic Authentication
- OAuth 2.0

Prerequisites

Prior to initiating an Amazon Glue job for data extraction from SAP OData using the SAP OData connection, complete the following prerequisites:

- The relevant SAP OData Service must be activated in the SAP system, ensuring the data source is available for consumption. If the OData service is not activated, the Glue job will not be able to access or extract data from SAP.

- Appropriate authentication mechanisms such as basic (custom) authentication or OAuth 2.0 must be configured in SAP to ensure that the Amazon Glue job can successfully establish a connection with the SAP OData service.
- Configure IAM policies to grant the Amazon Glue job appropriate permissions for accessing SAP, Secrets Manager, and other Amazon resources involved in the process.
- If the SAP system is hosted within a private network, VPC connectivity must be configured to ensure that the Amazon Glue job can securely communicate with SAP without exposing sensitive data over public internet.

Amazon Secrets Manager can be used to securely store sensitive information such as SAP credentials, which the Amazon Glue job can dynamically retrieve at runtime. This approach eliminates the need to hard-code credentials, enhancing security and flexibility.

The following prerequisites provide step-by-step guidance on how to set up each component for a smooth integration between Amazon Glue and SAP OData.

Topics

- [SAP OData activation](#)
- [IAM policies](#)
- [Connectivity / VPC Connection](#)
- [SAP Authentication](#)
- [Amazon Secrets Manager to store your Auth secret](#)

SAP OData activation

Complete the following steps for SAP OData connection:

ODP Sources

Before you can transfer data from an ODP provider, you must meet the following requirements:

- You have an SAP NetWeaver AS ABAP instance.
- Your SAP NetWeaver instance contains an ODP provider that you want to transfer data from. ODP providers include:
 - SAP DataSources (Transaction code RSO2)
 - SAP Core Data Services ABAP CDS Views

- SAP BW or SAP BW/4HANA systems (InfoObject, DataStore Object)
- Real-time replication of Tables and DB-Views from SAP Source System via SAP Landscape Replication Server (SAP SLT)
- SAP HANA Information Views in SAP ABAP based Sources
- Your SAP NetWeaver instance has the SAP Gateway Foundation component.
- You have created an OData service that extracts data from your ODP provider. To create the OData service, you use the SAP Gateway Service Builder. To access your ODP data, Amazon AppFlow calls this service by using the OData API. For more information, see [Generating a Service for Extracting ODP Data via OData](#) in the SAP BW/4HANA documentation.
- To generate an OData service based on ODP data sources, SAP Gateway Foundation must be installed locally in your ERP/BW stack or in a hub configuration.
 - For your ERP/BW applications, the SAP NetWeaver AS ABAP stack must be at 7.50 SP02 or above.
 - For the hub system (SAP Gateway), the SAP NetWeaver AS ABAP of the hub system must be 7.50 SP01 or above for remote hub setup.

Non-ODP Sources

- Your SAP NetWeaver stack version must be 7.40 SP02 or above.
- You must enable catalog service for service discovery.
 - **OData V2.0:** The OData V2.0 catalog service(s) can be enabled in your SAP Gateway via transaction /IWFND/MAINT_SERVICE
- Your SAP OData service must support client side pagination/query options such as \$top and \$skip. It must also support system query option \$count.
- For OAuth 2.0, you must enable OAuth 2.0 for the OData service and register the OAuth client per SAP documentation and set the authorized redirect URL as follows:
 - `https://<region>.console.aws.amazon.com/gluestudio/oauth`, replacing <region> with the region where Amazon Glue is running, example: us-east-1.
 - You must enable secure setup for connecting over HTTPS.
- You must provide required authorization for the user in SAP to discover the services and extract data using SAP OData services. Please refer to the security documentation provided by SAP.

IAM policies

Policies containing the API operations for creating and using connections

The following sample policy describes the required Amazon IAM permissions for creating and using connections. If you are creating a new role, create a policy that contains the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:ListConnectionTypes",
        "glue:DescribeConnectionType",
        "glue:RefreshOAuth2Tokens",
        "glue:ListEntities",
        "glue:DescribeEntity"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:DescribeSecret",
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutSecretValue"
      ],
      "Resource": "*"
    }
  ]
}
```

The role must grant access to all the resources used by the job, for example Amazon S3. If you don't want to use the above method, alternatively use the following managed IAM policies.

- [AWSGlueServiceRole](#) – Grants access to resources that various Amazon Glue processes require to run on your behalf. These resources include Amazon Glue, Amazon S3, IAM, CloudWatch Logs, and Amazon EC2. If you follow the naming convention for resources specified in this policy,

Amazon Glue processes have the required permissions. This policy is typically attached to roles specified when defining crawlers, jobs, and development endpoints.

- [AWSGlueConsoleFullAccess](#) – Grants full access to Amazon Glue resources when an identity that the policy is attached to uses the Amazon Management Console. If you follow the naming convention for resources specified in this policy, users have full console capabilities. This policy is typically attached to users of the Amazon Glue console.
- [SecretsManagerReadWrite](#) – Provides read/write access to Amazon Secrets Manager via the Amazon Management Console. Note: this excludes IAM actions, so combine with `IAMFullAccess` if rotation configuration is required.

IAM Policies/Permissions needed to configure VPC

The following IAM permissions are required while using VPC connection for creating Amazon Glue Connection. For more details, refer to [create an IAM policy for Amazon Glue](#).

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateNetworkInterface",
        "ec2>DeleteNetworkInterface",
        "ec2:DescribeNetworkInterfaces"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

Connectivity / VPC Connection

Steps for VPC Connection:

1. Use existing VPC connection or create a new connection by following the [Amazon VPC documentation](#).
2. Make sure you have NAT Gateway which routes the traffic to internet.
3. Choose VPC endpoint as Amazon S3 Gateway to create connection.
4. Enable DNS resolution and DNS hostname to use Amazon provided DNS Services.
5. Go to created VPC and add necessary endpoints for different services like STS, Amazon Glue, Secret Managers.
 - a. Choose Create Endpoint.
 - b. For Service Category, choose Amazon Services.
 - c. For Service Name, choose the service that you are connecting to.
 - d. Choose VPC and Enable DNS Name.
 - e. VCP Endpoints required for VPC connection:
 - i. [STS](#)
 - ii. [Amazon Glue](#)
 - iii. [Secrets Manager](#)

Security Group Configuration

Security group must allow traffic to its listening port from Amazon Glue VPC for Amazon Glue to be able to connect to it. It is a good practice to restrict the range of source IP addresses as much as possible.

Amazon Glue requires special security group that allows all inbound traffic from itself. You can create a self-referencing rule that allows all traffic originating from the security group. You can modify an existing security group and specify the security group as source.

Open the communication from the HTTPS ports of the URL endpoint (either NLB or SAP instance).

Connectivity options

- HTTPS connection with internal and external NLB, SSL certificate from certificate authority (CA), not self-signed SSL certificate
- HTTPS connection with SAP instance SSL certificate from certificate authority (CA), not self-signed SSL certificate

SAP Authentication

The SAP connector supports both CUSTOM (this is SAP BASIC authentication) and OAUTH authentication methods.

Custom Authentication

Amazon Glue supports Custom (Basic Authentication) as a method for establishing connections to your SAP systems, allowing the use of a username and password for secure access. This auth type works well for automation scenarios as it allows using username and password up front with the permissions of a particular user in the SAP OData instance. Amazon Glue is able to use the username and password to authenticate SAP OData APIs. In Amazon Glue, basic authorization is implemented as custom authorization.

For public SAP OData documentation for Basic Auth flow, see [HTTP Basic Authentication](#).

OAuth 2.0 Authentication

Amazon Glue also supports OAuth 2.0 as a secure authentication mechanism for establishing connections to your SAP systems. This enables seamless integration while ensuring compliance with modern authentication standards and enhancing the security of data access.

AUTHORIZATION_CODE Grant Type

The grant type determines how Amazon Glue communicates with SAP OData to request access to your data. SAP OData supports only the AUTHORIZATION_CODE grant type. This grant type is considered "three-legged" OAuth as it relies on redirecting users to the third-party authorization server to authenticate the user. It is used when creating connections via the Amazon Glue console.

Users may still opt to create their own connected app in SAP OData and provide their own client ID and client secret when creating connections through the Amazon Glue console. In this scenario, they will still be redirected to SAP OData to login and authorize Amazon Glue to access their resources.

This grant type results in a refresh token and access token. The access token is short lived, and may be refreshed automatically without user interaction using the refresh token.

For public SAP OData documentation on creating a connected app for Authorization Code OAuth flow, see [Authentication Using OAuth 2.0](#).

Amazon Secrets Manager to store your Auth secret

You will need to store the SAP OData connection secrets in Amazon Secrets Manager, configure the necessary permissions for retrieval as specified in the [IAM policies](#) section, and use it while creating a connection.

Use the Amazon Management Console for Amazon Secrets Manager to create a secret for your SAP source. For more information, see [Create an Amazon Secrets Manager secret](#). Details in Amazon Secrets Manager should include the elements in the following code.

Custom Authentication Secret

You will need to enter your SAP system username in place of *<your SAP username>* and its password in place of *<your SAP username password>* and True or False. In this context, setting `basicAuthDisableSSO` to `true` disables Single Sign-On (SSO) for Basic Authentication requests, requiring explicit user credentials for each request. Conversely, setting it to `false` allows the use of existing SSO sessions if available.

```
{
  "basicAuthUsername": "<your SAP username>",
  "basicAuthPassword": "<your SAP username password>",
  "basicAuthDisableSSO": "<True/False>",
  "customAuthenticationType": "CustomBasicAuth"
}
```

OAuth 2.0 Secret

In case you are using OAuth 2.0 as your authentication mechanism, the secret in the Amazon Secrets Manager should have the **User Managed Client Application ClientId** in the following format. You will need to enter your SAP client secret in place of *<your client secret>*.

```
{"USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET": "<your client secret>"
}
```

Create connections

To configure an SAP OData connection:

1. Sign in to the Amazon Management Console and open the [Amazon Glue console](#). In the Amazon Glue Studio, create a connection by following the steps below:
 - a. Click Data connections on the left panel.

- b. Click on **Create connection**.
 - c. Select **SAP OData** in **Choose data source**
 - d. Provide the **Application host URL** of the SAP OData instance you want to connect to. This application host url must be accessible over public internet for non VPC connection.
 - e. Provide the **Application service path** of the SAP OData instance you want to connect to. This is the same as the catalog service path. For example: `/sap/opu/odata/iwfnd/catalogservice;v=2`. Amazon Glue doesn't accept specific object path.
 - f. Provide the **Client number** of the SAP OData instance you want to connect to. Acceptable values are [001-999]. Example: 010
 - g. Provide the **Port number** of the SAP OData instance you want to connect to. Example: 443
 - h. Provide the **Logon language** of the SAP OData instance you want to connect to. Example: EN
 - i. Select the Amazon IAM role which Amazon Glue can assume and has permissions as outlined in the [IAM policies](#) section.
 - j. Select the **Authentication Type** which you want to use for this connection in Amazon Glue from the dropdown list: OAUTH2 or CUSTOM
 - i. CUSTOM - Select the secret you created as specified in the [Amazon Secrets Manager to store your Auth secret](#) section.
 - ii. OAUTH 2.0 - enter the following inputs only in case of OAuth 2.0:
 - A. Under **User Managed Client Application ClientId**, enter your client id.
 - B. `USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET` (your client secret) in the Amazon Secrets Manager that you created in the [Amazon Secrets Manager to store your Auth secret](#) section.
 - C. Under **Authorization Code URL**, enter your authorization code URL.
 - D. Under **Authorization Tokens URL**, enter your authorization token URL.
 - E. Under **OAuth Scopes**, enter your OAuth scopes separated by space. Example: `/IWFND/SG_MED_CATALOG_0002 ZAPI_SALES_ORDER_SRV_0001`
 - k. Select the network options if you want to use your network. For more details, see [Connectivity / VPC Connection](#).
2. Grant the IAM role associated with your Amazon Glue job permission to read `secretName`. For more details, see the [IAM policies](#).
 3. Choose **Test connection** and test your connection. If the connection test passes, click next, enter your connection name and save your connection. Test connection functionality is not available if you have chosen Network options (VPC).

Creating SAP OData job

Refer to [Building visual ETL jobs with Amazon Glue Studio](#)

Operational Data Provisioning (ODP) Sources

Operational Data Provisioning (ODP) provides a technical infrastructure that you can use to support data extraction and replication for various target applications and supports delta mechanisms in these scenarios. In case of a delta procedure, the data from a source (ODP Provider) is automatically written to a delta queue (Operational Delta Queue – ODQ) using an update process or passed to the delta queue using an extractor interface. An ODP Provider can be a DataSource (extractors), ABAP Core Data Services Views (ABAP CDS Views), SAP BW or SAP BW/4HANA, SAP Landscape Transformation Replication Server (SLT), and SAP HANA Information Views (calculation views). The target applications (referred to as ODQ 'subscribers' or more generally "ODP Consumers") retrieve the data from the delta queue and continue processing the data.

Full Load

In the context of SAP OData and ODP entities, a **Full Load** refers to the process of extracting all available data from an ODP entity in a single operation. This operation retrieves the complete dataset from the source system, ensuring that the target system has a comprehensive and up-to-date copy of the entity's data. Full loads are typically used for sources that do not support incremental loads or when a refresh of the target system is required.

Example

You can explicitly set the ENABLE_CDC flag to false, when creating the DynamicFrame. Note: ENABLE_CDC is false by default, if you don't want to initialize the delta queue, you don't have to send this flag or set it to true. Not setting this flag to true will result in a full load extraction.

```
sapodata_df = glueContext.create_dynamic_frame.from_options(  
    connection_type="SAP0Data",  
    connection_options={  
        "connectionName": "connectionName",  
        "ENTITY_NAME": "entityName",  
        "ENABLE_CDC": "false"  
    }, transformation_ctx=key)
```

Incremental Load

An **incremental load** in the context of ODP (Operational Data Provisioning) entities involves extracting only the new or changed data (deltas) from the source system since the last data extraction, avoiding preprocessing the already processed records. This approach significantly improves efficiency, reduces data transfer volumes, enhances performance, ensures efficient synchronization between systems, and minimizes processing time, especially for large datasets that change frequently.

Delta Token based Incremental Transfers

To enable Incremental Transfer using Change Data Capture (CDC) for ODP-enabled entities that support it, follow these steps:

1. Create the Incremental Transfer job in script mode.
2. When creating the DataFrame or Glue DynamicFrame, you need to pass the option "ENABLE_CDC": "True". This option ensures that you will receive a Delta Token from SAP, which can be used for subsequent retrieval of changed data.

The delta token will be present in the last row of the dataframe, in the DELTA_TOKEN column. This token can be used as a connector option in subsequent calls to incrementally retrieve the next set of data.

Example

- We set the ENABLE_CDC flag to true, when creating the DynamicFrame. Note: ENABLE_CDC is false by default, if you don't want to initialize the delta queue, you don't need to send this flag or set it to true. Not setting this flag to true will result in a full load extraction.

```
sapodata_df = glueContext.create_dynamic_frame.from_options(
    connection_type="SAPOData",
    connection_options={
        "connectionName": "connectionName",
        "ENTITY_NAME": "entityName",
        "ENABLE_CDC": "true"
    }, transformation_ctx=key)

# Extract the delta token from the last row of the DELTA_TOKEN column
delta_token_1 = your_logic_to_extract_delta_token(sapodata_df) # e.g.,
D20241029164449_000370000
```

- The extracted delta token can be passed as a an option to retrieve new events.

```
sapodata_df_2 = glueContext.create_dynamic_frame.from_options(
    connection_type="SAPOData",
    connection_options={
        "connectionName": "connectionName",
        "ENTITY_NAME": "entityName",
        // passing the delta token retrieved in the last run
        "DELTA_TOKEN": delta_token_1
    } , transformation_ctx=key)

# Extract the new delta token for the next run
delta_token_2 = your_logic_to_extract_delta_token(sapodata_df_2)
```

Note that the last record, in which the DELTA_TOKEN is present, is not a transactional record from source, and is only there for the purpose of passing the delta token value.

Apart from the DELTA_TOKEN, the following fields are returned in each row of the dataframe.

- **GLUE_FETCH_SQ**: This is a sequence field, generated from the EPOCH timestamp in the order the record was received, and is unique for each record. This can be used if you need to know or establish the order of changes in the source system. This field will be present only for ODP enabled entities.
- **DML_STATUS**: This will show UPDATED for all newly inserted and updated records from the source, and DELETED for records that have been deleted from source.

For more details about how to manage state and reuse the delta token to retrieve changed records through an example refer to the [Using the SAP OData state management script](#) section.

Delta Token Invalidation

A delta token is associated with the service collection and a user. If a new initial pull with “ENABLE_CDC” : “true” is initiated for the same service collection and the user, all previous delta tokens issued as a result of a previous initialization will be invalidated by SAP OData service. Invoking the connector with an expired delta token will lead to an exception:

```
Could not open data access via extraction API RODPS_REPL_ODP_OPEN
```

OData Services (Non-ODP Sources)

Full Load

For Non-ODP (Operational Data Provisioning) systems, a **Full Load** involves extracting the entire dataset from the source system and loading it into the target system. Since Non-ODP systems do not inherently support advanced data extraction mechanisms like deltas, the process is straightforward but can be resource-intensive depending on the size of the data.

Incremental Load

For systems or entities that do not support **ODP (Operational Data Provisioning)**, incremental data transfer can be managed manually by implementing a timestamp based mechanism to track and extract changes.

Timestamp based Incremental Transfers

For non-ODP enabled entities (or for ODP enabled entities that don't use the `ENABLE_CDC` flag), we can use a `filteringExpression` option in the connector to indicate the `datetime` interval for which we want to retrieve data. This method relies on a timestamp field in your data that represents when each record was last created/modified.

Example

Retrieving records that changed after 2024-01-01T00:00:00.000

```
sapodata_df = glueContext.create_dynamic_frame.from_options(  
    connection_type="SAPOData",  
    connection_options={  
        "connectionName": "connectionName",  
        "ENTITY_NAME": "entityName",  
        "filteringExpression": "LastChangeDateTime >= 2024-01-01T00:00:00.000"  
    }, transformation_ctx=key)
```

Note: In this example, `LastChangeDateTime` is the field that represents when each record was last modified. The actual field name may vary depending on your specific SAP OData entity.

To get a new subset of data in subsequent runs, you would update the `filteringExpression` with a new timestamp. Typically, this would be the maximum timestamp value from the previously retrieved data.

Example

```
max_timestamp = get_max_timestamp(sapodata_df) # Function to get the max timestamp
from the previous run
next_filtering_expression = f"LastChangeDateTime > {max_timestamp}"

# Use this next_filtering_expression in your next run
```

In the next section, we will provide an automated approach to manage these timestamp-based incremental transfers, eliminating the need to manually update the filtering expression between runs.

Writing to SAP OData

This section describes how to write data to your SAP OData Service using the Amazon Glue connector for SAP OData.

Prerequisites

- Access to an SAP OData service
- An SAP OData EntitySet Object you would like to write to. You will need the Object name.
- Valid SAP OData credentials and a valid connection
- Appropriate permissions as described in [IAM policies](#)

The SAP OData connector supports two write operations:

- INSERT
- UPDATE

While using the UPDATE write operation, ID_FIELD_NAMES must be provided to specify the external ID field for the records.

Example:

```
sapodata_write = glueContext.write_dynamic_frame.from_options(
    frame=frameToWrite,
    connection_type="sapodata",
    connection_options={
        "connectionName": "connectionName",
```

```
"ENTITY_NAME": "entityName",  
"WRITE_OPERATION": "INSERT"  
}
```

Using the SAP OData state management script

To use the SAP OData state management script in your Amazon Glue job, follow these steps:

- Download the state management script: `s3://aws-blogs-artifacts-public/artifacts/BDB-4789/sap_odata_state_management.zip` from the public Amazon S3 bucket.
- Upload the script to an Amazon S3 bucket that your Amazon Glue job has permissions to access.
- Reference the script in your Amazon Glue job: When creating or updating your Amazon Glue job, pass the `'--extra-py-files'` option referencing the script path in your Amazon S3 bucket. For example: `--extra-py-files s3://your-bucket/path/to/sap_odata_state_management.py`
- Import and use the state management library in your Amazon Glue job scripts.

Delta-token based Incremental Transfer example

Here's an example of how to use the state management script for delta-token based incremental transfers:

```
from sap_odata_state_management import StateManagerFactory, StateManagerType, StateType  
  
# Initialize the state manager  
state_manager = StateManagerFactory.create_manager(  
    manager_type=StateManagerType.JOB_TAG,  
    state_type=StateType.DELTA_TOKEN,  
    options={  
        "job_name": args['JOB_NAME'],  
        "logger": logger  
    }  
)  
  
# Get connector options (including delta token if available)  
key = "SAP0DataNode"  
connector_options = state_manager.get_connector_options(key)  
  
# Use the connector options in your Glue job  
df = glueContext.create_dynamic_frame.from_options(  

```

```

connection_type="SAPOData",
connection_options={
    "connectionName": "connectionName",
    "ENTITY_NAME": "entityName",
    "ENABLE_CDC": "true",
    **connector_options
}
)

# Process your data here...

# Update the state after processing
state_manager.update_state(key, sapodata_df.toDF())

```

Timestamp based Incremental Transfer example

Here's an example of how to use the state management script for delta-token based incremental transfers:

```

from sap_odata_state_management import StateManagerFactory, StateManagerType, StateType

# Initialize the state manager
state_manager = StateManagerFactory.create_manager(
    manager_type=StateManagerType.JOB_TAG,
    state_type=StateType.DELTA_TOKEN,
    options={
        "job_name": args['JOB_NAME'],
        "logger": logger
    }
)

# Get connector options (including delta token if available)
key = "SAPODataNode"
connector_options = state_manager.get_connector_options(key)

# Use the connector options in your Glue job
df = glueContext.create_dynamic_frame.from_options(
    connection_type="SAPOData",
    connection_options={
        "connectionName": "connectionName",
        "ENTITY_NAME": "entityName",
        "ENABLE_CDC": "true",
        **connector_options
    }
)

```

```
    }  
  )  
  
  # Process your data here...  
  
  # Update the state after processing  
  state_manager.update_state(key, sapodata_df.toDF())
```

In both examples, the state management script handles the complexities of storing the state (either delta token or timestamp) between job runs. It automatically retrieves the last known state when getting connector options and updates the state after processing, ensuring that each job run only processes new or changed data.

Partitioning for Non ODP entities

In Apache Spark, partitioning refers to the way data is divided and distributed across the worker nodes in a cluster for parallel processing. Each partition is a logical chunk of data that can be processed independently by a task. Partitioning is a fundamental concept in Spark that directly impacts performance, scalability, and resource utilization. Amazon Glue jobs use Spark's partitioning mechanism to divide the dataset into smaller chunks (partitions) that can be processed in parallel across the cluster's worker nodes. Note that partitioning is not applicable for ODP entities.

For more details, see [Amazon Glue Spark and PySpark jobs](#).

Prerequisites

An SAP OData's Object you would like to read from. You will need the object/EntitySet name. For example: `/sap/opu/odata/sap/API_SALES_ORDER_SRV/A_SalesOrder` .

Example

```
sapodata_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="SAPOData",  
    connection_options={  
        "connectionName": "connectionName",  
        "ENTITY_NAME": "/sap/opu/odata/sap/API_SALES_ORDER_SRV/A_SalesOrder"  
    }, transformation_ctx=key)
```

Partitioning Queries

Field Based partitioning

You can provide the additional Spark options `PARTITION_FIELD`, `LOWER_BOUND`, `UPPER_BOUND`, and `NUM_PARTITIONS` if you want to utilize concurrency in Spark. With these parameters, the original query would be split into `NUM_PARTITIONS` number of sub-queries that can be executed by Spark tasks concurrently. Integer, Date and DateTime fields support field-based partitioning in the SAP OData connector.

- `PARTITION_FIELD`: the name of the field to be used to partition the query.
- `LOWER_BOUND`: an inclusive lower bound value of the chosen partition field.

For any field whose data type is DateTime, the Spark timestamp format used in Spark SQL queries is accepted.

Examples of valid values: "2000-01-01T00:00:00.000Z"

- `UPPER_BOUND`: an exclusive upper bound value of the chosen partition field.
- `NUM_PARTITIONS`: number of partitions.
- `PARTITION_BY`: the type partitioning to be performed, `FIELD` to be passed in case of Field based partitioning.

Example

```
sapodata= glueContext.create_dynamic_frame.from_options(  
    connection_type="sapodata",  
    connection_options={  
        "connectionName": "connectionName",  
        "ENTITY_NAME": "/sap/opu/odata/sap/SEPM_HCM_SCENARIO_SRV/EmployeeSet",  
        "PARTITION_FIELD": "validStartDate"  
        "LOWER_BOUND": "2000-01-01T00:00:00.000Z"  
        "UPPER_BOUND": "2020-01-01T00:00:00.000Z"  
        "NUM_PARTITIONS": "10",  
        "PARTITION_BY": "FIELD"  
    }, transformation_ctx=key)
```

Record Based partitioning

The original query would be split into `NUM_PARTITIONS` number of sub-queries that can be executed by Spark tasks concurrently.

Record-based partitioning is only supported for non-ODP entities, as pagination in ODP entities is supported through the next token/skip token.

- **PARTITION_BY**: the type partitioning to be performed. **COUNT** is to be passed in case of record-based partitioning.

Example

```
sapodata= glueContext.create_dynamic_frame.from_options(  
    connection_type="sapodata",  
    connection_options={  
        "connectionName": "connectionName",  
        "ENTITY_NAME": "/sap/opu/odata/sap/SEPM_HCM_SCENARIO_SRV/EmployeeSet",  
        "NUM_PARTITIONS": "10",  
        "PARTITION_BY": "COUNT"  
    }, transformation_ctx=key)
```

Limitations / Callouts

- ODP entities are not compatible with Record Based Partitioning since pagination is handled using skip token/delta token. Consequently, for Record Based Partitioning, the default value for **maxConcurrency** is set to "null" irrespective of the user input.
- When both **limit** and **partition** is applied, the **limit** takes precedence over partitioning.

SAP OData connection options

The following are connection options for SAP OData:

- **ENTITY_NAME**(String) - (Required) Used for Read. The name of your object in SAP OData.

For example: /sap/opu/odata/sap/API_SALES_ORDER_SRV/A_SalesOrder

- **API_VERSION**(String) - (Optional) Used for Read. SAP OData Rest API version you want to use.
Example: 2.0.
- **SELECTED_FIELDS**(List<String>) - Default: empty(SELECT *). Used for Read. Columns you want to select for the object.

For example: SalesOrder

- **FILTER_PREDICATE(String)** - Default: empty. Used for Read. It should be in the Spark SQL format.

For example: `SalesOrder = "10"`

- **QUERY(String)** - Default: empty. Used for Read. Full Spark SQL query.

For example: `SELECT * FROM /sap/opu/odata/sap/API_SALES_ORDER_SRV/A_SalesOrder`

- **PARTITION_FIELD(String)** - Used for Read. Field to be used to partition query.

For example: `ValidStartDate`

- **LOWER_BOUND(String)**- Used for Read. An inclusive lower bound value of the chosen partition field.

For example: `"2000-01-01T00:00:00.000Z"`

- **UPPER_BOUND(String)** - Used for Read. An exclusive upper bound value of the chosen partition field.

For example: `"2024-01-01T00:00:00.000Z"`

- **NUM_PARTITIONS(Integer)** - Default: 1. Used for Read. Number of partitions for read.

- **INSTANCE_URL(String)** - The SAP instance application host URL.

For example: `https://example-externaldata.sierra.aws.dev`

- **SERVICE_PATH(String)** - The SAP instance application service path.

For example: `/sap/opu/odata/iwfnd/catalogservice;v=2`

- **CLIENT_NUMBER(String)** - The SAP instance application client number.

For example: `100`

- **PORT_NUMBER(String)** - Default: The SAP instance application port number.

For example: `443`

- **LOGON_LANGUAGE(String)** - The SAP instance application logon language.

For example: `EN`

- **ENABLE_CDC(String)** - Defines whether to run a job with CDC enabled, that is, with track changes.

For example: True/False

- DELTA_TOKEN(String) - Runs an incremental data pull based on the valid Delta Token supplied.

For example: D20241107043437_000463000

- PAGE_SIZE(Integer) - Defines the page size for querying the records. The default page size is 50,000. When a page size is specified, SAP returns only the defined number of records per API call, rather than the entire dataset. The connector will still provide the total number of records and handle pagination using your specified page size. If you require a larger page size, you can choose any value up to 500,000, which is the maximum allowed. Any specified page size exceeding 500,000 will be ignored. Instead, the system will use the maximum allowed page size. You can specify the page size in the Amazon Glue Studio UI by adding a connection option PAGE_SIZE with your desired value.

For example: 20000

SAP OData entity and field details

Entity	Data type	Supported operators

Connecting to Snowflake in Amazon Glue Studio

Note

You can use Amazon Glue for Spark to read from and write to tables in Snowflake in Amazon Glue 4.0 and later versions. To configure a Snowflake connection with Amazon Glue jobs programatically, see [Redshift connections](#).

Amazon Glue provides built-in support for Snowflake. Amazon Glue Studio provides a visual interface to connect to Snowflake, author data integration jobs, and run them on the Amazon Glue Studio serverless Spark runtime.

Amazon Glue Studio creates a unified connection for Snowflake. For more information, see [Considerations](#).

Topics

- [Creating a Snowflake connection](#)
- [Creating a Snowflake source node](#)
- [Creating a Snowflake target node](#)
- [Advanced options](#)

Creating a Snowflake connection

Note

Unified connections (connection v2) standardize all connections to use USERNAME, PASSWORD keys for basic auth credentials. You can still create a v1 connection via API with secrets containing sfUser, sfPassword.

When adding a **Data source - Snowflake** node in Amazon Glue Studio, you can choose an existing Amazon Glue Snowflake connection or create a new connection. You must choose a SNOWFLAKE type connection and not a JDBC type connection configured to connect to Snowflake. Follow the following procedure to create a Amazon Glue Snowflake connection:

To create a Snowflake connection

1. In Snowflake, generate a user, *snowflakeUser* and password, *snowflakePassword*.
2. Determine which Snowflake warehouse this user will interact with, *snowflakeWarehouse*. Either set it as the DEFAULT_WAREHOUSE for *snowflakeUser* in Snowflake or remember it for the next step.
3. In Amazon Secrets Manager, create a secret using your Snowflake credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for *snowflakeUser* with the key sfUser.
 - When selecting **Key/value pairs**, create a pair for *snowflakePassword* with the key sfPassword.
 - When selecting **Key/value pairs**, create a pair for *snowflakeWarehouse* with the key sfWarehouse. This is not needed if a default is set in Snowflake.
4. In the Amazon Glue Data Catalog, create a connection by following the steps in [Adding an Amazon Glue connection](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
 - When selecting a **Connection type**, select Snowflake.
 - When selecting **Snowflake URL**, provide the hostname of your Snowflake instance. The URL will use a hostname in the form *account_identifier*.snowflakecomputing.com.
 - When selecting an **Amazon Secret**, provide *secretName*.

Creating a Snowflake source node

Permissions needed

Amazon Glue Studio jobs using Snowflake data sources require additional permissions. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

SNOWFLAKE Amazon Glue connections use an Amazon Secrets Manager secret to provide credential information. Your job and data preview roles in Amazon Glue Studio must have permission to read this secret.

Adding a Snowflake data source

Prerequisites:

- An Amazon Secrets Manager secret for your Snowflake credentials
- A Snowflake type Amazon Glue Data Catalog connection

To add a Data Source – Snowflake node:

1. Choose the connection for your Snowflake data source. This assumes that the connection already exists and you can select from existing connections. If you need to create a connection, choose **Create Snowflake connection**. For more information, see [Overview of using connectors and connections](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**. Information about the connection are visible, including URL, security groups, subnet, availability zone, description, and created (UTC) and last updated (UTC) timestamps.

2. Choose a Snowflake source option:
 - **Choose a single table** – this is the table that contains the data you want to access from a single Snowflake table.
 - **Enter custom query** – allows you to access a dataset from multiple Snowflake tables based on your custom query.
3. If you chose a single table, enter the name of a Snowflake schema.

Or, choose **Enter custom query**. Choose this option to access a custom dataset from multiple Snowflake tables. When you choose this option, enter the Snowflake query.

4. In **Performance and security** options (optional),
 - **Enable query pushdown** – choose if you want to offload work to the Snowflake instance.
5. In **Custom Snowflake properties** (optional), enter parameters and values as needed.

Creating a Snowflake target node

Permissions needed

Amazon Glue Studio jobs using Snowflake data sources require additional permissions. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

SNOWFLAKE Amazon Glue connections use an Amazon Secrets Manager secret to provide credential information. Your job and data preview roles in Amazon Glue Studio must have permission to read this secret.

Adding a Snowflake data target

To create a Snowflake target node:

1. Choose an existing Snowflake table as the target, or enter a new table name.
2. When you use the **Data target - Snowflake** target node, you can choose from the following options:
 - **APPEND** – If a table already exists, dump all the new data into the table as an insert. If the table doesn't exist, create it and then insert all new data.
 - **MERGE** – Amazon Glue will update or append data to your target table based on the conditions you specify.

Choose options:

- **Choose keys and simple actions** – choose the columns to be used as matching keys between the source data and your target data set.

Specify the following options when matched:

- Update record in your target data set with data from source.
- Delete record in your target data set.

Specify the following options when not matched:

- Insert source data as a new row into your target data set.
- Do nothing.
- **Enter custom MERGE statement** – You can then choose **Validate Merge statement** to verify that the statement is valid or invalid.

- **TRUNCATE** – If a table already exists, truncate the table data by first clearing the contents of the target table. If truncate is successful, then insert all data. If the table doesn't exist, create the table and insert all data. If truncate is not successful, the operation will fail.
- **DROP** – If a table already exists, delete the table metadata and data. If deletion is successful, then insert all data. If the table doesn't exist, create the table and insert all data. If drop is not successful, the operation will fail.

Advanced options

See [Snowflake connections](#) in the Amazon Glue developer guide.

Connecting to Teradata Vantage in Amazon Glue Studio

Amazon Glue provides built-in support for Teradata Vantage. Amazon Glue Studio provides a visual interface to connect to Teradata, author data integration jobs, and run them on the Amazon Glue Studio serverless Spark runtime.

Amazon Glue Studio creates a unified connection for Teradata Vantage. For more information, see [Considerations](#).

Topics

- [Creating a Teradata Vantage connection](#)
- [Creating a Teradata source node](#)
- [Creating a Teradata target node](#)
- [Advanced options](#)

Creating a Teradata Vantage connection

To connect to Teradata Vantage from Amazon Glue, you will need to create and store your Teradata credentials in an Amazon Secrets Manager secret, then associate that secret with a Amazon Glue Teradata connection.

Prerequisites:

- If you are accessing your Teradata environment through Amazon VPC, configure Amazon VPC to allow your Amazon Glue job to communicate with the Teradata environment. We discourage accessing the Teradata environment over the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that Amazon Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Teradata instance and this location. Your job will need to establish a TCP connection with your Teradata client port. For more information about Teradata ports, see the [Teradata documentation](#).

Based on your network layout, secure VPC connectivity may require changes in Amazon VPC and other networking services. For more information about Amazon connectivity, consult [Amazon Connectivity Options](#) in the Teradata documentation.

To configure a Amazon Glue Teradata connection:

1. In your Teradata configuration, identify or create a user and password Amazon Glue will connect with, *teradataUser* and *teradataPassword*. For more information, consult [Vantage Security Overview](#) in the Teradata documentation.
2. In Amazon Secrets Manager, create a secret using your Teradata credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key user with the value *teradataUsername*.
 - When selecting **Key/value pairs**, create a pair for the key password with the value *teradataPassword*.
3. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
 - When selecting a **Connection type**, select Teradata.
 - When providing **JDBC URL**, provide the URL for your instance. You can also hardcode certain comma separated connection parameters in your JDBC URL. The URL must conform to the following format:
`jdbc:teradata://teradataHostname/ParameterName=ParameterValue,ParameterName`

Supported URL parameters include:

 - DATABASE– name of database on host to access by default.

- DBS_PORT– the database port, used when running on a nonstandard port.
 - When selecting a **Credential type**, select **Amazon Secrets Manager**, then set **Amazon Secret** to *secretName*.
4. In the following situations, you may require additional configuration:
- For Teradata instances hosted on Amazon in an Amazon VPC
 - You will need to provide Amazon VPC connection information to the Amazon Glue connection that defines your Teradata security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

Creating a Teradata source node

Prerequisites needed

- An Amazon Glue Teradata Vantage connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called “Creating a Teradata Vantage connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Teradata table you would like to read from, *tableName*, or query *targetQuery*.

Adding a Teradata data source

To add a Data source – Teradata node:

1. Choose the connection for your Teradata data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create a new connection**. For more information see the previous section, [the section called “Creating a Teradata Vantage connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **Teradata Source** option:
 - **Choose a single table** – access all data from a single table.
 - **Enter custom query** – access a dataset from multiple tables based on your custom query.
3. If you chose a single table, enter *tableName*.

If you chose **Enter custom query**, enter a SQL SELECT query.

4. In **Custom Teradata properties**, enter parameters and values as needed.

Creating a Teradata target node

Prerequisites needed

- A Amazon Glue Teradata Vantage connection, configured with an Amazon Secrets Manager secret, as described in the previous section, [the section called “Creating a Teradata Vantage connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Teradata table you would like to write to, *tableName*.

Adding a Teradata data target

To add a Data target – Teradata node:

1. Choose the connection for your Teradata data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Teradata connection**. For more information, see [Overview of using connectors and connections](#) .

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Configure **Table name** by providing *tableName*.
3. In **Custom Teradata properties**, enter parameters and values as needed.

Advanced options

You can provide advanced options when creating a Teradata node. These options are the same as those available when programming Amazon Glue for Spark scripts.

See [the section called “Teradata Vantage connections”](#).

Connecting to Vertica in Amazon Glue Studio

Amazon Glue provides built-in support for Vertica. Amazon Glue Studio provides a visual interface to connect to Vertica, author data integration jobs, and run them on the Amazon Glue Studio serverless Spark runtime.

Amazon Glue Studio creates a unified connection for Vertica. For more information, see [Considerations](#).

Topics

- [Creating a Vertica connection](#)
- [Creating a Vertica source node](#)
- [Creating a Vertica target node](#)
- [Advanced options](#)

Creating a Vertica connection

Prerequisites:

- An Amazon S3 bucket or folder to use for temporary storage when reading from and writing to the database, referred to by *tempS3Path*.

Note

When using Vertica in Amazon Glue job data previews, temporary files may not be automatically removed from *tempS3Path*. To ensure the removal of temporary files, directly end the data preview session by choosing **End session** in the **Data preview** pane. If you cannot guarantee the data preview session is ended directly, consider setting Amazon S3 Lifecycle configuration to remove old data. We recommend removing data older than 49 hours, based on maximum job runtime plus a margin. For more information about configuring Amazon S3 Lifecycle, see [Managing your storage lifecycle](#) in the Amazon S3 documentation.

- An IAM policy with appropriate permissions to your Amazon S3 path you can associate with your Amazon Glue job role.
- If your Vertica instance is in an Amazon VPC, configure Amazon VPC to allow your Amazon Glue job to communicate with the Vertica instance without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that Amazon Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Vertica instance and this location. Your job will need to establish a TCP connection with your Vertica client port, (default 5433). Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

To configure a connection to Vertica:

1. In Amazon Secrets Manager, create a secret using your Vertica credentials, *verticaUsername* and *verticaPassword*. To create a secret in Secrets Manager, follow the tutorial available in [Create an Amazon Secrets Manager secret](#) in the Amazon Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
 - When selecting **Key/value pairs**, create a pair for the key user with the value *verticaUsername*.
 - When selecting **Key/value pairs**, create a pair for the key password with the value *verticaPassword*.
2. In the Amazon Glue console, create a connection by following the steps in [the section called "Adding an Amazon Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
 - When selecting a **Connection type**, select Vertica.
 - When selecting **Vertica Host**, provide the hostname of your Vertica installation.
 - When selecting **Vertica Port**, the port your Vertica installation is available through.
 - When selecting an **Amazon Secret**, provide *secretName*.
3. In the following situations, you may require additional configuration:
 - For Vertica instances hosted on Amazon in an Amazon VPC
 - Provide Amazon VPC connection information to the Amazon Glue connection that defines your Vertica security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

You will need to perform the following steps before running your Amazon Glue job:

- Grant the IAM role associated with your Amazon Glue job permissions to *tempS3Path*.
- Grant the IAM role associated with your Amazon Glue job permission to read *secretName*.

Creating a Vertica source node

Prerequisites needed

- A Vertica type Amazon Glue Data Catalog connection, *connectionName* and a temporary Amazon S3 location, *tempS3Path*, as described in the previous section, [the section called "Creating a Vertica connection"](#).
- A Vertica table you would like to read from, *tableName*, or query *targetQuery*.

Adding a Vertica data source

To add a Data source – Vertica node:

1. Choose the connection for your Vertica data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Vertica connection**. For more information see the previous section, [the section called "Creating a Vertica connection"](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose the **Database** containing your table.
3. Choose the **Staging area in Amazon S3**, enter an S3A URI to *tempS3Path*.
4. Choose the **Vertica Source**.
 - **Choose a single table** – access all data from a single table.
 - **Enter custom query** – access a dataset from multiple tables based on your custom query.
5. If you chose a single table, enter *tableName* and optionally select a **Schema**.

If you chose **Enter custom query**, enter a SQL SELECT query and optionally select a **Schema**.

6. In **Custom Vertica properties**, enter parameters and values as needed.

Creating a Vertica target node

Prerequisites needed

- A Vertica type Amazon Glue Data Catalog connection, *connectionName* and a temporary Amazon S3 location, *tempS3Path*, as described in the previous section, [the section called “Creating a Vertica connection”](#).

Adding a Vertica data target

To add a Data target – Vertica node:

1. Choose the connection for your Vertica data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Vertica connection**. For more information see the previous section, [the section called “Creating a Vertica connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose the **Database** containing your table.
3. Choose the **Staging area in Amazon S3**, enter an S3A URI to *tempS3Path*.
4. Enter *tableName* and optionally select a **Schema**.
5. In **Custom Vertica properties**, enter parameters and values as needed.

Advanced options

You can provide advanced options when creating a Vertica node. These options are the same as those available when programming Amazon Glue for Spark scripts.

See [the section called “Vertica connections”](#).

Adding a JDBC connection using your own JDBC drivers

You can use your own JDBC driver when using a JDBC connection. When the default driver utilized by the Amazon Glue crawler is unable to connect to a database, you can use your own JDBC Driver. For example, if you want to use SHA-256 with your Postgres database, and older postgres drivers do not support this, you can use your own JDBC driver.

Supported datasources

Supported datasources	Unsupported datasources
MySQL	Snowflake
Postgres	
Oracle	
Redshift	
SQL Server	
Aurora*	

*Supported if the native JDBC driver is being used. Not all driver features can be leveraged.

Adding a JDBC driver to a JDBC connection

Note

If you choose to bring in your own JDBC driver versions, Amazon Glue crawlers will consume resources in Amazon Glue jobs and Amazon S3 buckets to ensure your provided driver are run in your environment. The additional usage of resources will be reflected in your account. The cost for Amazon Glue crawlers and jobs is under the Amazon Glue category in billing. Additionally, providing your own JDBC driver does not mean that the crawler is able to leverage all of the driver's features.

To add your own JDBC driver to a JDBC connection:

1. Add the JDBC driver file to an Amazon S3 location. You can create a bucket and/or folder or use an existing bucket and/or folder.
2. In the Amazon Glue console, choose **Connections** in the left-hand menu under **Data Catalog**, then create a new connection.
3. Complete the fields for **Connection properties** and choose JDBC for **Connection type**.

- In **Connection access**, enter the **JDBC URL** and **JDBC Driver Class name** – *optional*. The driver class name must be for a datasource supported by Amazon Glue crawlers.

Connection access

JDBC URL
Use the JDBC protocol to access Amazon Redshift, Amazon RDS, and publicly accessible databases.

JDBC syntax for most database engines is jdbc:protocol://host:port/databasename.

JDBC Driver Class name - optional

Type a custom JDBC driver class name for the crawler to connect to the data source.

JDBC Driver S3 Path - optional

✕
View
Browse S3

Browse for or enter an existing S3 path to a .jar file.

Please note that if you choose to bring in your own JDBC driver versions to be used with Glue Crawlers, the Glue Crawlers will consume resources in Glue Jobs and S3 to ensure your provided driver are run in your environment. The additional usage of resources will be reflected in your account.

Credential type

Username and password

Secret

Username

Password

- Choose the Amazon S3 path where the JDBC driver is located in the **JDBC Driver Amazon S3 Path** – *optional* field.
- Complete the fields for Credential type if entering a username and password or secret. When complete, choose **Create connection**.

Note

Testing connection is not supported currently. When crawling the data source with a JDBC driver you provided, the crawler skips this step.

7. Add the newly created connection to a crawler. In the Amazon Glue console, choose **Crawlers** in the left-hand menu under **Data Catalog**, then create a new crawler.
8. In the **Add crawler** wizard, in Step 2 choose **Add a data source**.

Add data source

✕

Data source
Choose the source of data to be crawled.

JDBC
▼

Connection
Select a connection to access the data sources below.

mysql-connection068fd134-c2f1-4234-ad6b-345968e73be8
▼

↻

Clear selection

Add new connection
↗

Include path

public/%
▼

You can substitute the percent (%) character for a schema or table. For databases that support schemas, enter MyDatabase/MySchema/% to match all tables in MySchema within MyDatabase. Oracle Database and MySQL don't support schema in the path; instead, enter MyDatabase/%. For Oracle database without SSL, MyDatabase can be either the system identifier (SID) or the service name (SERVICE_NAME). For Oracle database with SSL, MyDatabase must be the service name (SERVICE_NAME).

Additional metadata - optional

Select additional metadata properties for the crawler to crawl.

Exclude tables matching pattern

Cancel

Add a JDBC data source

9. Choose **JDBC** as the data source and choose the the connection that was created in the previous steps. Complete
10. In order to use your own JDBC driver with a Amazon Glue crawler, add the following permissions to the role used by the crawler:

- Grant permissions for the following job actions: CreateJob, DeleteJob, GetJob, GetJobRun, StartJobRun.
- Grant permissions for IAM actions: iam:PassRole
- Grant permissions for Amazon S3 actions: s3:DeleteObjects, s3:GetObject, s3:ListBucket, s3:PutObject.
- Grant service principal access to bucket/folder in the IAM policy.

Example IAM policy:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObject",
        "s3:ListBucket",
        "s3:DeleteObject"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/driver-parent-folder/driver.jar",
        "arn:aws:s3:::amzn-s3-demo-bucket"
      ]
    }
  ]
}
```

The Amazon Glue crawler creates two folders: `_glue_job_crawler` and `_crawler`.

If the driver jar is located in the `s3://amzn-s3-demo-bucket/driver.jar` folder, add the following resources:

```
"Resource": [
```

```

        "arn:aws:s3:::amzn-s3-demo-bucket/_glue_job_crawler/*",
        "arn:aws:s3:::amzn-s3-demo-bucket/_crawler/*"
    ]

```

If the driver jar is located in the `s3://amzn-s3-demo-bucket/tmp/driver/subfolder/driver.jar` folder, add the following resources:

```

"Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket/tmp/_glue_job_crawler/*",
    "arn:aws:s3:::amzn-s3-demo-bucket/tmp/_crawler/*"
]

```

11. If you are using a VPC, you must allow access to the Amazon Glue endpoint by creating the interface endpoint and add it to your route table. For more information, see [Creating an interface VPC endpoint for Amazon Glue](#)
12. If you are using encryption in your Data Catalog, create the Amazon KMS interface endpoint and add it to your route table. For more information, see [Creating a VPC endpoint for Amazon KMS](#).

Using custom connectors and connections with Amazon Glue Studio

Amazon Glue provides built-in support for the most commonly used data stores (such as Amazon Redshift, Amazon Aurora, Microsoft SQL Server, MySQL, MongoDB, and PostgreSQL) using JDBC connections. Amazon Glue also allows you to use custom JDBC drivers in your extract, transform, and load (ETL) jobs. For data stores that are not natively supported, such as SaaS applications, you can use connectors.

A *connector* is an optional code package that assists with accessing data stores in Amazon Glue Studio. You can subscribe to several connectors offered in Amazon Web Services Marketplace.

When creating ETL jobs, you can use a natively supported data store, a connector from Amazon Web Services Marketplace, or your own custom connectors. If you use a connector, you must first create a connection for the connector. A *connection* contains the properties that are required to connect to a particular data store. You use the connection with your data sources and data targets in the ETL job. Connectors and connections work together to facilitate access to the data stores.

The following connections are available when creating connections for connectors:

- **Amazon Aurora** – a scalable, high-performance relational database engine with built-in security, backup and restore, and in-memory acceleration.
- **Amazon DocumentDB** – a scalable, highly available, and fully managed document database service that supports MongoDB and SQL APIs.
- **Amazon Redshift** – a scalable, highly available, and fully managed document database service that supports MongoDB and SQL APIs.
- **Azure SQL** – a cloud-based relational database service from Microsoft Azure that provides scalable, reliable, and secure data storage and management capabilities.
- **Cosmos DB** – a globally distributed cloud database service from Microsoft Azure that provides scalable, high-performance data storage and querying capabilities.
- **Google BigQuery** – a serverless cloud data warehouse for running fast SQL queries on large datasets.
- **JDBC** – a relational database management system (RDBMS) that uses a Java API for connecting and interacting with data connections.
- **Kafka** – an open-source stream processing platform used for real-time data streaming and messaging.
- **MariaDB** – a community-developed fork of MySQL that offers enhanced performance, scalability, and features.
- **MongoDB** – a cross-platform document-oriented database that provides high scalability, flexibility, and performance.
- **MongoDB Atlas** – a cloud-based database as a service (DBaaS) offering from MongoDB that simplifies the management and scaling of MongoDB deployments.
- **Microsoft SQL Server** – a relational database management system (RDBMS) from Microsoft that provides robust data storage, analysis, and reporting capabilities.
- **Mixpanel** – an analytics platform that helps businesses analyze how users interact with their websites, mobile applications, and other digital products.
- **MySQL** – an open-source relational database management system (RDBMS) that is widely used in web applications and is known for its reliability and scalability.
- **Network** – a network data source represents a network-accessible resource or service that can be accessed by a data integration platform.
- **OpenSearch** – an OpenSearch data source is an application that OpenSearch can connect to and ingest data from.

- **Oracle** – a relational database management system (RDBMS) from Oracle Corporation that provides robust data storage, analysis, and reporting capabilities.
- **PostgreSQL** – an open-source relational database management system (RDBMS) that provides robust data storage, analysis, and reporting capabilities.
- **Salesforce** – Salesforce provides customer relationship management (CRM) software that help you with sales, customer service, e-commerce, and more. If you're a Salesforce user, you can connect Amazon Glue to your Salesforce account. Then, you can use Salesforce as a data source or destination in your ETL jobs. Run these jobs to transfer data between Salesforce and Amazon services or other supported applications.
- **SAP HANA** – an in-memory database and analytics platform that provides fast data processing, advanced analytics, and real-time data integration.
- **Snowflake** – a cloud-based data warehouse that provides scalable, high-performance data storage and analytics services.
- **Teradata** – a relational database management system (RDBMS) that provides high-performance data storage, analysis, and reporting capabilities.
- **Vertica** – a columnar-oriented analytical data warehouse designed for big data analytics that offers fast query performance, advanced analytics, and scalability.

Creating custom connectors

You can also build your own connector and then upload the connector code to Amazon Glue Studio.

Custom connectors are integrated into Amazon Glue Studio through the Amazon Glue Spark runtime API. The Amazon Glue Spark runtime allows you to plug in any connector that is compliant with the Spark, Athena, or JDBC interface. It allows you to pass in any connection option that is available with the custom connector.

You can encapsulate all your connection properties with [Amazon Glue Connections](#) and supply the connection name to your ETL job. Integration with Data Catalog connections allows you to use the same connection properties across multiple calls in a single Spark application or across different applications.

You can specify additional options for the connection. The job script that Amazon Glue Studio generates contains a `Datasource` entry that uses the connection to plug in your connector with the specified connection options. For example:

```
Datasource = glueContext.create_dynamic_frame.from_options(connection_type =
"custom.jdbc", connection_options = {"dbTable":"Account","connectionName":"my-custom-
jdbc-
connection"}, transformation_ctx = "DataSource0")
```

To add a custom connector to Amazon Glue Studio

1. Create the code for your custom connector. For more information, see [Developing custom connectors](#).
2. Add support for Amazon Glue features to your connector. Here are some examples of these features and how they are used within the job script generated by Amazon Glue Studio:
 - **Data type mapping** – Your connector can typecast the columns while reading them from the underlying data store. For example, a `dataTypeMapping` of `{"INTEGER":"STRING"}` converts all columns of type `Integer` to columns of type `String` when parsing the records and constructing the `DynamicFrame`. This helps users to cast columns to types of their choice.

```
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type
= "custom.jdbc", connection_options = {"dataTypeMapping":{"INTEGER":"STRING"}",
connectionName":"test-connection-jdbc"}, transformation_ctx = "DataSource0")
```

- **Partitioning for parallel reads** – Amazon Glue allows parallel data reads from the data store by partitioning the data on a column. You must specify the partition column, the lower partition bound, the upper partition bound, and the number of partitions. This feature enables you to make use of data parallelism and multiple Spark executors allocated for the Spark application.

```
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type
= "custom.jdbc", connection_options = {"upperBound":"200","numPartitions":"4",
"partitionColumn":"id","lowerBound":"0","connectionName":"test-connection-jdbc"},
transformation_ctx = "DataSource0")
```

- **Use Amazon Secrets Manager for storing credentials** – The Data Catalog connection can also contain a `secretId` for a secret stored in Amazon Secrets Manager. The Amazon secret can securely store authentication and credentials information and provide it to Amazon Glue at runtime. Alternatively, you can specify the `secretId` from the Spark script as follows:

```
DataSource = glueContext.create_dynamic_frame.from_options(connection_type
```

```
= "custom.jdbc", connection_options = {"connectionName":"test-connection-jdbc",
"secretId"-> "my-secret-id"}, transformation_ctx = "DataSource0")
```

- **Filtering the source data with row predicates and column projections** – The Amazon Glue Spark runtime also allows users to push down SQL queries to filter data at the source with row predicates and column projections. This allows your ETL job to load filtered data faster from data stores that support push-downs. An example SQL query pushed down to a JDBC data source is: `SELECT id, name, department FROM department WHERE id < 200`.

```
DataSource = glueContext.create_dynamic_frame.from_options(connection_type =
"custom.jdbc", connection_options = {"query":"SELECT id, name, department FROM
department
WHERE id < 200"}, "connectionName":"test-connection-jdbc"}, transformation_ctx =
"DataSource0")
```

- **Job bookmarks** – Amazon Glue supports incremental loading of data from JDBC sources. Amazon Glue keeps track of the last processed record from the data store, and processes new data records in the subsequent ETL job runs. Job bookmarks use the primary key as the default column for the bookmark key, provided that this column increases or decreases sequentially. For more information about job bookmarks, see [Job Bookmarks](#) in the *Amazon Glue Developer Guide*.

```
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
"custom.jdbc", connection_options = {"jobBookmarkKeys":["empno"],
"jobBookmarkKeysSortOrder"
:"asc", "connectionName":"test-connection-jdbc"}, transformation_ctx =
"DataSource0")
```

3. Package the custom connector as a JAR file and upload the file to Amazon S3.
4. Test your custom connector. For more information, see the instructions on GitHub at [Glue Custom Connectors: Local Validation Tests Guide](#).
5. In the Amazon Glue Studio console, choose **Connectors** in the console navigation pane.
6. On the **Connectors** page, choose **Create custom connector**.
7. On the **Create custom connector** page, enter the following information:
 - The path to the location of the custom code JAR file in Amazon S3.
 - A name for the connector that will be used by Amazon Glue Studio.
 - Your connector type, which can be one of **JDBC**, **Spark**, or **Athena**.

- The name of the entry point within your custom code that Amazon Glue Studio calls to use the connector.
 - For JDBC connectors, this field should be the class name of your JDBC driver.
 - For Spark connectors, this field should be the fully qualified data source class name, or its alias, that you use when loading the Spark data source with the `format` operator.
 - (JDBC only) The base URL used by the JDBC connection for the data store.
 - (Optional) A description of the custom connector.
8. Choose **Create connector**.
 9. From the **Connectors** page, create a connection that uses this connector, as described in [Creating connections for connectors](#).

Adding connectors to Amazon Glue Studio

A connector is a piece of code that facilitates communication between your data store and Amazon Glue. You can either subscribe to a connector offered in Amazon Web Services Marketplace, or you can create your own custom connector.

Subscribing to Amazon Web Services Marketplace connectors

Amazon Glue Studio makes it easy to add connectors from Amazon Web Services Marketplace.

To add a connector from Amazon Web Services Marketplace to Amazon Glue Studio

1. In the Amazon Glue Studio console, choose **Connectors** in the console navigation pane.
2. On the **Connectors** page, choose **Go to Amazon Web Services Marketplace**.
3. In Amazon Web Services Marketplace, in **Featured products**, choose the connector you want to use. You can choose one of the featured connectors, or use search. You can search on the name or type of connector, and you can use options to refine the search results.

If you want to use one of the featured connectors, choose **View product**. If you used search to locate a connector, then choose the name of the connector.

4. On the product page for the connector, use the tabs to view information about the connector. If you decide to purchase this connector, choose **Continue to Subscribe**.
5. Provide the payment information, and then choose **Continue to Configure**.
6. On the **Configure this software** page, choose the method of deployment and the version of the connector to use. Then choose **Continue to Launch**.

7. On the **Launch this software** page, you can review the **Usage Instructions** provided by the connector provider. When you're ready to continue, choose **Activate connection in Amazon Glue Studio**.

After a small amount of time, the console displays the **Create marketplace connection** page in Amazon Glue Studio.

8. Create a connection that uses this connector, as described in [Creating connections for connectors](#).

Alternatively, you can choose **Activate connector only** to skip creating a connection at this time. You must create a connection at a later date before you can use the connector.

Creating connections for connectors

An Amazon Glue connection is a Data Catalog object that stores connection information for a particular data store. Connections store login credentials, URI strings, virtual private cloud (VPC) information, and more. Creating connections in the Data Catalog saves the effort of having to specify all connection details every time you create a job.

To create a connection for a connector

1. In the Amazon Glue Studio console, choose **Connectors** in the console navigation pane. In the **Connections** section, choose **Create connection**.
2. Choose the data source you want to create a connection for in step 1 of the **Create data connection** wizard. There are several ways to view the available data sources, including:
 - Filter the available data sources by choosing a tab. By default, **All connectors** is selected.
 - Toggle **List** to view the data sources as a list or toggle back to **Grid** to view the available connectors in the grid layout.
 - Use the search bar to narrow the list of data sources. As you type, search matches are displayed and non-matching sources are removed from view.

Once you've chosen the data source, choose **Next**.

3. Configure the connection in Step 2 in the wizard.

Enter the connection details. Depending on the type of connector you selected, you're prompted to enter additional information:

4. Choose the data source you want to create a connection for in step 1 of the **Create data connection** wizard. There are several ways to view the available data sources. By default, you will see all available data sources in a grid layout. You can also:
 - Toggle **List** to view the data sources as a list or toggle back to **Grid** to view the available connectors in the grid layout.
 - Use the search bar to narrow the list of data sources. As you type, search matches are displayed and non-matching sources are removed from view.

Once you've chosen the data source, choose **Next**.

5. Configure the connection in Step 2 in the wizard.

Enter the connection details. Depending on the type of connector you selected, you may be required to enter additional connection information. This can include:

- **Connection details** – these fields will change depending on the data source you are connecting to. For example, if you are connecting to Amazon DocumentDB databases, you will enter the Amazon DocumentDB URL. If you are connecting to Amazon Aurora, you will choose the database instance and enter the database name. The following is the Connection details required for Amazon Aurora:
 - **Credential type** – choose between **Username and password** or **Amazon Secrets Manager**. Enter the requested authentication information.
 - For connectors that use JDBC, enter the information required to create the JDBC URL for the data store.
 - If you use a virtual private cloud (VPC), then enter the network information for your VPC.
6. Set the connection properties in step 3 of the wizard. You can add a description and tags as an optional part of this step. Name is required and is prepopulated with a default value. Choose **Next**.
 7. Review the connection source, details, and properties. If you need to make any changes, choose **Edit** for the step in the wizard. When ready, choose, **Create connection** .

Choose **Create connection**.

You are returned to the **Connectors** page, and the informational banner indicates the connection that was created. You can now use the connection in your Amazon Glue Studio jobs.

Creating a Kafka connection

When creating a Kafka connection, selecting **Kafka** from the drop-down menu will display additional settings to configure:

- Kafka cluster details
- Authentication
- Encryption
- Network options

Configure Kafka cluster details

1. Choose the cluster location. You can choose from an **Amazon managed streaming for Apache Kafka (MSK)** cluster or a **Customer managed Apache Kafka** cluster. For more information on Amazon Managed streaming for Apache Kafka, see [Amazon managed streaming for Apache Kafka \(MSK\)](#).

Note

Amazon Managed Streaming for Apache Kafka only supports TLS and SASL/SCRAM-SHA-512 authentication methods.

Kafka cluster details [Info](#)

Cluster location

- Amazon managed streaming for Apache Kafka (MSK)
- Customer managed Apache Kafka

Kafka bootstrap server URLs [Info](#)

A comma-separated list of bootstrap server URLs. Include the port number.

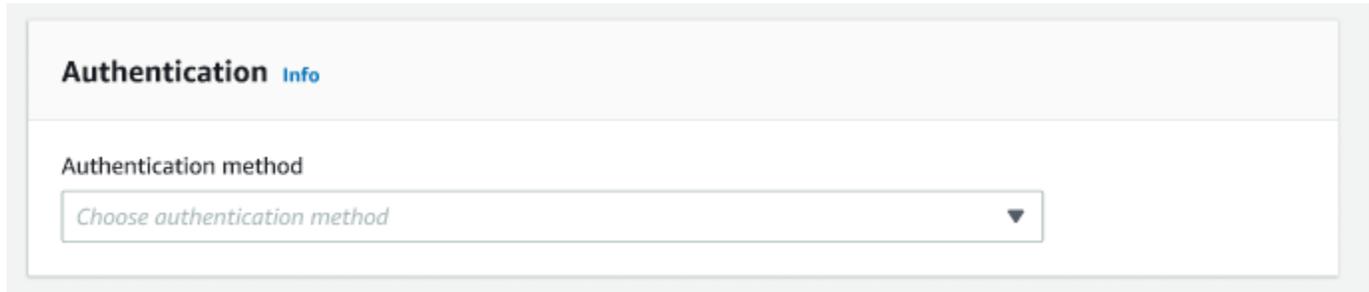

Enter list of URLs, separated by commas

Example: b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094, b-2.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094, b-3.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094

2. Enter the URLs for your Kafka bootstrap servers. You may enter more than one by separating each server by a comma. Include the port number at the end of the URL by appending `:<port number>`.

For example: `b-1.vpc-test-2.034a88o.kafka-us-east-1.amazonaws.com:9094`

Select authentication method

The screenshot shows a section titled "Authentication" with an "Info" link. Below the title is a label "Authentication method" and a dropdown menu. The dropdown menu is currently displaying the text "Choose authentication method" and has a downward-pointing arrow on the right side.

Amazon Glue supports the Simple Authentication and Security Layer (SASL) framework for authentication. The SASL framework supports various mechanisms of authentication, and Amazon Glue offers the SCRAM (username and password), GSSAPI (Kerberos protocol), and PLAIN (username and password) protocols.

When choosing an authentication method from the drop-down menu, the following client authentication methods can be selected:

- None - No authentication. This is useful if you create a connection for testing purposes.
- SASL/SCRAM-SHA-512 - Choose this authentication method to specify authentication credentials. There are two options available:
 - Use Amazon Secrets Manager (recommended) - if you select this option, you can store your credentials in Amazon Secrets Manager and let Amazon Glue access the information when needed. Specify the secret that stores the SSL or SASL authentication credentials.

Authentication [Info](#)

Authentication method
SASL/SCRAM-SHA-512

Authentication credentials

Use AWS Secrets Manager (recommended)
Store your token in AWS Secrets Manager, and let AWS Glue access it when needed.

Provide username and password directly
Provide your username and password directly to AWS Glue.

Secret from [AWS Secrets Manager](#)

Search secret by name or type ARN

- Provide username and password directly.
- SASL/GSSAPI (Kerberos) - if you select this option, you can select the location of the keytab file, krb5.conf file and enter the Kerberos principal name and Kerberos service name. The locations for the keytab file and krb5.conf file must be in an Amazon S3 location. Since MSK does not yet support SASL/GSSAPI, this option is only available for customer managed Apache Kafka clusters. For more information, see [MIT Kerberos Documentation: Keytab](#).
- SASL/PLAIN - Choose this authentication method to specify authentication credentials. There are two options available:
 - Use Amazon Secrets Manager (recommended) - if you select this option, you can store your credentials in Amazon Secrets Manager and let Amazon Glue access the information when needed. Specify the secret that stores the SSL or SASL authentication credentials.
 - Provide username and password directly.
- SSL Client Authentication - if you select this option, you can select the location of the Kafka client keystore by browsing Amazon S3. Optionally, you can enter the Kafka client keystore password and Kafka client key password.

Authentication Info

↗

Browse S3

Path must be in the form s3://bucket/prefix/path/. It must end with the file name and .jks extension.

Kafka client keystore password - *optional*

Enter password

Kafka client key password - *optional*

Enter password

Configure encryption settings

1. If the Kafka connection requires SSL connection, select the checkbox for **Require SSL connection**. Note that the connection will fail if it's unable to connect over SSL. SSL for encryption can be used with any of the authentication methods (SASL/SCRAM-SHA-512, SASL/GSSAPI, SASL/PLAIN, or SSL Client Authentication) and is optional.

If the authentication method is set to **SSL client authentication**, this option will be selected automatically and will be disabled to prevent any changes.

2. (Optional). Choose the location of private certificate from certificate authority (CA). Note that the location of the certification must be in an S3 location. Choose **Browse** to choose the file from a connected S3 bucket. The path must be in the form `s3://bucket/prefix/filename.pem`. It must end with the file name and `.pem` extension.
3. You can choose to skip validation of certificate from a certificate authority (CA). Choose the checkbox **Skip validation of certificate from certificate authority (CA)**. If this box is not checked, Amazon Glue validates certificates for three algorithms:
 - SHA256withRSA
 - SHA384withRSA
 - SHA512withRSA

Encryption [Info](#)

Require SSL connection
The connection will fail if it's unable to connect over SSL.

Location of private certificate from certificate authority (CA) - *optional*

Path must be in the form s3://bucket/prefix/path/. It must end with the file name and .pem extension.

Skip validation of certificate from certificate authority (CA)
AWS Glue validates for three algorithms: SHA256withRSA, SHA384withRSA and SHA512withRSA.

(Optional) Network options

The following are optional steps to configure VPC, Subnet and Security groups. If your Amazon Glue job needs to run on Amazon EC2 instances in a virtual private cloud (VPC) subnet, you must provide additional VPC-specific configuration information.

1. Choose the VPC (virtual private cloud) that contains your data source.
2. Choose the subnet with your VPC.
3. Choose one or more security groups to allow access to the data store in your VPC subnet. Security groups are associated to the ENI attached to your subnet. You must choose at least one security group with a self-referencing inbound rule for all TCP ports.

▼ Network options - *optional*

If your AWS Glue job needs to run on [Amazon Elastic Compute Cloud](#) (EC2) instances in a virtual private cloud (VPC) subnet, you must provide additional VPC-specific configuration information.

VPC [Info](#)

Choose the virtual private cloud that contains your data source.

 ▼

Subnet [Info](#)

Choose the subnet within your VPC.

 ▼

Security groups [Info](#)

Choose one or more security groups to allow access to the data store in your VPC subnet. Security groups are associated to the ENI attached to your subnet. You must choose at least one security group with a self-referencing inbound rule for all TCP ports.

 ▼

Authoring jobs with custom connectors

You can use connectors and connections for both data source nodes and data target nodes in Amazon Glue Studio.

Topics

- [Create jobs that use a connector for the data source](#)
- [Configure source properties for nodes that use connectors](#)
- [Configure target properties for nodes that use connectors](#)

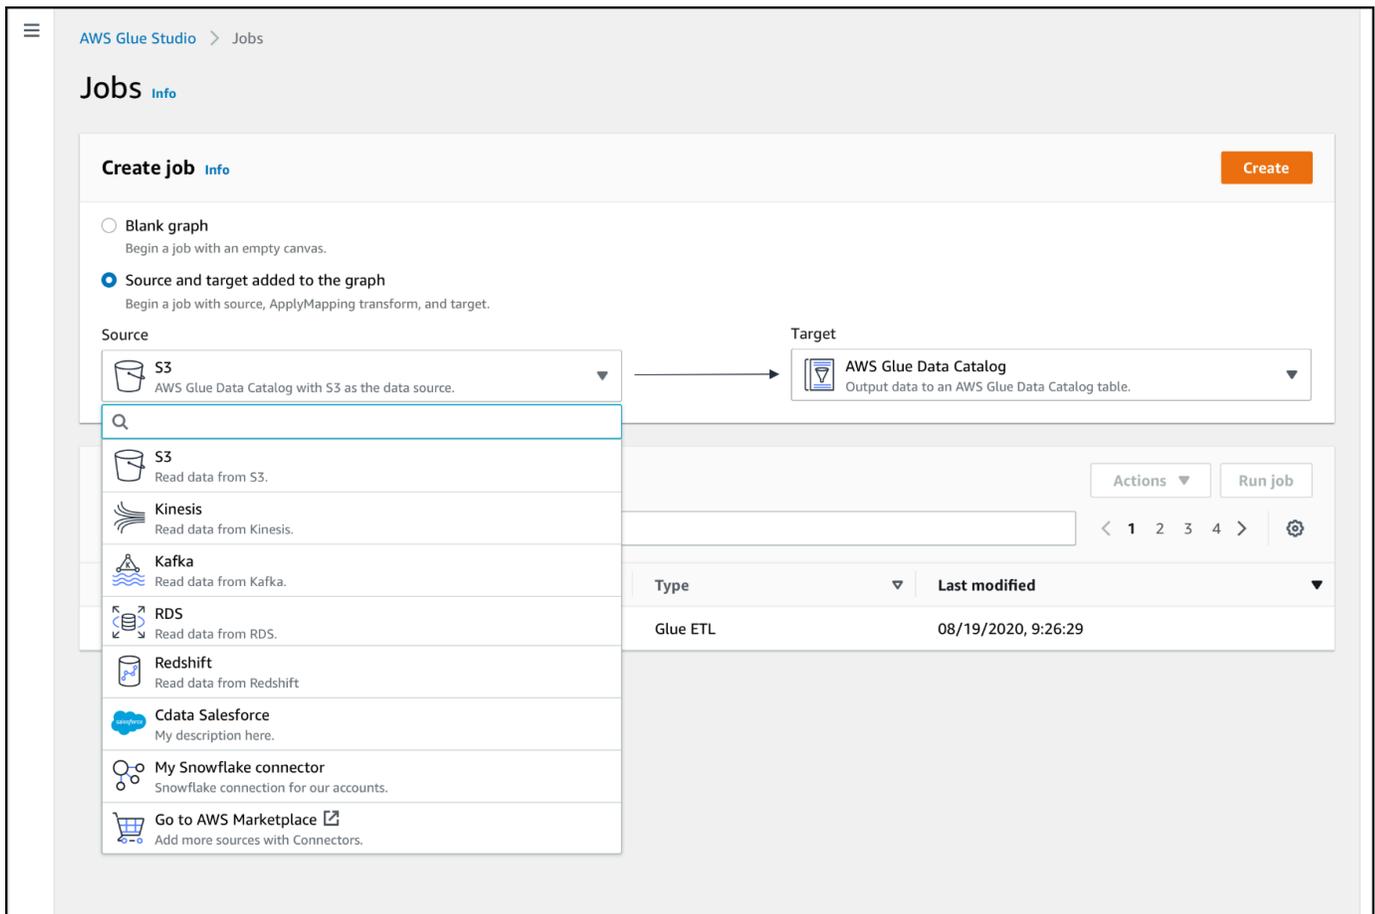

Create jobs that use a connector for the data source

When you create a new job, you can choose a connector for the data source and data targets.

To create a job that uses connectors for the data source or data target

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue Studio console at <https://console.amazonaws.cn/gluestudio/>.
2. On the **Connectors** page, in the **Your connections** resource list, choose the connection you want to use in your job, and then choose **Create job**.

Alternatively, on the Amazon Glue Studio **Jobs** page, under **Create job**, choose **Source and target added to the graph**. In the **Source** drop-down list, choose the custom connector that you want to use in your job. You can also choose a connector for **Target**.

3. Choose **Create** to open the visual job editor.
4. Configure the data source node, as described in [Configure source properties for nodes that use connectors](#).
5. Continue creating your ETL job by adding transforms, additional data stores, and data targets, as described in [Starting visual ETL jobs in Amazon Glue Studio](#).
6. Customize the job run environment by configuring job properties as described in [Modify the job properties](#).
7. Save and run the job.

Configure source properties for nodes that use connectors

After you create a job that uses a connector for the data source, the visual job editor displays a job graph with a data source node configured for the connector. You must configure the data source properties for that node.

To configure the properties for a data source node that uses a connector

1. Choose the connector data source node in the job graph or add a new node and choose the connector for the **Node type**. Then, on the right-side, in the node details panel, choose the **Data source properties** tab, if it's not already selected.

The screenshot displays the Amazon Glue Visual Job Editor interface. At the top, the job title is "Combine legislator data". On the right, there are buttons for "Job has not been saved", "Save", and "Run". Below the title bar are tabs for "Visual", "Script", "Job details", "Runs", and "Schedules". A toolbar contains icons for "Source", "Transform", "Target", "Undo", "Redo", "Remove", and search functions. The main workspace shows a job graph with several nodes: two "Data source - S3 bucket" nodes (Memberships source table and Persons source table), a "Transform - Join" node, a "Data source - Connection" node (Organizations table s...), a "Transform - ApplyMapping" node (Rename Org PK field), and another "Transform - ApplyMapping" node (Renamed keys for Join). On the right, the "Node properties" panel is open to the "Data source properties - Connector" tab. It includes an "Output schema" section, a "Connection" dropdown menu set to "MyEsConn", and a "Schema" section with an "Add schema" button. Below that, there are "Connection options" which are currently collapsed.

2. In the **Data source properties** tab, choose the connection that you want to use for this job.

Enter the additional information required for each connection type:

JDBC

- **Data source input type:** Choose to provide either a table name or a SQL query as the data source. Depending on your choice, you then need to provide the following additional information:

- **Table name:** The name of the table in the data source. If the data source does not use the term *table*, then supply the name of an appropriate data structure, as indicated by the custom connector usage information (which is available in Amazon Web Services Marketplace).
- **Filter predicate:** A condition clause to use when reading the data source, similar to a WHERE clause, which is used to retrieve a subset of the data.
- **Query code:** Enter a SQL query to use to retrieve a specific dataset from the data source. An example of a basic SQL query is:

```
SELECT column_list FROM  
           table_name WHERE where_clause
```

- **Schema:** Because Amazon Glue Studio is using information stored in the connection to access the data source instead of retrieving metadata information from a Data Catalog table, you must provide the schema metadata for the data source. Choose **Add schema** to open the schema editor.

For instructions on how to use the schema editor, see [Editing the schema in a custom transform node](#).

- **Partition column:** (Optional) You can choose to partition the data reads by providing values for **Partition column**, **Lower bound**, **Upper bound**, and **Number of partitions**.

The `lowerBound` and `upperBound` values are used to decide the partition stride, not for filtering the rows in table. All rows in the table are partitioned and returned.

Note

Column partitioning adds an extra partitioning condition to the query used to read the data. When using a query instead of a table name, you should validate that the query works with the specified partitioning condition. For example:

- If your query format is "SELECT col1 FROM table1", then test the query by appending a WHERE clause at the end of the query that uses the partition column.

- If your query format is "SELECT col1 FROM table1 WHERE col2=val", then test the query by extending the WHERE clause with AND and an expression that uses the partition column.

- **Data type casting:** If the data source uses data types that are not available in JDBC, use this section to specify how a data type from the data source should be converted into JDBC data types. You can specify up to 50 different data type conversions. All columns in the data source that use the same data type are converted in the same way.

For example, if you have three columns in the data source that use the Float data type, and you indicate that the Float data type should be converted to the JDBC String data type, then all three columns that use the Float data type are converted to String data types.

- **Job bookmark keys:** Job bookmarks help Amazon Glue maintain state information and prevent the reprocessing of old data. Specify one or more columns as bookmark keys. Amazon Glue Studio uses bookmark keys to track data that has already been processed during a previous run of the ETL job. Any columns you use for custom bookmark keys must be strictly monotonically increasing or decreasing, but gaps are permitted.

If you enter multiple bookmark keys, they're combined to form a single compound key. A compound job bookmark key should not contain duplicate columns. If you don't specify bookmark keys, Amazon Glue Studio by default uses the primary key as the bookmark key, provided that the primary key is sequentially increasing or decreasing (with no gaps). If the table doesn't have a primary key, but the job bookmark property is enabled, you must provide custom job bookmark keys. Otherwise, the search for primary keys to use as the default will fail and the job run will fail.

- **Job bookmark keys sorting order:** Choose whether the key values are sequentially increasing or decreasing.

Spark

- **Schema:** Because Amazon Glue Studio is using information stored in the connection to access the data source instead of retrieving metadata information from a Data Catalog table, you must provide the schema metadata for the data source. Choose **Add schema** to open the schema editor.

For instructions on how to use the schema editor, see [Editing the schema in a custom transform node](#).

- **Connection options:** Enter additional key-value pairs as needed to provide additional connection information or options. For example, you might enter a database name, table name, a user name, and password.

For example, for OpenSearch, you enter the following key-value pairs, as described in [the section called " Tutorial: Using the Amazon Glue Connector for Elasticsearch "](#):

- `es.net.http.auth.user` : *username*
- `es.net.http.auth.pass` : *password*
- `es.nodes` : `https://<Elasticsearch endpoint>`
- `es.port` : 443
- `path` : *<Elasticsearch resource>*
- `es.nodes.wan.only` : true

For an example of the minimum connection options to use, see the sample test script [MinimalSparkConnectorTest.scala](#) on GitHub, which shows the connection options you would normally provide in a connection.

Athena

- **Table name:** The name of the table in the data source. If you're using a connector for reading from Athena-CloudWatch logs, you would enter the table name `all_log_streams`.
- **Athena schema name:** Choose the schema in your Athena data source that corresponds to the database that contains the table. If you're using a connector for reading from Athena-CloudWatch logs, you would enter a schema name similar to `/aws/glue/name`.
- **Schema:** Because Amazon Glue Studio is using information stored in the connection to access the data source instead of retrieving metadata information from a Data Catalog table, you must provide the schema metadata for the data source. Choose **Add schema** to open the schema editor.

For instructions on how to use the schema editor, see [Editing the schema in a custom transform node](#).

- **Additional connection options:** Enter additional key-value pairs as needed to provide additional connection information or options.

For an example, see the README .md file at <https://github.com/aws-samples/aws-glue-samples/tree/master/GlueCustomConnectors/development/Athena>. In the steps in this document, the sample code shows the minimal required connection options, which are `tableName`, `schemaName`, and `className`. The code example specifies these options as part of the `optionsMap` variable, but you can specify them for your connection and then use the connection.

3. (Optional) After providing the required information, you can view the resulting data schema for your data source by choosing the **Output schema** tab in the node details panel. The schema displayed on this tab is used by any child nodes that you add to the job graph.
4. (Optional) After configuring the node properties and data source properties, you can preview the dataset from your data source by choosing the Data preview tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

Configure target properties for nodes that use connectors

If you use a connector for the data target type, you must configure the properties of the data target node.

To configure the properties for a data target node that uses a connector

1. Choose the connector data target node in the job graph. Then, on the right-side, in the node details panel, choose the **Data target properties** tab, if it's not already selected.
2. In the **Data target properties** tab, choose the connection to use for writing to the target.

Enter the additional information required for each connection type:

JDBC

- **Connection:** Choose the connection to use with your connector. For information about how to create a connection, see [Creating connections for connectors](#).
- **Table name:** The name of the table in the data target. If the data target does not use the term *table*, then supply the name of an appropriate data structure, as indicated by

the custom connector usage information (which is available in Amazon Web Services Marketplace).

- **Batch size (Optional):** Enter the number of rows or records to insert in the target table in a single operation. The default value is 1000 rows.

Spark

- **Connection:** Choose the connection to use with your connector. If you did not create a connection previously, choose **Create connection** to create one. For information about how to create a connection, see [Creating connections for connectors](#).
- **Connection options:** Enter additional key-value pairs as needed to provide additional connection information or options. You might enter a database name, table name, a user name, and password.

For example, for OpenSearch, you enter the following key-value pairs, as described in [the section called " Tutorial: Using the Amazon Glue Connector for Elasticsearch "](#):

- `es.net.http.auth.user` : *username*
- `es.net.http.auth.pass` : *password*
- `es.nodes` : `https://<Elasticsearch endpoint>`
- `es.port` : 443
- `path` : *<Elasticsearch resource>*
- `es.nodes.wan.only` : `true`

For an example of the minimum connection options to use, see the sample test script [MinimalSparkConnectorTest.scala](#) on GitHub, which shows the connection options you would normally provide in a connection.

3. After providing the required information, you can view the resulting data schema for your data source by choosing the **Output schema** tab in the node details panel.

Managing connectors and connections

You use the **Connections** page in Amazon Glue to manage your connectors and connections.

Topics

- [Viewing connector and connection details](#)

- [Editing connectors and connections](#)
- [Deleting connectors and connections](#)
- [Cancel a subscription for a connector](#)

Viewing connector and connection details

You can view summary information about your connectors and connections in the **Your connectors** and **Your connections** resource tables on the **Connectors** page. To view detailed information, perform the following steps.

To view connector or connection details

1. In the Amazon Glue Studio console, choose **Connectors** in the console navigation pane.
2. Choose the connector or connection that you want to view detailed information for.
3. Choose **Actions**, and then choose **View details** to open the detail page for that connector or connection.
4. On the detail page, you can choose to **Edit** or **Delete** the connector or connection.
 - For connectors, you can choose **Create connection** to create a new connection that uses the connector.
 - For connections, you can choose **Create job** to create a job that uses the connection.

Editing connectors and connections

You use the **Connectors** page to change the information stored in your connectors and connections.

To modify a connector or connection

1. In the Amazon Glue Studio console, choose **Connectors** in the console navigation pane.
2. Choose the connector or connection that you want to change.
3. Choose **Actions**, and then choose **Edit**.

You can also choose **View details** and on the connector or connection detail page, you can choose **Edit**.

4. On the **Edit connector** or **Edit connection** page, update the information, and then choose **Save**.

Deleting connectors and connections

You use the **Connectors** page to delete connectors and connections. If you delete a connector, then any connections that were created for that connector should also be deleted.

To remove connectors from Amazon Glue Studio

1. In the Amazon Glue Studio console, choose **Connectors** in the console navigation pane.
2. Choose the connector or connection you want to delete.
3. Choose **Actions**, and then choose **Delete**.

You can also choose **View details**, and on the connector or connection detail page, you can choose **Delete**.

4. Verify that you want to remove the connector or connection by entering **Delete**, and then choose **Delete**.

When deleting a connector, any connections that were created for that connector are also deleted.

Any jobs that use a deleted connection will no longer work. You can either edit the jobs to use a different data store, or remove the jobs. For information about how to delete a job, see [Delete jobs](#).

If you delete a connector, this doesn't cancel the subscription for the connector in Amazon Web Services Marketplace. To remove a subscription for a deleted connector, follow the instructions in [Cancel a subscription for a connector](#) .

Cancel a subscription for a connector

After you delete the connections and connector from Amazon Glue Studio, you can cancel your subscription in Amazon Web Services Marketplace if you no longer need the connector.

Note

If you cancel your subscription to a connector, this does not remove the connector or connection from your account. Any jobs that use the connector and related connections will no longer be able to use the connector and will fail.

Before you unsubscribe or re-subscribe to a connector from Amazon Web Services Marketplace, you should delete existing connections and connectors associated with that Amazon Web Services Marketplace product.

To unsubscribe from a connector in Amazon Web Services Marketplace

1. Sign in to the Amazon Web Services Marketplace console at <https://console.amazonaws.cn/marketplace>.
2. Choose **Manage subscriptions**.
3. On the **Manage subscriptions** page, choose **Manage** next to the connector subscription that you want to cancel.
4. Choose **Actions** and then choose **Cancel subscription**.
5. Select the check box to acknowledge that running instances are charged to your account, and then choose **Yes, cancel subscription**.

Developing custom connectors

You can write the code that reads data from or writes data to your data store and formats the data for use with Amazon Glue Studio jobs. You can create connectors for Spark, Athena, and JDBC data stores. Sample code posted on GitHub provides an overview of the basic interfaces you need to implement.

You will need a local development environment for creating your connector code. You can use any IDE or even just a command line editor to write your connector. Examples of development environments include:

- A local Scala environment with a local Amazon Glue ETL Maven library, as described in [Developing Locally with Scala](#) in the *Amazon Glue Developer Guide*.
- IntelliJ IDE, by downloading the IDE from <https://www.jetbrains.com/idea/>.

Topics

- [Developing Spark connectors](#)
- [Developing Athena connectors](#)
- [Developing JDBC connectors](#)

- [Examples of using custom connectors with Amazon Glue Studio](#)
- [Developing Amazon Glue connectors for Amazon Web Services Marketplace](#)

Developing Spark connectors

You can create a Spark connector with Spark DataSource API V2 (Spark 2.4) to read data.

To create a custom Spark connector

Follow the steps in the Amazon Glue GitHub sample library for developing Spark connectors, which is located at <https://github.com/aws-samples/aws-glue-samples/tree/master/GlueCustomConnectors/development/Spark/README.md>.

Developing Athena connectors

You can create an Athena connector to be used by Amazon Glue and Amazon Glue Studio to query a custom data source.

To create a custom Athena connector

Follow the steps in the Amazon Glue GitHub sample library for developing Athena connectors, which is located at <https://github.com/aws-samples/aws-glue-samples/tree/master/GlueCustomConnectors/development/Athena>.

Developing JDBC connectors

You can create a connector that uses JDBC to access your data stores.

To create a custom JDBC connector

1. Install the Amazon Glue Spark runtime libraries in your local development environment. Refer to the instructions in the Amazon Glue GitHub sample library at <https://github.com/aws-samples/aws-glue-samples/tree/master/GlueCustomConnectors/development/GlueSparkRuntime/README.md>.
2. Implement the JDBC driver that is responsible for retrieving the data from the data source. Refer to the [Java Documentation](#) for Java SE 8.

Create an entry point within your code that Amazon Glue Studio uses to locate your connector. The **Class name** field should be the full path of your JDBC driver.

3. Use the `GlueContext` API to read data with the connector. Users can add more input options in the Amazon Glue Studio console to configure the connection to the data source, if necessary. For a code example that shows how to read from and write to a JDBC database with a custom JDBC connector, see [Custom and Amazon Web Services Marketplace connectionType values](#).

Examples of using custom connectors with Amazon Glue Studio

You can refer to the following blogs for examples of using custom connectors:

- [Developing, testing, and deploying custom connectors for your data stores with Amazon Glue](#)
- Apache Hudi: [Writing to Apache Hudi tables using Amazon Glue Custom Connector](#)
- Google BigQuery: [Migrating data from Google BigQuery to Amazon S3 using Amazon Glue custom connectors](#)
- Snowflake (JDBC): [Performing data transformations using Snowflake and Amazon Glue](#)
- SingleStore: [Building fast ETL using SingleStore and Amazon Glue](#)
- Salesforce: [Ingest Salesforce data into Amazon S3 using the CData JDBC custom connector with Amazon Glue](#) -
- MongoDB: [Building Amazon Glue Spark ETL jobs using Amazon DocumentDB \(with MongoDB compatibility\) and MongoDB](#)
- Amazon Relational Database Service (Amazon RDS): [Building Amazon Glue Spark ETL jobs by bringing your own JDBC drivers for Amazon RDS](#)
- MySQL (JDBC): <https://github.com/aws-samples/aws-glue-samples/blob/master/GlueCustomConnectors/development/Spark/SparkConnectorMySQL.scala>

Developing Amazon Glue connectors for Amazon Web Services Marketplace

As an Amazon partner, you can create custom connectors and upload them to Amazon Web Services Marketplace to sell to Amazon Glue customers.

The process for developing the connector code is the same as for custom connectors, but the process of uploading and verifying the connector code is more detailed. Refer to the instructions in [Creating Connectors for Amazon Web Services Marketplace](#) on the GitHub website.

Restrictions for using connectors and connections in Amazon Glue Studio

When you're using custom connectors or connectors from Amazon Web Services Marketplace, take note of the following restrictions:

- The testConnection API isn't supported with connections created for custom connectors.
- Data Catalog connection password encryption isn't supported with custom connectors.
- You can't use job bookmarks if you specify a filter predicate for a data source node that uses a JDBC connector.
- Creating a Marketplace connection is not supported outside of the Amazon Glue Studio user interface.

Testing an Amazon Glue connection

As a best practice, before you use an Amazon Glue connection in an ETL job, use the Amazon Glue console to test the connection. Amazon Glue uses the parameters in your connection to confirm that it can access your data store and reports any errors. For information about Amazon Glue connections, see [Connecting to data](#).

To test an Amazon Glue connection

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data Catalog**, choose **Connections**. You can also choose **Data connections** above **Data Catalog** in the navigation pane.
3. In **Connections**, select the check box next to the desired connection, and then choose **Actions**. In the drop-down menu, choose **Test connection**.
4. In the **Test connection** dialog box, select a role or choose **Create IAM role** to go to the Amazon Identity and Access Management (IAM) console to create a new role. The role must have permissions on the data store.
5. Choose **Confirm**.

The test begins and can take several minutes to complete. If the test fails, choose **Troubleshoot** to view the steps to resolve the issue.

6. Choose **Logs** to view the logs in CloudWatch. You must have the required IAM permissions to view the logs. For more information, see [Amazon Managed \(Predefined\) Policies for CloudWatch Logs](#) in the *Amazon CloudWatch Logs User Guide*.

Configuring Amazon calls to go through your VPC

The special job parameter `disable-proxy-v2` allows you to route your calls to services such as Amazon S3, CloudWatch, and Amazon Glue through your VPC. By default, Amazon Glue uses a local proxy to send traffic through the Amazon Glue VPC to download scripts and libraries from Amazon S3, to send requests to CloudWatch for publishing logs and metrics, and to send requests to Amazon Glue for accessing data catalogs. This proxy allows the job to function normally even if your VPC doesn't configure a proper route to other Amazon services, such as Amazon S3, CloudWatch, and Amazon Glue. Amazon Glue now offers a parameter for you to turn off this behavior. For more information, see [Job parameters used by Amazon Glue](#). Amazon Glue will continue to use local proxy for publishing CloudWatch logs of your Amazon Glue jobs.

Note

- This feature is supported for Amazon Glue jobs with Amazon Glue version 2.0 and above. When using this feature, you need to ensure that your VPC has configured a route to Amazon S3 through a NAT or service VPC endpoint.
- The deprecated job parameter `disable-proxy` only routes your calls to Amazon S3 for downloading scripts and libraries through your VPC. It's recommended to use the new parameter `disable-proxy-v2` instead.

Example usage

Create an Amazon Glue job with `disable-proxy-v2`:

```
aws glue create-job \  
  --name no-proxy-job \  
  --role GlueDefaultRole \  
  --command "Name=glueetl,ScriptLocation=s3://my-bucket/glue-script.py" \  
  --connections Connections="traffic-monitored-connection" \  
  --default-arguments '{"--disable-proxy-v2" : "true"}'
```

Connecting to a JDBC data store in a VPC

Typically, you create resources inside Amazon Virtual Private Cloud (Amazon VPC) so that they cannot be accessed over the public internet. By default, Amazon Glue can't access resources inside a VPC. To enable Amazon Glue to access resources inside your VPC, you must provide additional VPC-specific configuration information that includes VPC subnet IDs and security group IDs. Amazon Glue uses this information to set up [elastic network interfaces](#) that enable your function to connect securely to other resources in your private VPC.

When using a VPC endpoint, add it to your route table. For more information, see [Creating an interface VPC endpoint for Amazon Glue](#) and [Prerequisites](#).

When using encryption in Data Catalog, create the KMS interface endpoint and add it to your route table. For more information, see [Creating a VPC endpoint for Amazon KMS](#).

Accessing VPC Data Using elastic network interfaces

When Amazon Glue connects to a JDBC data store in a VPC, Amazon Glue creates an elastic network interface (with the prefix `Glue_`) in your account to access your VPC data. You can't delete this network interface as long as it's attached to Amazon Glue. As part of creating the elastic network interface, Amazon Glue associates one or more security groups to it. To enable Amazon Glue to create the network interface, security groups that are associated with the resource must allow inbound access with a source rule. This rule contains a security group that is associated with the resource. This gives the elastic network interface access to your data store with the same security group.

To allow Amazon Glue to communicate with its components, specify a security group with a self-referencing inbound rule for all TCP ports. By creating a self-referencing rule, you can restrict the source to the same security group in the VPC and not open it to all networks. The default security group for your VPC might already have a self-referencing inbound rule for `ALL Traffic`.

You can create rules in the Amazon VPC console. To update rule settings via the Amazon Web Services Management Console, navigate to the VPC console (<https://console.amazonaws.cn/vpc/>), and select the appropriate security group. Specify the inbound rule for `ALL TCP` to have as its source the same security group name. For more information about security group rules, see [Security Groups for Your VPC](#).

Each elastic network interface is assigned a private IP address from the IP address range in the subnets that you specify. The network interface is not assigned any public IP addresses. Amazon Glue requires internet access (for example, to access Amazon services that don't have VPC endpoints). You can configure a network address translation (NAT) instance inside your VPC, or you can use the Amazon VPC NAT gateway. For more information, see [NAT Gateways](#) in the *Amazon VPC User Guide*. You can't directly use an internet gateway attached to your VPC as a route in your subnet route table because that requires the network interface to have public IP addresses.

The VPC network attributes `enableDnsHostnames` and `enableDnsSupport` must be set to true. For more information, see [Using DNS with your VPC](#).

Important

Don't put your data store in a public subnet or in a private subnet that doesn't have internet access. Instead, attach it only to private subnets that have internet access through a NAT instance or an Amazon VPC NAT gateway.

Elastic network interface properties

To create the elastic network interface, you must supply the following properties:

VPC

The name of the VPC that contains your data store.

Subnet

The subnet in the VPC that contains your data store.

Security groups

The security groups that are associated with your data store. Amazon Glue associates these security groups with the elastic network interface that is attached to your VPC subnet. To allow Amazon Glue components to communicate and also prevent access from other networks, at least one chosen security group must specify a self-referencing inbound rule for all TCP ports.

For information about managing a VPC with Amazon Redshift, see [Managing Clusters in an Amazon Virtual Private Cloud \(VPC\)](#).

For information about managing a VPC with Amazon Relational Database Service (Amazon RDS), see [Working with an Amazon RDS DB Instance in a VPC](#).

Using a MongoDB or MongoDB Atlas connection

After you create a connection for MongoDB or MongoDB Atlas, you can use the connection in your ETL job. You create a table in the Amazon Glue Data Catalog and specify the MongoDB or MongoDB Atlas connection for the `connection` attribute of the table.

Amazon Glue stores your connection `url` and credentials in the MongoDB connection. The connection URI formats are as follows:

- For MongoDB: `mongodb://host:port/database`. The host can be a hostname, IP address, or UNIX domain socket. If the connection string doesn't specify a port, it uses the default MongoDB port, 27017.
- For MongoDB Atlas: `mongodb+srv://server.example.com/database`. The host can be a hostname that follows corresponds to a DNS SRV record. The SRV format does not require a port and will use the default MongoDB port, 27017.

Additionally, you can specify options in your job script. For more information, see [the section called "MongoDB connection"](#).

Crawling an Amazon S3 data store using a VPC endpoint

For security, auditing, or control purposes you may want your Amazon S3 data store or Amazon S3 backed Data Catalog tables to only be accessed through an Amazon Virtual Private Cloud environment (Amazon VPC). This topic describes how to create and test a connection to the Amazon S3 data store or Amazon S3 backed Data Catalog tables in a VPC endpoint using the Network connection type.

Perform the following tasks to run a crawler on the data store:

- [the section called "Prerequisites"](#)
- [the section called "Creating the connection to Amazon S3"](#)
- [the section called "Testing the connection to Amazon S3"](#)
- [the section called "Creating a crawler for an Amazon S3 data store"](#)

- [the section called “Running a crawler”](#)

Prerequisites

Check that you have met these prerequisites for setting up your Amazon S3 data store or Amazon S3 backed Data Catalog tables to be accessed through an Amazon Virtual Private Cloud environment (Amazon VPC).

- A configured VPC. For example: vpc-01685961063b0d84b. For more information, see [Getting started with Amazon VPC](#) in the *Amazon VPC User Guide*.
- An Amazon S3 endpoint attached to the VPC. For example: vpc-01685961063b0d84b. For more information, see [Endpoints for Amazon S3](#) in the *Amazon VPC User Guide*.

Name	VPC ID	State	IPv4 CIDR	IPv6	DHCP options set	Main Route table	Main Network ACL	Tenancy	Default VPC
privateVPC	vpc-01685961063b0d84b	available	192.168.1.0/24	-	dopt-a79e5acc	rtb-0750198567d5...	acl-02d197f2c9f6e46...	default	No

- A network ACL attached to the VPC allows the traffic.
- A security group attached to the VPC allows the traffic.

Creating the connection to Amazon S3

Typically, you create resources inside Amazon Virtual Private Cloud (Amazon VPC) so that they cannot be accessed over the public internet. By default, Amazon Glue can't access resources inside a VPC. To enable Amazon Glue to access resources inside your VPC, you must provide additional VPC-specific configuration information that includes VPC subnet IDs and security group IDs. To create a Network connection you need to specify the following information:

- A VPC ID
- A subnet within the VPC
- A security group

To set up a Network connection:

1. Choose **Add connection** in the navigation pane of the Amazon Glue console.
2. Enter the connection name, choose **Network** as the connection type. Choose **Next**.

Add connection ✕

- Connection properties**

Testing the connection to Amazon S3

Once you have created your Network connection, you can test the connectivity to your Amazon S3 data store in a VPC endpoint.

The following errors may occur when testing a connection:

- **INTERNET CONNECTION ERROR:** indicates an Internet connection issue
- **INVALID BUCKET ERROR:** indicates a problem with the Amazon S3 bucket
- **S3 CONNECTION ERROR:** indicates a failure to connect to Amazon S3
- **INVALID CONNECTION TYPE:** indicates the Connection type does not have the expected value, NETWORK
- **INVALID CONNECTION TEST TYPE:** indicates a problem with the type of network connection test
- **INVALID TARGET:** indicates that the Amazon S3 bucket has not been specified properly

To test a Network connection:

1. Select the **Network** connection in the Amazon Glue console.
2. Choose **Test connection**.
3. Choose the IAM role that you created in the previous step and specify an Amazon S3 Bucket.

4. Choose **Test connection** to start the test. It might take few moments to show the result.

The screenshot shows the 'Test connection' dialog in the Amazon Glue console. The dialog title is 'Test connection'. Below the title, it says 'Test connection from your VPC and subnet to data stores and Amazon S3.' There are two main sections: 'IAM role' and 'Include path'. The 'IAM role' section has a dropdown menu with a refresh icon and a note: 'Ensure that this role has permission to access your data store. [Create IAM role.](#)' The 'Include path' section has a text input field containing 's3://crawlerestfiles' and a refresh icon. Below these sections is a list of S3 buckets under the heading 'S3'. The bucket 'crawlerestfiles' is selected with a radio button. Other buckets include 'athenaoutputprdept', 'crawlerestfiles1', 'dataforrunningcrawler', 'do-not-delete-gatedgarden-audit-261353713322', 'lf-kms-bucket', 'lifecycleconfiguration', and 'mys3accesslogsprdept'. At the bottom right of the dialog is a blue button labeled 'Test connection'.

If you receive an error, check the following:

- The correct privileges are provided to the role selected.
- The correct Amazon S3 bucket is provided.
- The security groups and Network ACL allow the required incoming and outgoing traffic.
- The VPC you specified is connected to an Amazon S3 VPC endpoint.

Once you have successfully tested the connection, you can create a crawler.

Creating a crawler for an Amazon S3 data store

You can now create a crawler that specifies the Network connection you've created. For more details on creating a crawler, see [Configuring a crawler](#).

1. Start by choosing **Crawlers** in the navigation pane on the Amazon Glue console.
2. Choose **Add crawler**.
3. Specify the crawler name and choose **Next**.
4. When asked for the data source, choose **S3**, and specify the Amazon S3 bucket prefix and the connection you created earlier.

Add crawler ✕

Troubleshooting

For troubleshooting related to Amazon S3 buckets using a VPC gateway, see [Why can't I connect to an S3 bucket using a gateway VPC endpoint?](#)

Working with Amazon Lake Formation-protected data

Full Table Access

Amazon Glue supports Full Table Access (FTA) for Amazon Lake Formation-protected tables. This allows your ETL jobs to read and write data with full table permissions.

Prerequisites

- Appropriate IAM roles and permissions
- Amazon Lake Formation configured for your data catalog
- Compatible table types (Hive or Iceberg)

Key considerations

Required permissions

- `lakeformation:GetDataAccess` IAM permission
- Amazon Lake Formation table permissions
- Amazon S3 bucket access permissions

Supported table types

- Hive tables
- Iceberg tables

Limitations

- Not compatible with Spark Streaming
- Cannot be used simultaneously with fine-grained access control
- Does not support Delta or Hudi tables

Best Practices

1. Ensure IAM roles are properly configured before job execution
2. Test access permissions in a development environment
3. Monitor job execution logs for permission-related issues
4. Maintain clear documentation of access patterns

Troubleshooting

Common issues include:

- Missing IAM permissions
- Incorrect Amazon Lake Formation configuration
- Table type compatibility problems

For complete setup instructions and configuration details, see [Using Amazon Lake Formation with full table access](#).

Troubleshooting connection issues in Amazon Glue

When an Amazon Glue crawler or a job uses connection properties to access a data store, you might encounter errors when you try to connect. Amazon Glue uses private IP addresses in the subnet when it creates elastic network interfaces in your specified virtual private cloud (VPC) and subnet. Security groups specified in the connection are applied on each of the elastic network interfaces. Check to see whether security groups allow outbound access and if they allow connectivity to the database cluster.

In addition, Apache Spark requires bidirectional connectivity among driver and executor nodes. One of the security groups needs to allow ingress rules on all TCP ports. You can prevent it from being open to the world by restricting the source of the security group to itself with a self-referencing security group.

Here are some typical actions you can take to troubleshoot connection problems:

- Check the port address of your connection.
- Check the user name and password string in your connection or secret.
- For a JDBC data store, verify that it allows incoming connections.
- Verify that your data store can be accessed within your VPC.
- If you store your connection credentials using Amazon Secrets Manager, make sure that your IAM role for Amazon Glue has permission to access your secret. For more information, see [Example: Permission to retrieve secret values](#) in the *Amazon Secrets Manager User Guide*. Depending on your network setup, you might also need to create a VPC endpoint to establish a private connection between your VPC and Secrets Manager. For more information, see [Using an Amazon Secrets Manager VPC endpoint](#).

Tutorial: Using the Amazon Glue Connector for Elasticsearch

Elasticsearch is a popular open-source search and analytics engine for use cases such as log analytics, real-time application monitoring, and clickstream analysis. You can use OpenSearch as a data store for your extract, transform, and load (ETL) jobs by configuring the Amazon Glue Connector for Elasticsearch in Amazon Glue Studio. This connector is available for free from [Amazon Web Services Marketplace](#).

Note

The [Amazon Web Services Marketplace Elasticsearch Spark Connector](#) has been deprecated. Please use the [Amazon Glue Connector for Elasticsearch](#) instead.

In this tutorial, we will show how to connect to your Amazon OpenSearch Service nodes with a minimal number of steps.

Topics

- [Prerequisites](#)
- [Step 1: \(Optional\) Create an Amazon secret for your OpenSearch cluster information](#)
- [Step 2: Subscribe to the connector](#)
- [Step 3: Activate the connector in Amazon Glue Studio and create a connection](#)
- [Step 4: Configure an IAM role for your ETL job](#)
- [Step 5: Create a job that uses the OpenSearch connection](#)
- [Step 6: Run the job](#)

Prerequisites

To use this tutorial, you must have the following:

- Access to Amazon Glue Studio
- Access to an OpenSearch cluster in the Amazon Cloud
- (Optional) Access to Amazon Secrets Manager.

Step 1: (Optional) Create an Amazon secret for your OpenSearch cluster information

To safely store and use your connection credential, save your credential in Amazon Secrets Manager. The secret you create will be used later in the tutorial by the connection. The credential key-value pairs will be fed into the Amazon Glue Connector for Elasticsearch as normal connection options.

For more information about creating secrets, see [Creating and Managing Secrets with Amazon Secrets Manager](#) in the *Amazon Secrets Manager User Guide*.

To create an Amazon secret

1. Sign in to the [Amazon Secrets Manager console](#).
2. On either the service introduction page or the **Secrets** list page, choose **Store a new secret**.
3. On the **Store a new secret** page, choose **Other type of secret**. This option means that you must supply the structure and details of your secret.
4. Add a **Key** and **Value** pair for the OpenSearch cluster user name. For example:

```
es.net.http.auth.user: username
```

5. Choose **+ Add row**, and enter another key-value pair for the password. For example:

```
es.net.http.auth.pass: password
```

6. Choose **Next**.
7. Enter a secret name. For example: **my-es-secret**. You can optionally include a description.

Record the secret name, which is used later in this tutorial, and then choose **Next**.

8. Choose **Next** again, and then choose **Store** to create the secret.

Next step

[Step 2: Subscribe to the connector](#)

Step 2: Subscribe to the connector

The Amazon Glue Connector for Elasticsearch is available for free from [Amazon Web Services Marketplace](#).

To subscribe to the Amazon Glue Connector for Elasticsearch on Amazon Web Services Marketplace

1. If you have not already configured your Amazon account to use License Manager, do the following:
 - a. Open the Amazon License Manager console at <https://console.amazonaws.cn/license-manager>.
 - b. Choose **Create customer managed license**.
 - c. In the **IAM permissions (one-time setup)** window, choose **I grant Amazon License Manager the required permissions**, and then choose **Grant permissions**.

If you do not see this window, then you have already configured the necessary permissions.

2. Open the Amazon Glue Studio console at <https://console.amazonaws.cn/gluestudio/>.
3. In the Amazon Glue Studio console, expand the menu icon () and then choose **Connectors** in the navigation pane.
4. On the **Connectors** page, choose **Go to Amazon Web Services Marketplace**.
5. In Amazon Web Services Marketplace, in the **Search Amazon Glue Studio products** section, enter **Amazon Glue Connector for Elasticsearch** in the search field, and then press Enter.
6. Choose the name of the connector, **Amazon Glue Connector for Elasticsearch**.
7. On the product page for the connector, use the tabs to view information about the connector. When you're ready to continue, choose **Continue to Subscribe**.
8. Review the terms of use for the software. Click **Accept Terms**.
9. When the subscription process completes, you will see a notification: "Thank you for subscribing to this product! You can now configure your software." Above the banner will be the button **Continue to Configuration**. Choose **Continue to Configuration**.
10. Choose the Fulfillment option on the **Configure this software** page. You can either choose between Amazon Glue 1.0/2.0 or Amazon Glue 3.0. Then, choose **Continue to Launch**.

Next step

[Step 3: Activate the connector in Amazon Glue Studio and create a connection](#)

Step 3: Activate the connector in Amazon Glue Studio and create a connection

After you choose **Continue to Launch**, you see the **Launch this software** page in Amazon Web Services Marketplace. After you use the link to activate the connector in Amazon Glue Studio, you create a connection.

To deploy the connector and create a connection in Amazon Glue Studio

1. On the **Launch this software** page in the Amazon Web Services Marketplace console, choose **Usage Instructions**, and then choose the link in the window that appears.

Your browser is redirected to the Amazon Glue Studio console **Create marketplace connection** page.

2. Enter a name for the connection. For example: **my-es-connection**.
3. In the **Connection access** section, for **Connection credential type**, choose **User name and password**.
4. For the **Amazon secret**, enter the name of your secret. For example: **my-es-secret**.
5. In the **Network options** section, enter the VPC information to connect to OpenSearch cluster.
6. Choose **Create connection and activate connector**.

Next step

[Step 4: Configure an IAM role for your ETL job](#)

Step 4: Configure an IAM role for your ETL job

When you create the Amazon Glue ETL job, you specify an Amazon Identity and Access Management (IAM) role for the job to use. The role must grant access to all resources used by the job, including Amazon S3 (for any sources, targets, scripts, driver files, and temporary directories), and also Amazon Glue Data Catalog objects.

The assumed IAM role for the Amazon Glue ETL job must also have access to the secret that was created in the previous section. By default, the AWS managed role `AWSGlueServiceRole` does not have access to the secret. To set up access control for your secrets, see [Authentication and Access Control for Amazon Secrets Manager](#) and [Limiting Access to Specific Secrets](#).

To configure an IAM role for your ETL job

1. Configure the permissions described in [the section called “Review IAM permissions needed for ETL jobs”](#).
2. Configure the additional permissions needed when using connectors with Amazon Glue Studio, as described in [the section called “Permissions required for using connectors”](#).

Next step

[Step 5: Create a job that uses the OpenSearch connection](#)

Step 5: Create a job that uses the OpenSearch connection

After creating a role for your ETL job, you can create a job in Amazon Glue Studio that uses the connection and connector for Open Spark ElasticSearch.

If your job runs within a Amazon Virtual Private Cloud (Amazon VPC), make sure the VPC is configured correctly. For more information, see [the section called “Configure a VPC for your ETL job”](#).

To create a job that uses the Elasticsearch Spark Connector

1. In Amazon Glue Studio, choose **Connectors**.
2. In the **Your connections** list, select the connection you just created and choose **Create job**.
3. In the visual job editor, choose the Data source node. On the right, on the **Data source properties - Connector** tab, configure additional information for the connector.
 - a. Choose **Add schema** and enter the schema of the data set in the data source. Connections do not use tables stored in the Data Catalog, which means that Amazon Glue Studio doesn't know the schema of the data. You must manually provide this schema information. For instructions on how to use the schema editor, see [the section called “Editing the schema in a custom transform node”](#).
 - b. Expand **Connection options**.
 - c. Choose **Add new option** and enter the information needed for the connector that was not entered in the Amazon secret:
 - **es.nodes**: `https://<OpenSearch domain endpoint>`
 - **es.port**: 443

- **path:** test
- **es.nodes.wan.only:** true

For an explanation of these connection options, refer to: <https://www.elastic.co/guide/en/elasticsearch/hadoop/current/configuration.html>.

4. Add a target node to the graph.

Your data target can be Amazon S3, or it can use information from an Amazon Glue Data Catalog or a connector to write data in a different location. For example, you can use a Data Catalog table to write to a database in Amazon RDS, or you can use a connector as your data target to write to data stores that are not natively supported in Amazon Glue.

If you choose a connector for your data target, you must choose a connection created for that connector. Also, if required by the connector provider, you must add options to provide additional information to the connector. If you use a connection that contains information for an Amazon secret, then you don't need to provide the user name and password authentication in the connection options.

5. Optionally, add additional data sources and one or more transform nodes as described in [the section called "Transform data with Amazon Glue managed transforms"](#).
6. Configure the job properties as described in [the section called "Modify the job properties"](#), starting with step 3, and save the job.

Next step

[Step 6: Run the job](#)

Step 6: Run the job

After you save your job, you can run the job to perform the ETL operations.

To run the job you created for the Amazon Glue Connector for Elasticsearch

1. Using the Amazon Glue Studio console, on the visual editor page, choose **Run**.
2. In the success banner, choose **Run Details**, or you can choose the **Runs** tab of the visual editor to view information about the job run.

Building Amazon Glue jobs with interactive sessions

Data engineers can author Amazon Glue jobs faster and more easily than before using interactive sessions in Amazon Glue.

Topics

- [Overview of Amazon Glue interactive sessions](#)
- [Getting started with Amazon Glue interactive sessions](#)
- [Configuring Amazon Glue interactive sessions for Jupyter and Amazon Glue Studio notebooks](#)
- [Converting a script or notebook into an Amazon Glue job](#)

- [Amazon Glue interactive session pricing](#)
- [Developing and testing Amazon Glue job scripts locally](#)
- [Development endpoints](#)

Overview of Amazon Glue interactive sessions

With Amazon Glue interactive sessions, you can rapidly build, test, and run data preparation and analytics applications. Interactive sessions provides a programmatic and visual interface for building and testing extract, transform, and load (ETL) scripts for data preparation. Interactive sessions run Apache Spark analytics applications and provide on-demand access to a remote Spark runtime environment. Amazon Glue transparently manages serverless Spark for these interactive sessions.

Interactive sessions are flexible, so you build and test your applications from the environment of your choice. You can create and work with interactive sessions through the Amazon Command Line Interface and the API. You can use Jupyter-compatible notebooks to visually author and test your notebook scripts. Interactive sessions provide an open-source Jupyter kernel that integrates almost anywhere that Jupyter does, including integrating with IDEs such as PyCharm, IntelliJ, and VS Code. This enables you to author code in your local environment and run it seamlessly on the interactive sessions backend.

Using the interactive sessions API, customers can programmatically run applications that use Apache Spark analytics without having to manage Spark infrastructure. You can run one or more Spark statements within a single interactive session.

Interactive sessions therefore provide a faster, cheaper, more-flexible way to build and run data preparation and analytics applications. To learn how to use interactive sessions, see the documentation in this section. [Magics supported by Amazon Glue](#)

Limitations

- Job bookmarks are not supported in interactive sessions.
- Creating notebook jobs using the Amazon Command Line Interface is not supported.
- Amazon Glue Studio notebooks do not support Scala.

Getting started with Amazon Glue interactive sessions

These sections describe how to run Amazon Glue interactive sessions locally.

Prerequisites for setting up interactive sessions locally

The following are prerequisites for installing interactive sessions:

- Supported Python versions are 3.6 - 3.10+.
- See sections below for MacOS/Linux and Windows instructions.
- Review the [interactive sessions pricing](#) documentation to understand the cost structure.

Installing Jupyter and Amazon Glue interactive sessions Jupyter kernels

Use the following to install the kernel locally.

The command, `install-glue-kernels`, installs the jupyter kernelspec for both pyspark and spark kernels and also installs logos in the right directory.

```
pip3 install --upgrade jupyter boto3 aws-glue-sessions
```

```
install-glue-kernels
```

Running Jupyter

To run Jupyter Notebook, complete the following steps.

1. Run the following command to launch Jupyter Notebook.

```
jupyter notebook
```

2. Choose **New**, and then choose one of the Amazon Glue kernels to begin coding against Amazon Glue.

Configuring session credentials and region

MacOS/Linux instructions

Amazon Glue interactive sessions requires the same IAM permissions as Amazon Glue Jobs and Dev Endpoints. Specify the role used with interactive sessions in one of two ways:

1. With the `%iam_role` and `%region` magics
2. With an additional line in `~/.aws/config`

Configuring a session role with magic

In the first cell, type `%iam_role <YourGlueServiceRole>` in the first cell executed.

Configuring a session role with `~/.aws/config`

Amazon Glue Service Role for interactive sessions can either be specified in the notebook itself or stored alongside the Amazon CLI config. If you have a role you typically use with Amazon Glue Jobs this will be that role. If you do not have a role you use for Amazon Glue jobs, please follow this guide, [Configuring IAM permissions for Amazon Glue](#), to set one up.

To set this role as the default role for interactive sessions:

1. With a text editor, open `~/.aws/config`.
2. Look for the profile you use for Amazon Glue. If you don't use a profile, use the `[Default]` profile.
3. Add a line in the profile for the role you intend to use like `glue_role_arn=<AWSGlueServiceRole>`.
4. [Optional]: If your profile does not have a default region set, I recommend adding one with `region=us-east-1`, replacing `us-east-1` with your desired region.
5. Save the config.

For more information, see [Interactive sessions with IAM](#).

Windows instructions

Amazon Glue interactive sessions requires the same IAM permissions as Amazon Glue Jobs and Dev Endpoints. Specify the role used with interactive sessions in one of two ways:

1. With the `%iam_role` and `%region` magics
2. With an additional line in `~/.aws/config`

Configuring a session role with magic

In the first cell, type `%iam_role <YourGlueServiceRole>` in the first cell executed.

Configuring a session role with `~/.aws/config`

Amazon Glue Service Role for interactive sessions can either be specified in the notebook itself or stored alongside the Amazon CLI config. If you have a role you typically use with Amazon Glue Jobs this will be that role. If you do not have a role you use for Amazon Glue jobs, please follow this guide, [Setting up IAM permissions for Amazon Glue](#), to set one up.

To set this role as the default role for interactive sessions:

1. With a text editor, open `~/.aws/config`.
2. Look for the profile you use for Amazon Glue. If you don't use a profile, use the `[Default]` profile.
3. Add a line in the profile for the role you intend to use like `glue_role_arn=<AWSGlueServiceRole>`.
4. [Optional]: If your profile does not have a default region set, I recommend adding one with `region=us-east-1`, replacing `us-east-1` with your desired region.
5. Save the config.

For more information, see [Interactive sessions with IAM](#).

Upgrading from the interactive sessions preview

The kernel was upgraded with new names when it was released with version 0.27. To clean up preview versions of the kernels run the following from a terminal or PowerShell.

Note

If you are a part of any other Amazon Glue preview that requires a custom service model, removing the kernel will remove the custom service model.

```
# Remove Old Glue Kernels
jupyter kernelspec remove glue_python_kernel
jupyter kernelspec remove glue_scala_kernel

# Remove Custom Model
cd ~/.aws/models
rm -rf glue/
```

Using interactive sessions with SageMaker AI Studio

Amazon Glue Interactive Sessions is an on-demand, serverless, Apache Spark runtime environment that data scientists and engineers can use to rapidly build, test, and run data preparation and analytics applications. You can initiate an Amazon Glue interactive session by starting a Amazon SageMaker AI Studio Classic notebook.

For more information, see [Prepare Data using Amazon Glue interactive sessions](#).

Using interactive sessions with Microsoft Visual Studio Code

Prerequisites

- Install Amazon Glue interactive sessions and verify it works with Jupyter Notebook.
- Download and install Visual Studio Code with Jupyter. For details, see [Jupyter Notebook in VS Code](#).

To get started with interactive sessions with VSCode

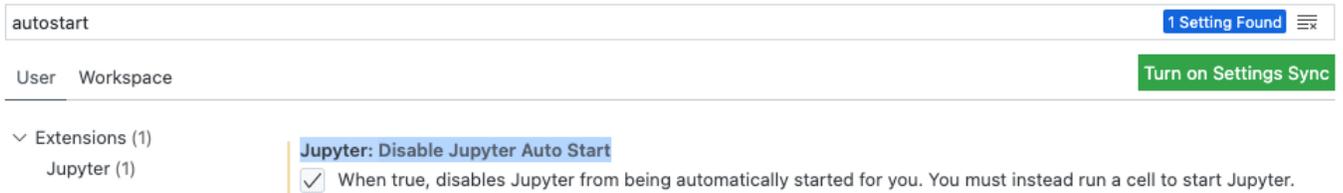

1. Disable Jupyter AutoStart in VS Code.

In Visual Studio Code, Jupyter kernels will auto-start which will prevent your magics from taking effect as the session will already be started. To disable **Auto Start** on Windows, go to

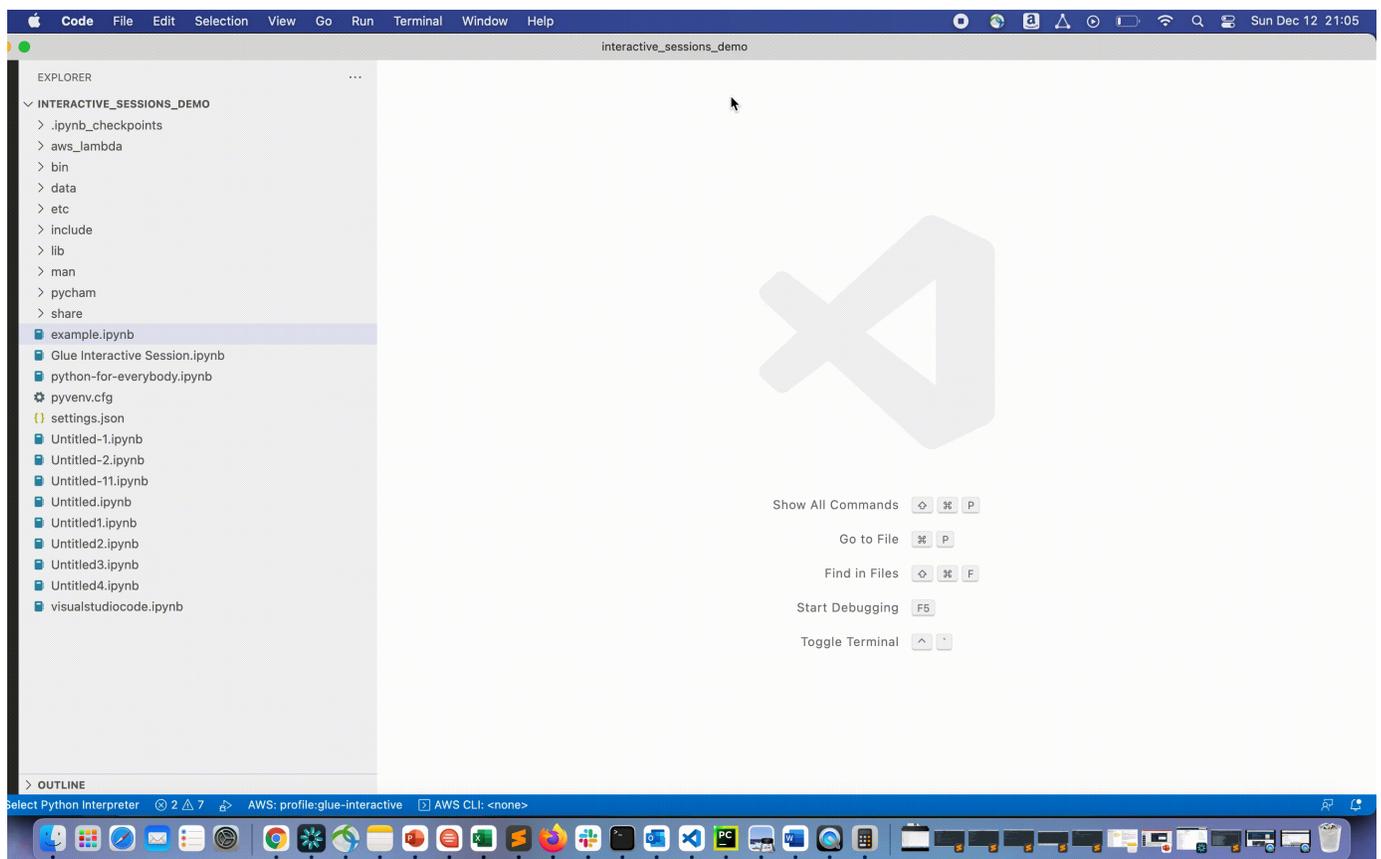

File > Preferences > Extensions > Jupyter > right-click on Jupyter then choose Extension Settings.

On MacOS, go to **Code > Settings > Extensions > Jupyter > right-click on Jupyter then choose Extension Settings.**

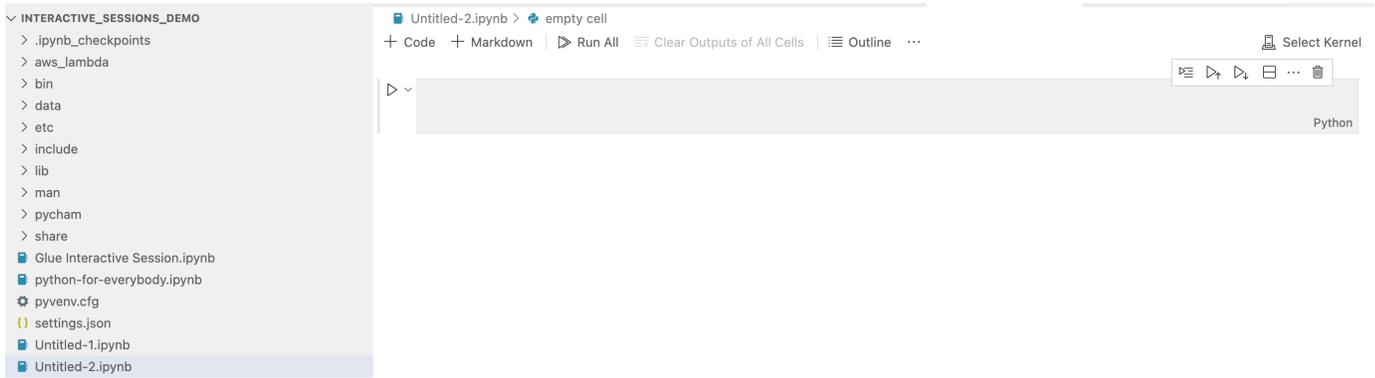

Scroll down until you see **Jupyter: Disable Jupyter Auto Start**. Check the box "When true, disables Jupyter from being automatically started for you. You must instead run a cell to start Jupyter."

2. Go to **File > New File > Save** to save this file with name of your choice as an `.ipynb` extension or select **jupyter** under **select a language** and save the file.

3. Double-click on the file. The Jupyter shell will display and a notebook will be opened.

4. On Windows, when you first create a file, by default no kernel is selected. Click on **Select Kernel** and a list of available kernels is displayed. Choose **Glue PySpark**.

On MacOS, If you do not see the **Glue PySpark** kernel, try the following steps:

1. Run a local Jupyter session to obtain the URL.

For example, run the following command to launch Jupyter Notebook.

```
jupyter notebook
```

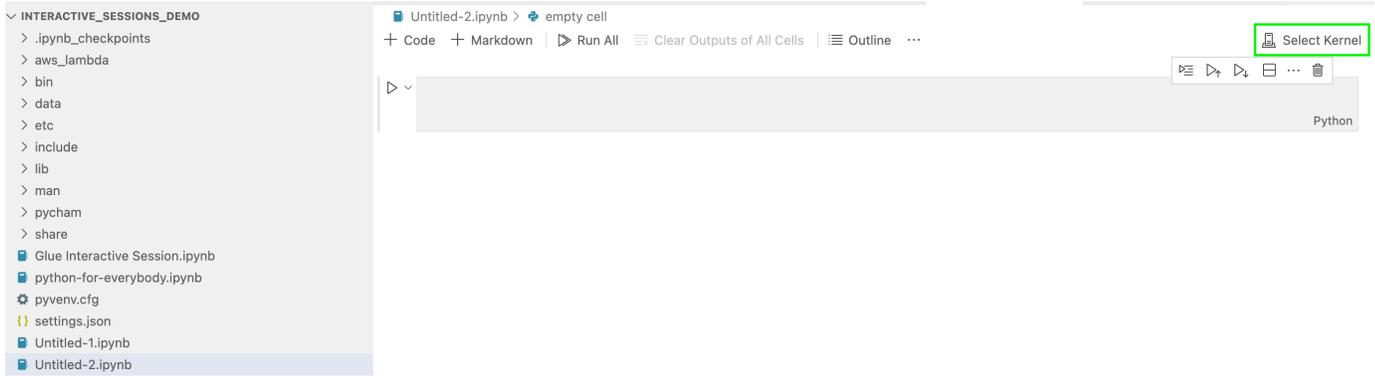

When the notebook first runs, you will see a URL that looks like `http://localhost:8888/?token=3398XXXXXXXXXXXXXXXXXX`.

Copy the URL.

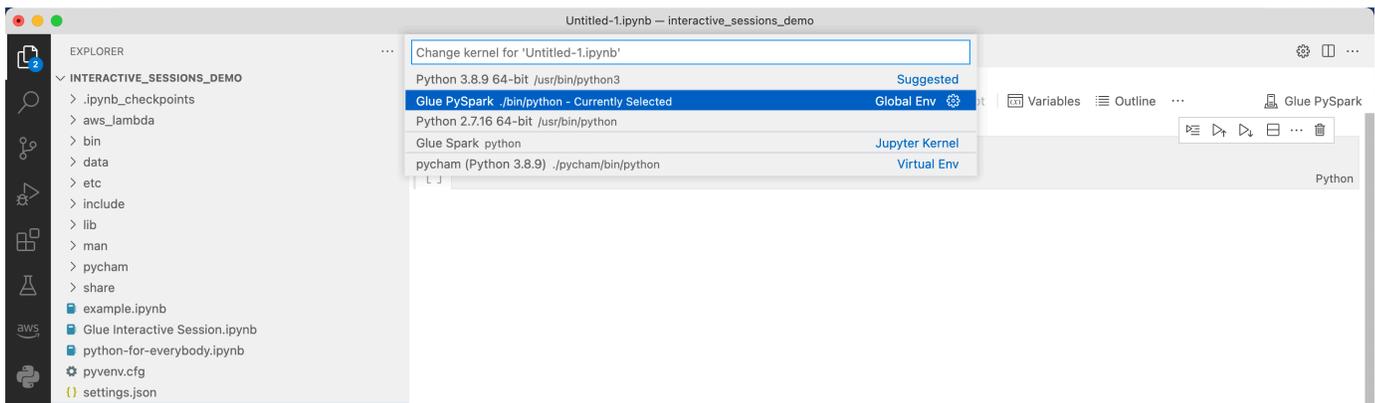

2. In VS Code, click the current kernel, then **Select Another Kernel...**, then select **Existing Jupyter Server...**. Paste the URL you copied from the step above.

If you receive an error message, see the [VS Code Jupyter wiki](#).

3. If successful, this will set the kernel to **Glue PySpark**.

Choose the **Glue PySpark** or **Glue Spark** kernel (for Python and Scala respectively).

If you don't see **Amazon Glue PySpark** and **Amazon Glue Spark** kernels in the drop-down list, please ensure you have installed the Amazon Glue kernel in the step above, or that your `python.defaultInterpreterPath` setting in Visual Studio Code is correct. For more information, see [python.defaultInterpreterPath setting description](#).

5. Create an Amazon Glue Interactive Session. Proceed to create a session in the same manner as you did in Jupyter Notebook. Specify any magics at the top of your first cell and run a statement of code.

Interactive sessions with IAM

These sections describe security considerations for Amazon Glue interactive sessions.

Topics

- [IAM principals used with interactive sessions](#)
- [Setting up a client principal](#)

- [Setting up a runtime role](#)
- [Make your session private with TagOnCreate](#)
- [IAM policy considerations](#)

IAM principals used with interactive sessions

You use two IAM principals used with Amazon Glue interactive sessions.

- **Client principal:** The client principal (either a user or a role) authorizes API operations for interactive sessions from an Amazon Glue client that's configured with the principal's identity-based credentials. For example, this could be an IAM role that you typically use to access the Amazon Glue console. This could also be a role given to a user in IAM whose credentials are used for the Amazon Command Line Interface, or an Amazon Glue client used by the interactive sessions Jupyter kernel.
- **Runtime role:** The runtime role is an IAM role that the client principal passes to interactive sessions API operations. Amazon Glue uses this role to run statements in your session. For example, this role could be the one used for running Amazon Glue ETL jobs.

For more information, see [Setting up a runtime role](#).

Setting up a client principal

You must attach an identity policy to the client principal to allow it to call the interactive sessions API. This role must have `iam:PassRole` access to the execution role that you would pass to the interactive sessions API, such as `CreateSession`. For example, you can attach the **AWSGlueConsoleFullAccess** managed policy to an IAM role which allows users in your account with the policy attached to access all the sessions created in your account (such as runtime statement or cancel statement).

If you would like to protect your session and make it private only to certain IAM roles, such as ones associated with the user who created the session then you can use Amazon Glue Interactive Session's Tag Based Authorization Control called `TagOnCreate`. For more information, see [Make your session private with TagOnCreate](#) on how an owner tag-based scoped down managed policy can make your session private with `TagOnCreate`. For more information on identity-based policies, see [Identity-based policies for Amazon Glue](#).

Setting up a runtime role

You must pass an IAM role to the `CreateSession` API operation in order to allow Amazon Glue to assume and run statements in interactive sessions. The role should have the same IAM permissions as those required to run a typical Amazon Glue job. For example, you can create a service role using the **AWSGlueServiceRole** policy that allows Amazon Glue to call Amazon services on your behalf. If you use the Amazon Glue console, it will automatically create a service role on your behalf or use an existing one. You can also create your own IAM role and attach your own IAM policy to allow similar permissions.

If you would like to protect your session and make it private only to the user who created the session then you can use Amazon Glue Interactive Session's Tag Based Authorization Control called `TagOnCreate`. For more information, see [Make your session private with TagOnCreate](#) on how an owner tag-based scoped down managed policy can make your session private with `TagOnCreate`. For more information on identity-based policies, see [Identity-based policies for Amazon Glue](#). If you are creating the execution role by yourself from the IAM console and you want to make your service private with `TagOnCreate` feature then follow the steps below.

1. Create an IAM role with role type set to Glue.
2. Attach this Amazon Glue managed policy: *AwsGlueSessionUserRestrictedServiceRole*
3. Prefix the role name with the policy name *AwsGlueSessionUserRestrictedServiceRole*. For example, you can create a role with name *AwsGlueSessionUserRestrictedServiceRole-myrole* and attach Amazon Glue managed policy *AwsGlueSessionUserRestrictedServiceRole*.
4. Attach a trust policy like following to allow Amazon Glue to assume the role:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
    },
  ],
  "Action": [
    "sts:AssumeRole"
  ]
}
```

```
    ]
  }
]
}
```

For an interactive sessions Jupyter kernel, you can specify the `iam_role` key in your Amazon Command Line Interface profile. For more information, see [Configuring sessions with ~/.aws/config](#). If you're interacting with interactive sessions using an Amazon Glue notebook, then you can pass the execution role in the `%iam_role` magic in the first cell that you run.

Make your session private with TagOnCreate

Amazon Glue interactive sessions supports tagging and Tag Based Authorization (TBAC) for interactive sessions as a named resource. In addition to TBAC using `TagResource` and `UntagResource` APIs, Amazon Glue interactive sessions supports the `TagOnCreate` feature to 'tag' a session with a given tag only during session creation with `CreateSession` operation. This also means those tags will be removed on `DeleteSession`, aka `UntagOnDelete`.

`TagOnCreate` offers a powerful security mechanism to make your session private to the creator of the session. For example, you can attach an IAM policy with "owner" `RequestTag` and value of `#{aws:userId}` to a client principal (such as an user) in order to allow creating a session only if an "owner" tag with matching value of the callers `userId` is provided as `userId` tag in `CreateSession` request. This policy allows Amazon Glue interactive sessions to create a session resource and tag the session with the `userId` tag only during session creation time. In addition to it you can scope down the access (like running statements) to your session only to the creator (aka owner tag with value `#{aws:userId}`) of the session by attaching an IAM policy with "owner" `ResourceTag` to the execution role you passed in during `CreateSession`.

In order to make it easier for you to use `TagOnCreate` feature to make a session private to the session creator, Amazon Glue provides specialized managed policies and service roles.

If you want to create a Amazon Glue Interactive Session using an IAM `AssumeRole` principal (that is, using credential vended by assuming an IAM role) and you want to make the session private to the creator, then use policies similar to the **`AWSGlueSessionUserRestrictedNotebookPolicy`** and **`AWSGlueSessionUserRestrictedNotebookServiceRole`** respectively. These policies allow Amazon Glue to use `#{aws:PrincipalTag}` to extract the owner tag value. This requires you to pass a `userId` tag with value `#{aws:userId}` as `SessionTag` in the `assume role` credential. See [ID session tags](#). If you are using an Amazon EC2 instance with an instance profile vending the credential and you

want to create a session or interact with the session from within the Amazon EC2 instance , then you would require to pass a `userId` tag with value `${aws:userId}` as `SessionTag` in the assume role credential.

For example, If you are creating a session using an IAM AssumeRole principal credential and you want to make your service private with `TagOnCreate` feature then follow the steps below.

1. Create a runtime role yourself from the IAM console. Please attach this Amazon Glue managed policy `AwsGlueSessionUserRestrictedNotebookServiceRole` and prefix the role name with the policy name `AwsGlueSessionUserRestrictedNotebookServiceRole`. For example, you can create a role with name `AwsGlueSessionUserRestrictedNotebookServiceRole-myrole` and attach Amazon Glue managed policy `AwsGlueSessionUserRestrictedNotebookServiceRole`.
2. Attach a trust policy like below to allow Amazon Glue to assume the above role.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
      "Action": [
        "sts:AssumeRole"
      ]
    }
  ]
}
```

3. Create another role named with a prefix `AwsGlueSessionUserRestrictedNotebookPolicy` and attach the Amazon Glue managed policy `AwsGlueSessionUserRestrictedNotebookPolicy` to make the session private. In addition to the managed policy please attach the following inline policy to allow `iam:PassRole` to the role you created in step 1.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam::*:role/
        AwsGlueSessionUserRestrictedNotebookServiceRole*"
      ],
      "Condition": {
        "StringLike": {
          "iam:PassedToService": [
            "glue.amazonaws.com"
          ]
        }
      }
    }
  ]
}
```

4. Attach a trust policy like following to the above IAM Amazon Glue to assume the role.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
      "Action": [
        "sts:AssumeRole",

```

```
        "sts:TagSession"
      ]
    }
  ]
}
```

Note

Optionally, you can use a single role (for example, notebook role) and attach both of the above managed policies *AwsGlueSessionUserRestrictedNotebookServiceRole* and *AwsGlueSessionUserRestrictedNotebookPolicy*. Also attach the additional inline policy to allow `iam:passrole` of your role to Amazon Glue. And finally attach the above trust policy to allow `sts:AssumeRole` and `sts:TagSession`.

AWSGlueSessionUserRestrictedNotebookPolicy

The **AWSGlueSessionUserRestrictedNotebookPolicy** provides access to create a Amazon Glue Interactive Session from a notebook only if a tag key "owner" and value matching the Amazon user id of the principal (user or Role). For more information, see [Where you can use policy variables](#) . This policy is attached to the principal (User or role) that creates Amazon Glue Interactive Session notebooks from Amazon Glue Studio. This policy also permits sufficient access to the Amazon Glue Studio notebook to interact with the Amazon Glue Studio Interactive Session resources that are created with the "owner" tag value matching the Amazon user ID of the principal. This policy denies permission to change or remove "owner" tag from a Amazon Glue session resource after the session is created.

AWSGlueSessionUserRestrictedNotebookServiceRole

The **AWSGlueSessionUserRestrictedNotebookServiceRole** provides sufficient access to the Amazon Glue Studio notebook to interact with the Amazon Glue Interactive Session resources that are created with the "owner" tag value matching the Amazon user ID of the principal (user or role) of the notebook creator. For more information, see [Where you can use policy variables](#) . This service-role policy is attached to the role that is passed as magic to a notebook or passed as execution role to the `CreateSession` API. This policy also permits to create a Amazon Glue Interactive Session from a notebook only if a tag key "owner" and value matching the Amazon user ID of the principal. This policy denies permission to change or remove "owner" tag from an Amazon Glue session resource after the session is created. This policy also includes permissions for writing

and reading from Amazon S3 buckets, writing CloudWatch logs, creating and deleting tags for Amazon EC2 resources used by Amazon Glue.

Make your session private with user policies

You can attach the **AWSGlueSessionUserRestrictedPolicy** to IAM roles attached to each of the users in your account to restrict them from creating a session only with an owner tag with a value matching their own `${aws:userId}`. Instead of using the **AWSGlueSessionUserRestrictedNotebookPolicy** and **AWSGlueSessionUserRestrictedNotebookServiceRole** you need to use policies similar to the **AWSGlueSessionUserRestrictedPolicy** and **AWSGlueSessionUserRestrictedServiceRole** respectively. For more information, see [Using-identity based policies](#). This policy scopes down the access to a session only to the creator, the `${aws:userId}` of the user who created the session with an owner tag bearing their own `${aws:userId}`. If you have created the execution role yourself using the IAM console by following the steps in [Setting up a runtime role](#), then in addition to attaching the **AWSGlueSessionUserRestrictedPolicy** managed policy, also attach the following inline policy to each of the users in your account to allow `iam:PassRole` for the execution role you created earlier.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam::*:role/AWSGlueSessionUserRestrictedServiceRole*"
      ],
      "Condition": {
        "StringLike": {
          "iam:PassedToService": [
            "glue.amazonaws.com"
          ]
        }
      }
    }
  ]
}
```

```
]
}
```

AWSGlueSessionUserRestrictedPolicy

The **AWSGlueSessionUserRestrictedPolicy** provides access to create an Amazon Glue Interactive Session using the `CreateSession` API only if a tag key "owner" and value matching their Amazon user ID is provided. This identity policy is attached to the user that invokes the `CreateSession` API. This policy also permits to interact with the Amazon Glue Interactive Session resources that were created with a "owner" tag and value matching their Amazon user id. This policy denies permission to change or remove "owner" tag from a Amazon Glue session resource after the session is created.

AWSGlueSessionUserRestrictedServiceRole

The **AWSGlueSessionUserRestrictedServiceRole** provides full access to all Amazon Glue resources except for sessions and allows users to create and use only the interactive sessions that are associated with the user. This policy also includes other permissions needed by Amazon Glue to manage Glue resources in other Amazon services. The policy also allows adding tags to Amazon Glue resources in other Amazon services.

IAM policy considerations

Interactive sessions are IAM resources in Amazon Glue. Because they are IAM resources, access and interaction to a session is governed by IAM policies. Based on the IAM policies attached to a client principal or execution role configured by an admin, a client principal (user or role) will be able to create new sessions and interact with its own sessions and other sessions.

If an admin has attached an IAM policy such as `AWSGlueConsoleFullAccess` or `AWSGlueServiceRole` that allows access to all Amazon Glue resources in that account, a client principal will be able to collaborate with each other. For example, one user will be able to interact with sessions that are created by other users if policies allow this.

If you'd like to configure a policy tailored to your specific needs, see [IAM documentation about configuring resources for a policy](#) . For example, in order to isolate sessions that belong to an user, you can use the `TagOnCreate` feature supported by Amazon Glue Interactive sessions. See [Make your session private with TagOnCreate](#) .

Interactive sessions supports limiting session creation based on certain VPC conditions. See [Control policies that control settings using condition keys](#).

Configuring Amazon Glue interactive sessions for Jupyter and Amazon Glue Studio notebooks

Introduction to Jupyter Magics

Jupyter Magics are commands that can be run at the beginning of a cell or as a whole cell body. Magics start with % for line-magics and %% for cell-magics. Line-magics such as %region and %connections can be run with multiple magics in a cell, or with code included in the cell body like the following example.

```
%region us-east-2
%connections my_rds_connection
dy_f = glue_context.create_dynamic_frame.from_catalog(database='rds_tables',
table_name='sales_table')
```

Cell magics must use the entire cell and can have the command span multiple lines. An example of %%sql is below.

```
%%sql
select * from rds_tables.sales_table
```

Magics supported by Amazon Glue interactive sessions for Jupyter

The following are magics that you can use with Amazon Glue interactive sessions for Jupyter notebooks.

Sessions magics

Name	Type	Description
%help	n/a	Return a list of descriptions and input types for all magic commands.
%profile	String	Specify a profile in your Amazon configuration to use as the credentials provider.

Name	Type	Description
<code>%region</code>	String	Specify the Amazon Web Services Region; in which to initialize a session. Default from <code>~/.aws/configure</code> . Example: <code>%region us-west-1</code>
<code>%idle_timeout</code>	Int	The number of minutes of inactivity after which a session will timeout after a cell has been executed. The default idle timeout value for Spark ETL sessions is the default timeout, 2880 minutes (48 hours). For other session types, consult documentation for that session type. Example: <code>%idle_timeout 3000</code>
<code>%session_id</code>	n/a	Return the session ID for the running session.
<code>%session_id_prefix</code>	String	Define a string that will precede all session IDs in the format [session_id_prefix]-[session_id] . If a session ID is not provided, a random UUID will be generated. This magic is not supported when you run a Jupyter Notebook in Amazon Glue Studio. Example: <code>%session_id_prefix 001</code>
<code>%status</code>		Return the status of the current Amazon Glue session including its duration, configuration and executing user / role.
<code>%stop_session</code>		Stop the current session.
<code>%list_sessions</code>		Lists all currently running sessions by name and ID.

Name	Type	Description
<code>%session_type</code>	String	Sets the session type to one of Streaming , ETL, or Ray. Example: <code>%session_type Streaming</code>
<code>%glue_version</code>	String	The version of Amazon Glue to be used by this session. Example: <code>%glue_version 3.0</code>

Magics for selecting job types

Name	Type	Description
<code>%streaming</code>	String	Changes the session type to Amazon Glue Streaming.
<code>%etl</code>	String	Changes the session type to Amazon Glue ETL.
<code>%glue_ray</code>	String	Changes the session type to Amazon Glue for Ray. See Magics supported by Amazon Glue Ray interactive sessions .

Amazon Glue for Spark config magics

The `%%configure` magic is a json-formatted dictionary consisting of all configuration parameters for a session. Each parameter can be specified here or through individual magics.

Name	Type	Description
<code>%%configure</code>	Dictionary	Specify a JSON-formatted dictionary consisting of all configuration parameters for a session. Each parameter can be

Name	Type	Description
		<p>specified here or through individual magics.</p> <p>For a list of parameters and examples on how to use <code>%%configure</code>, see %configure cell magic arguments.</p>
<code>%iam_role</code>	String	<p>Specify an IAM role ARN to execute your session with. Default from <code>~/.aws/configure</code>.</p> <p>Example: <code>%iam_role AWSGlueServiceRole</code></p>
<code>%number_of_workers</code>	Int	<p>The number of workers of a defined <code>worker_type</code> that are allocated when a job runs. <code>worker_type</code> must be set too. The default <code>number_of_workers</code> is 5.</p> <p>Example: <code>%number_of_workers 2</code></p>
<code>%additional_python_modules</code>	List	<p>Comma separated list of additional Python modules to include in your cluster (can be from PyPI or S3).</p> <p>Example: <code>%additional_python_modules pandas, numpy</code>.</p>

Name	Type	Description
%tags	String	<p>Adds tags to a session. Specify the tags within curly brackets { }. Each tag name pair is enclosed in parentheses (" ") and separated by a comma (,).</p> <pre data-bbox="894 443 1507 640">%tags {"billing":"Data-Platform", "team":"analytics"}</pre> <p>Use the %status magic to view tags associated with the session.</p> <pre data-bbox="894 800 1507 877">%status</pre> <pre data-bbox="894 911 1507 1822">Session ID: <sessionId> Status: READY Role: <example-role> CreatedOn: 2023-05-26 11:12:17. 056000-07:00 GlueVersion: 3.0 Job Type: glueetl Tags: {'owner':'example-owner', 'team':'analytics', 'billing' :'Data-Platform'} Worker Type: G.4X Number of Workers: 5 Region: us-west-2 Applying the following default arguments: --glue_kernel_version 0.38.0 --enable-glue-datacatalog true Arguments Passed: ['--glue_ kernel_version: 0.38.0', '-- enable-glue-datacatalog: true']</pre>

Name	Type	Description
%assume_role	Dictionary	<p>Specify a json-formatted dictionary or an IAM role ARN string to create a session for cross-account access.</p> <p>Example with ARN:</p> <pre data-bbox="894 474 1507 751">%assume_role { 'arn:aws:iam::XXXXXXXXXXXX: role/AWSGlueServiceRole' }</pre> <p>Example with credentials:</p> <pre data-bbox="894 863 1507 1262">%assume_role {{ "aws_access_key_id" = "XXXXXXXXXXXX", "aws_secret_access_key" = "XXXXXXXXXXXX", "aws_session_token" = "XXXXXXXXXXXX" }}</pre>

%%configure cell magic arguments

The %%configure magic is a json-formatted dictionary consisting of all configuration parameters for a session. Each parameter can be specified here or through individual magics. See below for examples for arguments supported by the %%configure cell magic. Use the -- prefix for run arguments specified for the job. Example:

```
%%configure
{
  "--user-jars-first": "true",
  "--enable-glue-datacatalog": "false"
}
```

For more information on job parameters, see [Job parameters](#).

Session Configuration

Parameter	Type	Description
<code>max_retries</code>	Int	The maximum number of times to retry this job if it fails. <pre>%%configure { "max_retries": "0" }</pre>
<code>max_concurrent_runs</code>	Int	The maximum number of concurrent runs allowed for a job. Example: <pre>%%configure { "max_concurrent_runs": "3" }</pre>

Session parameters

Parameter	Type	Description
<code>--enable-spark-ui</code>	Boolean	Enable Spark UI to monitor and debug Amazon Glue ETL jobs. <pre>%%configure { "--enable-spark-ui": "true" }</pre>

Parameter	Type	Description
<code>--spark-event-logs-path</code>	String	<p>Specifies an Amazon S3 path. When using the Spark UI monitoring feature.</p> <p>Example:</p> <pre>%%configure { "--spark-event-logs-path": "s3://path/to/event/logs/" }</pre>
<code>--script_location</code>	String	<p>Specifies the S3 path to a script that executes a job.</p> <p>Example:</p> <pre>%%configure { "script_location": "s3://new- folder-here" }</pre>
<code>--SECURITY_CONFIGURATION</code>	String	<p>The name of a Amazon Glue security configuration</p> <p>Example:</p> <pre>%%configure { "--security_configuration": { "encryption_type": "kms", "kms_key_id": "YOUR_KMS _KEY_ARN" } }</pre>

Parameter	Type	Description
<code>--job-language</code>	String	<p>The script programming language. Accepts a value of 'scala' or 'python'. Default is 'python'.</p> <p>Example:</p> <pre>%%configure { "--job-language": "scala" }</pre>
<code>--class</code>	String	<p>The Scala class that serves as the entry point for your Scala script. Default is null.</p> <p>Example:</p> <pre>%%configure { "--class": "className" }</pre>
<code>--user-jars-first</code>	Boolean	<p>Prioritizes the customer's extra JAR files in the classpath. Default is null.</p> <p>Example:</p> <pre>%%configure { "--user-jars-first": "true" }</pre>

Parameter	Type	Description
<code>--use-postgres-driver</code>	Boolean	<p>Prioritizes the Postgres JDBC driver in the class path to avoid a conflict with the Amazon Redshift JDBC driver. Default is null.</p> <p>Example:</p> <pre>%%configure { "--use-postgres-driver": "true" }</pre>
<code>--extra-files</code>	List(string)	<p>The Amazon S3 paths to additional files, such as configuration files that Amazon Glue copies to the working directory of your script before executing it.</p> <p>Example:</p> <pre>%%configure { "--extra-files": "s3://path/to/ additional/files/" }</pre>

Parameter	Type	Description
<code>--job-bookmark-option</code>	String	<p>Controls the behavior of a job bookmark. Accepts a value of 'job-bookmark-enable', 'job-bookmark-disable' or 'job-bookmark-pause'. Default is 'job-bookmark-disable'.</p> <p>Example:</p> <pre>%%configure { "--job-bookmark-option": "job- bookmark-enable" }</pre>
<code>--TempDir</code>	String	<p>Specifies an Amazon S3 path to a bucket that can be used as a temporary directory for the job. Default is null.</p> <p>Example:</p> <pre>%%configure { "--TempDir": "s3://path/to/temp /dir" }</pre>

Parameter	Type	Description
<code>--enable-s3-parquet-optimized-committer</code>	Boolean	<p>Enables the EMRFS Amazon S3-optimized committer for writing Parquet data into Amazon S3. Default is 'true'.</p> <p>Example:</p> <pre>%%configure { "--enable-s3-parquet-optimized-committer": "false" }</pre>
<code>--enable-rename-algorithm-v2</code>	Boolean	<p>Sets the EMRFS rename algorithm version to version 2. Default is 'true'.</p> <p>Example:</p> <pre>%%configure { "--enable-rename-algorithm-v2": "true" }</pre>
<code>--enable-glue-data-catalog</code>	Boolean	<p>Enables you to use the Amazon Glue Data Catalog as an Apache Spark Hive metastore.</p> <p>Example:</p> <pre>%%configure { "--enable-glue-datacatalog": "true" }</pre>

Parameter	Type	Description
<code>--enable-metrics</code>	Boolean	<p>Enables the collection of metrics for job profiling for job run. Default is 'false'.</p> <p>Example:</p> <pre>%%configure { "--enable-metrics": "true" }</pre>
<code>--enable-continuous-cloudwatch-log</code>	Boolean	<p>Enables real-time continuous logging for Amazon Glue jobs. Default is 'false'.</p> <p>Example:</p> <pre>%%configure { "--enable-continuous-cloudw atch-log": "true" }</pre>
<code>--enable-continuous-log-filter</code>	Boolean	<p>Specifies a standard filter or no filter when you create or edit a job enabled for continuous logging. Default is 'true'.</p> <p>Example:</p> <pre>%%configure { "--enable-continuous-log-fi lter": "true" }</pre>

Parameter	Type	Description
<code>--continuous-log-stream-prefix</code>	String	<p>Specifies a custom Amazon CloudWatch log stream prefix for a job enabled for continuous logging. Default is null.</p> <p>Example:</p> <pre>%%configure { "--continuous-log-stream-prefix": "prefix" }</pre>
<code>--continuous-log-conversionPattern</code>	String	<p>Specifies a custom conversion log pattern for a job enabled for continuous logging. Default is null.</p> <p>Example:</p> <pre>%%configure { "--continuous-log-conversionPattern": "pattern" }</pre>

Parameter	Type	Description
<code>--conf</code>	String	<p>Controls Spark config parameters. It is for advanced use cases. Use <code>--conf</code> before each parameter. Example:</p> <pre>%%configure { "--conf": "spark.hadoop.hive .metastore.glue.catalogid=1 23456789012 --conf hive.meta store.client.factory.class= com.amazonaws.glue.catalog. metastore.AWSGlueDataCatalo gHiveClientFactory --conf hive.metastore.schema.verif ication=false" }</pre>
<code>timeout</code>	Int	<p>Determines the maximum amount of time that the Spark session should wait for a statement to complete before terminating it.</p> <pre>%%configure { "timeout": "30" }</pre>
<code>auto-scaling</code>	Boolean	<p>Determines whether or not to use auto-scaling.</p> <pre>%%configure { "--enable-auto-scaling": "true" }</pre>

Spark jobs (ETL & streaming) magics

Name	Type	Description
<code>%worker_type</code>	String	Standard, G.1X, G.2X, G.4X, G.8X, G.12X, G.16X, R.1X, R.2X, R.4X, or R.8X. <code>number_of_workers</code> must be set too. The default <code>worker_type</code> is G.1X.
<code>%connections</code>	List	Specify a comma-separated list of connections to use in the session. Example: <pre>%connections my_rds_connection dy_f = glue_context.create_dynamic _frame.from_catalog(databas e='rds_tables', table_nam e='sales_table')</pre>
<code>%extra_py_files</code>	List	Comma separated list of additional Python files from Amazon S3.
<code>%extra_jars</code>	List	Comma-separated list of additional jars to include in the cluster.
<code>%spark_conf</code>	String	Specify custom spark configurations for your session. For example, <code>%spark_conf spark.serializer=org.apache.spark.serializer.KryoSerializer</code> .

Magics for Ray jobs

Name	Type	Description
<code>%min_workers</code>	Int	The minimum number of workers that are allocated to a Ray job. Default: 1. Example: <code>%min_workers 2</code>
<code>%object_memory_head</code>	Int	The percentage of free memory on the instance head node after a warm start. Minimum: 0. Maximum: 100. Example: <code>%object_memory_head 100</code>
<code>%object_memory_worker</code>	Int	The percentage of free memory on the instance worker nodes after a warm start. Minimum: 0. Maximum: 100. Example: <code>%object_memory_worker 100</code>

Action magics

Name	Type	Description
<code>%%sql</code>	String	Run SQL code. All lines after the initial <code>%sql</code> magic will be passed as part of the SQL code. Example: <code>%%sql select * from rds_tables.sales_table</code>
<code>%matplotlib</code>	Matplotlib figure	Visualize your data using the matplotlib library. Example:

Name	Type	Description
		<pre>import matplotlib.pyplot as plt # Set X-axis and Y-axis values x = [5, 2, 8, 4, 9] y = [10, 4, 8, 5, 2] # Create a bar chart plt.bar(x, y) # Show the plot %matplotlib plt</pre>
%plotly	Plotly figure	<p>Visualize your data using the plotly library.</p> <p>Example:</p> <pre>import plotly.express as px #Create a graphical figure fig = px.line(x=["a","b","c"], y=[1,3,2], title="sample figure") #Show the figure %plotly fig</pre>

Naming sessions

Amazon Glue interactive sessions are Amazon resources and require a name. Names should be unique for each session and may be restricted by your IAM administrators. For more information, see [Interactive sessions with IAM](#). The Jupyter kernel automatically generates unique session names for you. However sessions can be named manually in two ways:

1. Using the Amazon Command Line Interface config file located at `~.aws/config`. See [Setting Up Amazon Config with the Amazon Command Line Interface](#).

2. Using the `%session_id_prefix` magics. See [Magics supported by Amazon Glue interactive sessions for Jupyter](#).

A session name is generated as follows:

- When the prefix and `session_id` are provided: the session name will be `{prefix}-{UUID}`.
- When nothing is provided: the session name will be `{UUID}`.

Prefixing session names allows you to recognize your session when listing it in the Amazon CLI or console.

Specifying an IAM role for interactive sessions

You must specify an Amazon Identity and Access Management (IAM) role to use with Amazon Glue ETL code that you run with interactive sessions.

The role requires the same IAM permissions as those required to run Amazon Glue jobs. See [Create an IAM role for Amazon Glue](#) for more information on creating a role for Amazon Glue jobs and interactive sessions.

IAM roles can be specified in two ways:

- Using the Amazon Command Line Interface config file located at `~/.aws/config` (Recommended). For more information, see [Configuring sessions with `~/.aws/config`](#).

Note

When the `%profile` magic is used, the configuration for `glue_iam_role` of that profile is honored.

- Using the `%iam_role` magic. For more information, see [Magics supported by Amazon Glue interactive sessions for Jupyter](#).

Configuring sessions with named profiles

Amazon Glue interactive sessions uses the same credentials as the Amazon Command Line Interface or `boto3`, and interactive sessions honors and works with named profiles like the Amazon

CLI found in `~/ .aws/config` (Linux and MacOS) or `%USERPROFILE%\ .aws\config` (Windows). For more information, see [Using named profiles](#).

Interactive sessions takes advantage of named profiles by allowing the Amazon Glue Service Role and Session ID Prefix to be specified in a profile. To configure a profile role, add a line for the `iam_role` key and/or `session_id_prefix` to your named profile as shown below. The `session_id_prefix` does not require quotes. For example, if you want to add a `session_id_prefix`, enter the value of the `session_id_prefix=myprefix`.

```
[default]
region=us-east-1
aws_access_key_id=AKIAIOSFODNN7EXAMPLE
aws_secret_access_key=wJalrXUtnFEMI/K7MDENG/bPxrFiCYEXAMPLEKEY
glue_iam_role=arn:aws:iam::<AccountID>:role/<GlueServiceRole>
session_id_prefix=<prefix_for_session_names>

[user1]
region=eu-west-1
aws_access_key_id=AKIAI44QH8DHBEXAMPLE
aws_secret_access_key=je7MtGbClwBF/2Zp9Utk/h3yCo8nvbEXAMPLEKEY
glue_iam_role=arn:aws:iam::<AccountID>:role/<GlueServiceRoleUser1>
session_id_prefix=<prefix_for_session_names_for_user1>
```

If you have a custom method of generating credentials, you can also configure your profile to use the `credential_process` parameter in your `~/ .aws/config` file. For example:

```
[profile developer]
region=us-east-1
credential_process = "/Users/Dave/generate_my_credentials.sh" --username helen
```

You can find more details about sourcing credentials through the `credential_process` parameter here: [Sourcing credentials with an external process](#).

If a `region` or `iam_role` are not set in the profile that you are using, you must specify them using the `%region` and `%iam_role` magics in the first cell that you run.

Converting a script or notebook into an Amazon Glue job

There are two ways you can convert a script or notebook into an Amazon Glue job:

- Use **nbconvert** to convert your Jupyter `.ipynb` notebook document file into a `.py` file. For more information, see [nbconvert: Convert Notebooks to other formats](#).
- Upload the file to Amazon Glue Studio Notebooks.
 - In the Amazon Glue Studio console, choose **Jobs** from the navigation menu.
 - In the **Create job** section, choose **Jupyter Notebook**.
 - In the **Options** section, choose **Upload and edit an existing notebook**.
 - Select **Choose file** to upload an `.ipynb` file.

Working with streaming operations in Amazon Glue interactive sessions

Switching streaming session type

Use the Amazon Glue interactive sessions configuration magic, `%streaming`, to define the job you are running and initialize a streaming interactive session.

Sampling input stream for interactive development

One tool we have derived to help enhance the interactive experience in Amazon Glue interactive sessions is the addition of a new method under `GlueContext` to obtain a snapshot of a stream in a static `DynamicFrame`. `GlueContext` allows you to inspect, interact and implement your workflow.

With the `GlueContext` class instance, you will be able to locate the method `getSampleStreamingDynamicFrame`. Required arguments for this method are:

- `dataFrame`: The Spark Streaming `DataFrame`
- `options`: See available options below

Available options include :

- **windowSize**: This is also called Microbatch Duration. This parameter will determine how long a streaming query will wait after previous batch was triggered. This parameter value must be smaller than `pollingTimeInMs`.
- **pollingTimeInMs**: The total length of time the method will run. It will fire off at least one micro batch to obtain sample records from the input stream.

- **recordPollingLimit:** This parameter helps you limit the total number of records you will poll from the stream.
- (Optional) You can also use `writeStreamFunction` to apply this custom function to every record sampling function. See below for examples in Scala and Python.

Scala

```
val sampleBatchFunction = (batchDF: DataFrame, batchId: Long) => {//Optional but you can replace your own forEachBatch function here
val jsonString: String = s""""{"pollingTimeInMs": "10000", "windowSize": "5 seconds"}""""
val dynFrame = glueContext.getSampleStreamingDynamicFrame(YOUR_STREAMING_DF,
  JsonOptions(jsonString), sampleBatchFunction)
dynFrame.show()
```

Python

```
def sample_batch_function(batch_df, batch_id):
    //Optional but you can replace your own forEachBatch function here
    options = {
        "pollingTimeInMs": "10000",
        "windowSize": "5 seconds",
    }
    glue_context.getSampleStreamingDynamicFrame(YOUR_STREAMING_DF, options,
        sample_batch_function)
```

Note

When the sampled `DynFrame` is empty, it could be caused by a few reasons:

- The Streaming source is set to "Latest" and no new data has been ingested during the sampling period.
- The polling time is not enough to process the records it ingested. Data won't show up unless the whole batch has been processed.

Running streaming applications in interactive sessions

In Amazon Glue interactive sessions, you can run a the Amazon Glue streaming application like how you would create a streaming application in the Amazon Glue Console. Since interactive sessions is session-based, encountering exceptions in the runtime does not cause the session to stop. We now have the added benefit of developing your batch function iteratively. For example:

```
def batch_function(data_frame, batch_id):
    log.info(data_frame.count())
    invalid_method_call()
glueContext.foreachBatch(frame=streaming_df, batch_function = batch_function, options =
{**})
```

In the example above, we included an invalid usage of a method and unlike regular Amazon Glue jobs which will exit the entire application, the user's coding context and definitions are fully preserved and the session is still operational. There is no need to bootstrap a new cluster and rerun all the preceding transformation. This allows you to focus on quickly iterating your batch function implementations to obtain desirable outcomes.

It is important to note that Interactive Session evaluates each statement in a blocking manner so that the session will only execute one statement at a time. Since streaming queries are continuous and never ending, sessions with active streaming queries won't be able to handle any follow up statements unless they are interrupted. You can issue the interruption command directly from Jupyter Notebook and our kernel will handle the cancellation for you.

Take the following sequence of statements which are waiting for execution as an example:

```
Statement 1:
    val number = df.count()
    #Spark Action with deterministic result
    Result: 5

Statement 2:
    streamingQuery.start().awaitTermination()
    #Spark Streaming Query that will be executing continuously
    Result: Constantly updated with each microbatch

Statement 3:
    val number2 = df.count()
```

```
#This will not be executed as previous statement will be running indefinitely
```

Amazon Glue interactive session pricing

Amazon charges for Amazon Glue interactive sessions based on how long the session is active and the number of Data Processing Units (DPU) used. You are charged an hourly rate for the number of DPUs used to run your workloads, billed in increments of one second. Amazon Glue interactive sessions assigns a default of 5 DPUs and requires a minimum of 2 DPUs. There is also a 1-minute minimum billing duration for each interactive session. To see the Amazon Glue rates and pricing examples, or to estimate your costs using the Amazon Pricing Calculator, see [Amazon Glue pricing](#).

Configure your Amazon Glue interactive sessions

You can use Jupyter magics in your Amazon interactive session to modify your session and configuration parameters. Magics are short commands prefixed with `%` at the start of Jupyter cells that provide a quick and easy way to help you control your environment. For example, if you want to change the number of workers allocated to your job from the default 5 to 10, you can specify `%number_of_workers 10`. If you want to configure your session to stop after 10 minutes of idle time instead of the default 2880, you can specify `%idle_timeout 10`.

For the complete list of Amazon magics available, see [Configuring Amazon interactive sessions for Jupyter and Amazon Glue Studio notebooks](#).

Developing and testing Amazon Glue job scripts locally

When you develop and test your Amazon Glue for Spark job scripts, there are multiple available options:

- Amazon Glue Studio console
 - Visual editor
 - Script editor
 - Amazon Glue Studio notebook
- Interactive sessions
 - Jupyter notebook
- Docker image

- Local development
- Remote development

You can choose any of the above options based on your requirements.

If you prefer no code or less code experience, the Amazon Glue Studio visual editor is a good choice.

If you prefer an interactive notebook experience, Amazon Glue Studio notebook is a good choice. For more information, see [Using Notebooks with Amazon Glue Studio and Amazon Glue](#). If you want to use your own local environment, interactive sessions is a good choice. For more information, see [Using interactive sessions with Amazon Glue](#).

If you prefer local/remote development experience, the Docker image is a good choice. This helps you to develop and test Amazon Glue for Spark job scripts anywhere you prefer without incurring Amazon Glue cost.

If you prefer local development without Docker, installing the Amazon Glue ETL library directory locally is a good choice.

Developing using Amazon Glue Studio

The Amazon Glue Studio visual editor is a graphical interface that makes it easy to create, run, and monitor extract, transform, and load (ETL) jobs in Amazon Glue. You can visually compose data transformation workflows and seamlessly run them on Amazon Glue's Apache Spark-based serverless ETL engine. You can inspect the schema and data results in each step of the job. For more information, see the [Amazon Glue Studio User Guide](#).

Developing using interactive sessions

Interactive sessions allow you to build and test applications from the environment of your choice. For more information, see [Using interactive sessions with Amazon Glue](#).

Develop and test Amazon Glue jobs locally using a Docker image

For a production-ready data platform, the development process and CI/CD pipeline for Amazon Glue jobs is a key topic. You can flexibly develop and test Amazon Glue jobs in a Docker container. Amazon Glue hosts Docker images on Docker Hub to set up your development environment with additional utilities. You can use your preferred IDE, notebook, or REPL using Amazon Glue ETL

library. This topic describes how to develop and test Amazon Glue version 5.0 jobs in a Docker container using a Docker image.

Available Docker images

The following Docker images are available for Amazon Glue on [Amazon ECR](#):

- For Amazon Glue version 5.0: `public.ecr.aws/glue/aws-glue-libs:5`
- For Amazon Glue version 4.0: `public.ecr.aws/glue/aws-glue-libs:glue_libs_4.0.0_image_01`
- For Amazon Glue version 3.0: `public.ecr.aws/glue/aws-glue-libs:glue_libs_3.0.0_image_01`
- For Amazon Glue version 2.0: `public.ecr.aws/glue/aws-glue-libs:glue_libs_2.0.0_image_01`

Note

Amazon Glue Docker images are compatible with both x86_64 and arm64.

In this example, we use `public.ecr.aws/glue/aws-glue-libs:5` and run the container on a local machine (Mac, Windows, or Linux). This container image has been tested for Amazon Glue version 5.0 Spark jobs. The image contains the following:

- Amazon Linux 2023
- Amazon Glue ETL Library
- Apache Spark 3.5.4
- Open table format libraries; Apache Iceberg 1.7.1, Apache Hudi 0.15.0, and Delta Lake 3.3.0
- Amazon Glue Data Catalog Client
- Amazon Redshift connector for Apache Spark
- Amazon DynamoDB connector for Apache Hadoop

To set up your container, pull the image from ECR Public Gallery and then run the container. This topic demonstrates how to run your container with the following methods, depending on your requirements:

- `spark-submit`
- REPL shell (pyspark)
- `pytest`
- Visual Studio Code

Prerequisites

Before you start, make sure that Docker is installed and the Docker daemon is running. For installation instructions, see the Docker documentation for [Mac](#) or [Linux](#). The machine running the Docker hosts the Amazon Glue container. Also make sure that you have at least 7 GB of disk space for the image on the host running the Docker.

For more information about restrictions when developing Amazon Glue code locally, see [Local development restrictions](#).

Configuring Amazon

To enable Amazon API calls from the container, set up Amazon credentials by following steps. In the following sections, we will use this Amazon named profile.

1. [Create an Amazon named profile](#).
2. Open `cmd` on Windows or a terminal on Mac/Linux and run the following command in a terminal:

```
PROFILE_NAME="<your_profile_name>"
```

In the following sections, we use this Amazon named profile.

If you're running Docker on Windows, choose the Docker icon (right-click) and choose **Switch to Linux containers** before pulling the image.

Run the following command to pull the image from ECR Public:

```
docker pull public.ecr.aws/glue/aws-glue-libs:5
```

Run the container

You can now run a container using this image. You can choose any of following based on your requirements.

spark-submit

You can run an Amazon Glue job script by running the `spark-submit` command on the container.

1. Write your script and save it as `sample.py` in the example below and save it under the `/local_path_to_workspace/src/` directory using the following commands:

```
$ WORKSPACE_LOCATION=/local_path_to_workspace
$ SCRIPT_FILE_NAME=sample.py
$ mkdir -p ${WORKSPACE_LOCATION}/src
$ vim ${WORKSPACE_LOCATION}/src/${SCRIPT_FILE_NAME}
```

2. These variables are used in the `docker run` command below. The sample code (`sample.py`) used in the `spark-submit` command below is included in the appendix at the end of this topic.

Run the following command to execute the `spark-submit` command on the container to submit a new Spark application:

```
$ docker run -it --rm \
  -v ~/.aws:/home
  /hadoop/.aws \
  -v $WORKSPACE_LOCATION:/home/hadoop/workspace/ \
  -e AWS_PROFILE=$PROFILE_NAME \
  --name glue5_spark_submit \
  public.ecr.aws/glue/aws-glue-libs:5 \
  spark-submit /home/hadoop/workspace/src/${SCRIPT_FILE_NAME}
```

3. (Optionally) Configure `spark-submit` to match your environment. For example, you can pass your dependencies with the `--jars` configuration. For more information, consult [Dynamically Loading Spark Properties](#) in the Spark documentation.

REPL shell (Pyspark)

You can run REPL (`read-eval-print loops`) shell for interactive development. Run the following command to execute the PySpark command on the container to start the REPL shell:

```
$ docker run -i --rm \
  -v ~/.aws:/home/hadoop/.aws \
  -v $WORKSPACE_LOCATION:/home/hadoop/workspace/ \
  --workdir /home/hadoop/workspace \
  -e AWS_PROFILE=$PROFILE_NAME \
  --name glue5_pytest \
  public.ecr.aws/glue/aws-glue-libs:5 \
  -c "python3 -m pytest --disable-warnings"
```

Once pytest finishes executing unit tests, your output will look something like this:

```
===== test session starts =====
platform linux -- Python 3.11.6, pytest-8.3.4, pluggy-1.5.0
rootdir: /home/hadoop/workspace
plugins: integration-mark-0.2.0
collected 1 item

tests/test_sample.py . [100%]

===== 1 passed, 1 warning in 34.28s =====
```

Setting up the container to use Visual Studio Code

To set up the container with Visual Studio Code, complete the following steps:

1. Install Visual Studio Code.
2. Install [Python](#).
3. Install [Visual Studio Code Remote - Containers](#)
4. Open the workspace folder in Visual Studio Code.
5. Press Ctrl+Shift+P (Windows/Linux) or Cmd+Shift+P (Mac).
6. Type Preferences: Open Workspace Settings (JSON).
7. Press Enter.
8. Paste the following JSON and save it.

```
{
  "python.defaultInterpreterPath": "/usr/bin/python3.11",
  "python.analysis.extraPaths": [
    "/usr/lib/spark/python/lib/py4j-0.10.9.7-src.zip:/usr/lib/spark/python:/usr/
lib/spark/python/lib/",
```

```
]
}
```

To set up the container:

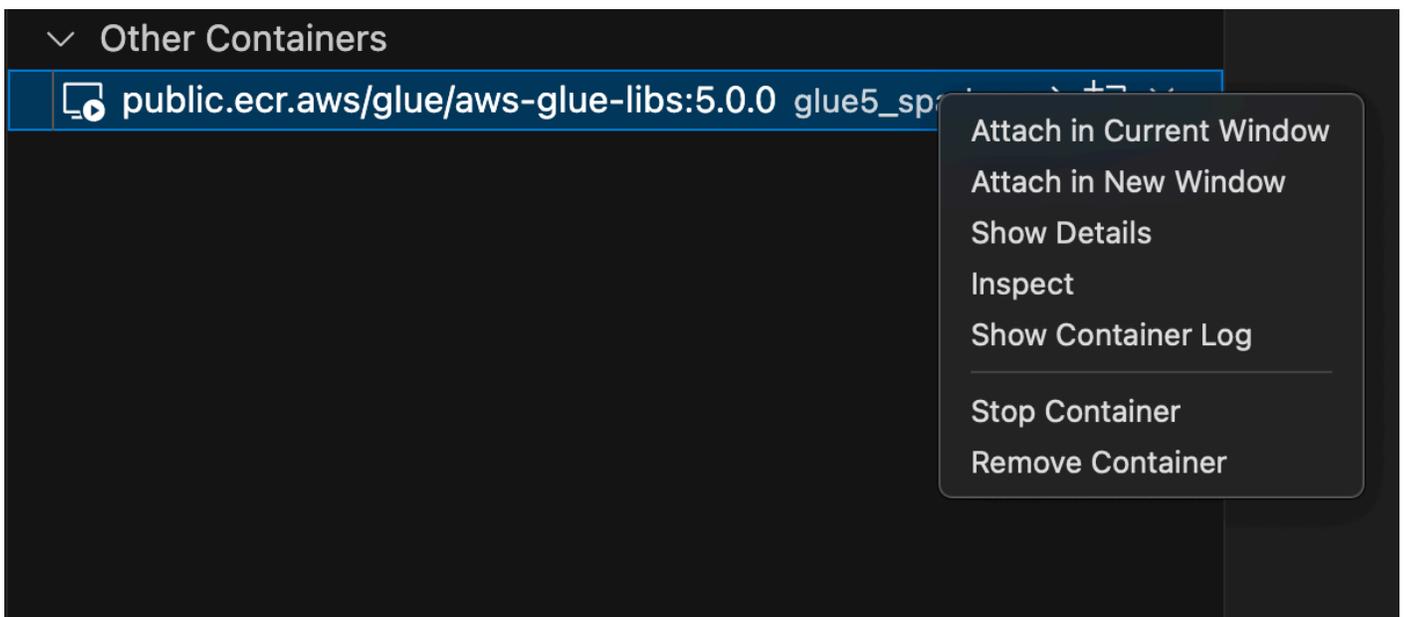

1. Run the Docker container.

```
$ docker run -it --rm \
  -v ~/.aws:/home/hadoop/.aws \
  -v $WORKSPACE_LOCATION:/home/hadoop/workspace/ \
  -e AWS_PROFILE=$PROFILE_NAME \
  --name glue5_pyspark \
  public.ecr.aws/glue/aws-glue-libs:5 \
  pyspark
```

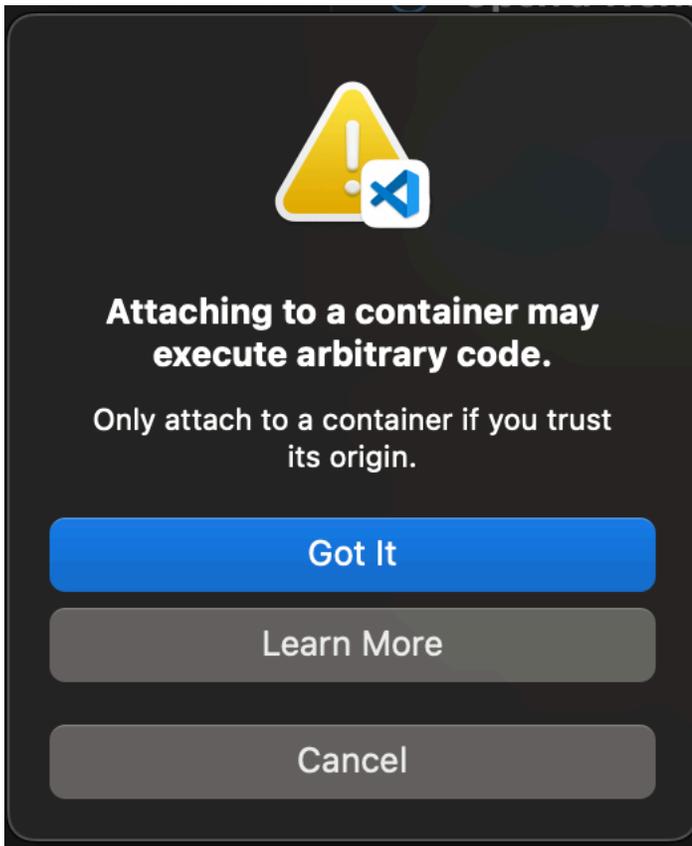

2. Start Visual Studio Code.

3. Choose **Remote Explorer** on the left menu, and choose `amazon/aws-glue-libs:glue_libs_4.0.0_image_01`.

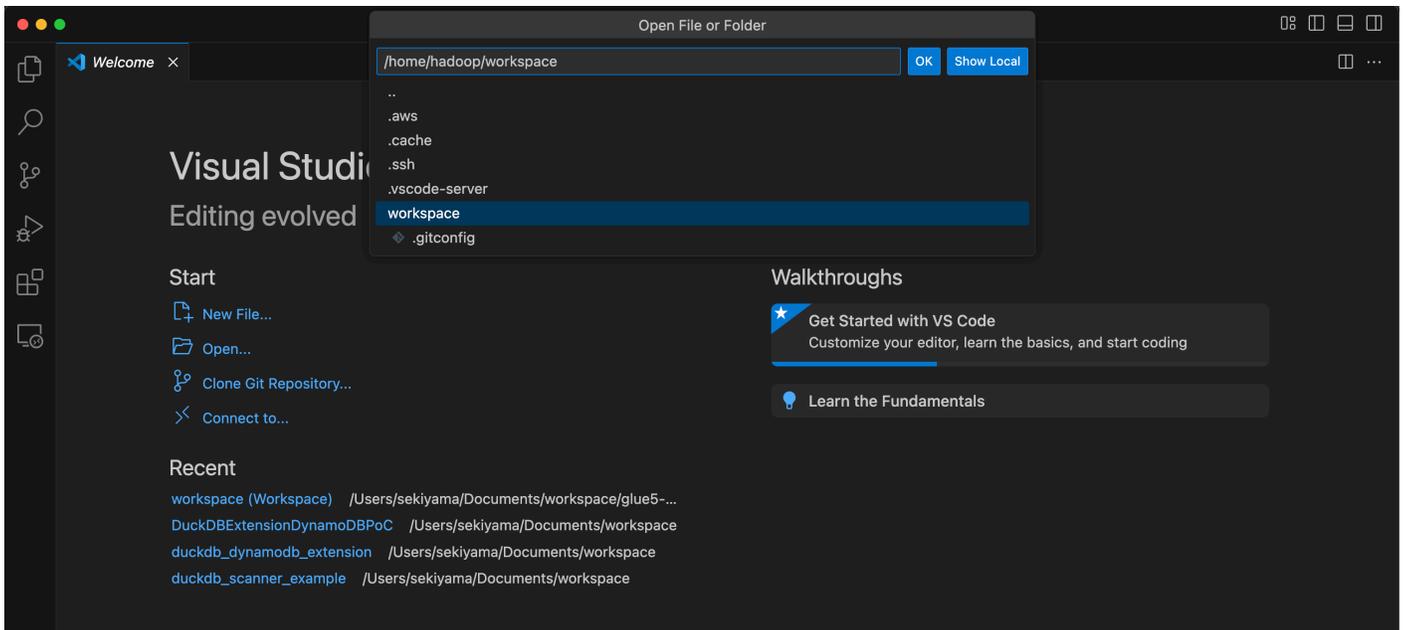

4. Right-click and choose **Attach in Current Window**.

5. If the following dialog appears, choose **Got it**.

6. Open `/home/hadoop/workspace/`.

7. Create a Amazon Glue PySpark script and choose **Run**.

You will see the successful run of the script.

```

src > sample.py > GluePythonSampleTest > __init__
1 import sys
2 from pyspark.context import SparkContext
3 from awsglue.context import GlueContext
4 from awsglue.job import Job
5 from awsglue.utils import getResolvedOptions
6
7
8 class GluePythonSampleTest:
9     def __init__(self):
10         params = []
11         if '--JOB_NAME' in sys.argv:
12             params.append('--JOB_NAME')
13         args = getResolvedOptions(sys.argv, params)
14
15         self.context = GlueContext(SparkContext.getOrCreate())
16         self.job = Job(self.context)
17
18         if 'JOB_NAME' in args:
19             jobname = args['JOB_NAME']
20         else:
21             jobname = "test"
22         self.job.init(jobname, args)
23
24     def run(self):
25         dyf = read_json(self.context, "s3://awsglue-datasets/examples/us-legislators/all/persons.json")
26         dyf.printSchema()
27
28         self.job.commit()

```

```

bash-5.2$ /usr/bin/python3.11 /home/hadoop/workspace/src/sample.py

Changes between Amazon Glue 4.0 and Amazon Glue 5.0 Docker image

The major changes between the Amazon Glue 4.0 and Amazon Glue 5.0 Docker image:

- In Amazon Glue 5.0, there is a single container image for both batch and streaming jobs. This differs from Glue 4.0, where there was one image for batch and another for streaming.
- In Amazon Glue 5.0, the default user name of the container is hadoop. In Amazon Glue 4.0, the default user name was glue_user.
- In Amazon Glue 5.0, several additional libraries including JupyterLab and Livy have been removed from the image. You can manually install them.
- In Amazon Glue 5.0, all of Iceberg, Hudi and Delta libraries are pre-loaded by default, and the environment variable DATALAKE_FORMATS is no longer needed. Prior to Amazon Glue 4.0, the

environment variable `DATALAKE_FORMATS` environment variable was used to specify which specific table formats should be loaded.

The above list is specific to the Docker image. To learn more about Amazon Glue 5.0 updates, see [Introducing Amazon Glue 5.0 for Apache Spark](#) and [Migrating Amazon Glue for Spark jobs to Amazon Glue version 5.0](#).

Considerations

Keep in mind that the following features are not supported when using the Amazon Glue container image to develop job scripts locally.

- [Job bookmarks](#)
- Amazon Glue Parquet writer ([Using the Parquet format in Amazon Glue](#))
- [FillMissingValues transform](#)
- [FindMatches transform](#)
- [Vectorized SIMD CSV reader](#)
- The property [customJdbcDriverS3Path](#) for loading JDBC driver from Amazon S3 path
- [Amazon Glue Data Quality](#)
- [Sensitive Data Detection](#)
- Amazon Lake Formation permission-based credential vending

Appendix: Adding JDBC drivers and Java libraries

To add JDBC driver not currently available in the container, you can create a new directory under your workspace with JAR files you need and mount the directory to `/opt/spark/jars/` in docker run command. JAR files found under `/opt/spark/jars/` within the container are automatically added to Spark Classpath and will be available for use during job run.

For example, use the following docker run command to add JDBC driver jars to PySpark REPL shell.

```
docker run -it --rm \
  -v ~/.aws:/home/hadoop/.aws \
  -v $WORKSPACE_LOCATION:/home/hadoop/workspace/ \
  -v $WORKSPACE_LOCATION/jars:/opt/spark/jars/ \
  --workdir /home/hadoop/workspace \
  -e AWS_PROFILE=$PROFILE_NAME \
```

```
--name glue5_jdbc \  
public.ecr.aws/glue/aws-glue-libs:5 \  
pyspark
```

As highlighted in **Considerations**, `customJdbcDriverS3Path` connection option cannot be used to import a custom JDBC driver from Amazon S3 in Amazon Glue container images.

Development endpoints

Note

The console experience for dev endpoints has been removed as of March 31, 2023. Creating, updating, and monitoring dev endpoints is still available via the [Development endpoints API](#) and [Amazon Glue CLI](#).

We strongly recommend migrating from dev endpoints to interactive sessions for the reasons listed below. For required actions on how to migrate from dev endpoints to interactive sessions, see [Migrating from dev endpoints to interactive sessions](#).

Description	Dev endpoints	Interactive sessions
Glue version support	Supports Amazon Glue version 0.9 and 1.0	Supports Amazon Glue version 2.0 and later
Dev endpoints are not available in the Asia Pacific (Jakarta) (ap-southeast-3), Middle East (UAE) (me-central-1), Europe (Spain) (eu-south-2), Europe (Zurich) (eu-central-2), or other new regions going forward	Interactive sessions are not currently available in the Middle East (UAE) (me-central-1) region, but may be made available later	
Access method to the Spark cluster	Supports SSH, REPL shell, Jupyter notebook, IDE (e.g. PyCharm)	supports Amazon Glue Studio notebook, Jupyter notebook, various IDEs (for example,

Description	Dev endpoints	Interactive sessions
		Visual Studio Code, PyCharm), and SageMaker AI notebook
Time to first query	Requires 10-15 minutes to setup a Spark cluster	Can take up to 1 minute to set up an ephemeral Spark cluster
Price model	<p>Amazon charges for development endpoints based on the time that the endpoint is provisioned and the number of DPUs. Development endpoints do not time out. There is a 10-minute minimum billing duration for each provisioned development endpoint. Additionally, Amazon charges for Jupyter notebook on Amazon EC2 instances, and SageMaker AI notebooks when you configure them with dev endpoints.</p>	<p>Amazon charges for interactive sessions based on the time that the session is active and the number of DPUs. Interactive sessions have configurable idle timeouts. Amazon Glue Studio notebooks provide a built-in interface for interactive sessions and are offered at no additional cost. There is a 1-minute minimum billing duration for each interactive session. Amazon Glue Studio notebooks provide a built-in interface for interactive sessions and are offered at no additional cost</p>
Console experience	Only available via the CLI and API	Available through the Amazon Glue console, CLI, and APIs

Migrating from dev endpoints to interactive sessions

Use the following checklist to determine the appropriate method to migrate from dev endpoints to interactive sessions.

Does your script depend on Amazon Glue 0.9 or 1.0 specific features (for example, HDFS, YARN, etc.)?

If the answer is yes, see [Migrating Amazon Glue jobs to Amazon Glue version 3.0](#). to learn how to migrate from Glue 0.9 or 1.0 to Glue 3.0 and later.

Which method do you use to access your dev endpoint?

If you use this method	Then do this
SageMaker AI notebook, Jupyter notebook, or JupyterLab	Migrate to Amazon Glue Studio notebook by downloading <code>.ipynb</code> files on Jupyter and create a new Amazon Glue Studio notebook job by uploading the <code>.ipynb</code> file. Alternatively, you can also use SageMaker AI Studio and select the Amazon Glue kernel.
Zeppelin notebook	Convert the notebook to a Jupyter notebook manually by copying and pasting code or automatically using a third-party converter such as <code>ze2nb</code> . Then, use the notebook in Amazon Glue Studio notebook or SageMaker AI Studio.
IDE	See Author Amazon Glue jobs with PyCharm using Amazon Glue interactive sessions , or Using interactive sessions with Microsoft Visual Studio Code .
REPL	Install the aws-glue-session package locally, then run the following command: <ul style="list-style-type: none"> • For Python: <code>jupyter console --kernel glue_pyspark</code> • For Scala: <code>jupyter console --kernel glue_spark</code>
SSH	No corresponding option on interactive sessions. Alternatively, you can use a Docker image. To learn more, see Developing using a Docker image .

The following sections provide information on using dev endpoints to develop jobs in Amazon Glue version 1.0.

Topics

- [Developing scripts using development endpoints](#)
- [Managing notebooks](#)

Developing scripts using development endpoints

Note

Development Endpoints are only supported for versions of Amazon Glue prior to 2.0. For an interactive environment where you can author and test ETL scripts, use [Notebooks on Amazon Glue Studio](#).

Amazon Glue can create an environment—known as a *development endpoint*—that you can use to iteratively develop and test your extract, transform, and load (ETL) scripts. You can create, edit, and delete development endpoints using the Amazon Glue console or API.

Managing your development environment

When you create a development endpoint, you provide configuration values to provision the development environment. These values tell Amazon Glue how to set up the network so that you can access the endpoint securely and the endpoint can access your data stores.

You can then create a notebook that connects to the endpoint, and use your notebook to author and test your ETL script. When you're satisfied with the results of your development process, you can create an ETL job that runs your script. With this process, you can add functions and debug your scripts in an interactive manner.

Follow the tutorials in this section to learn how to use your development endpoint with notebooks.

Development endpoint workflow

To use an Amazon Glue development endpoint, you can follow this workflow:

1. Create a development endpoint using the API. The endpoint is launched in a virtual private cloud (VPC) with your defined security groups.
2. The API polls the development endpoint until it is provisioned and ready for work. When it's ready, connect to the development endpoint using one of the following methods to create and test Amazon Glue scripts.
 - Create an SageMaker AI notebook in your account. For more information about how to create a notebook, see [the section called "Authoring code with Amazon Glue Studio notebooks"](#).
 - Open a terminal window to connect directly to a development endpoint.
 - If you have the professional edition of the JetBrains [PyCharm Python IDE](#), connect it to a development endpoint and use it to develop interactively. If you insert pydevd statements in your script, PyCharm can support remote breakpoints.
3. When you finish debugging and testing on your development endpoint, you can delete it.

How Amazon Glue development endpoints work with SageMaker notebooks

One of the common ways to access your development endpoints is to use [Jupyter](#) on SageMaker notebooks. The Jupyter notebook is an open-source web application which is widely used in visualization, analytics, machine learning, etc. An Amazon Glue SageMaker notebook provides you a Jupyter notebook experience with Amazon Glue development endpoints. In the Amazon Glue SageMaker notebook, the Jupyter notebook environment is pre-configured with [SparkMagic](#), an open source Jupyter plugin to submit Spark jobs to a remote Spark cluster. [Apache Livy](#) is a service that allows interaction with a remote Spark cluster over a REST API. In the Amazon Glue

SageMaker notebook, SparkMagic is configured to call the REST API against a Livy server running on an Amazon Glue development endpoint.

The following text flow explains how each component works:

Amazon Glue SageMaker notebook: (Jupyter # SparkMagic) # (network) # Amazon Glue development endpoint: (Apache Livy # Apache Spark)

Once you run your Spark script written in each paragraph on a Jupyter notebook, the Spark code is submitted to the Livy server via SparkMagic, then a Spark job named "livy-session-N" runs on the Spark cluster. This job is called a Livy session. The Spark job will run while the notebook session is alive. The Spark job will be terminated when you shutdown the Jupyter kernel from the notebook, or when the session is timed out. One Spark job is launched per notebook (.ipynb) file.

You can use a single Amazon Glue development endpoint with multiple SageMaker notebook instances. You can create multiple notebook files in each SageMaker notebook instance. When you open an each notebook file and run the paragraphs, then a Livy session is launched per notebook file on the Spark cluster via SparkMagic. Each Livy session corresponds to single Spark job.

Default behavior for Amazon Glue development endpoints and SageMaker notebooks

The Spark jobs run based on the [Spark configuration](#). There are multiple ways to set the Spark configuration (for example, Spark cluster configuration, SparkMagic's configuration, etc.).

By default, Spark allocates cluster resources to a Livy session based on the Spark cluster configuration. In the Amazon Glue development endpoints, the cluster configuration depends on the worker type. Here's a table which explains the common configurations per worker type.

	Standard	G.1X	G.2X
spark.driver.memory	5G	10G	20G
spark.executor.memory	5G	10G	20G

	Standard	G.1X	G.2X
<code>spark.executor.cores</code>	4	8	16
<code>spark.dynamicAllocation.enabled</code>	TRUE	TRUE	TRUE

The maximum number of Spark executors is automatically calculated by combination of DPU (or `NumberOfWorkers`) and worker type.

	Standard	G.1X	G.2X
The number of max Spark executors	$(\text{DPU} - 1) * 2 - 1$	$(\text{NumberOfWorkers} - 1)$	$(\text{NumberOfWorkers} - 1)$

For example, if your development endpoint has 10 workers and the worker type is G.1X, then you will have 9 Spark executors and the entire cluster will have 90G of executor memory since each executor will have 10G of memory.

Regardless of the specified worker type, Spark dynamic resource allocation will be turned on. If a dataset is large enough, Spark may allocate all the executors to a single Livy session since `spark.dynamicAllocation.maxExecutors` is not set by default. This means that other Livy sessions on the same dev endpoint will wait to launch new executors. If the dataset is small, Spark will be able to allocate executors to multiple Livy sessions at the same time.

Note

For more information about how resources are allocated in different use cases and how you set a configuration to modify the behavior, see [Advanced configuration: sharing development endpoints among multiple users](#).

Adding a development endpoint

Use development endpoints to iteratively develop and test your extract, transform, and load (ETL) scripts in Amazon Glue. Working with development endpoints is only available through the Amazon Command Line Interface.

1. In a command line window, enter a command similar to the following.

```
aws glue create-dev-endpoint --endpoint-name "endpoint1" --role-arn "arn:aws-cn:iam::account-id:role/role-name" --number-of-nodes "3" --glue-version "1.0" --arguments '{"GLUE_PYTHON_VERSION": "3"}' --region "region-name"
```

This command specifies Amazon Glue version 1.0. Because this version supports both Python 2 and Python 3, you can use the `arguments` parameter to indicate the desired Python version. If the `glue-version` parameter is omitted, Amazon Glue version 0.9 is assumed. For more information about Amazon Glue versions, see the [Glue version job property](#).

For information about additional command line parameters, see [create-dev-endpoint](#) in the *Amazon CLI Command Reference*.

2. (Optional) Enter the following command to check the development endpoint status. When the status changes to `READY`, the development endpoint is ready to use.

```
aws glue get-dev-endpoint --endpoint-name "endpoint1"
```

Accessing your development endpoint

When you create a development endpoint in a virtual private cloud (VPC), Amazon Glue returns only a private IP address. The public IP address field is not populated. When you create a non-VPC development endpoint, Amazon Glue returns only a public IP address.

If your development endpoint has a **Public address**, confirm that it is reachable with the SSH private key for the development endpoint, as in the following example.

```
ssh -i dev-endpoint-private-key.pem glue@public-address
```

Suppose that your development endpoint has a **Private address**, your VPC subnet is routable from the public internet, and its security groups allow inbound access from your client. In this case,

follow these steps to attach an *Elastic IP address* to a development endpoint to allow access from the internet.

Note

If you want to use Elastic IP addresses, the subnet that is being used requires an internet gateway associated through the route table.

To access a development endpoint by attaching an Elastic IP address

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, choose **Dev endpoints**, and navigate to the development endpoint details page. Record the **Private address** for use in the next step.
3. Open the Amazon EC2 console at <https://console.amazonaws.cn/ec2/>.
4. In the navigation pane, under **Network & Security**, choose **Network Interfaces**.
5. Search for the **Private DNS (IPv4)** that corresponds to the **Private address** on the Amazon Glue console development endpoint details page.

You might need to modify which columns are displayed on your Amazon EC2 console. Note the **Network interface ID (ENI)** for this address (for example, `eni-12345678`).

6. On the Amazon EC2 console, under **Network & Security**, choose **Elastic IPs**.
7. Choose **Allocate new address**, and then choose **Allocate** to allocate a new Elastic IP address.
8. On the **Elastic IPs** page, choose the newly allocated **Elastic IP**. Then choose **Actions, Associate address**.
9. On the **Associate address** page, do the following:
 - For **Resource type**, choose **Network interface**.
 - In the **Network interface** box, enter the **Network interface ID (ENI)** for the private address.
 - Choose **Associate**.
10. Confirm that the newly associated Elastic IP address is reachable with the SSH private key that is associated with the development endpoint, as in the following example.

```
ssh -i dev-endpoint-private-key.pem glue@elastic-ip
```

For information about using a bastion host to get SSH access to the development endpoint's private address, see the Amazon Security Blog post [Securely Connect to Linux Instances Running in a Private Amazon VPC](#).

Tutorial: Set up a Jupyter notebook in JupyterLab to test and debug ETL scripts

In this tutorial, you connect a Jupyter notebook in JupyterLab running on your local machine to a development endpoint. You do this so that you can interactively run, debug, and test Amazon Glue extract, transform, and load (ETL) scripts before deploying them. This tutorial uses Secure Shell (SSH) port forwarding to connect your local machine to an Amazon Glue development endpoint. For more information, see [Port forwarding](#) on Wikipedia.

Step 1: Install JupyterLab and Sparkmagic

You can install JupyterLab by using `conda` or `pip`. `conda` is an open-source package management system and environment management system that runs on Windows, macOS, and Linux. `pip` is the package installer for Python.

If you're installing on macOS, you must have Xcode installed before you can install Sparkmagic.

1. Install JupyterLab, Sparkmagic, and the related extensions.

```
$ conda install -c conda-forge jupyterlab
$ pip install sparkmagic
$ jupyter nbextension enable --py --sys-prefix widgetsnbextension
$ jupyter labextension install @jupyter-widgets/jupyterlab-manager
```

2. Check the sparkmagic directory from Location.

```
$ pip show sparkmagic | grep Location
Location: /Users/username/.pyenv/versions/anaconda3-5.3.1/lib/python3.7/site-packages
```

3. Change your directory to the one returned for Location, and install the kernels for Scala and PySpark.

```
$ cd /Users/username/.pyenv/versions/anaconda3-5.3.1/lib/python3.7/site-packages
$ jupyter-kernelspec install sparkmagic/kernels/sparkkernel
$ jupyter-kernelspec install sparkmagic/kernels/pysparkkernel
```

4. Download a sample config file.

```
$ curl -o ~/.sparkmagic/config.json https://raw.githubusercontent.com/jupyter-incubator/sparkmagic/master/sparkmagic/example_config.json
```

In this configuration file, you can configure Spark-related parameters like `driverMemory` and `executorCores`.

Step 2: Start JupyterLab

When you start JupyterLab, your default web browser is automatically opened, and the URL `http://localhost:8888/lab/workspaces/{workspace_name}` is shown.

```
$ jupyter lab
```

Step 3: Initiate SSH port forwarding to connect to your development endpoint

Next, use SSH local port forwarding to forward a local port (here, 8998) to the remote destination that is defined by Amazon Glue (`169.254.76.1:8998`).

1. Open a separate terminal window that gives you access to SSH. In Microsoft Windows, you can use the BASH shell provided by [Git for Windows](#), or you can install [Cygwin](#).
2. Run the following SSH command, modified as follows:
 - Replace *private-key-file-path* with a path to the `.pem` file that contains the private key corresponding to the public key that you used to create your development endpoint.
 - If you're forwarding a different port than 8998, replace 8998 with the port number that you're actually using locally. The address `169.254.76.1:8998` is the remote port and isn't changed by you.
 - Replace *dev-endpoint-public-dns* with the public DNS address of your development endpoint. To find this address, navigate to your development endpoint in the Amazon Glue console, choose the name, and copy the **Public address** that's listed on the **Endpoint details** page.

```
ssh -i private-key-file-path -NTL 8998:169.254.76.1:8998 glue@dev-endpoint-public-dns
```

You will likely see a warning message like the following:

```
The authenticity of host 'ec2-xx-xxx-xxx-xx.us-west-2.compute.amazonaws.com
(xx.xxx.xxx.xx)'
can't be established. ECDSA key fingerprint is SHA256:4e97875Brt+1wKzRko
+Jf1Snp21X7aTP3BcFnHYLEts.
Are you sure you want to continue connecting (yes/no)?
```

Enter **yes** and leave the terminal window open while you use JupyterLab.

3. Check that SSH port forwarding is working with the development endpoint correctly.

```
$ curl localhost:8998/sessions
{"from":0,"total":0,"sessions":[]}
```

Step 4: Run a simple script fragment in a notebook paragraph

Now your notebook in JupyterLab should work with your development endpoint. Enter the following script fragment into your notebook and run it.

1. Check that Spark is running successfully. The following command instructs Spark to calculate 1 and then print the value.

```
spark.sql("select 1").show()
```

2. Check if Amazon Glue Data Catalog integration is working. The following command lists the tables in the Data Catalog.

```
spark.sql("show tables").show()
```

3. Check that a simple script fragment that uses Amazon Glue libraries works.

The following script uses the `persons_json` table metadata in the Amazon Glue Data Catalog to create a `DynamicFrame` from your sample data. It then prints out the item count and the schema of this data.

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
```

```
# Create a Glue context
glueContext = GlueContext(SparkContext.getOrCreate())

# Create a DynamicFrame using the 'persons_json' table
persons_DyF = glueContext.create_dynamic_frame.from_catalog(database="legislators",
    table_name="persons_json")

# Print out information about *this* data
print("Count: ", persons_DyF.count())
persons_DyF.printSchema()
```

The output of the script is as follows.

```
Count: 1961
root
 |-- family_name: string
 |-- name: string
 |-- links: array
 |   |-- element: struct
 |   |   |-- note: string
 |   |   |-- url: string

 |   |-- element: struct
 |   |   |-- url: string
 |-- given_name: string
 |-- birth_date: string
 |-- id: string
 |-- contact_details: array
 |   |-- element: struct
```

```
|      |      |-- type: string  
|      |      |-- value: string  
|-- death_date: string
```

Troubleshooting

- During the installation of JupyterLab, if your computer is behind a corporate proxy or firewall, you might encounter HTTP and SSL errors due to custom security profiles managed by corporate IT departments.

The following is an example of a typical error that occurs when conda can't connect to its own repositories:

```
CondaHTTPError: HTTP 000 CONNECTION FAILED for url <https://repo.anaconda.com/pkgs/  
main/win-64/current_repodata.json>
```

This might happen because your company can block connections to widely used repositories in Python and JavaScript communities. For more information, see [Installation Problems](#) on the JupyterLab website.

- If you encounter a *connection refused* error when trying to connect to your development endpoint, you might be using a development endpoint that is out of date. Try creating a new development endpoint and reconnecting.

Tutorial: Use a SageMaker AI notebook with your development endpoint

In Amazon Glue, you can create a development endpoint and then create a SageMaker AI notebook to help develop your ETL and machine learning scripts. A SageMaker AI notebook is a fully managed machine learning compute instance running the Jupyter Notebook application.

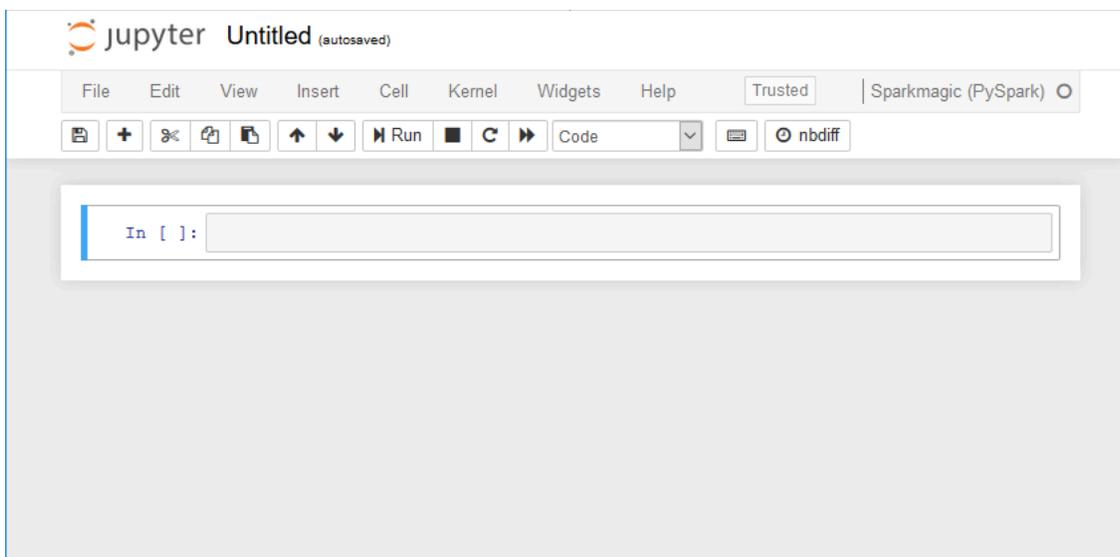

1. In the Amazon Glue console, choose **Dev endpoints** to navigate to the development endpoints list.
2. Select the check box next to the name of a development endpoint that you want to use, and on the **Action** menu, choose **Create SageMaker notebook**.
3. Fill out the **Create and configure a notebook** page as follows:
 - a. Enter a notebook name.
 - b. Under **Attach to development endpoint**, verify the development endpoint.

- c. Create or choose an Amazon Identity and Access Management (IAM) role.

Creating a role is recommended. If you use an existing role, ensure that it has the required permissions. For more information, see [the section called “Step 6: Create an IAM policy for SageMaker AI notebooks”](#).

- d. (Optional) Choose a VPC, a subnet, and one or more security groups.
 - e. (Optional) Choose an Amazon Key Management Service encryption key.
 - f. (Optional) Add tags for the notebook instance.
4. Choose **Create notebook**. On the **Notebooks** page, choose the refresh icon at the upper right, and continue until the **Status** shows Ready.
 5. Select the check box next to the new notebook name, and then choose **Open notebook**.
 6. Create a new notebook: On the **jupyter** page, choose **New**, and then choose **Sparkmagic (PySpark)**.

Your screen should now look like the following:

7. (Optional) At the top of the page, choose **Untitled**, and give the notebook a name.
8. To start a Spark application, enter the following command into the notebook, and then in the toolbar, choose **Run**.

```
spark
```

After a short delay, you should see the following response:

```
In [1]: spark
Starting Spark application
```

ID	YARN Application ID	Kind	State	Spark UI	Driver log	Current session?
0	application_1576209965005_0001	pyspark	idle	Link	Link	✓

```
SparkSession available as 'spark'.
<pyspark.sql.session.SparkSession object at 0x7f3d54913550>
```

9. Create a dynamic frame and run a query against it: Copy, paste, and run the following code, which outputs the count and schema of the persons_json table.

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import *
glueContext = GlueContext(SparkContext.getOrCreate())
persons_DyF = glueContext.create_dynamic_frame.from_catalog(database="legislators",
    table_name="persons_json")
print ("Count: ", persons_DyF.count())
persons_DyF.printSchema()
```

Tutorial: Use a REPL shell with your development endpoint

In Amazon Glue, you can create a development endpoint and then invoke a REPL (Read–Evaluate–Print Loop) shell to run PySpark code incrementally so that you can interactively debug your ETL scripts before deploying them.

In order to use a REPL on a development endpoint, you need to have authorization to SSH to the endpoint.

1. On your local computer, open a terminal window that can run SSH commands, and paste in the edited SSH command. Run the command.

Assuming that you accepted Amazon Glue version 1.0 with Python 3 for the development endpoint, the output will look like this:

```
Python 3.6.8 (default, Aug  2 2019, 17:42:44)
[GCC 4.8.5 20150623 (Red Hat 4.8.5-28)] on linux
Type "help", "copyright", "credits" or "license" for more information.
SLF4J: Class path contains multiple SLF4J bindings.
```

```

SLF4J: Found binding in [jar:file:/usr/share/aws/glue/etl/jars/glue-assembly.jar!/
org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: Found binding in [jar:file:/usr/lib/spark/jars/slf4j-log4j12-1.7.16.jar!/
org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: See http://www.slf4j.org/codes.html#multiple_bindings for an explanation.
SLF4J: Actual binding is of type [org.slf4j.impl.Log4jLoggerFactory]
Setting default log level to "WARN".
To adjust logging level use sc.setLogLevel(newLevel). For SparkR, use
setLogLevel(newLevel).

version 2.4.3

Using Python version 3.6.8 (default, Aug  2 2019 17:42:44)
SparkSession available as 'spark'.
>>>

```

2. Test that the REPL shell is working correctly by typing the statement, `print(spark.version)`. As long as that displays the Spark version, your REPL is now ready to use.
3. Now you can try executing the following simple script, line by line, in the shell:

```

import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext

```

```
from awsglue.transforms import *
glueContext = GlueContext(SparkContext.getOrCreate())
persons_DyF = glueContext.create_dynamic_frame.from_catalog(database="legislators",
    table_name="persons_json")
print ("Count: ", persons_DyF.count())
persons_DyF.printSchema()
```

Tutorial: Set up PyCharm professional with a development endpoint

This tutorial shows you how to connect the [PyCharm Professional](#) Python IDE running on your local machine to a development endpoint so that you can interactively run, debug, and test Amazon Glue ETL (extract, transfer, and load) scripts before deploying them. The instructions and screen captures in the tutorial are based on PyCharm Professional version 2019.3.

To connect to a development endpoint interactively, you must have PyCharm Professional installed. You can't do this using the free edition.

Note

The tutorial uses Amazon S3 as a data source. If you want to use a JDBC data source instead, you must run your development endpoint in a virtual private cloud (VPC). To connect with SSH to a development endpoint in a VPC, you must create an SSH tunnel. This tutorial does not include instructions for creating an SSH tunnel. For information on using SSH to connect to a development endpoint in a VPC, see [Securely Connect to Linux Instances Running in a Private Amazon VPC](#) in the Amazon security blog.

Topics

- [Connecting PyCharm professional to a development endpoint](#)
- [Deploying the script to your development endpoint](#)
- [Configuring a remote interpreter](#)
- [Running your script on the development endpoint](#)

Connecting PyCharm professional to a development endpoint

1. Create a new pure-Python project in PyCharm named `legislators`.
2. Create a file named `get_person_schema.py` in the project with the following content:

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

def main():
    # Create a Glue context
    glueContext = GlueContext(SparkContext.getOrCreate())

    # Create a DynamicFrame using the 'persons_json' table
    persons_DyF =
glueContext.create_dynamic_frame.from_catalog(database="legislators",
table_name="persons_json")

    # Print out information about this data
    print("Count: ", persons_DyF.count())
    persons_DyF.printSchema()

if __name__ == "__main__":
    main()
```

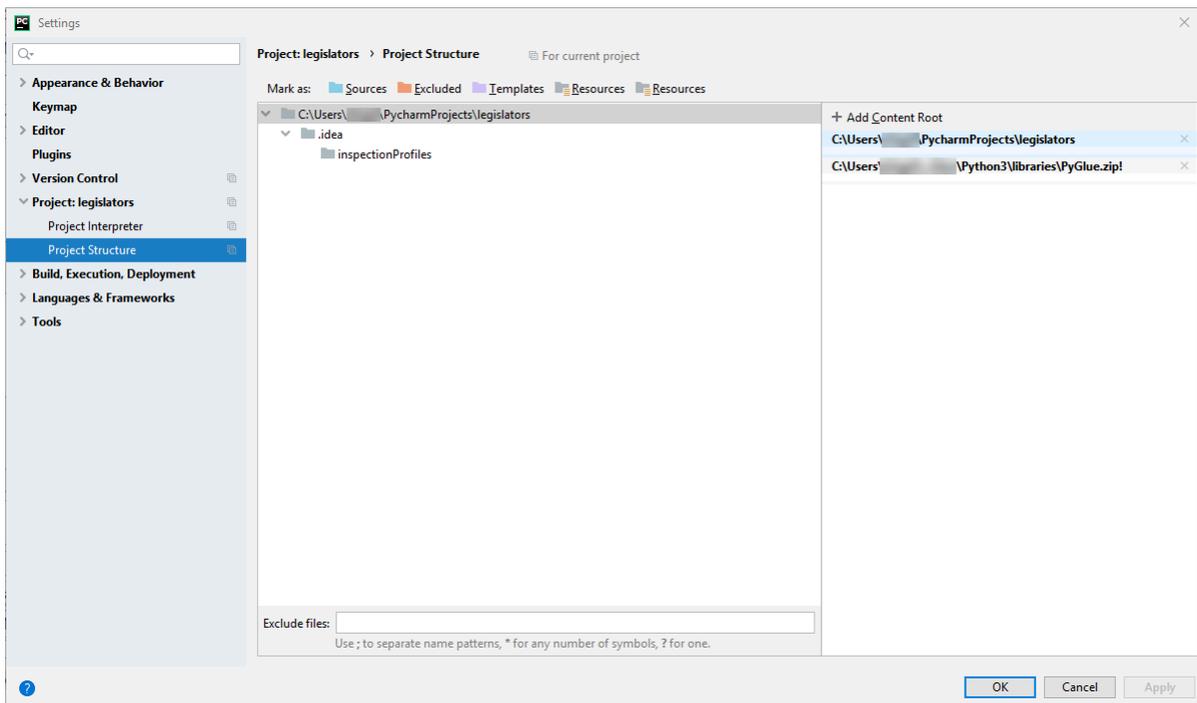

3. Do one of the following:

- For Amazon Glue version 0.9, download the Amazon Glue Python library file, `PyGlue.zip`, from <https://s3.amazonaws.com/aws-glue-jes-prod-us-east-1-assets/etl/python/PyGlue.zip> to a convenient location on your local machine.
- For Amazon Glue version 1.0 and later, download the Amazon Glue Python library file, `PyGlue.zip`, from <https://s3.amazonaws.com/aws-glue-jes-prod-us-east-1-assets/etl-1.0/python/PyGlue.zip> to a convenient location on your local machine.

4. Add `PyGlue.zip` as a content root for your project in PyCharm:

- In PyCharm, choose **File, Settings** to open the **Settings** dialog box. (You can also press `Ctrl+Alt+S`.)
- Expand the `legislators` project and choose **Project Structure**. Then in the right pane, choose **+ Add Content Root**.
- Navigate to the location where you saved `PyGlue.zip`, select it, then choose **Apply**.

The **Settings** screen should look something like the following:

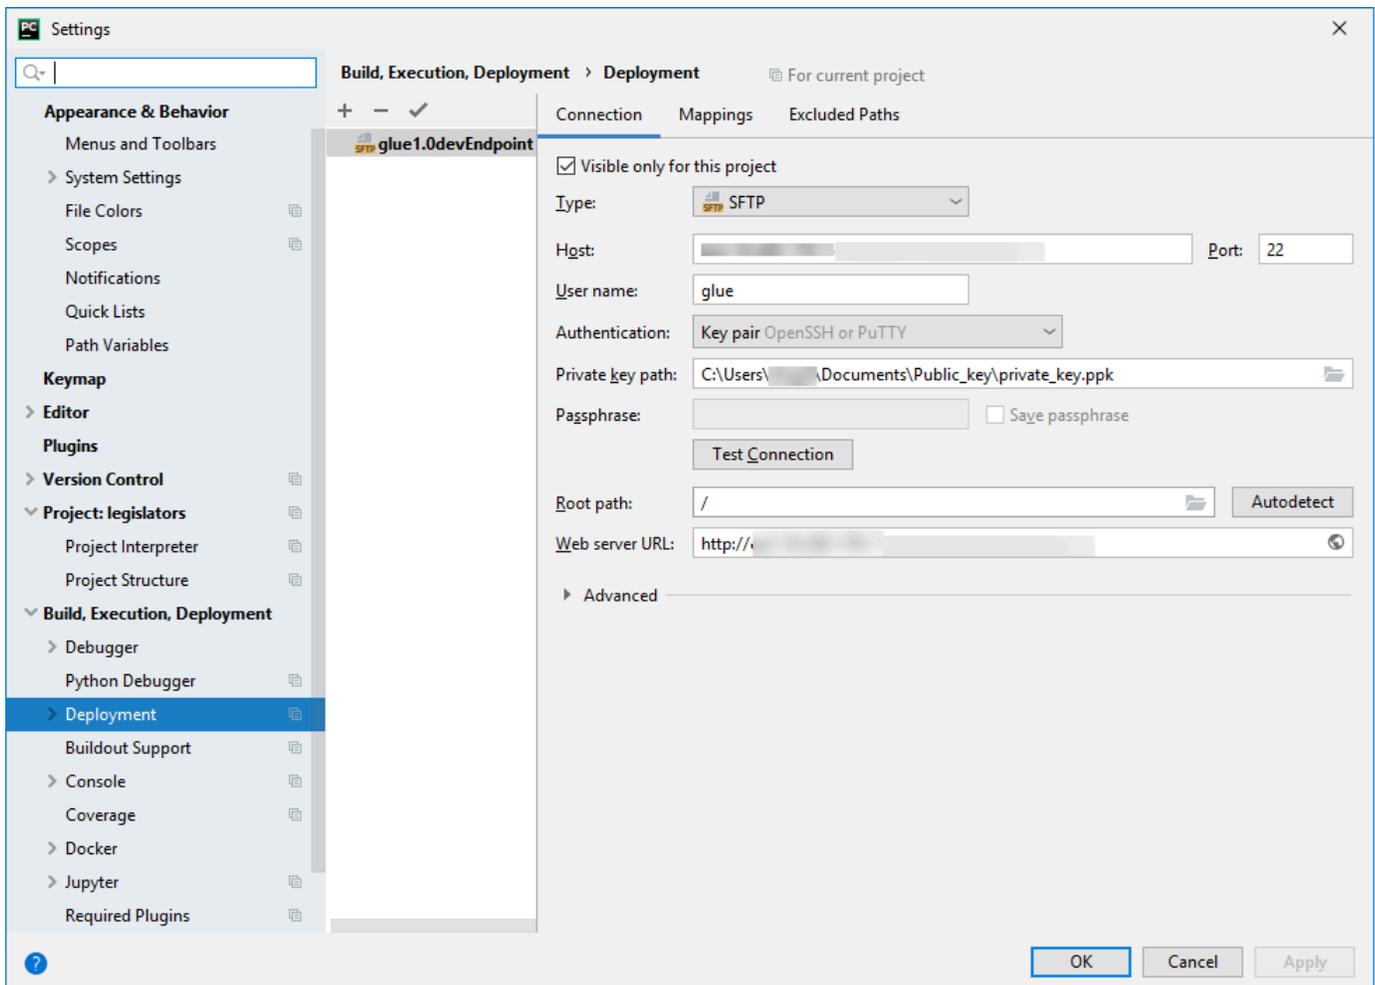

Leave the **Settings** dialog box open after you choose **Apply**.

5. Configure deployment options to upload the local script to your development endpoint using SFTP (this capability is available only in PyCharm Professional):
 - In the **Settings** dialog box, expand the **Build, Execution, Deployment** section. Choose the **Deployment** subsection.
 - Choose the **+** icon at the top of the middle pane to add a new server. Set its **Type** to SFTP and give it a name.
 - Set the **SFTP host** to the **Public address** of your development endpoint, as listed on its details page. (Choose the name of your development endpoint in the Amazon Glue console to display the details page). For a development endpoint running in a VPC, set **SFTP host** to the host address and local port of your SSH tunnel to the development endpoint.
 - Set the **User name** to glue.
 - Set the **Auth type** to **Key pair (OpenSSH or Putty)**. Set the **Private key file** by browsing to the location where your development endpoint's private key file is located. Note that PyCharm only supports DSA, RSA and ECDSA OpenSSH key types, and does not accept keys in Putty's private format. You can use an up-to-date version of ssh-keygen to generate a key-pair type that PyCharm accepts, using syntax like the following:

```
ssh-keygen -t rsa -f <key_file_name> -C "<your_email_address>"
```

- Choose **Test connection**, and allow the connection to be tested. If the connection succeeds, choose **Apply**.

The **Settings** screen should now look something like the following:

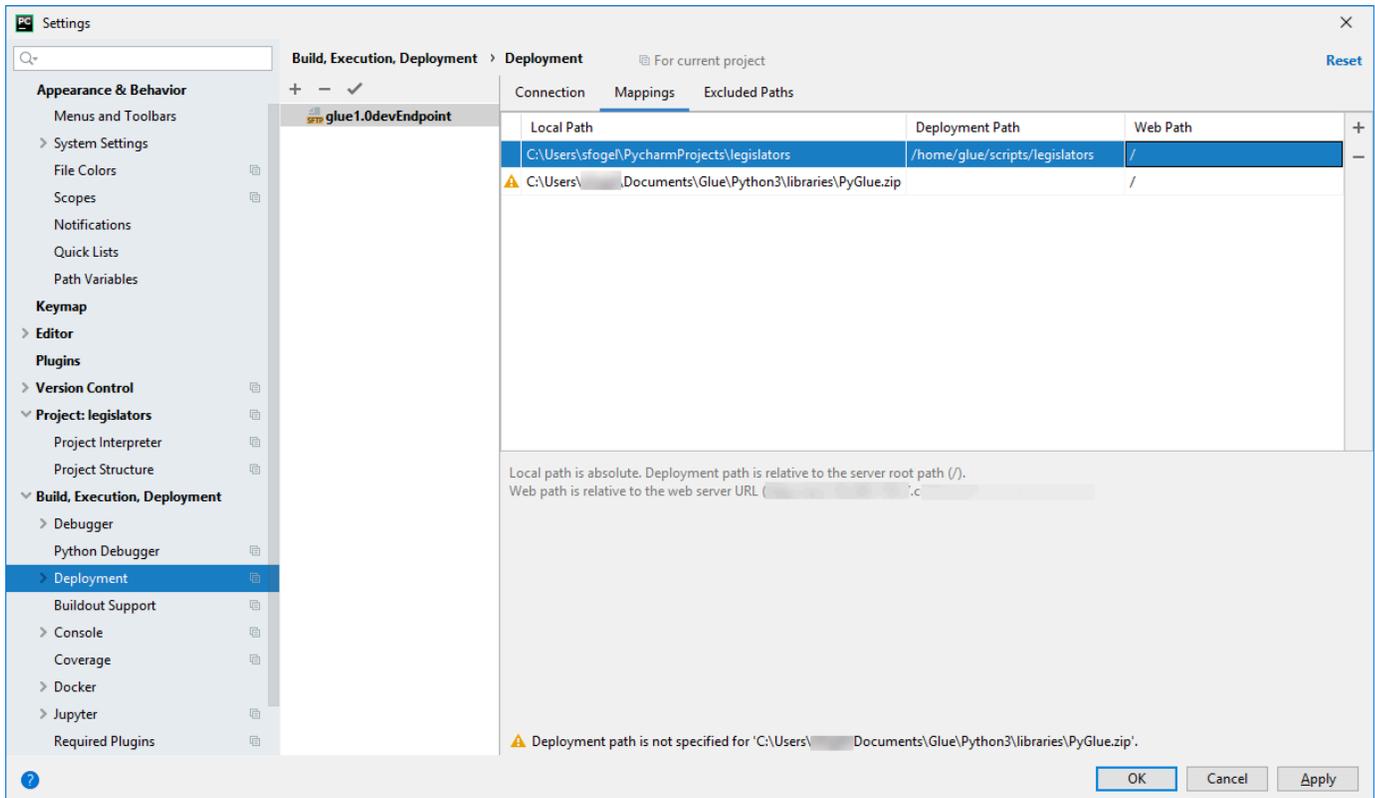

Again, leave the **Settings** dialog box open after you choose **Apply**.

6. Map the local directory to a remote directory for deployment:

- In the right pane of the **Deployment** page, choose the middle tab at the top, labeled **Mappings**.
- In the **Deployment Path** column, enter a path under `/home/glue/scripts/` for deployment of your project path. For example: `/home/glue/scripts/legislators`.
- Choose **Apply**.

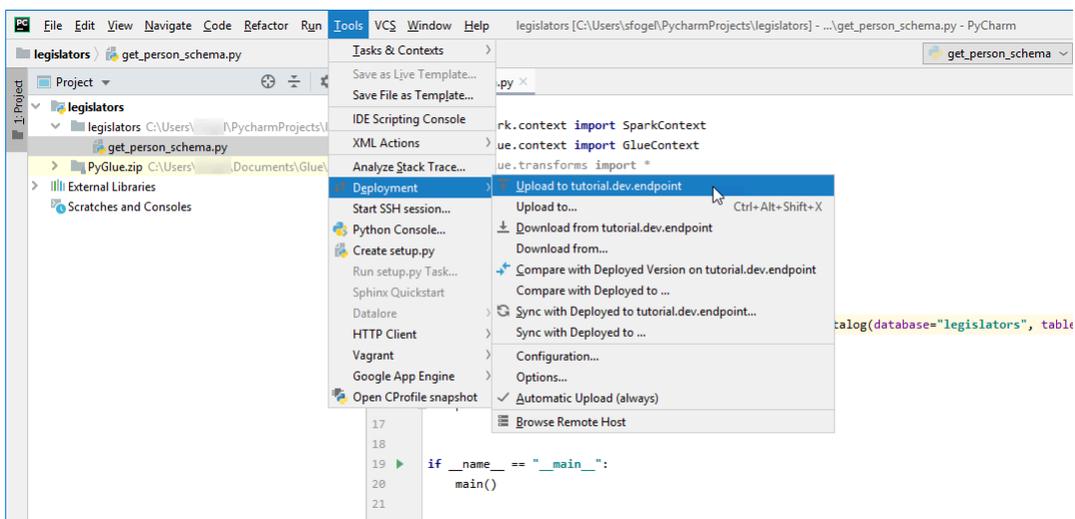

The **Settings** screen should now look something like the following:

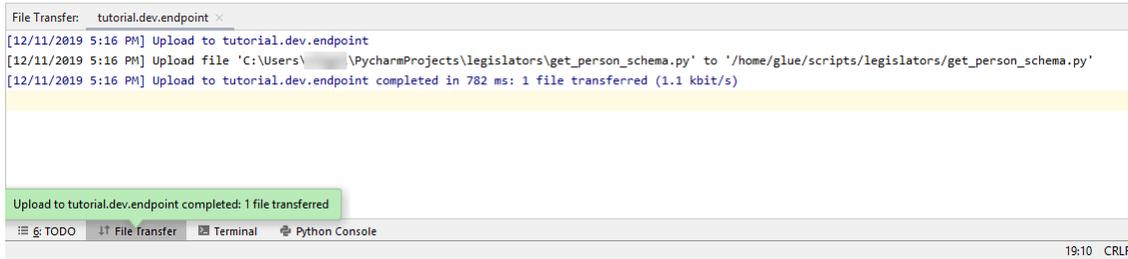

Choose **OK** to close the **Settings** dialog box.

Deploying the script to your development endpoint

1. Choose **Tools**, **Deployment**, and then choose the name under which you set up your development endpoint, as shown in the following image:

After your script has been deployed, the bottom of the screen should look something like the following:

2. On the menu bar, choose **Tools, Deployment, Automatic Upload (always)**. Ensure that a check mark appears next to **Automatic Upload (always)**.

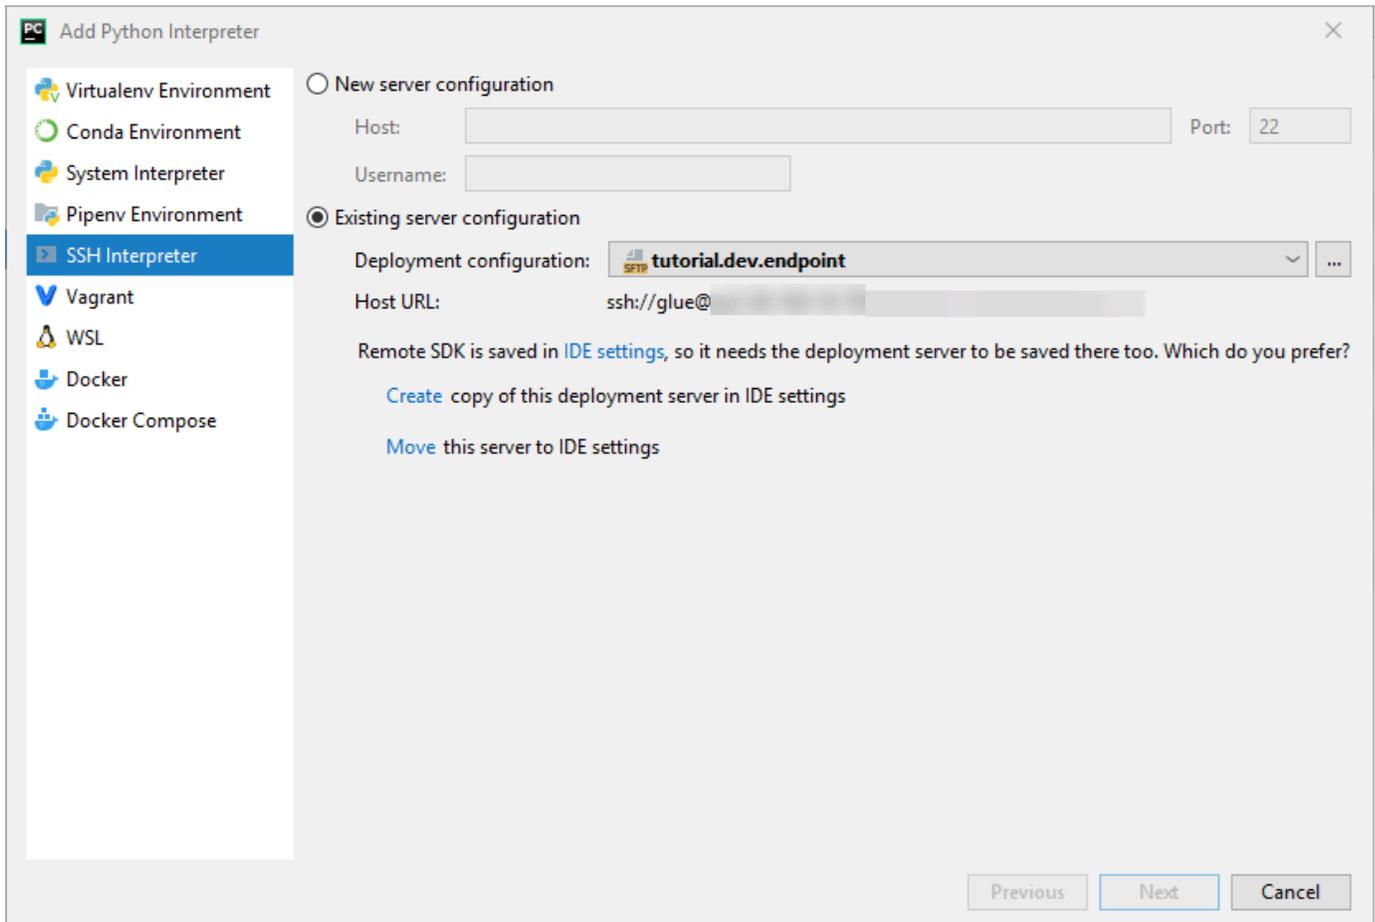

When this option is enabled, PyCharm automatically uploads changed files to the development endpoint.

Configuring a remote interpreter

Configure PyCharm to use the Python interpreter on the development endpoint.

1. From the **File** menu, choose **Settings**.
2. Expand the project **legislators** and choose **Project Interpreter**.
3. Choose the gear icon next to the **Project Interpreter** list, and then choose **Add**.
4. In the **Add Python Interpreter** dialog box, in the left pane, choose **SSH Interpreter**.
5. Choose **Existing server configuration**, and in the **Deployment configuration** list, choose your configuration.

Your screen should look something like the following image.

6. Choose **Move this server to IDE settings**, and then choose **Next**.
7. In the **Interpreter** field, change the path to `/usr/bin/gluepython` if you are using Python 2, or to `/usr/bin/gluepython3` if you are using Python 3. Then choose **Finish**.

Running your script on the development endpoint

To run the script:

- In the left pane, right-click the file name and choose **Run '<filename>'**.

After a series of messages, the final output should show the count and the schema.

```
Count: 1961
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
```

```
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- sort_name: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- death_date: string
```

Process finished with exit code 0

You are now set up to debug your script remotely on your development endpoint.

Advanced configuration: sharing development endpoints among multiple users

This section explains how you can take advantage of development endpoints with SageMaker notebooks in typical use cases to share development endpoints among multiple users.

Single-tenancy configuration

In single tenant use-cases, to simplify the developer experience and to avoid contention for resources it is recommended that you have each developer use their own development endpoint sized for the project they are working on. This also simplifies the decisions related to worker type and DPU count leaving them up to the discretion of the developer and project they are working on.

You won't need to take care of resource allocation unless you runs multiple notebook files concurrently. If you run code in multiple notebook files at the same time, multiple Livy sessions will be launched concurrently. To segregate Spark cluster configurations in order to run multiple Livy sessions at the same time, you can follow the steps which are introduced in multi tenant use-cases.

For example, if your development endpoint has 10 workers and the worker type is `G.1X`, then you will have 9 Spark executors and the entire cluster will have 90G of executor memory since each executor will have 10G of memory.

Regardless of the specified worker type, Spark dynamic resource allocation will be turned on. If a dataset is large enough, Spark may allocate all the executors to a single Livy session since `spark.dynamicAllocation.maxExecutors` is not set by default. This means that other Livy sessions on the same dev endpoint will wait to launch new executors. If the dataset is small, Spark will be able to allocate executors to multiple Livy sessions at the same time.

Note

For more information about how resources are allocated in different use cases and how you set a configuration to modify the behavior, see [Advanced configuration: sharing development endpoints among multiple users](#).

Multi-tenancy configuration

Note

Please note, development endpoints are intended to emulate the Amazon Glue ETL environment as a single-tenant environment. While multi-tenant use is possible, it is an advanced use-case and it is recommended most users maintain a pattern of single-tenancy for each development endpoint.

In multi tenant use-cases, you might need to take care of resource allocation. The key factor is the number of concurrent users who use a Jupyter notebook at the same time. If your team works in a "follow-the-sun" workflow and there is only one Jupyter user at each time zone, then the number of concurrent users is only one, so you won't need to be concerned with resource allocation. However, if your notebook is shared among multiple users and each user submits code in an ad-hoc basis, then you will need to consider the below points.

To partition Spark cluster resources among multiple users, you can use SparkMagic configurations. There are two different ways to configure SparkMagic.

(A) Use the `%%configure -f` directive

If you want to modify the configuration per Livy session from the notebook, you can run the `%%configure -f` directive on the notebook paragraph.

For example, if you want to run Spark application on 5 executors, you can run the following command on the notebook paragraph.

```
%%configure -f
{"numExecutors":5}
```

Then you will see only 5 executors running for the job on the Spark UI.

We recommend limiting the maximum number of executors for dynamic resource allocation.

```
%%configure -f
{"conf":{"spark.dynamicAllocation.maxExecutors":"5"}}
```

(B) Modify the SparkMagic config file

SparkMagic works based on the [Livy API](#). SparkMagic creates Livy sessions with configurations such as `driverMemory`, `driverCores`, `executorMemory`, `executorCores`, `numExecutors`, `conf`, etc. Those are the key factors that determine how much resources are consumed from the entire Spark cluster. SparkMagic allows you to provide a config file to specify those parameters which are sent to Livy. You can see a sample config file in this [Github repository](#).

If you want to modify configuration across all the Livy sessions from a notebook, you can modify `home/ec2-user/.sparkmagic/config.json` to add `session_config`.

To modify the config file on a SageMaker notebook instance, you can follow these steps.

1. Open a SageMaker notebook.
2. Open the Terminal kernel.
3. Run the following commands:

```
sh-4.2$ cd .sparkmagic
sh-4.2$ ls
config.json logs
```

```
sh-4.2$ sudo vim config.json
```

For example, you can add these lines to `/home/ec2-user/.sparkmagic/config.json` and restart the Jupyter kernel from the notebook.

```
"session_configs": {
  "conf": {
    "spark.dynamicAllocation.maxExecutors": "5"
  }
},
```

Guidelines and best practices

To avoid this kind of resource conflict, you can use some basic approaches like:

- Have a larger Spark cluster by increasing the `NumberOfWorkers` (scaling horizontally) and upgrading the `workerType` (scaling vertically)
- Allocate fewer resources per user (fewer resources per Livy session)

Your approach will depend on your use case. If you have a larger development endpoint, and there is not a huge amount of data, the possibility of a resource conflict will decrease significantly because Spark can allocate resources based on a dynamic allocation strategy.

As described above, the number of Spark executors can be automatically calculated based on a combination of DPU (or `NumberOfWorkers`) and worker type. Each Spark application launches one driver and multiple executors. To calculate you will need the `NumberOfWorkers = NumberOfExecutors + 1`. The matrix below explains how much capacity you need in your development endpoint based on the number of concurrent users.

Number of concurrent notebook users	Number of Spark executors you want to allocate per user	Total <code>NumberOfWorkers</code> for your dev endpoint
3	5	18
10	5	60
50	5	300

If you want to allocate fewer resources per user, the `spark.dynamicAllocation.maxExecutors` (or `numExecutors`) would be the easiest parameter to configure as a Livy session parameter. If you set the below configuration in `/home/ec2-user/.sparkmagic/config.json`, then SparkMagic will assign a maximum of 5 executors per Livy session. This will help segregating resources per Livy session.

```
"session_configs": {
  "conf": {
    "spark.dynamicAllocation.maxExecutors": "5"
  }
},
```

Suppose there is a dev endpoint with 18 workers (G.1X) and there are 3 concurrent notebook users at the same time. If your session config has `spark.dynamicAllocation.maxExecutors=5` then each user can make use of 1 driver and 5 executors. There won't be any resource conflicts even when you run multiple notebook paragraphs at the same time.

Trade-offs

With this session config `"spark.dynamicAllocation.maxExecutors": "5"`, you will be able to avoid resource conflict errors and you do not need to wait for resource allocation when there are concurrent user accesses. However, even when there are many free resources (for example, there are no other concurrent users), Spark cannot assign more than 5 executors for your Livy session.

Other notes

It is a good practice to stop the Jupyter kernel when you stop using a notebook. This will free resources and other notebook users can use those resources immediately without waiting for kernel expiration (auto-shutdown).

Common issues

Even when following the guidelines, you may experience certain issues.

Session not found

When you try to run a notebook paragraph even though your Livy session has been already terminated, you will see the below message. To activate the Livy session, you need to restart the Jupyter kernel by choosing **Kernel > Restart** in the Jupyter menu, then run the notebook paragraph again.

```
An error was encountered:  
Invalid status code '404' from http://localhost:8998/sessions/13 with error payload:  
"Session '13' not found."
```

Not enough YARN resources

When you try to run a notebook paragraph even though your Spark cluster does not have enough resources to start a new Livy session, you will see the below message. You can often avoid this issue by following the guidelines, however, there might be a possibility that you face this issue. To work around the issue, you can check if there are any unneeded, active Livy sessions. If there are unneeded Livy sessions, you will need to terminate them to free the cluster resources. See the next section for details.

```
Warning: The Spark session does not have enough YARN resources to start.  
The code failed because of a fatal error:  
    Session 16 did not start up in 60 seconds..
```

Some things to try:

- a) Make sure Spark has enough available resources for Jupyter to create a Spark context.
- b) Contact your Jupyter administrator to make sure the Spark magics library is configured correctly.
- c) Restart the kernel.

Monitoring and debugging

This section describes techniques for monitoring resources and sessions.

Monitoring and debugging cluster resource allocation

You can watch the Spark UI to monitor how many resources are allocated per Livy session, and what are the effective Spark configurations on the job. To activate the Spark UI, see [Enabling the Apache Spark Web UI for Development Endpoints](#).

(Optional) If you need a real-time view of the Spark UI, you can configure an SSH tunnel against the Spark history server running on the Spark cluster.

```
ssh -i <private-key.pem> -N -L 8157:<development endpoint public address>:18080  
glue@<development endpoint public address>
```

You can then open <http://localhost:8157> on your browser to view the Spark UI.

Free unneeded Livy sessions

Review these procedures to shut down any unneeded Livy sessions from a notebook or a Spark cluster.

(a). Terminate Livy sessions from a notebook

You can shut down the kernel on a Jupyter notebook to terminate unneeded Livy sessions.

(b). Terminate Livy sessions from a Spark cluster

If there are unneeded Livy sessions which are still running, you can shut down the Livy sessions on the Spark cluster.

As a pre-requisite to perform this procedure, you need to configure your SSH public key for your development endpoint.

To log in to the Spark cluster, you can run the following command:

```
$ ssh -i <private-key.pem> glue@<development endpoint public address>
```

You can run the following command to see the active Livy sessions:

```
$ yarn application -list
20/09/25 06:22:21 INFO client.RMPProxy: Connecting to ResourceManager at
ip-255-1-106-206.ec2.internal/172.38.106.206:8032
Total number of applications (application-types: [] and states: [SUBMITTED, ACCEPTED,
RUNNING]):2
Application-Id Application-Name Application-Type User Queue State Final-State Progress
Tracking-URL
application_1601003432160_0005 livy-session-4 SPARK livy default RUNNING UNDEFINED 10%
http://ip-255-1-4-130.ec2.internal:41867
application_1601003432160_0004 livy-session-3 SPARK livy default RUNNING UNDEFINED 10%
http://ip-255-1-179-185.ec2.internal:33727
```

You can then shut down the Livy session with the following command:

```
$ yarn application -kill application_1601003432160_0005
20/09/25 06:23:38 INFO client.RMPProxy: Connecting to ResourceManager at
ip-255-1-106-206.ec2.internal/255.1.106.206:8032
Killing application application_1601003432160_0005
```

```
20/09/25 06:23:39 INFO impl.YarnClientImpl: Killed application
application_1601003432160_0005
```

Managing notebooks

Note

Development Endpoints are only supported for versions of Amazon Glue prior to 2.0. For an interactive environment where you can author and test ETL scripts, use [Notebooks on Amazon Glue Studio](#).

A notebook enables interactive development and testing of your ETL (extract, transform, and load) scripts on a development endpoint. Amazon Glue provides an interface to SageMaker AI Jupyter notebooks. With Amazon Glue, you create and manage SageMaker AI notebooks. You can also open SageMaker AI notebooks from the Amazon Glue console.

In addition, you can use Apache Spark with SageMaker AI on Amazon Glue development endpoints which support SageMaker AI (but not Amazon Glue ETL jobs). SageMaker Spark is an open source Apache Spark library for SageMaker AI. For more information, see [Using Apache Spark with Amazon SageMaker](#).

Important

Managing SageMaker AI notebooks with Amazon Glue development endpoints is available in the following Amazon Regions:

Region	Code
US East (Ohio)	us-east-2
US East (N. Virginia)	us-east-1
US West (N. California)	us-west-1
US West (Oregon)	us-west-2
Asia Pacific (Tokyo)	ap-northeast-1

Region	Code
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Mumbai)	ap-south-1
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Canada (Central)	ca-central-1
Europe (Frankfurt)	eu-central-1
Europe (Ireland)	eu-west-1
Europe (London)	eu-west-2

Building visual ETL jobs

Build visual ETL jobs with Amazon Glue Studio

Amazon Glue Studio provides a visual interface for creating, running, and monitoring Extract/Transform/Load (ETL) jobs in Amazon Glue. A job in Amazon Glue consists of the business logic that performs extract, transform, and load (ETL) work. With Amazon Glue Studio, you can visually compose data transformation workflows and seamlessly run them on Amazon Glue's Apache Spark-based serverless ETL engine. You can create jobs that move and transform data between various data stores and streams using a drag-and-drop interface without having to learn Spark or write code.

An Amazon Glue job encapsulates a script that connects to your source data, processes it, and then writes it out to your data target. Typically, a job runs extract, transform, and load (ETL) scripts. Jobs can run scripts designed for Apache Spark and Ray runtime environments. Jobs can also run general-purpose Python scripts (Python shell jobs.) Amazon Glue triggers can start jobs based on a schedule or event, or on demand. You can monitor job runs to understand runtime metrics such as completion status, duration, and start time.

You can use scripts that Amazon Glue generates or you can provide your own. With a source schema and target location or schema, the Amazon Glue Studio code generator can automatically create an Apache Spark API (PySpark) script. You can use this script as a starting point and edit it to meet your goals.

Amazon Glue can write output files in several data formats. Each job type may support different output formats. For some data formats, common compression formats can be written.

Managing Amazon Glue Jobs in the Amazon Console

To view existing jobs, sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>. Then choose the **Jobs** tab in Amazon Glue. The **Jobs** list displays the location of the script that is associated with each job, when the job was last modified, and the current job bookmark option.

You can create jobs in the **ETL** section of the Amazon Glue console. While creating a new job, or after you have saved your job, you can use Amazon Glue Studio to modify your ETL jobs. You

can do this by editing the nodes in the visual editor or by editing the job script in developer mode. You can also add and remove nodes in the visual editor to create more complicated ETL jobs.

Next steps for creating a job in Amazon Glue Studio

You use the visual job editor to configure nodes for your job. Each node represents an action, such as reading data from the source location or applying a transform to the data. Each node you add to your job has properties that provide information about either the data location or the transform.

The next steps for creating and managing your jobs are:

- [Starting visual ETL jobs in Amazon Glue Studio](#)
- [View the job script](#)
- [Modify the job properties](#)
- [Save the job](#)
- [Start a job run](#)
- [View information for recent job runs](#)
- [Accessing the job monitoring dashboard](#)

Build visual ETL flows with Amazon SageMaker

With an Amazon SageMaker Unified Studio workflow, you can set up and run a series of tasks in Amazon SageMaker Unified Studio. Amazon SageMaker Unified Studio workflows use Apache Airflow to model data processing procedures and orchestrate your Amazon SageMaker Unified Studio code artifacts. For more information, see [Using workflows in Amazon SageMaker Unified Studio](#).

Starting visual ETL jobs in Amazon Glue Studio

You can use the simple visual interface in Amazon Glue Studio to create your ETL jobs. You use the **Jobs** page to create new jobs. You can also use a script editor or notebook to work directly with code in the Amazon Glue Studio ETL job script.

On the **Jobs** page, you can see all the jobs that you have created either with Amazon Glue Studio or Amazon Glue. You can view, manage, and run your jobs on this page.

Also see the [blog tutorial](#)

on another example of how to create ETL jobs with Amazon Glue Studio.

Starting jobs in Amazon Glue Studio

Amazon Glue allows you to create a job through a visual interface, an interactive code notebook, or with a script editor. You can start a job by clicking on any of the options or create a new job based on a sample job.

Sample jobs create a job with the tool of your choice. For example, sample jobs allow you to create a visual ETL job that joins CSV files into a catalog table, create a job in an interactive code notebook with Amazon Glue for Ray or Amazon Glue for Spark when working with pandas, or create a job in an interactive code notebook with SparkSQL.

Creating a job in Amazon Glue Studio from scratch

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue Studio console at <https://console.amazonaws.cn/gluestudio/>.
2. Choose **ETL jobs** from the navigation pane.
3. In the **Create job** section, select a configuration option for your job.

Options to create a job from scratch:

- **Visual ETL** – author in a visual interface focused on data flow
- **Author using an Interactive code notebook** – interactively author jobs in a notebook interface based on Jupyter Notebooks

When you select this option, you must provide additional information before creating a notebook authoring session. For more information about how to specify this information, see [Getting started with notebooks in Amazon Glue Studio](#).

- **Author code with a script editor** – For those familiar with programming and writing ETL scripts, choose this option to create a new Spark ETL job. Choose the engine (Python shell, Ray, Spark (Python), or Spark (Scala)). Then, choose **Start fresh** or **Upload script**. uploading an existing script from a local file. If you choose to use the script editor, you can't use the visual job editor to design or edit your job.

A Spark job is run in an Apache Spark environment managed by Amazon Glue. By default, new scripts are coded in Python. To write a new Scala script, see [Creating and editing Scala scripts in Amazon Glue Studio](#).

Creating a job in Amazon Glue Studio from an example job

You can choose to create a job from an example job. In the **Example jobs** section, choose a sample job, then choose **Create sample job**. Creating a sample job from one of the options provides a quick template you can work from.

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue Studio console at <https://console.amazonaws.cn/gluestudio/>.
2. Choose **ETL jobs** from the navigation pane.
3. Select an option create a job from a sample job:
 - **Visual ETL job to join multiple sources** – Read three CSV files, combine the data, change the data types, then write the data to Amazon S3 and catalog it for querying later.
 - **Spark notebook using Pandas** – Explore and visualize data using the popular Pandas framework combined with Spark.
 - **Spark notebook using SQL** – Use SQL to get started quickly with Apache Spark. Access data through the Amazon Glue Data Catalog and transform it using familiar commands.
4. Choose **Create sample job**.

Job editor features

The job editor provides the following features for creating and editing jobs.

- A visual diagram of your job, with a node for each job task: Data source nodes for reading the data; transform nodes for modifying the data; data target nodes for writing the data.

You can view and configure the properties of each node in the job diagram. You can also view the schema and sample data for each node in the job diagram. These features help you to verify that your job is modifying and transforming the data in the right way, without having to run the job.

- A Script viewing and editing tab, where you can modify the code generated for your job.
- A Job details tab, where you can configure a variety of settings to customize the environment in which your Amazon Glue ETL job runs.
- A Runs tab, where you can view the current and previous runs of the job, view the status of the job run, and access the logs for the job run.
- A Data quality tab, where you can apply data quality rules to your job.

- A Schedules tab, where you can configure the start time for your job, or set up a recurring job runs.
- A Version Control tab, where you can configure a Git service to use with your job.

Using schema previews in the visual job editor

While creating or editing your job, you can use the **Output schema** tab to view the schema for your data.

Before you can see the schema, the job editor needs permissions to access the data source. You can specify an IAM role on the Job details tab of the editor or on the **Output schema** tab for a node. If the IAM role has all the necessary permissions to access the data source, you can then view the schema on the **Output schema** tab for a node.

Using data previews in the visual job editor

Data previews help you create and test your job using a sample of your data without having to repeatedly run the job. By using data preview, you can:

- Test an IAM role to make sure you have access to your data sources or data targets.
- Check that the transform is modifying the data in the intended way. For example, if you use a Filter transform, you can make sure that the filter is selecting the right subset of data.
- Check your data. If your dataset contains columns with values of multiple types, the data preview shows a list of tuples for these columns. Each tuple contains the data type and its value.

Note

If you use a data preview session and a custom SQL or custom code node, the data preview session will execute the SQL or code block as-is for the entire dataset.

While creating or editing your job, you can use the **Data preview** tab beneath the job canvas to view a sample of your data. A new data preview session will start automatically when the role is already configured on the job or a default IAM role has been set up in the account. If a role has not been previously configured, you can start a session by selecting the role.

Data preview | **Output schema** 📄 📄

Start a data preview session

IAM role
To start a data preview session, choose an IAM role for this job. Changing the role will end an existing data preview session.

Admin ▼
No description available.

[Create IAM role.](#) 🔗

▶ **Additional Settings**

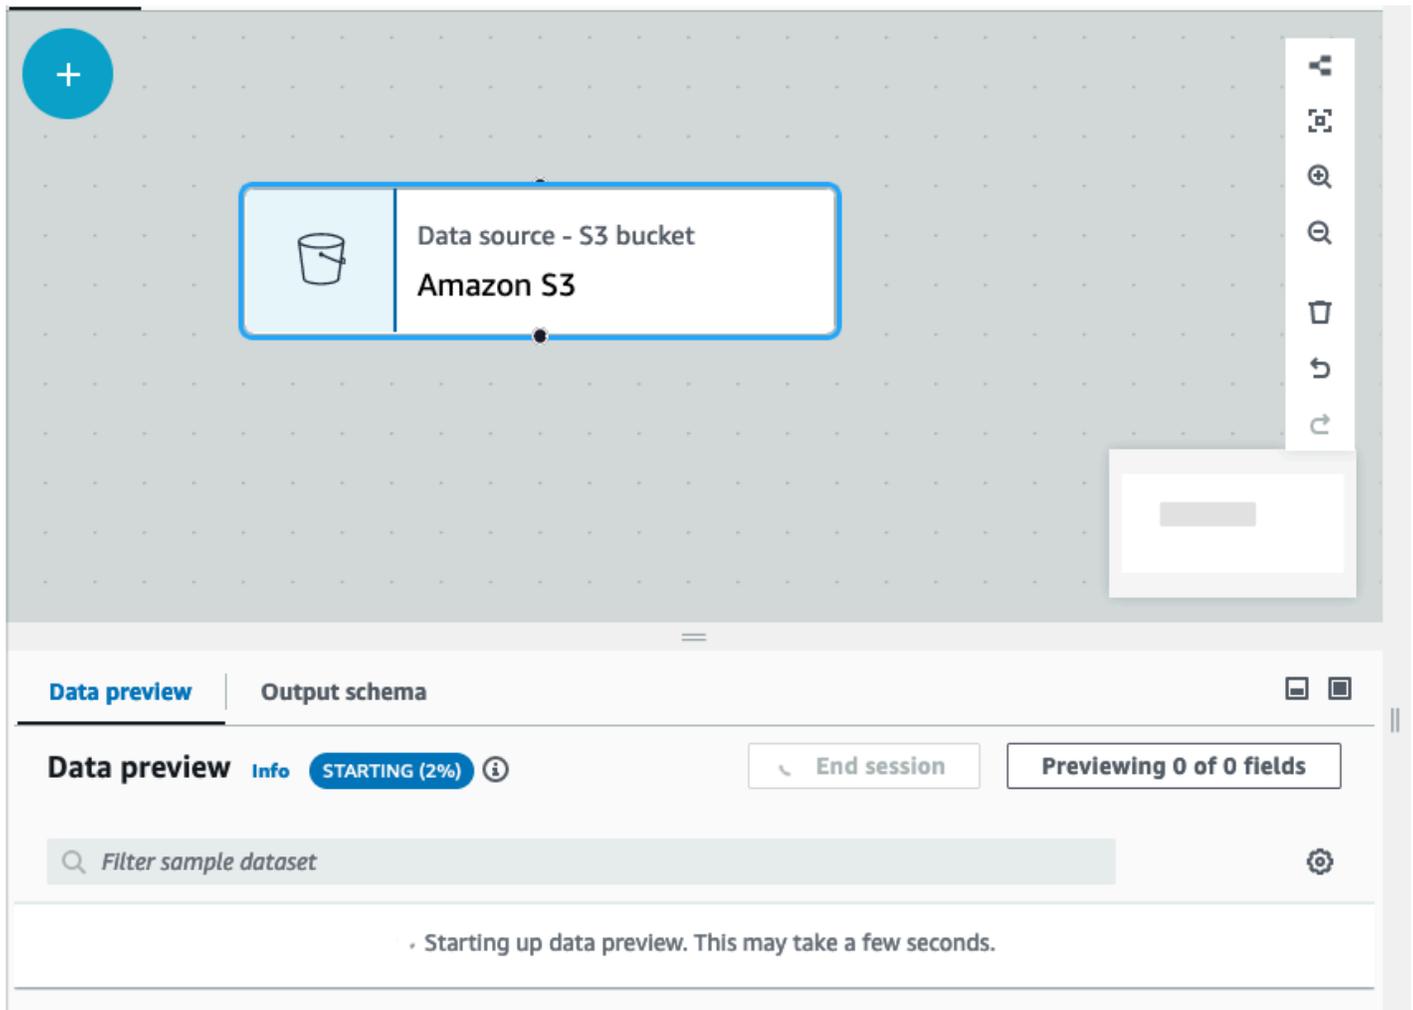

Start session

Note

The role you choose for the data preview session will also be used for the job.

You can see the status and the progress of your session as well as the session details by clicking the info icon.

When the session is ready, Amazon Glue Studio will load the data for the node you selected. You can view the % **complete** as it progresses.

The screenshot displays the Amazon Glue Studio interface. At the top, a blue circular button with a white plus sign is visible. The main workspace is a light gray grid with a central node labeled "Data source - S3 bucket" and "Amazon S3" next to a bucket icon. A vertical toolbar on the right contains icons for zooming, deleting, and refreshing. Below the workspace, the "Data preview" tab is active, showing a progress indicator "STARTING (2%)" and an "End session" button. A search bar labeled "Filter sample dataset" is present, and a message at the bottom states: "Starting up data preview. This may take a few seconds."

As you author your visual job, Amazon Glue Studio will automatically update the schema for the selected node when you toggle **Infer schema from session** in the **Output schema** tab.

The screenshot displays the Amazon Glue job editor. At the top, a job diagram shows a 'Transform - SQL Query' node. Below it, the 'Data preview' section is active, showing the 'Output schema' for the selected node. The schema table is as follows:

Key	Data type
firstname	string
lastname	string
title	string

To the right, the configuration panel for the SQL query node is visible. It shows the 'Input sources' as 'Amazon S3' and the 'SQL aliases' as 'myDataSource'. The 'SQL query' section contains a code editor with the following query:

```
1 select firstname, lastname, title from myDataSource
2
```

To configure your data preview preferences:

Choose the settings icon (a gear symbol) to configure your preferences for data previews. These settings apply to all nodes in the job diagram. You can:

- Choose to wrap the text from one line to the next. This option is enabled by default
- Change the number of rows (default to 200)
- Choose an IAM role or create an IAM role if needed
- Choose to automatically start a new session when you author a job. This provisions a new interactive session when authoring jobs. **This setting applies at the account level.** Once set, it will apply to all users in your account when editing any job.
- Choose to automatically infer schema. Output schemas will be automatically inferred for the selected node
- Choose to automatically import Amazon Glue libraries. This is useful as it will prevent data preview from restarting new sessions when adding new transforms that require a session restart

Preferences ✕

Wrap lines
Enable to wrap lines of table cell content, disable to truncate text.

Number of rows
Enter the amount of entries to sample from the dataset.

IAM role
To start a data preview session, choose an IAM role for this job. Changing the role will end an existing data preview session.

Admin
No description available. ▼

[Create IAM role.](#) 

Automatically start data preview sessions
Data preview will automatically start new interactive sessions when entering the visual job editor enabling you to preview data more efficiently.
⚠ This setting applies to all users in your account.

Infer schema from session
Output schemas will be automatically inferred based on the result of the datapreview execution

Automatically import glue libraries
Some ETL transform require extra libraries to be imported in the datapreview session, enabling this option will automatically import them to your sessions in order to prevent session from restarting during your job authoring. Note: the IAM role require read permission to Glue S3 bucket to prevent failures.

Cancel **Confirm**

Additional features include the ability to:

- Choose the **Previewing x of y fields** button to select which columns (fields) to preview. When you preview your data using the default settings, the job editor shows the first 5 columns of your dataset. You can change this to show all or none (not recommended).

- Scroll through the data preview window both horizontally and vertically.
- Use the maximize button to expand the Data preview tab to over-layer the job graph to better view the data and data structures. Similarly, use the minimize button to minimize the Data preview tab. You can also grab the handle pane and drag up to expand the **Data preview** tab.

The screenshot displays the Amazon Glue console interface. At the top, there are navigation tabs: Visual, Script, Job details, Runs, Data quality New, Schedules, and Version Control. Below these is a job graph showing a 'Data source - S3 bucket Amazon S3' (with a green checkmark) connected to a 'Data target - Snowflake'. Below the job graph is a 'Data preview' window. The 'Data preview' window has a title bar with 'Data preview' and 'Output schema' tabs. A red box highlights the maximize and minimize buttons in the top right corner of the window. Below the title bar, there is a 'Data preview (200)' status, an 'Info' icon, a 'READY' status, a refresh button, an 'End session' button, and a 'Previewing 5 of 5 fields' button. Below this is a search bar labeled 'Filter sample dataset'. The main content of the data preview is a table with the following data:

venueid	venue name	venue city	venue state	venue seats
1	Toyota Park	Bridgeview	IL	0
2	Columbus Crew Stadium	Columbus	OH	0
3	RFK Stadium	Washington	DC	0

- Use **End session** to stop the data preview. When you stop the session, you can choose a new IAM role, and set additional settings (such as turn on or off settings to automatically start a new session, infer schema, or import Amazon Glue libraries, and start the session again).

Restrictions when using data previews

When using data previews, you might encounter the following restrictions or limitations.

- The first time you choose the Data preview tab you must choose IAM role. This role must have the necessary permissions to access the data and other resources needed to create the data previews.

- After you provide an IAM role, it takes a while before the data is available for viewing. For datasets with less than 1 GB of data, it can take up to one minute. If you have a large dataset, you should use partitions to improve the loading time. Loading data directly from Amazon S3 has the best performance.
- If you have a very large dataset, and it takes more than 15 minutes to query the data for the data preview, the request will time out. Data previews have a 30 minute IDLE timeout. To alleviate this, reduce the dataset size to use data previews.
- By default, you see the first 50 columns in the Data preview tab. If the columns have no data values, you will get a message that there is no data to display. You can increase the number of rows sampled, or selected different columns to see data values.
- Data previews are currently not supported for streaming data sources, or for data sources that use custom connectors.
- Errors on one node effect the entire job. If any one node has an error with data previews, the error will show up on all nodes until you correct it.
- If you change a data source for the job, then the child nodes of that data source might need to be updated to match the new schema. For example, if you have an ApplyMapping node that modifies a column, and the column does not exist in the replacement data source, you will need to update the ApplyMapping transform node.
- If you view the Data preview tab for a SQL query transform node, and the SQL query uses an incorrect field name, the Data preview tab shows an error.

Script code generation

When you use the visual editor to create a job, the ETL code is automatically generated for you. Amazon Glue Studio creates a functional and complete job script, and saves it in an Amazon S3 location.

There are two forms of code generated by Amazon Glue Studio: the original, or Classic version, and a newer, streamlined version. By default, the new code generator is used to create the job script. You can generate a job script using classic code generator on the **Script** tab by choosing the **Generate classic script** toggle button.

Some of the differences in the new version of the generated code include:

- Large comment blocks are no longer added to the script

- Output structures in the code use the node name that you specify in the visual editor. In the class script, the output structures are simply named `DataSource0`, `DataSource1`, `Transform0`, `Transform1`, `DataSink0`, `DataSink1`, and so on.
- Long commands are split across multiple lines to remove the need to scroll across the page to see the entire command.

New features in Amazon Glue Studio require the new version of code generation, and will not work with the classic code script. You are prompted to update these jobs when you attempt to run them.

Transform data with Amazon Glue managed transforms

Amazon Glue Studio provides two types of transforms:

- **Amazon Glue-native transforms** - available to all users and are managed by Amazon Glue.
- **Custom visual transforms** - allows you to upload your own transforms to use in Amazon Glue Studio

Amazon Glue managed data transform nodes

Amazon Glue Studio provides a set of built-in transforms that you can use to process your data. Your data passes from one node in the job diagram to another in a data structure called a `DynamicFrame`, which is an extension to an Apache Spark SQL `DataFrame`.

In the pre-populated diagram for a job, between the data source and data target nodes is the **Change Schema** transform node. You can configure this transform node to modify your data, or you can use additional transforms.

The following built-in transforms are available with Amazon Glue Studio:

- **[ChangeSchema](#)**: Map data property keys in the data source to data property keys in the data target. You can rename keys, modify the data types for keys, and choose which keys to drop from the dataset.
- **[SelectFields](#)**: Choose the data property keys that you want to keep.
- **[DropFields](#)**: Choose the data property keys that you want to drop.
- **[RenameField](#)**: Rename a single data property key.
- **[Spigot](#)**: Write samples of the data to an Amazon S3 bucket.

- **[Join](#)**: Join two datasets into one dataset using a comparison phrase on the specified data property keys. You can use inner, outer, left, right, left semi, and left anti joins.
- **[Union](#)**: Combine rows from more than one data source that have the same schema.
- **[SplitFields](#)**: Split data property keys into two `DynamicFrames`. Output is a collection of `DynamicFrames`: one with selected data property keys, and one with the remaining data property keys.
- **[SelectFromCollection](#)**: Choose one `DynamicFrame` from a collection of `DynamicFrames`. The output is the selected `DynamicFrame`.
- **[FillMissingValues](#)**: Locate records in the dataset that have missing values and add a new field with a suggested value that is determined by imputation
- **[Filter](#)**: Split a dataset into two, based on a filter condition.
- **[Drop Null Fields](#)**: Removes columns from the dataset if all values in the column are 'null'.
- **[Drop Duplicates](#)**: Removes rows from your data source by choosing to match entire rows or specify keys.
- **[SQL](#)**: Enter SparkSQL code into a text entry field to use a SQL query to transform the data. The output is a single `DynamicFrame`.
- **[Aggregate](#)**: Performs a calculation (such as average, sum, min, max) on selected fields and rows, and creates a new field with the newly calculated value(s).
- **[Flatten](#)**: Extract fields inside structs into top level fields.
- **[UUID](#)**: Add a column with a Universally Unique Identifier for each row.
- **[Identifier](#)**: Add a column with a numeric identifier for each row.
- **[To timestamp](#)**: Convert a column to timestamp type.
- **[Format timestamp](#)**: Convert a timestamp column to a formatted string.
- **[Conditional Router transform](#)**: Apply multiple conditions to incoming data. Each row of the incoming data is evaluated by a group filter condition and processed into its corresponding group.
- **[Concatenate Columns transform](#)**: Build a new string column using the values of other columns with an optional spacer.
- **[Split String transform](#)**: Break up a string into an array of tokens using a regular expression to define how the split is done.
- **[Array To Columns transform](#)**: Extract some or all the elements of a column of type array into new columns.

- **[Add Current Timestamp transform](#)**: Mark the rows with the time on which the data was processed. This is useful for auditing purposes or to track latency in the data pipeline.
- **[Pivot Rows to Columns transform](#)**: Aggregate a numeric column by rotating unique values on selected columns which become new columns. If multiple columns are selected, the values are concatenated to name the new columns.
- **[Unpivot Columns To Rows transform](#)**: Convert columns into values of new columns generating a row for each unique value.
- **[Autobalance Processing transform](#)**: Redistribute the data better among the workers. This is useful where the data is unbalanced or as it comes from the source doesn't allow enough parallel processing on it.
- **[Derived Column transform](#)**: Define a new column based on a math formula or SQL expression in which you can use other columns in the data, as well as constants and literals.
- **[Lookup transform](#)**: Add columns from a defined catalog table when the keys match the defined lookup columns in the data.
- **[Explode Array or Map Into Rows transform](#)**: Extract values from a nested structure into individual rows that are easier to manipulate.
- **[Record matching transform](#)**: Invoke an existing Record Matching machine learning data classification transform.
- **[Remove null rows transform](#)**: Remove from the dataset rows that have all columns as null, or empty.
- **[Parse JSON column transform](#)**: Parse a string column containing JSON data and convert it to a struct or an array column, depending if the JSON is an object or an array, respectively.
- **[Extract JSON path transform](#)**: Extract new columns from a JSON string column.
- **[Extract string fragments from a regular expression](#)**: Extract string fragments using a regular expression and create new column out of it, or multiple columns if using regex groups.
- **[Custom transform](#)**: Enter code into a text entry field to use custom transforms. The output is a collection of `DynamicFrames`.

Using a data preparation recipe in Amazon Glue Studio

The **Data preparation recipe** transform allows you to author a data preparation recipe from scratch using an interactive grid style authoring interface. It also allows you to import an existing Amazon Glue DataBrew recipe and then edit it in Amazon Glue Studio.

The **Data Preparation Recipe** node is available from the Resource panel. You can connect the **Data Preparation Recipe** node to another node in the visual workflow, whether it is a Data source node or another transformation node. After choosing a Amazon Glue DataBrew recipe and version, the applied steps in the recipe are visible in the node properties tab.

Prerequisites

- If importing an Amazon Glue DataBrew recipe, you have the required IAM permissions as described in [Import a Amazon Glue DataBrew recipe in Amazon Glue Studio](#) .
- A data preview session must be created.

Limitations

- Amazon Glue DataBrew recipes are only supported in [commercial DataBrew regions](#).
- Not all Amazon Glue DataBrew recipes are supported by Amazon Glue. Some recipes will not be able to be run in Amazon Glue Studio.
 - Recipes with UNION and JOIN transforms are not supported, however, Amazon Glue Studio already has "Join" and "Union" transform nodes which can be used before or after a **Data Preparation Recipe** node.
- **Data Preparation Recipe** nodes are supported for jobs starting with Amazon Glue version 4.0. This version will be auto-selected after a **Data Preparation Recipe** node is added to the job.
- **Data Preparation Recipe** nodes require Python. This is automatically set when the **Data Preparation Recipe** node is added to the job.
- Adding a new **Data Preparation Recipe** node to the visual graph will automatically restart your Data Preview session with the correct libraries to use the **Data Preparation Recipe** node.
- The following transforms are not supported for import or editing in a **Data Preparation Recipe** node: GROUP_BY, PIVOT, UNPIVOT, and TRANSPOSE.

Additional features

When you've selected the **Data Preparation Recipe** transform, you have the ability to take additional actions after choosing **Author recipe**.

- Add step – you can add additional steps to a recipe as needed by choosing the add step icon, or use the toolbar in the Preview pane by choosing an action.

- Import recipe – choose **More** then **Import recipe** to use in your Amazon Glue Studio job.

- Download as YAML – choose **More** then **Download as YAML** to download your recipe to save outside of Amazon Glue Studio.
- Download as JSON – choose **More** then **Download as JSON** to download your recipe to save outside of Amazon Glue Studio.
- Undo and redo recipe steps – You can undo and redo recipe steps in the Preview pane when working with data in the grid.

Author and run data preparation recipes in a visual ETL Amazon Glue job

In this scenario, you can author data preparation recipes without having to first create them in DataBrew. Before you can start authoring recipes, you must:

- Have an active Data Preview session running. When the data preview session is **READY**, then **Author Recipe** will become active and you can begin authoring or editing your recipe.

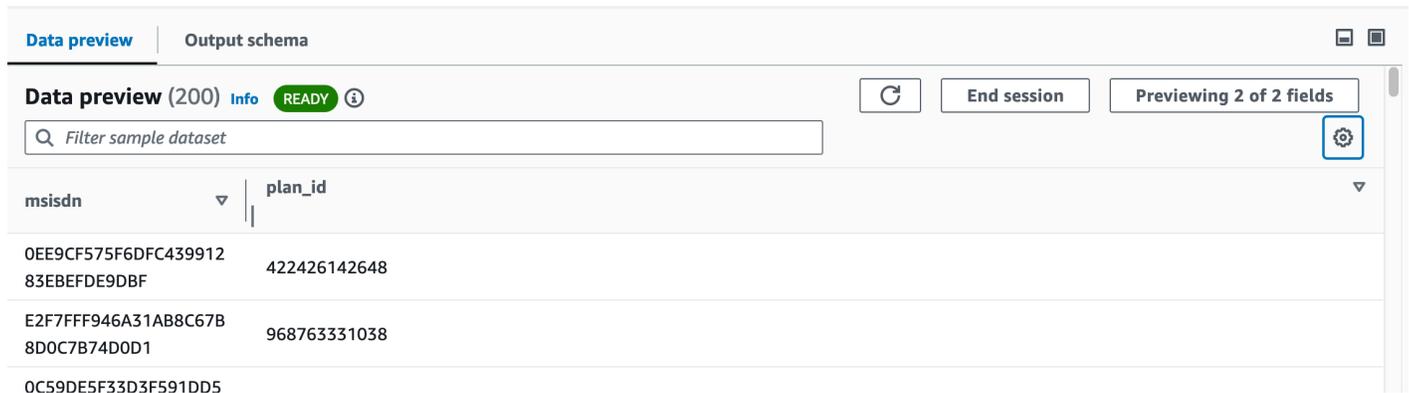

- Ensure that the toggle for **Automatically import glue libraries** is enabled.

Automatically import glue libraries

Some ETL transform require extra libraries to be imported in the datapreview session, enabling this option will automatically import them to your sessions in order to prevent session from restarting during your job authoring. Note: the IAM role require read permission to Glue S3 bucket to prevent failures.

You can do this by choosing the gear icon in the Data Preview pane.

The screenshot shows the Amazon Glue Data Preview interface. At the top, there are tabs for 'Data preview' and 'Output schema'. Below the tabs, there is a 'Data preview (200)' section with an 'Info' icon, a 'READY' status indicator, and a refresh button. A search bar with the placeholder text 'Filter sample dataset' is present. To the right of the search bar is a gear icon for settings. Below the search bar is a table with two columns: 'msisdn' and 'plan_id'. The table contains three rows of data:

msisdn	plan_id
0EE9CF575F6DFC439912 83EBEFDE9DBF	422426142648
E2F7FFF946A31AB8C67B 8D0C7B74D0D1	968763331038
0C59DE5F33D3F591DD5	

To author a data preparation recipe in Amazon Glue Studio:

1. Add the **Data Preparation Recipe** transform to your job canvas. Your transform should be connected to a data source node parent. When adding the **Data Preparation Recipe** node, the node will restart with the proper libraries and you will see the Data Frame being prepared.

The screenshot displays the Amazon Glue Studio interface. At the top, there is a header with 'Untitled job' and a warning 'Job has not been saved' with 'Actions', 'Save', and 'Run' buttons. Below the header is a toolbar with various data manipulation icons such as Filter, Sort, Column, Format, Clean, Extract, Missing, Invalid, Duplicates, Outliers, Split, Merge, Create, Functions, Conditions, and Nest-Unnest. The main workspace shows a 'Preparing dataframe' message with a table icon and text: 'Your session will be ready soon!', 'Preparing dataframe', and 'Your session will take about a minute to be ready. Once ready there will be no additional load time.' On the right side, the 'Transform' sidebar is open, showing 'Authoring Data Preparation Recipe' with an 'Author Recipe' button, a 'Recipe (0)' section, and a 'Build your Recipe' section with an 'Add step' button.

2. Once the Data Preview session is ready, the data with any previously applied steps will appear on the bottom of the screen.
3. Choose **Author Recipe**. This will allow you to start a new recipe in Amazon Glue Studio.

Transform ✕

Join - Transform

4. In the **Transform** panel to the right of the job canvas, enter a name for your data preparation recipe.
5. On the left-side, the canvas will be replaced with a grid view of your data. To the right, the **Transform** panel will change to show you your recipe steps. Choose **Add step** to add the first step in your recipe.

The screenshot shows the Amazon Glue console interface. The top navigation bar includes the AWS logo, 'Services', a search bar, and user information for 'N. Virginia' and 'MyRole/AWSUser @ 0123-4567-8901'. The main interface is split into two panes:

- Preview Pane (Left):** Displays a table with 23 columns and 259 rows. The table has columns for 'rated', 'created_at', and 'creation_date'. A summary row at the top shows statistics for each column. Below the summary, individual rows of data are visible, including boolean values like 'true' and 'false', and timestamps.
- Transform Pane (Right):** Shows the 'Recipe' authoring area. It includes a 'Done Authoring Recipe' button, a 'Data Cleanup Recipe' with a 'Clear all' button, and a central area with the text 'Build your recipe' and 'Start applying transformation steps to your data. All your data preparation steps will be tracked in the recipe.' Below this is an 'Add step' button.

At the bottom of the console, there is a footer with 'Feedback', 'English (US)', and copyright information: '© 2008 - 2023. Amazon Web Services, Inc. or its affiliates. All rights reserved. Privacy Policy Terms of Use'.

- In the **Transform** panel, choose to sort, take an action on the column, and filter values. For example, choose **Rename column**.

The screenshot displays the Amazon Glue console interface. On the left, a data table is shown with columns for 'id', 'name', 'age', 'email', 'phone', 'address', 'city', 'state', and 'zip'. The table contains 259 rows of data. On the right, the 'Transform' panel is visible, showing a recipe titled 'Done Authoring Recipe'. The panel includes a 'Add step' button, a 'Find steps' dropdown, and a list of column actions: Rename, Change type, Move column, Duplicate, and Delete. The 'FILTER' section is also visible, with options for Missing values, Invalid values, and By condition.

- In the Transform panel on the right-side, options for renaming a column allow you to choose the source column to rename, and to enter the new column name. Once you have done so, choose **Apply**.

You can preview each step, undo a step, and re-order steps and use any of the action icons, such as Filter, Sort, Split, Merge, etc. When you perform actions in the data grid, the steps are added to the recipe in the Transform panel.

The screenshot displays the Amazon Glue Studio interface. On the left, the 'Preview' pane shows a table with columns: 'rated', 'iic_created_at', and 'creation_date'. The table contains 259 rows of data. On the right, the 'Transform' pane shows a 'Recipe' with 13 steps:

1. Change type of columnName to Boolean
2. Delete column extra_data
3. Create duplicate column copy_of_last_name from last_name
4. Change type of address to Struct
5. Move rating after height_cm
6. Move height_cm before weight_kg
7. Move height_cm to End of table
8. Move nationality to Index 5
9. Move first_name to Start of table
10. Rename date_of_birth to birth_date
11. Sort column A by Ascending
12. Change type of is_present to Boolean
13. Change type of hourly_rate to Number

At the bottom of the interface, there is a toolbar with various icons. The 'UNDO' and 'REDO' icons are highlighted with a red box.

If you need to make a change, you can do this in the Preview pane by previewing the result of each step, undoing a step, and re-ordering steps. For example:

- Undo/redo step – undo a step by choosing the **undo** icon. You can repeat a step by choosing the **redo** icon.

- Reorder step – when you reorder a step, Amazon Glue Studio will validate each step and let you know if the step is invalid.
8. Once you've applied a step, the Transform panel will show you all the steps in your recipe. You can clear all the steps to start over, add more steps by choosing the add icon, or choose **Done Authoring Recipe**.

The screenshot displays the Amazon Glue Studio interface. On the left, a 'Preview' pane shows a table with columns: 'rated', 'arc_created_at', and 'creation_date'. The table contains 259 rows of data. On the right, a 'Transform' pane shows a 'Recipe' section with a 'Data Cleanup Recipe' selected. The recipe steps are:

1. Change type of columnName to Boolean
2. Delete column extra_data
3. Create duplicate column copy_of_last_name from last_name
4. Change type of address to Struct
5. Move rating after height_cm
6. Move height_cm before weight_kg
7. Move height_cm to End of table
8. Move nationality to Index 5
9. Move first_name to Start of table
10. Rename date_of_birth to birth_date
11. Sort column A by Ascending
12. Change type of is_present to Boolean
13. Change type of hourly_rate to Number

The 'Save' button is highlighted in the top right corner of the interface.

9. Choose **Save** at the top right side of your screen. Your recipe steps will not be saved until you save your job.

Import a Amazon Glue DataBrew recipe in Amazon Glue Studio

In Amazon Glue DataBrew, a recipe is a set of data transformation steps. Amazon Glue DataBrew recipes prescribes how to transform data that have already been read and doesn't describe where and how to read data, as well as how and where to write data. This is configured in Source and Target nodes in Amazon Glue Studio. For more information on recipes, see [Creating and using Amazon Glue DataBrew recipes](#).

To use Amazon Glue DataBrew recipes in Amazon Glue Studio, begin with creating recipes in Amazon Glue DataBrew. If you have recipes you want to use, you can skip this step.

IAM permissions for Amazon Glue DataBrew

This topic provides information to help you understand the actions and resources that you an IAM administrator can use in an Amazon Identity and Access Management (IAM) policy for the Data Preparation Recipe transform.

For additional information about security in Amazon Glue, see [Access Management](#).

Note

The following table lists the permissions that a user needs if importing an existing Amazon Glue DataBrew recipe.

Data Preparation Recipe transform actions

Action	Description
<code>databrew:ListRecipes</code>	Grants permission to retrieve Amazon Glue DataBrew recipes.
<code>databrew:ListRecipeVersions</code>	Grants permission to retrieve Amazon Glue DataBrew recipe versions.
<code>databrew:DescribeRecipe</code>	Grants permission to retrieve Amazon Glue DataBrew recipe description.

The role you're using for accessing this functionality should have a policy that allows several Amazon Glue DataBrew actions. You can achieve this by either using the `AWSGlueConsoleFullAccess` policy that includes the necessary actions or add the following inline policy to your role:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```

    "Effect": "Allow",
    "Action": [
      "databrew:ListRecipes",
      "databrew:ListRecipeVersions",
      "databrew:DescribeRecipe"
    ],
    "Resource": [
      "*"
    ]
  }
]
}

```

To use the Data Preparation Recipe transform, you must add the `IAM:PassRole` action to the permissions policy.

Additional required permissions

Action	Description
<code>iam:PassRole</code>	Grants permission for IAM to allow the user to pass the approved roles.

Without these permissions the following error occurs:

```

"errorCode": "AccessDenied"
"errorMessage": "User: arn:aws:sts::account_id:assumed-role/AWSGlueServiceRole is not
authorized to perform: iam:PassRole on resource: arn:aws:iam::account_id:role/service-
role/AWSGlueServiceRole
because no identity-based policy allows the iam:PassRole action"

```

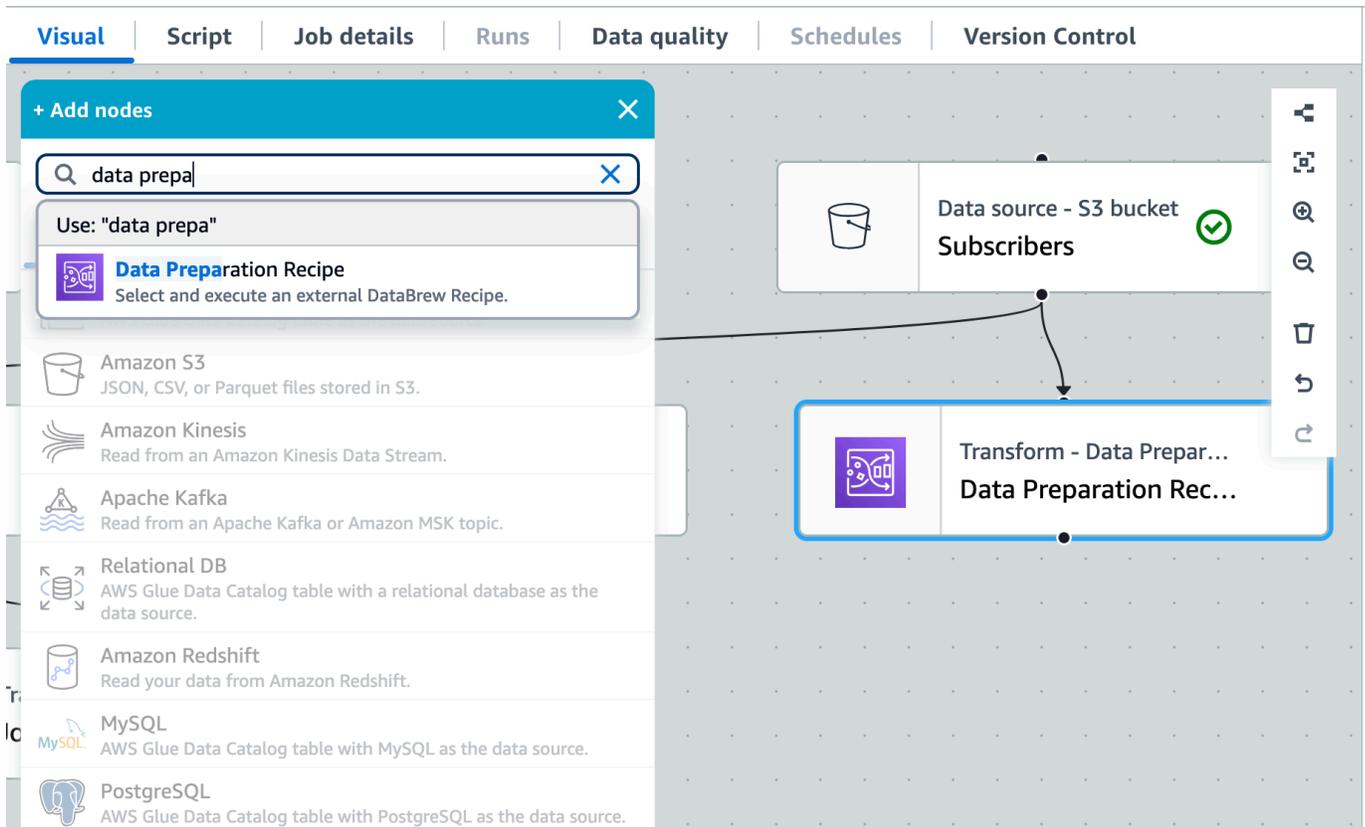

Importing an Amazon Glue DataBrew recipe

To import an Amazon Glue DataBrew recipe and use in Amazon Glue Studio:

If you have an existing **Data Preparation Recipe** node and you want to edit the recipe steps directly in Amazon Glue Studio, you will have to import the recipe steps into your Amazon Glue Studio job.

1. Start a Amazon Glue job in Amazon Glue Studio with a datasource.

2. Add the **Data Preparation Recipe** node to the job canvas.

3. In the Transform panel, enter a name for your recipe.
4. Choose one or more parent nodes by selecting the available nodes on the canvas from the drop-down list.
5. Choose **Author Recipe**. If **Author Recipe** is grey it is unavailable until node parents have been selected and a data preview session has finished.

Transform

Select the **more actions** icon and choose **Import recipe**.

Transform

Authoring Data Preparation Recipe

Done authoring recipe

☰ Recipe (0) ⋮

Import recipe

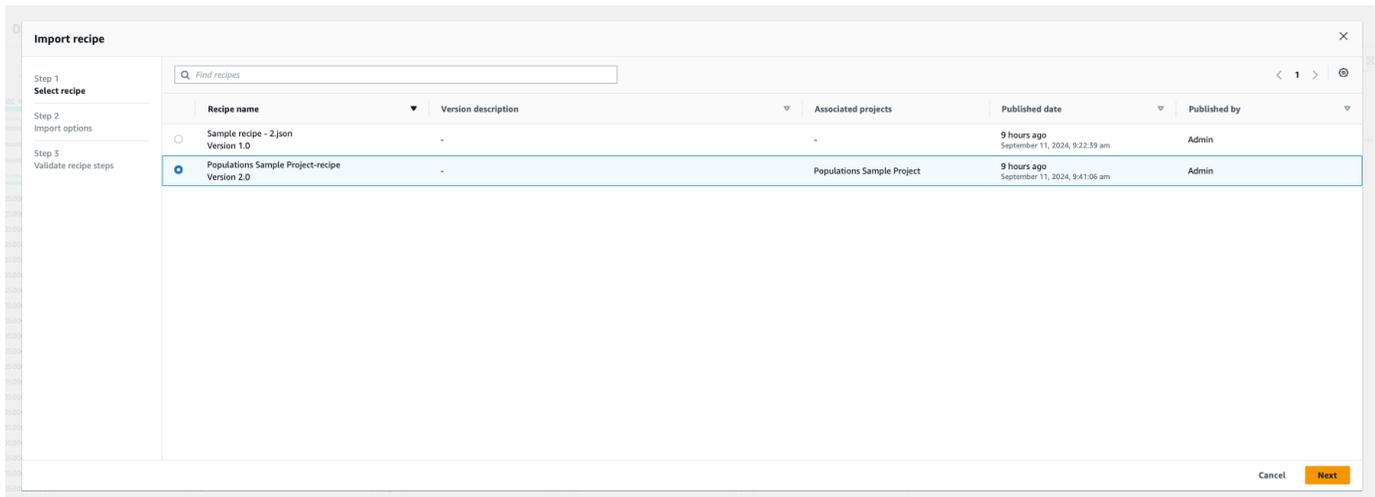

Build your Recipe

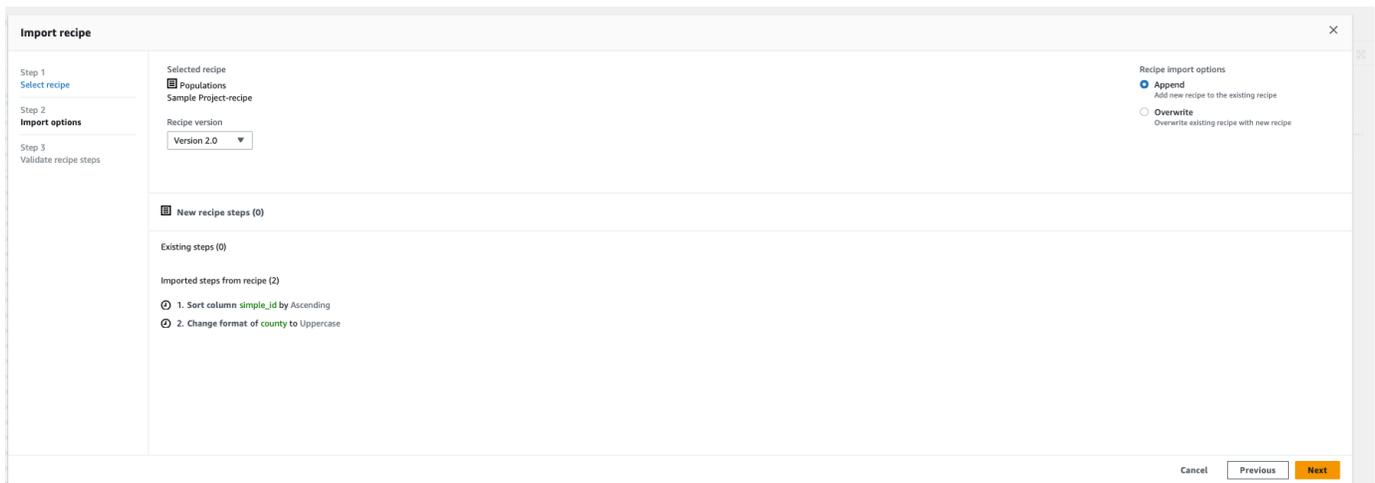

Start applying transformation steps to your data. All your data preparation steps will be tracked in the recipe.

➕ Add step

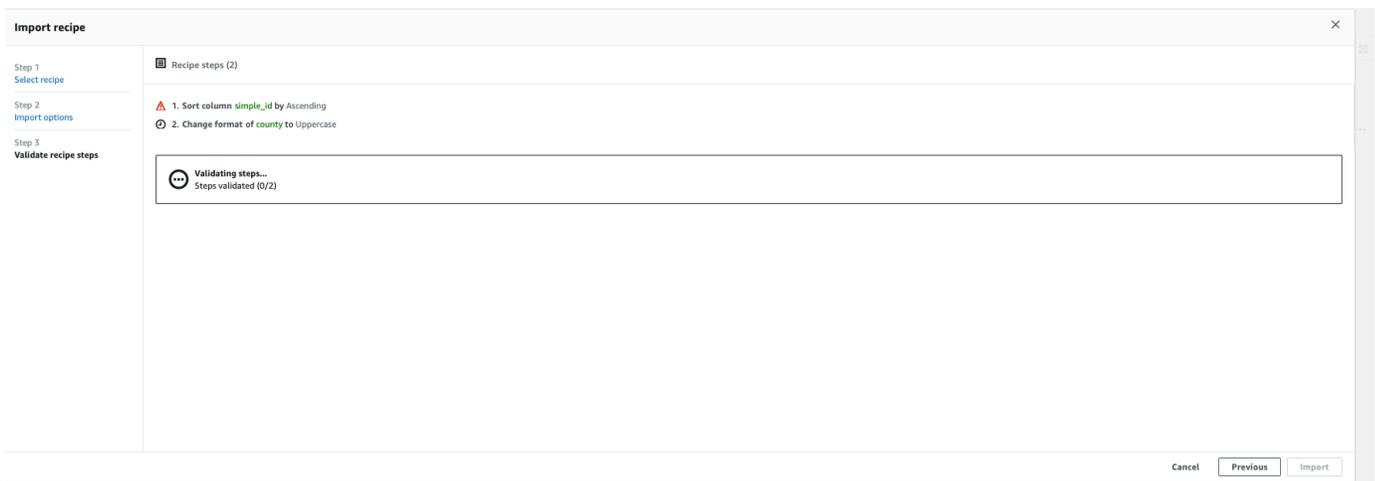

7. Use the Import recipe wizard to complete the steps. In step 1, search for your recipe, select it, and choose **Next**.

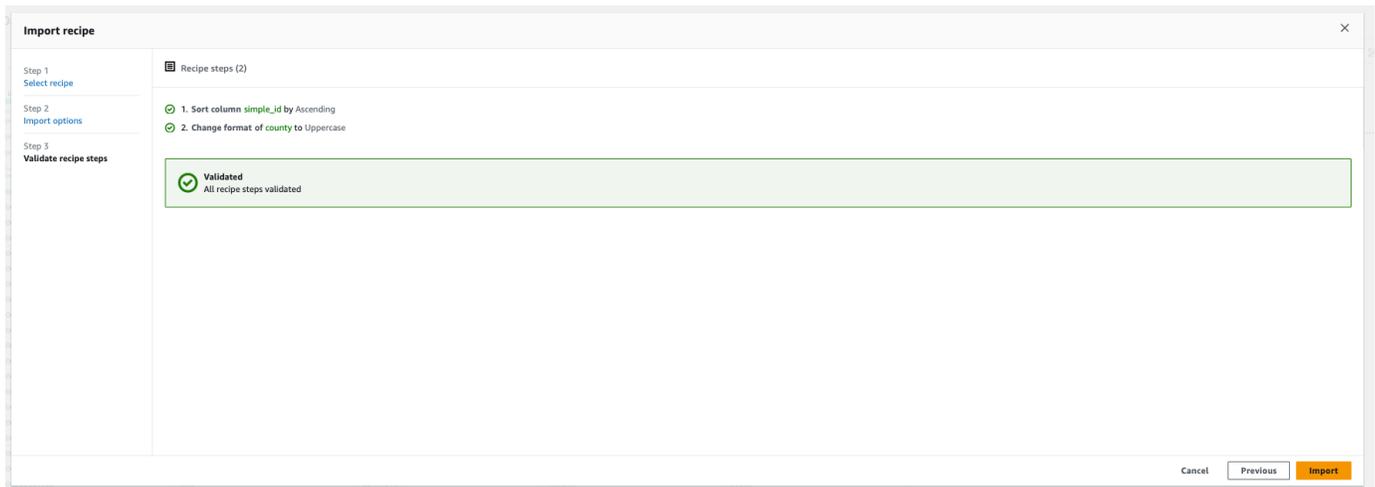

8. In step 2, choose your import options. You can choose to Append a new recipe to an existing recipe or Overwrite an existing recipe. Choose **Next**.

9. In step 3, validate the recipe steps. Once you import your Amazon Glue DataBrew recipe, you can edit this recipe directly in Amazon Glue Studio.

10. After this, the steps will be imported as part of your Amazon Glue job. Make necessary configuration changes in the **Job details** tab, like naming your job and adjusting allocated capacity as needed. Choose **Save** to save your job and recipe.

Note

JOIN, UNION, GROUP_BY, PIVOT, UNPIVOT, TRANSPOSE are not supported for recipe import, nor will they be available in recipe authoring mode.

11. Optionally, you can finish authoring the job by adding other transformations nodes as needed and add Data target node(s).

If you reorder steps after you import a recipe, Amazon Glue performs validation on those steps. For example, if you renamed and then deleted a column, and you moved the delete step on top, then the rename step would be invalid. You can then edit the steps to fix the validation error.

Migrating from Amazon Glue DataBrew to Amazon Glue Studio

If you have recipes in Amazon Glue DataBrew, use the following checklist to migrate your recipes to Amazon Glue Studio.

If you want to	Then do this
Allow users to retrieve Amazon Glue DataBrew recipes, recipe versions, and recipe descriptions.	Add IAM permissions to a policy that allows your role to access the necessary actions. See IAM permissions for Amazon Glue DataBrew .
Import an existing Amazon Glue DataBrew recipe into Amazon Glue Studio.	Follow the steps in Importing an Amazon Glue DataBrew recipe .
Import a recipe with JOIN and UNION.	Recipes with UNION and JOIN transforms are not supported. Use the Join and Union transforms in Amazon Glue Studio before or after a Data Preparation Recipe node.

Using Change Schema to remap data property keys

A *Change Schema* transform remaps the source data property keys into the desired configured for the target data. In a Change Schema transform node, you can:

- Change the name of multiple data property keys.
- Change the data type of the data property keys, if the new data type is supported and there is a transformation path between the two data types.
- Choose a subset of data property keys by indicating which data property keys you want to drop.

You can also add additional *Change Schema* nodes to the job diagram as needed – for example, to modify additional data sources or following a *Join* transform.

Using Change Schema with decimal datatype

When using the **Change Schema** transform with decimal datatype, the **Change Schema** transform modifies the precision to the default value of (10,2). To modify this and set the precision for your use case, you can use the **SQL Query** transform and cast the columns with a specific precision.

For example, if you have an input column named "DecimalCol" of type Decimal, and you want to remap it to an output column named "OutputDecimalCol" with a specific precision of (18,6), you would:

1. Add a subsequent **SQL Query** transform after the **Change Schema** transform.

2. In the **SQL Query** transform, use an SQL query to cast the remapped column to the desired precision. The SQL query would look like this:

```
SELECT col1, col2, CAST(DecimalCol AS DECIMAL(18,6)) AS OutputDecimalCol
FROM __THIS__
```

In the above SQL query:

- `col1` and `col2` are other columns in your data that you want to pass through without modification.
- `DecimalCol` is the original column name from the input data.
- `CAST(DecimalCol AS DECIMAL(18,6))` casts the `DecimalCol` to a Decimal type with a precision of 18 digits and 6 decimal places.
- `AS OutputDecimalCol` renames the casted column to `OutputDecimalCol`.

By using the **SQL Query** transform, you can override the default precision set by the **Change Schema** transform and explicitly cast the Decimal columns to the desired precision. This approach allows you to leverage the **Change Schema** transform for renaming and restructuring your data while handling the precision requirements for Decimal columns through the subsequent **SQL Query** transformation.

Adding a Change Schema transform to your job

Note

The **Change Schema** transform is not case-sensitive.

To add a Change Schema transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **Change Schema** to add a new transform to your job diagram, if needed.
2. In the node properties panel, enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab in the node properties panel.
4. Modify the input schema:

- To rename a data property key, enter the new name of the key in the **Target key** field.
 - To change the data type for a data property key, choose the new data type for the key from the **Data type** list.
 - To remove a data property key from the target schema, choose the **Drop** check box for that key.
5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
 6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

Using Drop Duplicates

The Drop Duplicates transform removes rows from your data source by giving you two options. You can choose to remove the duplicate row that are completely the same, or you can choose to choose the fields to match and remove only those rows based on your chosen fields.

For example, in this data set, you have duplicate rows where all the values in some of the rows are exactly the same as another row, and some of the values in rows are the same or different.

Row	Name	Email	Age	State	Note
1	Joy	joy@gmail	33	NY	
2	Tim	tim@gmail	45	OH	
3	Rose	rose@gmail	23	NJ	
4	Tim	tim@gmail	42	OH	
5	Rose	rose@gmail	23	NJ	

Row	Name	Email	Age	State	Note
6	Tim	tim@gmail	42	OH	this is a duplicate row and matches completely on all values as row #4
7	Rose	rose@gmail	23	NJ	This is a duplicate row and matches completely on all values as row #5

If you choose to match entire rows, rows 6 and 7 will be removed from the data set. The data set is now:

Row	Name	Email	Age	State
1	Joy	joy@gmail	33	NY
2	Tim	tim@gmail	45	OH
3	Rose	rose@gmail	23	NJ
4	Tim	tim@gmail	42	OH
5	Rose	rose@gmail	23	NJ

If you chose to specify keys, you can choose to remove rows that match on 'name' and 'email'. This gives you finer control of what is a 'duplicate row' for your data set. By specifying 'name' and 'email', the data set is now:

Row	Name	Email	Age	State
1	Joy	joy@gmail	33	NY
2	Tim	tim@gmail	45	OH
3	Rose	rose@gmail	23	NJ

Some things to keep in mind:

- In order for rows to be recognized as a duplicate, values are case sensitive. all values in rows need to have the same casing - this applies to either option you choose (Match entire rows or Specify keys).
- All values are read in as strings.
- The **Drop Duplicates** transform utilizes the Spark `dropDuplicates` command.
- When using the **Drop Duplicates** transform, the first row is kept and other rows are dropped.
- The **Drop Duplicates** transform does not change the schema of the dataframe. If you choose to specify keys, all fields are kept in the resulting dataframe.

Using `SelectFields` to remove most data property keys

You can create a subset of data property keys from the dataset using the `SelectFields` transform. You indicate which data property keys you want to keep and the rest are removed from the dataset.

Note

The `SelectFields` transform is case sensitive. Use `ApplyMapping` if you need a case-insensitive way to select fields.

To add a `SelectFields` transform node to your job diagram

1. (Optional) Open the Resource panel, and then choose **SelectFields** to add a new transform to your job diagram, if needed.

2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab in the node details panel.
4. Under the heading **SelectFields**, choose the data property keys in the dataset that you want to keep. Any data property keys not selected are dropped from the dataset.

You can also choose the check box next to the column heading **Field** to automatically choose all the data property keys in the dataset. Then you can deselect individual data property keys to remove them from the dataset.

5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

Using DropFields to keep most data property keys

You can create a subset of data property keys from the dataset using the *DropFields* transform. You indicate which data property keys you want to remove from the dataset and the rest of the keys are retained.

Note

The *DropFields* transform is case sensitive. Use *Change Schema* if you need a case-insensitive way to select fields.

To add a DropFields transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **DropFields** to add a new transform to your job diagram, if needed.

2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab in the node details panel.
4. Under the heading **DropFields**, choose the data property keys to drop from the data source.

You can also choose the check box next to the column heading **Field** to automatically choose all the data property keys in the dataset. Then you can deselect individual data property keys so they are retained in the dataset.

5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

Renaming a field in the dataset

You can use the *RenameField* transform to change the name for an individual property key in the dataset.

Note

The *RenameField* transform is case sensitive. Use *ApplyMapping* if you need a case-insensitive transform.

Tip

If you use the *Change Schema* transform, you can rename multiple data property keys in the dataset with a single transform.

To add a RenameField transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **RenameField** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab.
4. Under the heading **Data field**, choose a property key from the source data and then enter a new name in the **New field name field**.
5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

Using Spigot to sample your dataset

To test the transformations performed by your job, you might want to get a sample of the data to check that the transformation works as intended. The *Spigot* transform writes a subset of records from the dataset to a JSON file in an Amazon S3 bucket. The data sampling method can be either a specific number of records from the beginning of the file or a probability factor used to pick records.

To add a Spigot transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **Spigot** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.

3. Choose the **Transform** tab in the node details panel.
4. Enter an Amazon S3 path or choose **Browse S3** to choose a location in Amazon S3. This is the location where the job writes the JSON file that contains the data sample.
5. Enter information for the sampling method. You can specify a value for **Number of records** to write starting from the beginning of the dataset and a **Probability threshold** (entered as a decimal value with a maximum value of 1) of picking any given record.

For example, to write the first 50 records from the dataset, you would set **Number of records** to 50 and **Probability threshold** to 1 (100%).

Joining datasets

The *Join* transform allows you to combine two datasets into one. You specify the key names in the schema of each dataset to compare. The output `DynamicFrame` contains rows where keys meet the join condition. The rows in each dataset that meet the join condition are combined into a single row in the output `DynamicFrame` that contains all the columns found in either dataset.

To add a Join transform node to your job diagram

1. If there is only one data source available, you must add a new data source node to the job diagram.
2. Choose one of the source nodes for the join. Open the Resource panel and then choose **Join** to add a new transform to your job diagram.
3. On the **Node properties** tab, enter a name for the node in the job diagram.
4. In the **Node properties** tab, under the heading **Node parents**, add a parent node so that there are two datasets providing inputs for the join. The parent can be a data source node or a transform node.

Note

A join can have only two parent nodes.

5. Choose the **Transform** tab.

If you see a message indicating that there are conflicting key names, you can either:

- Choose **Resolve it** to automatically add an *ApplyMapping* transform node to your job diagram. The *ApplyMapping* node adds a prefix to any keys in the dataset that have the

same name as a key in the other dataset. For example, if you use the default value of **right**, then any keys in the right dataset that have the same name as a key in the left dataset will be renamed to `(right)key name`.

- Manually add a transform node earlier in the job diagram to remove or rename the conflicting keys.
6. Choose the type of join in the **Join type** list.
 - **Inner join:** Returns a row with columns from both datasets for every match based on the join condition. Rows that don't satisfy the join condition aren't returned.
 - **Left join:** All rows from the left dataset and only the rows from the right dataset that satisfy the join condition.
 - **Right join:** All rows from the right dataset and only the rows from the left dataset that satisfy the join condition.
 - **Outer join:** All rows from both datasets.
 - **Left semi join:** All rows from the left dataset that have a match in the right dataset based on the join condition.
 - **Left anti join:** All rows in the left dataset that don't have a match in the right dataset based on join condition.
 7. On the **Transform** tab, under the heading **Join conditions**, choose **Add condition**. Choose a property key from each dataset to compare. Property keys on the left side of the comparison operator are referred to as the left dataset and property keys on the right are referred to as the right dataset.

For more complex join conditions, you can add additional matching keys by choosing **Add condition** more than once. If you accidentally add a condition, you can choose the delete icon

()

to remove it.

8. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
9. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to

access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

For an example of the join output schema, consider a join between two datasets with the following property keys:

```
Left: {id, dept, hire_date, salary, employment_status}
Right: {id, first_name, last_name, hire_date, title}
```

The join is configured to match on the `id` and `hire_date` keys using the `=` comparison operator.

Because both datasets contain `id` and `hire_date` keys, you chose **Resolve it** to automatically add the prefix **right** to the keys in the right dataset.

The keys in the output schema would be:

```
{id, dept, hire_date, salary, employment_status,
(right)id, first_name, last_name, (right)hire_date, title}
```

Using Union to combine rows

You use the Union transform node when you want to combine rows from more than one data source that have the same schema.

There are two types of Union transformations:

1. ALL – when applying ALL, the resulting union does not remove duplicate rows.
2. DISTINCT – when applying DISTINCT, the resulting union removes duplicate rows.

Unions vs. Joins

You use Union to combine rows. You use Join to combine columns.

Using the Union transform in the Visual ETL canvas

1. Add more than one data source to perform a union transform. To add a data source, open the Resource Panel, then choose the data source from the Sources tab. Before using the Union transformation, you must ensure that all data sources involved in the union have the same schema and structure.

2. When you have at least two data sources that you want to combine using the Union transform, create the Union transform by adding it to the canvas. Open the Resource Panel on the canvas and search for 'Union'. You can also choose the Transforms tab in the Resource Panel and scroll down until you find the Union transform, then choose **Union**.
3. Select the Union node on the job canvas. In the Node properties window, choose the parent nodes to connect to the Union transform.
4. Amazon Glue checks for compatibility to make sure that the Union transform can be applied to all data sources. If the schema for the data sources are the same, the operation will be allowed. If the data sources do not have the same schema, an invalid error message is displayed: "The input schemas of this union are not the same. Consider using ApplyMapping to match the schemas." To fix this, choose Use **ApplyMapping**.
5. Choose the Union type.
 1. All – By default, the All Union type is selected; this will result in duplicate rows if there are any in the data combination.
 2. Distinct – Choose Distinct if you want duplicate rows to be removed from the resulting data combination.

Using SplitFields to split a dataset into two

The *SplitFields* transform allows you to choose some of the data property keys in the input dataset and put them into one dataset and the unselected keys into a separate dataset. The output from this transform is a collection of `DynamicFrames`.

Note

You must use a *SelectFromCollection* transform to convert the collection of `DynamicFrames` into a single `DynamicFrame` before you can send the output to a target location.

The *SplitFields* transform is case sensitive. Add an *ApplyMapping* transform as a parent node if you need case-insensitive property key names.

To add a `SplitFields` transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **SplitFields** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab.
4. Choose which property keys you want to put into the first dataset. The keys that you do not choose are placed in the second dataset.
5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.
7. Configure a `SelectFromCollection` transform node to process the resulting datasets.

Overview of `SelectFromCollection` transform

Certain transforms have multiple datasets as their output instead of a single dataset, for example, `SplitFields`. The `SelectFromCollection` transform selects one dataset (`DynamicFrame`) from a collection of datasets (an array of `DynamicFrames`). The output for the transform is the selected `DynamicFrame`.

You must use this transform after you use a transform that creates a collection of `DynamicFrames`, such as:

- Custom code transforms
- `SplitFields`

If you don't add a *SelectFromCollection* transform node to your job diagram after any of these transforms, you will get an error for your job.

The parent node for this transform must be a node that returns a collection of `DynamicFrames`. If you choose a parent for this transform node that returns a single `DynamicFrame`, such as a *Join* transform, your job returns an error.

Similarly, if you use a *SelectFromCollection* node in your job diagram as the parent for a transform that expects a single `DynamicFrame` as input, your job returns an error.

Node parents

Select which node(s) will provide inputs for this one

Split Fields ×
 SplitFields - Transform

⚠ Parent node *Split Fields* outputs a collection, but node *Drop Fields* does not accept a collection.

Using *SelectFromCollection* to choose which dataset to keep

Use the *SelectFromCollection* transform to convert a collection of `DynamicFrames` into a single `DynamicFrame`.

To add a *SelectFromCollection* transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **SelectFromCollection** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab.
4. Under the heading **Frame index**, choose the array index number that corresponds to the `DynamicFrame` you want to select from the collection of `DynamicFrames`.

For example, if the parent node for this transform is a *SplitFields* transform, on the **Output schema** tab of that node you can see the schema for each `DynamicFrame`. If you want to keep the `DynamicFrame` associated with the schema for **Output 2**, you would select **1** for the value of **Frame index**, which is the second value in the list.

Only the `DynamicFrame` that you choose is included in the output.

5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

Find and fill missing values in a dataset

You can use the *FillMissingValues* transform to locate records in the dataset that have missing values and add a new field with a value determined by imputation. The input data set is used to train the machine learning (ML) model that determines what the missing value should be. If you use incremental data sets, then each incremental set is used as the training data for the ML model, so the results might not be as accurate.

To use a *FillMissingValues* transform node in your job diagram

1. (Optional) Open the Resource panel and then choose **FillMissingValues** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab.
4. For **Data field**, choose the column or field name from the source data that you want to analyze for missing values.
5. (Optional) In the **New field name** field, enter a name for the field added to each record that will hold the estimated replacement value for the analyzed field. If the analyzed field doesn't have a missing value, the value in the analyzed field is copied into the new field.

If you don't specify a name for the new field, the default name is the name of the analyzed column with `_filled` appended. For example, if you enter **Age** for **Data field** and don't specify a value for **New field name**, a new field named **Age_filled** is added to each record.

6. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
7. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

Filtering keys within a dataset

Use the *Filter* transform to create a new dataset by filtering records from the input dataset based on a regular expression. Rows that don't satisfy the filter condition are removed from the output.

- For string data types, you can filter rows where the key value matches a specified string.
- For numeric data types, you can filter rows by comparing the key value to a specified value using the comparison operators $<$, $>$, $=$, \neq , \leq , and \geq .

If you specify multiple filter conditions, the results are combined using an AND operator by default, but you can choose OR instead.

The *Filter* transform is case sensitive. Add an *ApplyMapping* transform as a parent node if you need case-insensitive property key names.

To add a Filter transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **Filter** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent isn't already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab.
4. Choose either **Global AND** or **Global OR**. This determines how multiple filter conditions are combined. All conditions are combined using either AND or OR operations. If you have only a single filter conditions, then you can choose either one.

5. Choose the **Add condition** button in the **Filter condition** section to add a filter condition.

In the **Key** field, choose a property key name from the dataset. In the **Operation** field, choose the comparison operator. In the **Value** field, enter the comparison value. Here are some examples of filter conditions:

- `year >= 2018`
- `State matches 'CA*'`

When you filter on string values, make sure that the comparison value uses a regular expression format that matches the script language selected in the job properties (Python or Scala).

6. Add additional filter conditions, as needed.
7. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
8. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

Using DropNullFields to remove fields with null values

Use the *DropNullFields* transform to remove fields from the dataset if all values in the field are 'null'. By default, Amazon Glue Studio will recognize null objects, but some values such as empty strings, strings that are "null", -1 integers or other placeholders such as zeros, are not automatically recognized as nulls.

To use the DropNullFields

1. Add a DropNullFields node to the job diagram.
2. On the **Node properties** tab, choose additional values that represent a null value. You can choose to select none or all of the values:

Node properties
Transform
Output schema
Data preview
✕

DropNullFields [Info](#)
Remove fields or columns where all the values are the null objects.

Choose additional values that represent a null value below.

Empty String (" " or "")

"null" String

-1 Integer

Add custom null values
Specify custom null values by entering the value and choosing the datatype.

String
▼

✕

Add new value

- Empty String (" " or "") - fields that contain empty strings will be removed
 - "null string" - fields that contain the string with the word 'null' will be removed
 - -1 integer - fields that contain a -1 (negative one) integer will be removed
3. If needed, you can also specify custom null values. These are null values that may be unique to your dataset. To add a custom null value, choose **Add new value**.
 4. Enter the custom null value. For example, this can zero, or any value that is being used to represent a null in the dataset.
 5. Choose the data type in the drop-down field. Data types can either be String or Integer.

Note

Custom null values and their data types must match exactly in order for the fields to be recognized as null values and the fields removed. Partial matches where only the custom null value matches but the data type does not will not result in the fields being removed.

Using a SQL query to transform data

You can use a **SQL** transform to write your own transform in the form of a SQL query.

A SQL transform node can have multiple datasets as inputs, but produces only a single dataset as output. It contains a text field, where you enter the Apache SparkSQL query. You can assign aliases to each dataset used as input, to help simplify the SQL query. For more information about the SQL syntax, see the [Spark SQL documentation](#).

Note

If you use a Spark SQL transform with a data source located in a VPC, add an Amazon Glue VPC endpoint to the VPC that contains the data source. For more information about configuring development endpoints, see [Adding a Development Endpoint](#), [Setting Up Your Environment for Development Endpoints](#), and [Accessing Your Development Endpoint](#) in the *Amazon Glue Developer Guide*.

To use a SQL transform node in your job diagram

1. (Optional) Add a transform node to the job diagram, if needed. Choose **SQL Query** for the node type.

Note

If you use a data preview session and a custom SQL or custom code node, the data preview session will execute the SQL or code block as-is for the entire dataset.

2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, or if you want multiple inputs for the SQL transform, choose a node from the **Node parents** list to use as the input source for the transform. Add additional parent nodes as needed.
3. Choose the **Transform** tab in the node details panel.
4. The source datasets for the SQL query are identified by the names you specified in the **Name** field for each node. If you do not want to use these names, or if the names are not suitable for a SQL query, you can associate a name to each dataset. The console provides default aliases, such as `MyDataSource`.

For example, if a parent node for the SQL transform node is named `Rename Org PK field`, you might associate the name `org_table` with this dataset. This alias can then be used in the SQL query in place of the node name.

5. In the text entry field under the heading **Code block**, paste or enter the SQL query. The text field displays SQL syntax highlighting and keyword suggestions.
6. With the SQL transform node selected, choose the **Output schema** tab, and then choose **Edit**. Provide the columns and data types that describe the output fields of the SQL query.

Specify the schema using the following actions in the **Output schema** section of the page:

- To rename a column, place the cursor in the **Key** text box for the column (also referred to as a *field* or *property key*) and enter the new name.
 - To change the data type for a column, select the new data type for the column from the drop-down list.
 - To add a new top-level column to the schema, choose the Overflow () button, and then choose **Add root key**. New columns are added at the top of the schema.
 - To remove a column from the schema, choose the delete icon () to the far right of the Key name.
7. When you finish specifying the output schema, choose **Apply** to save your changes and exit the schema editor. If you do not want to save you changes, choose **Cancel** to edit the schema editor.
 8. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

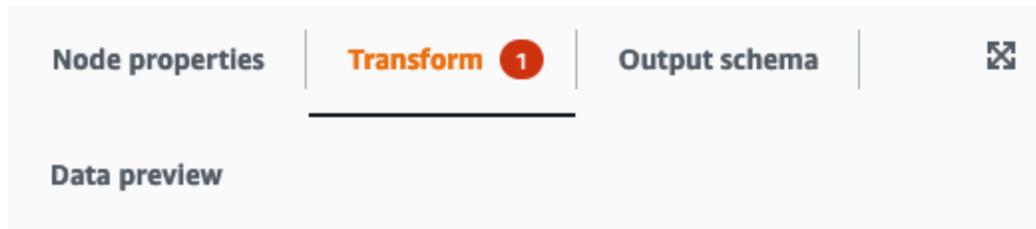

Using Aggregate to perform summary calculations on selected fields

To use the Aggregate transform

1. Add the Aggregate node to the job diagram.

- On the **Node properties** tab, choose fields to group together by selecting the drop-down field (optional). You can select more than one field at a time or search for a field name by typing in the search bar.

When fields are selected, the name and datatype are shown. To remove a field, choose 'X' on the field.

▼ **Aggregate** [Info](#)

This transform first groups your rows by fields you choose, and then computes the aggregated value for fields you choose by specific function (e.g., sum, average, max).

Fields to group by - *optional*

Select the fields you would like to group your rows by, so the aggregation would be done for each unique group.

Choose one or more fields ▼

Aggregate another column

 Add an aggregation.

- Choose **Aggregate another column**. It is required to select at least one field.

Field to aggregate Aggregation function [Info](#)

Choose a field ▼ Choose a function ▼ 

Aggregate another column

4. Choose a field in the **Field to aggregate** drop-down.
5. Choose the aggregation function to apply to the chosen field:
 - avg - calculates the average
 - countDistinct - calculates the number of unique non-null values
 - count - calculates the number of non-null values
 - first - returns the first value that satisfies the 'group by' criteria
 - last - returns the last value that satisfies the 'group by' criteria
 - kurtosis - calculates the the sharpness of the peak of a frequency-distribution curve
 - max - returns the highest value that satisfies the 'group by' criteria
 - min - returns the lowest value that satisfies the 'group by' criteria
 - skewness - measure of the asymmetry of the probability distribution of a normal distribution
 - stddev_pop - calculates the population standard deviation and returns the square root of the population variance
 - sum - the sum of all values in the group
 - sumDistinct - the sum of distinct values in the group
 - var_samp - the sample variance of the group (ignores nulls)
 - var_pop - the population variance of the group (ignores nulls)

Flatten nested structs

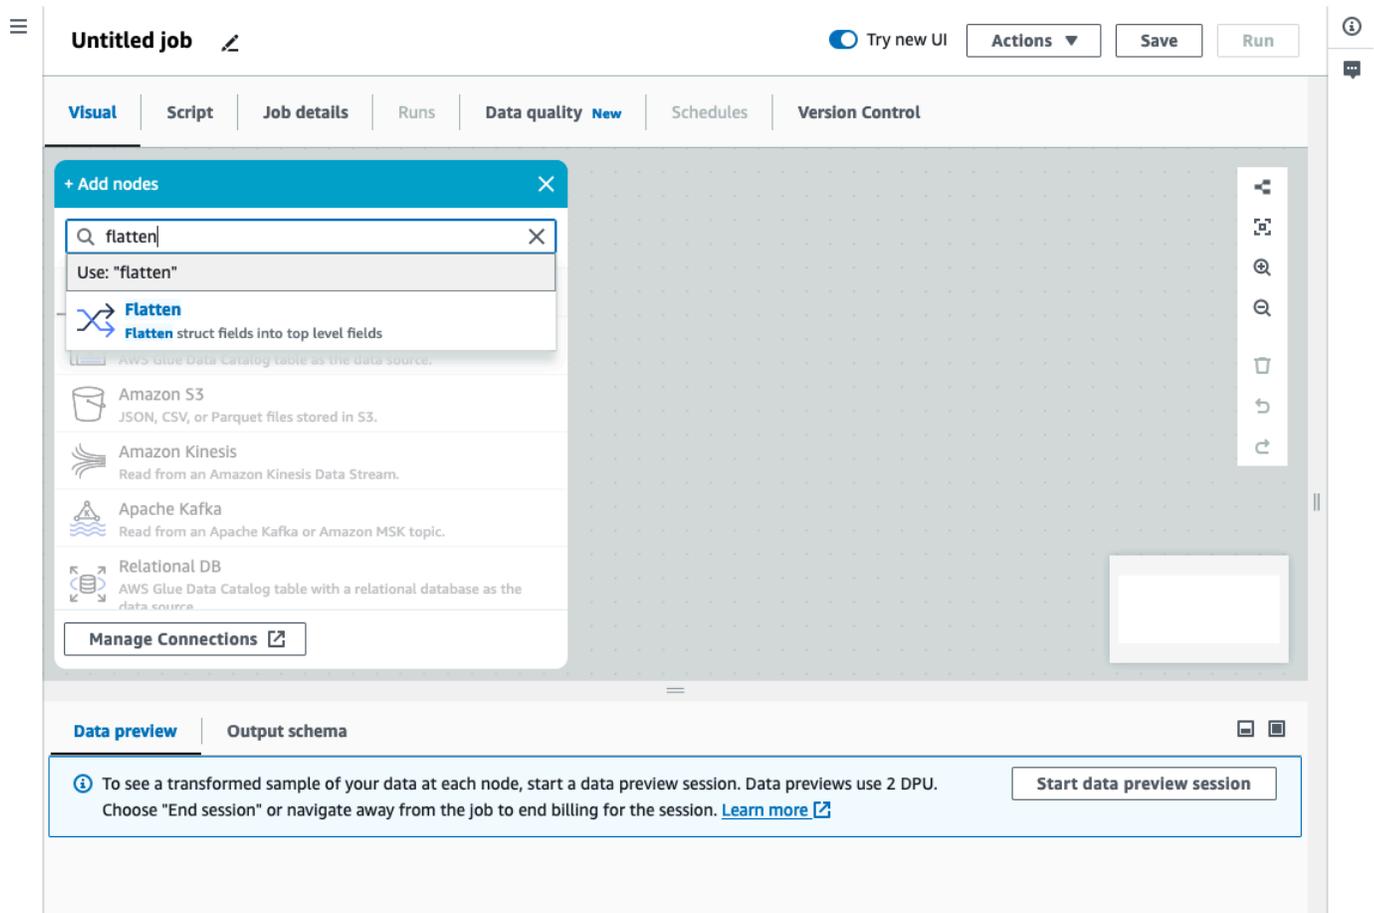

Flatten the fields of nested structs in the data, so they become top level fields. The new fields are named using the field name prefixed with the names of the struct fields to reach it, separated by dots.

For example, if the data has a field of type Struct named “phone_numbers”, which among other fields has one of type “Struct” named “home_phone” with two fields: “country_code”

and “number”. Once flattened, these two fields will become top level fields named: “phone_numbers.home_phone.country_code” and “phone_numbers.home_phone.number” respectively.

To add a *Flatten* transform node in your job diagram

1. Open the Resource panel and then choose the **Transforms** tab, then **Flatten** to add a new transform to your job diagram. You can also use the search bar by entering 'Flatten', then clicking the Flatten node. The node selected at the time of adding the node will be its parent.

2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. (Optional) On the **Transform** tab, you can limit the maximum nesting level to flatten. For instance, setting that value to 1 means that only top-level structs will be flattened. Setting the max to 2 will flatten the top level and the structs directly under it.

Add a UUID column

When you add a *UUID* (Universally Unique Identified) column, each row will be assigned a unique 36-character string.

To add a *UUID* transform node in your job diagram

1. Open the Resource panel and then choose **UUID** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. (Optional) On the **Transform** tab, you can customize the name of the new column. By default it will be named "uuid".

Add an identifier column

Assign a numeric *Identifier* for each row in the dataset.

To add an *Identifier* transform node in your job diagram

1. Open the Resource panel and then choose **Identifier** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. (Optional) On the **Transform** tab, you can customize the name of the new column. By default, it will be named "id".
4. (Optional) If the job processes and stores data incrementally, you want to avoid the same ids to be reused between job runs.

On the **Transform** tab, mark the **unique** checkbox option. It will include the job timestamp in the identifier, making it unique between multiple runs. To allow for the larger number, the column instead of type long will be a decimal.

Convert a column to timestamp type

You can use the transform *To timestamp* to change the data type of a numeric or string column into timestamp, so that it can be stored with that data type or applied to other transforms that require a timestamp.

To add a *To timestamp* transform node in your job diagram

1. Open the Resource panel and then choose **To timestamp** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, enter the name of the column to be converted.
4. On the **Transform** tab, define how to parse the column selected by choosing the type.

If the value is a number, it can be expressed in seconds (Unix/Python timestamp), milliseconds or microseconds, choose the corresponding option.

If the value is a formatted string, choose the "iso" type, the string needs to conform to one of the variants of the ISO format, for example: "2022-11-02T14:40:59.915Z".

If you don't know the type at this point or different rows use different types, then you can choose "autodetect" and the system will make its best guess, with a small performance cost.

5. (Optional) On the **Transform** tab, instead of converting the selected column, you can create a new one and keep the original by entering a name for the new column.

Convert a timestamp column to a formatted string

Format a timestamp column into a string based on a pattern. You can use *Format timestamp* to get date and time as a string with the desired format. You can define the format using [Spark date syntax](#) as well as most of the [Python date codes](#).

For example, if you want your date string to be formatted like "2023-01-01 00:00", you can define such format using the Spark syntax as "yyyy-MM-dd HH:mm" or the equivalent Python date codes as "%Y-%m-%d %H:%M"

To add a *Format timestamp* transform node in your job diagram

1. Open the Resource panel and then choose **Format timestamp** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, enter the name of the column to be converted.
4. On the **Transform** tab, enter the **Timestamp format** pattern to use, expressed using [Spark date syntax](#) or [Python date codes](#).
5. (Optional) On the **Transform** tab, instead of converting the selected column, you can create a new one and keep the original by entering a name for the new column.

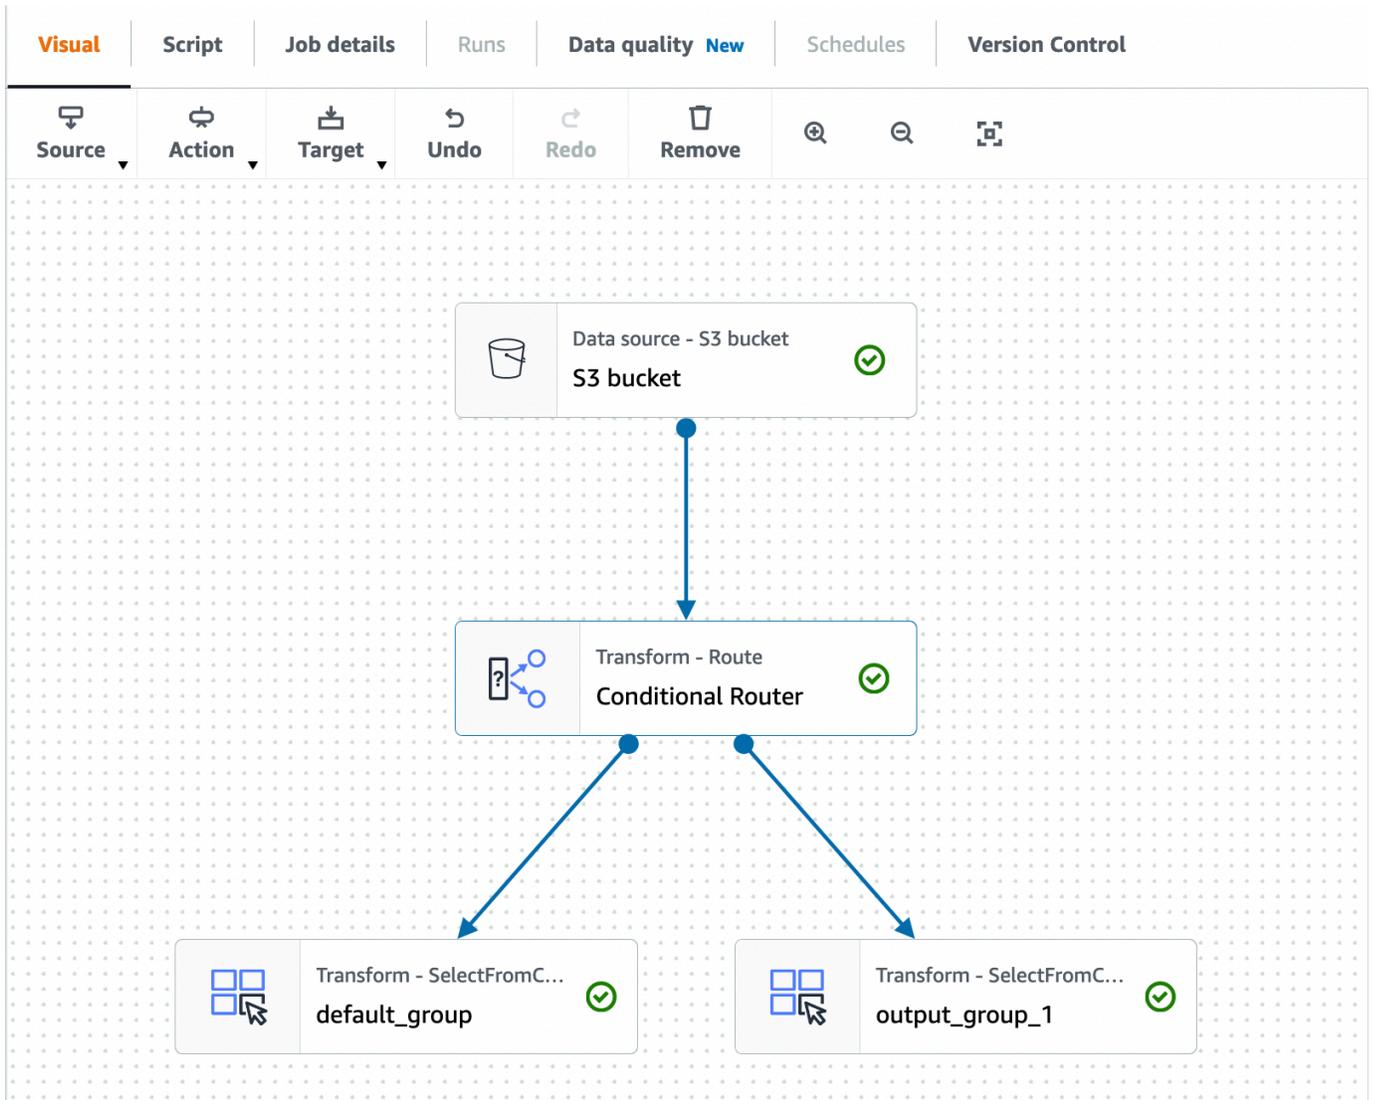

Creating a Conditional Router transformation

The Conditional Router transform allows you to apply multiple conditions to incoming data. Each row of the incoming data is evaluated by a group filter condition and processed into its corresponding group. If a row meets more than one group filter condition, the transform passes the row to multiple groups. If a row does not meet any condition, it can either be dropped or routed to a default output group.

This transform is similar to the filter transform, but useful for users who want to test the same input data on multiple conditions.

To add a Conditional Router transform:

1. Choose a node where you will perform the conditional router transformation. This can be a source node or another transform.
2. Choose **Action**, then use the search bar to find and choose 'Conditional Router'. A **Conditional Router** transform is added along with two output nodes. One output node, 'Default group', contains records which do not meet any of the conditions defined in the other output node(s). The default group cannot be edited.

You can add additional output groups by choosing **Add group**. For each output group, you can name the group and add filter conditions and a logical operator.

Node properties | **Transform** | Output schema | Data preview 

Add group

output_group_1

Remove group

Define a set of conditions a record has to meet in order to be routed to the output group.

Group name
The name of this output group, as it would appear in your job. Letters, numbers, _ and - are allowed.

Logical operator

AND
Trigger only when ALL conditions are met.

OR
Trigger when at least one of the conditions is met.

Filter condition [Info](#)
Specify your filter condition by choosing the key, operator, and entering a value.

Start by adding a filter condition.

Add condition

Default group

Records which do not meet any of the conditions defined above will be routed here.

3. Rename the output group name by entering a new name for the group. Amazon Glue Studio will automatically name your groups for you (for example, 'output_group_1').
4. Choose a logical operator (**AND**, **OR**) and add a **Filter condition** by specifying the **Key**, **Operation**, and **Value**. Logical operators allow you to implement more than one filter condition and perform the logical operator on each filter condition you specify.

When specifying the key, you can choose from available keys in your schema. You can then choose the available operation depending on the type of key you selected. For example, if the key type is 'string', then the available operation to choose from is 'matches'.

Filter condition **Info**

Specify your filter condition by choosing the key, operator, and entering a value.

Key	Operation	Value	
year ▼	= ▼	2023	
Add condition			

5. Enter the value in the **Value** field. To add additional filter conditions, choose **Add condition**. To remove filter conditions, choose the trash can icon.

Using the Concatenate Columns transform to append columns

The Concatenate transform allows you to build a new string column using the values of other columns with an optional spacer. For example, if we define a concatenated column “date” as the concatenation of “year”, “month” and “day” (in that order) with “-” as the spacer, we would get:

day	month	year	date
01	01	2020	2020-01-01
02	01	2020	2020-01-02
03	01	2020	2020-01-03
04	01	2020	2020-01-04

To add a Concatenate transform:

1. Open the Resource panel. Then choose **Concatenate Columns** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.

3. On the **Transform** tab, enter the name of the column that will hold the concatenated string as well as the columns to concatenate. The order in which you check the columns in the dropdown will be the order used.

Node properties
Transform
Output schema
Data preview
✕

Name of the concatenated column
Name of the string column that will be generated

List of column named separated by comma or spaces
The fields listed will be concatenated on that order

Array new column Name - *optional*
String to place between the concatenated fields, by default there is no spacer.

Null value - *optional*
The string to use when a column value is null, for example: 'NULL' or 'NA', by default an empty string will be used

4. **Spacer - optional** – Enter a string to place between the concatenated fields. By default, there is no spacer.
5. **Null value - optional** – Enter a string to use when a column value is null. By default, in the cases where columns have the value 'NULL' or 'NA', an empty string is used.

Using the Split String transform to break up a string column

The Split String transform allows you to break up a string into an array of tokens using a regular expression to define how the split is done. You can then keep the column as an array type or apply an **Array To Columns** transform after this one, to extract the array values onto top level fields, assuming that each token has a meaning we know beforehand. Also, if the order of the tokens is irrelevant (for instance, a set of categories), you can use the **Explode** transform to generate a separate row for each value.

For example, you can split a the column “categories” using a comma as a pattern to add a column “categories_arr”.

product_id	categories	categories_arr
1	sports,winter	[sports, winter]
2	garden,tools	[garden, tools]
3	videogames	[videogames]
4	game,boardgame,social	[game, boardgame, social]

To add a Split String transform:

1. Open the Resource panel and then choose Split String to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the Node properties tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, choose the column to split and enter the pattern to use to split the string. In most cases you can just enter the character(s) unless it has a special meaning as a regular expression and needs to be escaped. The characters that need escaping are: \ . [] { } () < > * + - = ! ? ^ \$ | by adding a backslash in front of the character. For instance if you want to separate by a dot ('.') you need to enter \. However, a comma doesn't have a special meaning and can just be specified as is: , .

Node properties
Transform
Output schema
Data preview
⌵

Column to split
Column whose string will be split into an string array

Splitting regular expression
Regex defining the separator token, examples: ',', '\|' (pipe needs to be escaped) or '\s+' (whitespace split)

Array column Name - *optional*
Name to use for the column with the extracted array resulting of the split. If not specified, instead of a new column the existing one is replaced

4. (Optional) If you want to keep the original string column, then you can enter a name for a new array column, this way keeping both the original string column and the new tokenized array column.

Using the Array To Columns transform to extract the elements of an array into top level columns

The Array To Columns transform allows you extract some or all the elements of a column of type array into new columns. The transform will fill the new columns as much as possible if the array has enough values to extract, optionally taking the elements in the positions specified.

For instance, if you have an array column “subnet”, which was the result of applying the “Split String” transform on a ip v4 subnet, you can extract the first and forth positions into new columns “first_octect” and “forth_octect”. The output of the transform in this example would be (notice the last two rows have shorter arrays than expected):

subnet	first_octect	fourth_octect
[54, 240, 197, 238]	54	238
[192, 168, 0, 1]	192	1

subnet	first_octect	fourth_octect
[192, 168]	192	
[]		

To add a Array To Columns transform:

1. Open the Resource panel and then choose **Array To Columns** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, choose the array column to extract and enter the list of new columns for the tokens extracted.

Node properties
Transform
Output schema
Data preview

Array type column
Column of type array from which the new columns are extracted

Output columns
The names (separated by commas) of the columns to create out of the array fields. The data type will be the same as the array. For each row, the transform will try to fill them as much as possible using the array elements, the rest will be NULL

Array indexes to use - optional
List of array positions (starting from 1 and separated by commas), indicating which columns to take to fill the columns. Only need to set this if you want to skip some positions of the array

4. (Optional) If you don't want to take the array tokens in order to assign to columns, you can specify the indexes to take which will be assigned to the list of columns in the same order specified. For instance if the output columns are "column1, column2, column3" and the

indexes "4, 1, 3", the fourth element of the array will go to column1, the first to column2 and the third to column3 (if the array is shorter than the index number, a NULL value will be set).

Using the Add Current Timestamp transform

The **Add Current Timestamp** transform allows you to mark the rows with the time on which the data was processed. This is useful for auditing purposes or to track latency in the data pipeline. You can add this new column as a timestamp data type or a formatted string.

To add a Add Current Timestamp transform:

1. Open the Resource panel and then choose **Add Current Timestamp** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.

The screenshot shows the configuration interface for the 'Add Current Timestamp' transform. It features four tabs: 'Node properties', 'Transform' (selected), 'Output schema', and 'Data preview'. Below the tabs, there are two optional configuration fields:

- Timestamp column - optional:** A text input field with a placeholder: "Name to use for the new column, by default: timestamp. With type "string" if a dataFormat is specified, otherwise "timestamp".
- Timestamp format - optional:** A text input field with a placeholder: "Optional pattern to format as a string, accepts most Python date format codes, such as '%Y-%m-%d %H:%M:%S'; as well as Spark patterns such as 'yyyy-MM-dd'T'HH:mm:ss.SSSZ'".

3. (Optional) On the **Transform** tab, enter a custom name for the new column and a format if you rather the column to be a formatted date string.

Using the Pivot Rows to Columns transform

The **Pivot Rows to Columns** transform allows you to aggregate a numeric column by rotating unique values on selected columns which become new columns (if multiple columns are selected, the values are concatenated to name the new columns). That way rows are consolidated while

having more columns with partial aggregations for each unique value. For example, if you have this dataset of sales by month and country (sorted to be easier to illustrate):

year	month	country	amount
2020	Jan	uk	32
2020	Jan	de	42
2020	Jan	us	64
2020	Feb	uk	67
2020	Feb	de	4
2020	Feb	de	7
2020	Feb	us	6
2020	Feb	us	12
2020	Jan	us	90

If you pivot **amount** and **country** as the aggregation columns, new columns are created from the original **country** column. In the table below, you have new columns for **de**, **uk**, and **us** instead of the **country** column.

year	month	de	uk	us
2020	Jan	42	32	64
2020	Jan	11	67	18
2021	Jan			90

If instead you want to pivot both the month and county, you get a column for each combination of the values of those columns:

year	Jan_de	Jan_uk	Jan_us	Feb_de	Feb_uk	Feb_us
2020	42	32	64	11	67	18
2021			90			

To add a Pivot Rows To Columns transform:

1. Open the Resource panel and then choose **Pivot Rows To Columns** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, choose the numeric column which will be aggregated to produce the values for the new columns, the aggregation function to apply and the column(s) to convert its unique values into new columns.

Node properties
Transform
Output schema
Data preview
⌵

Aggregation column
Numeric column on which the aggregation function is applied

Aggregation
The Spark function to apply to the aggregation column.

Columns to convert
List of columns whose values will become new columns. If multiple columns are specified, the values are concatenated using underscore.

Choose options
⌵

Using the Unpivot Columns To Rows transform

The **Unpivot** transform allows you convert columns into values of new columns generating a row for each unique value. It's the opposite of pivot but note that it's not equivalent since it cannot separate rows with identical values that were aggregated or split combinations into the original columns (you can do that later using a Split transform). For example, if you have the following table:

year	month	de	uk	us
2020	Jan	42	32	64
2020	Feb	11	67	18
2021	Jan			90

You can unpivot the columns: "de", "uk" and "us" into a column "country" with the value "amount", and get the following (sorted here for illustration purposes):

year	month	country	amount
2020	Jan	uk	32
2020	Jan	de	42
2020	Jan	us	64
2020	Feb	uk	67
2020	Feb	de	11
2020	Feb	us	18
2021	Jan	us	90

Notice the columns that have a NULL value ("de" and "uk" of Jan 2021) don't get generated by default. You can enable that option to get:

year	month	country	amount
2020	Jan	uk	32
2020	Jan	de	42
2020	Jan	us	64
2020	Feb	uk	67
2020	Feb	de	11
2020	Feb	us	18
2021	Jan	us	90
2021	Jan	de	
2021	Jan	uk	

To add a Unpivot Columns to Rows transform:

1. Open the Resource panel and then choose **Unpivot Columns to Rows** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, enter the new columns to be created to hold the names and values of the columns chosen to unpivot.

Node properties	Transform	Output schema	Data preview	✕
------------------------	------------------	---------------	--------------	---

Unpivot names column
Column to create out of the source columns names

Unpivot values column
Column to create out of values of the old columns

Columns to unpivot into the new value column
List of columns whose name will become values of the new column

Using the Autobalance Processing transform to optimize your runtime

The **Autobalance Processing** transform redistributes the data among the workers for better performance. This helps in cases where the data is unbalanced or as it comes from the source doesn't allow enough parallel processing on it. This is common where the source is gzipped or is JDBC. The redistribution of data has a modest performance cost, so the optimization might not always compensate that effort if the data was already well balanced. Underneath, the transform uses Apache Spark repartition to randomly reassign data among a number of partitions optimal for the cluster capacity. For advanced users, it's possible to enter a number of partitions manually. In addition, it can be used to optimize the writing of partitioned tables by reorganizing the data based on specified columns. This results in output files that are more consolidated.

1. Open the Resource panel and then choose **Autobalance Processing** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. (Optional) On the **Transform** tab, you can enter a number of partitions. In general, it's recommended that you let the system decide this value, however you can tune the multiplier or enter a specific value if you need to control this. If you are going to save the data

partitioned by columns, you can choose the same columns as repartition columns. This way it will minimize the number of files on each partition and avoid having many files per partitions, which would hinder the performance of the tools querying that data.

Node properties
Transform
Output schema
Data preview
✕

Number of partitions - optional
 Number of partitions on which to randomly distribute the data. If the number ends with the x letter then it means it's a multiple of the number of cores in the cluster. By default: 2x

Repartition columns - optional
 Instead of randomly reassign the data to partitions, assign data with the same values of the columns specified to the same partition.

Choose options
▼

Using the Derived Column transform to combine other columns

The **Derived Column** transform allows you to define a new column based on a math formula or SQL expression in which you can use other columns in the data, as well as constants and literals. For instance, to derive a "percentage" column from the columns "success" and "count", you can enter the SQL expression: "success * 100 / count || '%'".

Example result:

success	count	percentage
14	100	14%
6	20	3%
3	40	7.5%

To add a Derived Column transform:

1. Open the Resource panel and then choose **Derived Column** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.

2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, enter the name of the column and the expression for its content.

Node properties	Transform	Output schema	Data preview	
-----------------	------------------	---------------	--------------	---

Name of the derived column
Name to use for the new column or replace an existing one

SQL Expression
A SQL expression that defines the column, which can be derived from other existing columns and use operators to modify or combine them. For instance, to derive a percentage from the columns "success" and "count", you can enter: "success * 100 / count"

Using the Lookup transform to add matching data from a catalog table

The **Lookup** transform allows you to add columns from a defined catalog table when the keys match the defined lookup columns in the data. This is equivalent to doing a left outer join between the data and the lookup table using as condition matching columns.

To add a Lookup transform:

1. Open the Resource panel and then choose **Lookup** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, enter the fully qualified catalog table name to use to perform the lookups. For example, if your database is "mydb" and your table "mytable" then enter "mydb.mytable". Then enter the criteria to find a match in the lookup table, if the lookup key is composed. Enter the list of key columns separated by commas. If one or more of the key columns don't have the same name then you need to define the match mapping.

For example, if the data columns are “user_id” and “region” and in the users table the corresponding columns are named “id” and “region”, then in the **Columns to match** field, enter: “user_id=id, region”. You could do region=region but it’s not needed since they are the same.

4. Finally, enter the columns to bring from the row matched in the lookup table to incorporate them into the data. If no match was found those columns will be set to NULL.

Note

Underneath the **Lookup** transform, it is using a left join in order to be efficient. If the lookup table has a composite key, ensure the columns to match are setup to match all the key columns so that only one match can occur. Otherwise, multiple lookup rows will match and this will result in extra rows added for each of those matches.

Node properties	Transform	Output schema	Data preview	
<p>AWS Glue Data Catalog table Qualified name of the catalog table to use for the lookup, specifying the database and table name separated by a dot</p> <input type="text"/>				
<p>Lookup key columns to match Columns in the lookup table to match separated by commas; if the column names don't match, you can specify the mapping between the data and the lookup table separating the names with an equals sign =</p> <input type="text"/>				
<p>Lookup columns to take Columns in the lookup table to add to the data when a match is found in the lookup table</p> <input type="text"/>				

Using the Explode Array or Map Into Rows transform

The **Explode** transform allows you to extract values from a nested structure into individual rows that are easier to manipulate. In the case of an array, the transform will generate a row for each value of the array, replicating the values for the other columns in the row. In the case of a map,

the transform will generate a row for each entry with the key and value as columns plus any other columns in the row.

For example, if we have this dataset which has a “category” array column with multiple values.

product_id	category
1	[sports, winter]
2	[garden, tools]
3	[videogames]
4	[game, boardgame, social]
5	[]

If you explode the 'category' column into a column with the same name, you will override the column. You can select that you want NULLs included to get the following (ordered for illustration purposes):

product_id	category
1	sports
1	winter
2	garden
2	tool
3	videogames
4	game
4	boardgame
4	social
5	

To add a Explode Array Or Map Into Rows transform:

1. Open the Resource panel and then choose **Explode Array Or Map Into Rows** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, choose the column to explode (it must be an array or map type). Then enter a name for the column for the items of the array or the names of the columns for the keys and values if you are exploding a map.
4. (Optional) On the **Transform** tab, by default if the column to explode is NULL or has an empty structure, it will be omitted on the exploded dataset. If you want to keep the row (with the new columns as NULL) then check "Include NULLs".

Node properties	Transform	Output schema	Data preview	
-----------------	------------------	---------------	--------------	---

Column to explode
A column of type array or map

New column name
The name of the column to put the array values or the dictionary keys

Values column - optional
If exploding a dictionary, you can specify a name for a column to contain the values. Default name: "value"

Include NULLs - optional
If selected, NULL values will also generate a new rows, otherwise the row with a NULL value is omitted

Using the Record Matching transform to invoke an existing data classification transform

This transform invokes an existing Record Matching machine learning data classification transform.

The transform evaluates the current data against the trained model based on labels. A column "match_id" is added to assign each row to a group of items that are considered equivalent based on the algorithm training. For more information, see [Record matching with Lake Formation FindMatches](#).

Note

The version of Amazon Glue used by the visual job must match the version that Amazon Glue used to create the Record Matching transform.

Transform		Output schema		Data preview

To add a Record Matching transform node to your job diagram

1. Open the Resource panel, and then choose **Record Matching** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.

- In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
- On the **Transform** tab, enter the ID taken from the **Machine learning transforms** page:

AWS Glue > ML transforms

Machine learning transforms (1) [Info](#)
Clean all your data using machine learning transforms.

Q Filter transforms

	Transform name ▲	ID	Status ▼	Label count ▼
<input type="radio"/>	Test	tfm-3d291b652cec092a79aeda5062f2c96e7c528474	✔ Ready for use	352

- (Optional) On the **Transform** tab, you can check the option to add the confidence scores. At the cost of extra computing, the model will estimate a confidence score for each match as an additional column.

Removing null rows

This transform removes from the dataset rows that have all columns as null. In addition, you can extend this criteria to include empty fields, so as to keep rows where at least one column is non empty.

To add a Remove Null Rows transform node to your job diagram

- Open the Resource panel, and then choose **Remove Null Rows** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
- In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
- (Optional) On the **Transform** tab, check the **Extended** option if you want to require rows not just to not be null but also not empty, this way empty strings, arrays or maps will be considered nulls for the purpose of this transform.

Parsing a string column containing JSON data

This transform parses a string column containing JSON data and convert it to a struct or an array column, depending if the JSON is an object or an array, respectively. Optionally you can keep both the parsed and original column.

The JSON schema can be provided or inferred (in the case of JSON objects), with optional sampling.

To add a Parse JSON Column transform node to your job diagram

1. Open the Resource panel, and then choose **Parse JSON Column** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, select the column containing the JSON string.
4. (Optional) On the **Transform** tab, enter the schema that the JSON data follows using SQL syntax, for instance: "field1 STRING, field2 INT" in the case of an object or "ARRAY<STRING>" in the case of an array.

If the case of an array the schema is required but in the case of an object, if the schema is not specified it will be inferred using the data. To reduce the impact of inferring the schema (especially on a large dataset), you can avoid reading the whole data twice by entering a **Ratio of samples to use to infer schema**. If the value is lower than 1, the corresponding ratio of random samples is used to infer the schema. If the data is reliable and the object is consistent between rows, you can use a small ratio such as 0.1 to improve performance.

5. (Optional) On the **Transform** tab, you can enter a new column name if you want to keep both the original string column and the parsed column.

Extracting a JSON path

This transform extracts new columns from a JSON string column. This transform is useful when you only need a few data elements and don't want to import the entire JSON content into the table schema.

To add an Extract JSON Path transform node to your job diagram

1. Open the Resource panel, and then choose **Extract JSON Path** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, select the column containing the JSON string. Enter one or more JSON path expressions separated by commas, each one referencing how to extract a value out of the JSON array or object. For instance, if the JSON column contained an objects with properties "prop_1" and "prop2" you could extract both specifying their names "prop_1, prop_2".

If the JSON field has special characters, for instance to extract the property from this JSON `{ "a . a": 1 }` you could use the path `$[' a . a ']`. The exception is the comma because it is reserved to separate paths. Then enter the corresponding column names for each path, separated by commas.

4. (Optional) On the **Transform** tab, you can check to drop the JSON column once extracted, this makes sense when you don't need the rest of the JSON data once you have extracted the parts you need.

Extracting string fragments using a regular expression

This transform extracts string fragments using a regular expression and creates a new column out of it, or multiple columns if using regex groups.

To add a Regex Extractor transform node to your job diagram

1. Open the Resource panel, and then choose **Regex Extractor** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, enter the regular expression and the column on which it needs to be applied. Then enter the name of the new column on which to store the matching string. The new column will be null only if the source column is null, if the regex doesn't match the column will be empty.

If the regex uses groups, there has to be a corresponding column name separated by comma but you can skip groups by leaving the column name empty.

For example, if you have a column "purchase_date" with a string using both long and short ISO date formats, then you want to extract the year, month, day and hour, when available. Notice the hour group is optional, otherwise in the rows where not available, all the extracted groups would be empty strings (because the regex didn't match). In this case, we don't want the group to make the time optional but the inner one, so we leave the name empty and it doesn't get extracted (that group would include the T character).

Creating a custom transformation

If you need to perform more complicated transformations on your data, or want to add data property keys to the dataset, you can add a **Custom code** transform to your job diagram. The Custom code node allows you to enter a script that performs the transformation.

When using custom code, you must use a schema editor to indicate the changes made to the output through the custom code. When editing the schema, you can perform the following actions:

- Add or remove data property keys
- Change the data type of data property keys
- Change the name of data property keys
- Restructure a nested property key

You must use a *SelectFromCollection* transform to choose a single `DynamicFrame` from the result of your Custom transform node before you can send the output to a target location.

Use the following tasks to add a custom transform node to your job diagram.

Adding a custom code transform node to the job diagram

To add a custom transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **Custom transform** to add a custom transform to your job diagram.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, or if you want multiple inputs for the custom transform, then choose a node from the **Node parents** list to use as the input source for the transform.

Entering code for the custom transform node

You can type or copy code into an input field. The job uses this code to perform the data transformation. You can provide a code snippet in either Python or Scala. The code should take one or more `DynamicFrames` as input and returns a collection of `DynamicFrames`.

To enter the script for a custom transform node

1. With the custom transform node selected in the job diagram, choose the **Transform** tab.
2. In the text entry field under the heading **Code block**, paste or enter the code for the transformation. The code that you use must match the language specified for the job on the **Job details** tab.

When referring to the input nodes in your code, Amazon Glue Studio names the `DynamicFrames` returned by the job diagram nodes sequentially based on the order of creation. Use one of the following naming methods in your code:

- Classic code generation – Use functional names to refer to the nodes in your job diagram.
 - Data source nodes: `DataSource0`, `DataSource1`, `DataSource2`, and so on.
 - Transform nodes: `Transform0`, `Transform1`, `Transform2`, and so on.
- New code generation – Use the name specified on the **Node properties** tab of a node, appended with `'_node1'`, `'_node2'`, and so on. For example, `S3bucket_node1`, `ApplyMapping_node2`, `S3bucket_node2`, `MyCustomNodeName_node1`.

For more information about the new code generator, see [Script code generation](#).

The following examples show the format of the code to enter in the code box:

Python

The following example takes the first `DynamicFrame` received, converts it to a `DataFrame` to apply the native filter method (keeping only records that have over 1000 votes), then converts it back to a `DynamicFrame` before returning it.

```
def FilterHighVoteCounts (glueContext, dfc) -> DynamicFrameCollection:
    df = dfc.select(list(dfc.keys())[0]).toDF()
    df_filtered = df.filter(df["vote_count"] > 1000)
    dyf_filtered = DynamicFrame.fromDF(df_filtered, glueContext, "filter_votes")
    return(DynamicFrameCollection({"CustomTransform0": dyf_filtered}, glueContext))
```

Scala

The following example takes the first `DynamicFrame` received, converts it to a `DataFrame` to apply the native filter method (keeping only records that have over 1000 votes), then converts it back to a `DynamicFrame` before returning it.

```
object FilterHighVoteCounts {
    def execute(glueContext : GlueContext, input : Seq[DynamicFrame]) :
    Seq[DynamicFrame] = {
        val frame = input(0).toDF()
        val filtered = DynamicFrame(frame.filter(frame("vote_count") > 1000),
        glueContext)
        Seq(filtered)
    }
}
```

Editing the schema in a custom transform node

When you use a custom transform node, Amazon Glue Studio cannot automatically infer the output schemas created by the transform. You use the schema editor to describe the schema changes implemented by the custom transform code.

A custom code node can have any number of parent nodes, each providing a `DynamicFrame` as input for your custom code. A custom code node returns a collection of `DynamicFrames`. Each `DynamicFrame` that is used as input has an associated schema. You must add a schema that describes each `DynamicFrame` returned by the custom code node.

Note

When you set your own schema on a custom transform, Amazon Glue Studio does not inherit schemas from previous nodes. To update the schema, select the Custom transform node, then choose the Data preview tab. Once the preview is generated, choose 'Use Preview Schema'. The schema will then be replaced by the schema using the preview data.

To edit the output schemas for a custom transform node

1. With the custom transform node selected in the job diagram, in the node details panel, choose the **Output schema** tab.
2. Choose **Edit** to make changes to the schema.

If you have nested data property keys, such as an array or object, you can choose the **Expand-Rows** icon

()

on the top right of each schema panel to expand the list of child data property keys. After you choose this icon, it changes to the **Collapse-Rows** icon

()

which you can choose to collapse the list of child property keys.

3. Modify the schema using the following actions in the section on the right side of the page:
 - To rename a property key, place the cursor in the **Key** text box for the property key, then enter the new name.
 - To change the data type for a property key, use the list to choose the new data type for the property key.
 - To add a new top-level property key to the schema, choose the **Overflow** () icon to the left of the **Cancel** button, and then choose **Add root key**.
 - To add a child property key to the schema, choose the **Add-Key** icon () with the parent key. Enter a name for the child key and choose the data type.
 - To remove a property key from the schema, choose the **Remove** icon () to the far right of the key name.

4. If your custom transform code uses multiple `DynamicFrames`, you can add additional output schemas.

- To add a new, empty schema, choose the **Overflow**

(...)

icon, and then choose **Add output schema**.

- To copy an existing schema to a new output schema, make sure the schema you want to copy is displayed in the schema selector. Choose the **Overflow**

(...)

icon, and then choose **Duplicate**.

If you want to remove an output schema, make sure the schema you want to copy is displayed in the schema selector. Choose the **Overflow**

(...)

icon, and then choose **Delete**.

5. Add new root keys to the new schema or edit the duplicated keys.

6. When you are modifying the output schemas, choose the **Apply** button to save your changes and exit the schema editor.

If you do not want to save your changes, choose the **Cancel** button.

Configure the custom transform output

A custom code transform returns a collection of `DynamicFrames`, even if there is only one `DynamicFrame` in the result set.

To process the output from a custom transform node

1. Add a *SelectFromCollection* transform node, which has the custom transform node as its parent node. Update this transform to indicate which dataset you want to use. See [Using SelectFromCollection to choose which dataset to keep](#) for more information.
2. Add additional *SelectFromCollection* transforms to the job diagram if you want to use additional `DynamicFrames` produced by the custom transform node.

Consider a scenario in which you add a custom transform node to split a flight dataset into multiple datasets, but duplicate some of the identifying property keys in each output schema,

such as the flight date or flight number. You add a *SelectFromCollection* transform node for each output schema, with the custom transform node as its parent.

3. (Optional) You can then use each *SelectFromCollection* transform node as input for other nodes in the job, or as a parent for a data target node.

Transform data with custom visual transforms

Custom visual transforms allow you to create transforms and make them available for use in Amazon Glue Studio jobs. Custom visual transforms enable ETL developers, who may not be familiar with coding, to search and use a growing library of transforms using the Amazon Glue Studio interface.

You can create a custom visual transform, then upload it to Amazon S3 to make available for use through the visual editor in Amazon Glue Studio to work with these jobs.

- [Step 4. Update custom visual transforms as needed](#)
- [Step 5. Use custom visual transforms in Amazon Glue Studio](#)
- [Usage examples](#)
- [Examples of custom visual scripts](#)
- [Video](#)

Getting started with custom visual transforms

To create a custom visual transform, you go through the following steps.

- Step 1. Create a JSON config file
- Step 2. Implement the transform logic
- Step 3. Validate the custom visual transform
- Step 4. Update the custom visual transform as needed
- Step 5. Use the custom visual transform in Amazon Glue Studio

Get started by setting up the Amazon S3 bucket and continue to **Step 1. Create a JSON config file.**

Prerequisites

Customer-supplied transforms reside within a customer Amazon account. That account owns the transforms and therefore has all permissions to view (search and use), edit, or delete them.

In order to use a custom transform in Amazon Glue Studio, you will need to create and upload two files to the Amazon S3 assets bucket in that Amazon account:

- **Python file** – contains the transform function
- **JSON file** – describes the transform. This is also known as the config file that is required to define the transform.

In order to pair the files together, use the same name for both. For example:

- myTransform.json
- myTransform.py

Optionally, you can give your custom visual transform a custom icon by providing a **SVG file** containing the icon. In order to pair the files together, use the same name for the icon:

- myTransform.svg

Amazon Glue Studio will automatically match them using their respective file names. File names cannot be the same for any existing module.

Recommended convention for transform file name

Amazon Glue Studio will import your file as module (for example, `import myTransform`) in your job script. Therefore, your file name must follow the same naming rules set for python variable names (identifiers). Specifically, they must start with either a letter or an underscore and then be composed entirely of letters, digits, and/or underscores.

Note

Ensure your transform file name is not conflicting with existing loaded python modules (for example, `sys`, `array`, `copy` etc.) to avoid unexpected runtime issues.

Setting up the Amazon S3 bucket

Transforms you create are stored in Amazon S3 and is owned by your Amazon account. You create new custom visual transforms by simply uploading files (json and py) to the Amazon S3 assets folder where all job scripts are currently stored (for example, `s3://aws-glue-assets-
<accountid>-<region>/transforms`). If using a custom icon, upload it as well. By default, Amazon Glue Studio will read all .json files from the /transforms folder in the same S3 bucket.

Step 1. Create a JSON config file

A JSON config file is required to define and describe your custom visual transform. The schema for the config file is as follows.

JSON file structure

Fields

- `name`: `string` – (required) the transform system name used to identify transforms. Follow the same naming rules set for python variable names (identifiers). Specifically, they must start with either a letter or an underscore and then be composed entirely of letters, digits, and/or underscores.
- `displayName`: `string` – (optional) the name of the transform displayed in the Amazon Glue Studio visual job editor. If no `displayName` is specified, the name is used as the name of the transform in Amazon Glue Studio.
- `description`: `string` – (optional) the transform description is displayed in Amazon Glue Studio and is searchable.
- `functionName`: `string` – (required) the Python function name is used to identify the function to call in the Python script.
- `path`: `string` – (optional) the full Amazon S3 path to the Python source file. If not specified, Amazon Glue uses file name matching to pair the .json and .py files together. For example, the name of the JSON file, `myTransform.json`, will be paired to the Python file, `myTransform.py`, on the same Amazon S3 location.
- `parameters`: Array of `TransformParameter` object – (optional) the list of parameters to be displayed when you configure them in the Amazon Glue Studio visual editor.

TransformParameter fields

- **name:** `string` – (required) the parameter name that will be passed to the python function as a named argument in the job script. Follow the same naming rules set for python variable names (identifiers). Specifically, they must start with either a letter or an underscore and then be composed entirely of letters, digits, and/or underscores.
- **displayName:** `string` – (optional) the name of the transform displayed in the Amazon Glue Studio visual job editor. If no `displayName` is specified, the name is used as the name of the transform in Amazon Glue Studio.
- **type:** `string` – (required) the parameter type accepting common Python data types. Valid values: `'str' | 'int' | 'float' | 'list' | 'bool'`.
- **isOptional:** `boolean` – (optional) determines whether the parameter is optional. By default all parameters are required.
- **description:** `string` — (optional) description is displayed in Amazon Glue Studio to help the user configure the transform parameter.
- **validationType:** `string` – (optional) defines the way this parameter is validated. Currently, it only supports regular expressions. By default, the validation type is set to `RegularExpression`.
- **validationRule:** `string` – (optional) regular expression used to validate form input before submit when `validationType` is set to `RegularExpression`. Regular expression syntax must be compatible with [RegExp EcmaScript specifications](#).
- **validationMessage:** `string` – (optional) the message to display when validation fails.
- **listOptions:** An array of `TransformParameterListOption` object OR a `string` or the `string` value `'column'` – (optional) options to display in Select or Multiselect UI control. Accepting a list of comma separated value or a strongly type JSON object of type `TransformParameterListOption`. It can also dynamically populate the list of columns from the parent node schema by specifying the `string` value `"column"`.
- **listType:** `string` – (optional) Define options types for `type = 'list'`. Valid values: `'str' | 'int' | 'float' | 'list' | 'bool'`. Parameter type accepting common python data types.

TransformParameterListOption fields

- **value:** `string | int | float | bool` – (required) option value.
- **label:** `string` – (optional) option label displayed in the select dropdown.

Transform parameters in Amazon Glue Studio

By default, parameters are required unless mark as `isOptional` in the `.json` file. In Amazon Glue Studio, parameters are displayed in the **Transform** tab. The example shows user-defined parameters such as Email Address, Phone Number, Your age, Your gender and Your origin country.

The screenshot displays the Amazon Glue Studio interface. On the left, a workflow is shown with a 'Data source - S3 bucket Amazon S3' node connected to a 'Transform - Dynamic Trans... My Transform' node. On the right, the 'Transform' tab is active, showing a list of parameters for the transform job:

- Email Address**: Enter your work email address below. (Text input field)
- Phone Number**: Enter your mobile phone number below. (Text input field)
- Your age**: (Text input field)
- Your gender**: (Dropdown menu)
- Your origin country? - optional**: What country were you born in? (Dropdown menu with 'Choose options' selected)
- Do you want to receive promotional newsletter from us? - optional**: (Checkbox, currently unchecked)

You can enforce some validations in Amazon Glue Studio using regular expressions in the `.json` file by specifying the `validationRule` parameter and specifying a validation message in `validationMessage`.

```
"validationRule": "^\\((?\\d{3})\\)?[- ]?(\\d{3})[- ]?(\\d{4})$",
"validationMessage": "Please enter a valid US number"
```

Note

Since validation occurs in the browser, your regular expression syntax must be compatible with [RegExp EcmaScript specifications](#). Python syntax is not supported for these regular expressions.

Adding validation will prevent the user from saving the job with incorrect user input. Amazon Glue Studio displays the validation message as displayed in the example:

Node properties | **Transform** 1 | Output schema | Data preview

Email Address

Displaying a column selector as parameter

If the configuration requires the user to choose a column from the schema, you can display a column selector so the user isn't required to type the column name. By setting the `listOptions` field to "column", Amazon Glue Studio dynamically displays a column selector based on the parent node output schema. Amazon Glue Studio can display either a single or multiple column selector.

The following example uses the schema:

Node properties	Data source properties - S3	Output schema	Data preview
Schema			Edit
Key	Data type	Partition	
CustomerID	string	-	
Title	string	-	
FirstName	string	-	
LastName	string	-	
EmailAddress	string	-	
Phone	string	-	
CompanyName	string	-	

To define your Custom Visual Transform parameter to display a single column:

1. In your JSON file, for the `parameters` object, set the `listOptions` value to "column". This allows a user to choose a column from a pick list in Amazon Glue Studio.

```
{
  "name": "mb_to_timestamp",
  "displayName": "MB Convert column to timestamp",
  "description": "Convert a timestamp string or a system epoch column into a new timestamp type column.",
  "functionName": "mb_to_timestamp",
  "parameters": [
    {
      "name": "colName",
      "displayName": "Name of the column with the time",
      "type": "str",
      "listOptions": "column",
      "description": "Column with an epoch or string to be converted"
    }
  ]
}
```

2. You can also allow multiple columns selection by defining the parameter as:
 - `listOptions: "column"`
 - `type: "list"`

```

{
  "name": "mb_to_timestamp",
  "displayName": "MB Convert column to timestamp",
  "description": "Convert a timestamp string or a system epoch column into a new timestamp type column.",
  "functionName": "mb_to_timestamp",
  "parameters": [
    {
      "name": "colNames",
      "displayName": "Name of the column with the time",
      "type": "list",
      "listOptions": "column",
      "listType": "str",
      "description": "Column with an epoch or string to be converted"
    }
  ]
}

```

Step 2. Implement the transform logic

Note

Custom visual transforms only support Python scripts. Scala is not supported.

To add the code that implements the function defined by the .json config file, it is recommended to place the Python file in the same location as the .json file, with the same name but with the “.py” extension. Amazon Glue Studio automatically pairs the .json and .py files so that you don’t need to specify the path of the Python file in the config file.

In the Python file, add the declared function, with the named parameters configured and register it to be used in `DynamicFrame`. The following is an example of a Python file:

```

from awsglue import DynamicFrame

# self refers to the DynamicFrame to transform,
# the parameter names must match the ones defined in the config
# if it's optional, need to provide a default value
def myTransform(self, email, phone, age=None, gender="",
                country="", promotion=False):
    resulting_dynf = # do some transformation on self
    return resulting_dynf

DynamicFrame.myTransform = myTransform

```

It is recommended to use an Amazon Glue notebook for the quickest way to develop and test the python code. See [Getting started with notebooks in Amazon Glue Studio](#).

To illustrate how to implement the transform logic, the custom visual transform in the example below is a transform to filter incoming data to keep only the data related to a specific US state. The .json file contains the parameter for functionName as custom_filter_state and two arguments ("state" and "colName" with type "str").

The example config .json file is:

```
{
  "name": "custom_filter_state",
  "displayName": "Filter State",
  "description": "A simple example to filter the data to keep only the state indicated.",
  "functionName": "custom_filter_state",
  "parameters": [
    {
      "name": "colName",
      "displayName": "Column name",
      "type": "str",
      "description": "Name of the column in the data that holds the state postal code"
    },
    {
      "name": "state",
      "displayName": "State postal code",
      "type": "str",
      "description": "The postal code of the state whole rows to keep"
    }
  ]
}
```

To implement the companion script in Python

1. Start a Amazon Glue notebook and run the initial cell provided for the session to be started. Running the initial cell creates the basic components required.
2. Create a function that performs the filtering as describe in the example and register it on DynamicFrame. Copy the code below and paste into a cell in the Amazon Glue notebook.

```

from awsglue import DynamicFrame

def custom_filter_state(self, colName, state):
    return self.filter(lambda row: row[colName] == state)

DynamicFrame.custom_filter_state = custom_filter_state

```

3. Create or load sample data to test the code in the same cell or a new cell. If you add the sample data in a new cell, don't forget to run the cell. For example:

```

# A few of rows of sample data to test
data_sample = [
    {"state": "CA", "count": 4},
    {"state": "NY", "count": 2},
    {"state": "WA", "count": 3}
]
df1 = glueContext.sparkSession.sparkContext.parallelize(data_sample).toDF()
dynf1 = DynamicFrame.fromDF(df1, glueContext, None)

```

4. Test to validate the “custom_filter_state” with different arguments:

```

[14]: dynf1.custom_filter_state("state", "NY").show()
      {"count": 2, "state": "NY"}

```

5. After running several tests, save the code with the .py extension and name the .py file with a name that mirrors the .json file name. The .py and .json files should be in the same transform folder.

Copy the following code and paste it to a file and rename it with a .py file extension.

```

from awsglue import DynamicFrame

def custom_filter_state(self, colName, state):
    return self.filter(lambda row: row[colName] == state)

DynamicFrame.custom_filter_state = custom_filter_state

```

6. In Amazon Glue Studio, open a visual job and add the transform to the job by selecting it from the list of available **Transforms**.

To reuse this transform in a Python script code, add the Amazon S3 path to the .py file in the job under “Referenced files path” and in the script, import the name of the python file (without the extension) by adding it to the top of the file. For example: `import <name of the file (without the extension)>`

Step 3. Validate and troubleshoot custom visual transforms in Amazon Glue Studio

Amazon Glue Studio validates the JSON config file before custom visual transforms are loaded into Amazon Glue Studio. Validation includes:

- Presence of required fields
- JSON format validation
- Incorrect or invalid parameters
- Presence of both the .py and .json files in the same Amazon S3 path
- Matching filenames for the .py and .json

If validation succeeds, the transform is listed in the list of available **Actions** in the visual editor. If a custom icon has been provided, it should be visible beside the **Action**.

If validation fails, Amazon Glue Studio does not load the custom visual transform.

Step 4. Update custom visual transforms as needed

Once created and used, the transform script can be updated as long as the transform follows the corresponding json definition:

- The name used when assigning to DynamicFrame must match the json `functionName`.
- The function arguments must be defined in the json file as described in [Step 1. Create a JSON config file](#).
- The Amazon S3 path of the Python file cannot change, since the jobs depend directly on it.

Note

If any updates need to be made, ensure the script and the .json file are consistently updated and any visual jobs are correctly saved again with the new transform. If visual jobs are not saved after the updates were made, the updates will not be applied and validated. If the Python script file is renamed or not placed next to the .json file, then you need to specify the full path in the .json file.

Custom icon

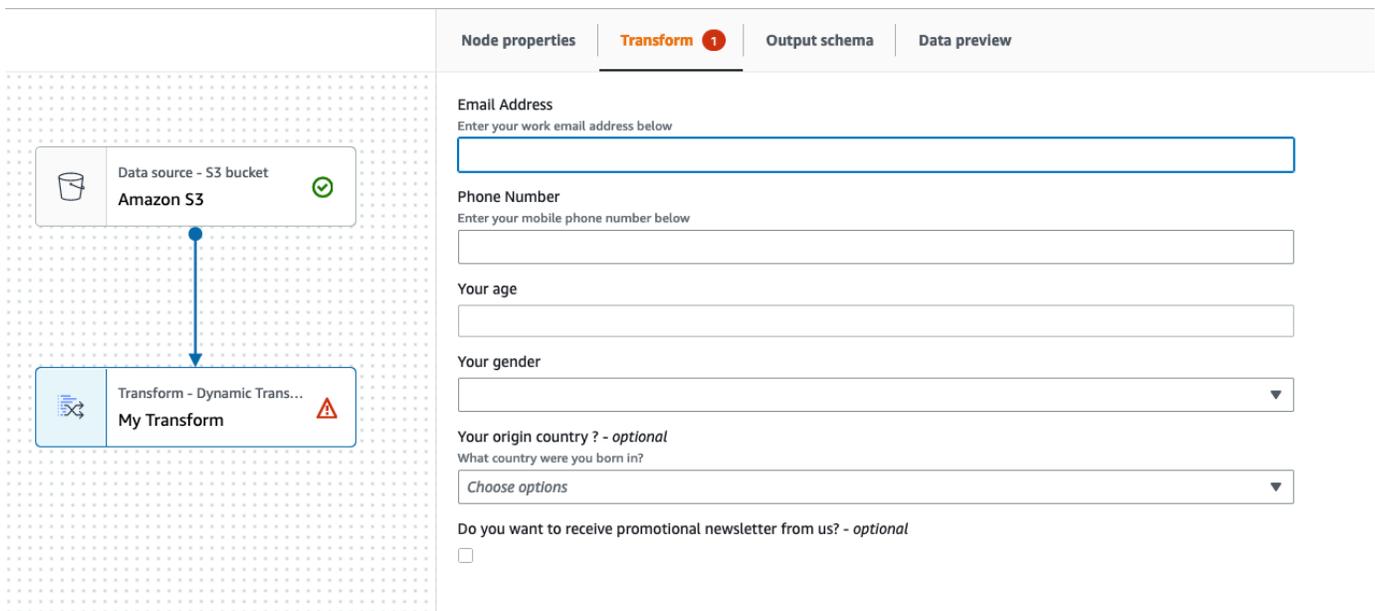

If you determine the default icon for your **Action** does not visually distinguish it as part of your workflows, you can provide a custom icon, as described in [the section called " Getting started with custom visual transforms "](#). You can update the icon by updating the corresponding SVG hosted in Amazon S3.

For best results, design your image to be viewed at 32x32px following guidelines from the Cloudscape Design System. For more information about Cloudscape guidelines, see [The Cloudscape documentation](#)

Step 5. Use custom visual transforms in Amazon Glue Studio

To use a custom visual transform in Amazon Glue Studio, you upload the config and source files, then select the transform from the **Action** menu. Any parameters that need values or input are available to you in the **Transform** tab.

1. Upload the two files (Python source file and JSON config file) to the Amazon S3 assets folder where the job scripts are stored. By default, Amazon Glue pulls all JSON files from the / **transforms** folder within the same Amazon S3 bucket.
2. From the **Action** menu, choose the custom visual transform. It is named with the transform `displayName` or name that you specified in the .json config file.
3. Enter values for any parameters that were configured in the config file.

The screenshot shows the Amazon Glue console interface. On the left, a workflow diagram illustrates a data source 'Data source - S3 bucket Amazon S3' (with a green checkmark) connected to a transform node 'Transform - Dynamic Trans... My Transform' (with a red warning triangle). On the right, the 'Transform' tab is selected, showing a configuration form with the following fields:

- Email Address:** A text input field with the description 'Enter your work email address below'.
- Phone Number:** A text input field with the description 'Enter your mobile phone number below'.
- Your age:** A text input field.
- Your gender:** A dropdown menu.
- Your origin country? - optional:** A dropdown menu with the description 'What country were you born in?' and a 'Choose options' button.
- Do you want to receive promotional newsletter from us? - optional:** A checkbox.

Usage examples

The following is an example of all possible parameters in a .json config file.

```
{
  "name": "MyTransform",
  "displayName": "My Transform",
  "description": "This transform description will be displayed in UI",
  "functionName": "myTransform",
  "parameters": [
    {
      "name": "email",
      "displayName": "Email Address",
      "type": "str",
      "description": "Enter your work email address below",
      "validationType": "RegularExpression",
      "validationRule": "^\\w+([\\.-]?\\w+)*@\\w+([\\.-]?\\w+)*(\\.\\w{2,3})+$",
      "validationMessage": "Please enter a valid email address"
    },
    {
      "name": "phone",
      "displayName": "Phone Number",
      "type": "str",
      "description": "Enter your mobile phone number below",
      "validationRule": "^\\((?\\d{3})\\)?[- ]?(\\d{3})[- ]?(\\d{4})$",
      "validationMessage": "Please enter a valid US number"
    }
  ]
}
```

```

    },
    {
      "name": "age",
      "displayName": "Your age",
      "type": "int",
      "isOptional": true
    },
    {
      "name": "gender",
      "displayName": "Your gender",
      "type": "str",
      "listOptions": [
        {"label": "Male", "value": "male"},
        {"label": "Female", "value": "female"},
        {"label": "Other", "value": "other"}
      ],
      "isOptional": true
    },
    {
      "name": "country",
      "displayName": "Your origin country ?",
      "type": "list",
      "listOptions": "Afghanistan,Albania,Algeria,American

    "type": "bool",
    "isOptional": true
}
]
}

```

Examples of custom visual scripts

The following examples perform equivalent transformations. However, the second example (SparkSQL) is the cleanest and most efficient, followed by the Pandas UDF and finally the low level mapping in the first example. The following example is a complete example of a simple transformation to add up two columns:

```

from awsglue import DynamicFrame

# You can have other auxiliary variables, functions or classes on this file, it won't
# affect the runtime
def record_sum(rec, col1, col2, resultCol):
    rec[resultCol] = rec[col1] + rec[col2]
    return rec

# The number and name of arguments must match the definition on json config file
# (expect self which is the current DynamicFrame to transform

```

```
# If an argument is optional, you need to define a default value here
# (resultCol in this example is an optional argument)
def custom_add_columns(self, col1, col2, resultCol="result"):
    # The mapping will alter the columns order, which could be important
    fields = [field.name for field in self.schema()]
    if resultCol not in fields:
        # If it's a new column put it at the end
        fields.append(resultCol)
    return self.map(lambda record: record_sum(record, col1, col2,
resultCol)).select_fields(paths=fields)

# The name we assign on DynamicFrame must match the configured "functionName"
DynamicFrame.custom_add_columns = custom_add_columns
```

The following example is an equivalent transform leveraging the SparkSQL API.

```
from awsglue import DynamicFrame

# The number and name of arguments must match the definition on json config file
# (expect self which is the current DynamicFrame to transform
# If an argument is optional, you need to define a default value here
# (resultCol in this example is an optional argument)
def custom_add_columns(self, col1, col2, resultCol="result"):
    df = self.toDF()
    return DynamicFrame.fromDF(
        df.withColumn(resultCol, df[col1] + df[col2]) # This is the conversion logic
        , self.glue_ctx, self.name)

# The name we assign on DynamicFrame must match the configured "functionName"
DynamicFrame.custom_add_columns = custom_add_columns
```

The following example uses the same transformations but using a pandas UDF, which is more efficient than using a plain UDF. For more information about writing pandas UDFs see: [Apache Spark SQL documentation](#).

```
from awsglue import DynamicFrame
import pandas as pd
from pyspark.sql.functions import pandas_udf
```

```
# The number and name of arguments must match the definition on json config file
# (expect self which is the current DynamicFrame to transform
# If an argument is optional, you need to define a default value here
# (resultCol in this example is an optional argument)
def custom_add_columns(self, col1, col2, resultCol="result"):
    @pandas_udf("integer") # We need to declare the type of the result column
    def add_columns(value1: pd.Series, value2: pd.Series) # pd.Series:
        return value1 + value2

    df = self.toDF()
    return DynamicFrame.fromDF(
        df.withColumn(resultCol, add_columns(col1, col2)) # This is the conversion
        logic
        , self.glue_ctx, self.name)

# The name we assign on DynamicFrame must match the configured "functionName"
DynamicFrame.custom_add_columns = custom_add_columns
```

Video

The following video provides an introduction to visual custom transforms and demonstrates how to use them.

Using Data Lake frameworks with Amazon Glue Studio

Overview

Open source data lake frameworks simplify incremental data processing for files stored in data lakes built on Amazon S3. Amazon Glue 3.0 and later supports the following open-source data lake storage frameworks:

- Apache Hudi
- Linux Foundation Delta Lake
- Apache Iceberg

As of Amazon Glue 4.0, Amazon Glue provides native support for these frameworks so that you can read and write data that you store in Amazon S3 in a transactionally consistent manner. There's no need to install a separate connector or complete extra configuration steps in order to use these frameworks in Amazon Glue jobs.

Data Lake frameworks can be used as a source or a target within Amazon Glue Studio through Spark Script Editor jobs. For more information on using Apache Hudi, Apache Iceberg and Delta Lake see: [Using data lake frameworks with Amazon Glue ETL jobs](#).

Creating open table formats from an Amazon Glue Streaming source

Amazon Glue streaming ETL jobs continuously consume data from streaming sources, clean and transform the data in-flight, and make it available for analysis in seconds.

Amazon offers a broad selection of services to support your needs. A database replication service such as Amazon Database Migration Service can replicate the data from your source systems to Amazon S3, which commonly hosts the storage layer of the data lake. Although it's straightforward to apply updates on a relational database management system (RDBMS) that backs an online source application, it's difficult to apply this CDC process on your data lakes. The open-source data management frameworks simplify incremental data processing and data pipeline development, and are a good option to solve this problem.

For more information, see:

- [Create an Apache Hudi-based near-real-time transactional data lake using Amazon Glue Streaming](#)
- [Build a real-time GDPR-aligned Apache Iceberg data lake](#)

Using Hudi framework in Amazon Glue Studio

When creating or editing a job, Amazon Glue Studio automatically adds the corresponding Hudi libraries for you depending on the version of Amazon Glue you are using. For more information, see [Using the Hudi framework in Amazon Glue](#).

Using Apache Hudi framework in Data Catalog data sources

To add a Hudi data source format to a job:

1. From the Source menu, choose Amazon Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. Amazon Glue Studio displays the format type as Apache Hudi and the Amazon S3 URL.

Using Hudi framework in Amazon S3 data sources

1. From the Source menu, choose Amazon S3.
2. If you choose Data Catalog table as the Amazon S3 source type, choose a database and table.
3. Amazon Glue Studio displays the format as Apache Hudi and the Amazon S3 URL.
4. If you choose Amazon S3 location as the **Amazon S3 source type**, choose the Amazon S3 URL by clicking **Browse Amazon S3**.
5. In **Data format**, select Apache Hudi.

Note

If Amazon Glue Studio is unable to infer the schema from the Amazon S3 folder or file you selected, choose **Additional options** to select a new folder or file.

In **Additional options** choose from the following options under **Schema inference**:

- Let Amazon Glue Studio automatically choose a sample file — Amazon Glue Studio will choose a sample file in the Amazon S3 location so that the schema can be inferred. In the **Auto-sampled file** field, you can view the file that was automatically selected.
- Choose a sample file from Amazon S3 — choose the Amazon S3 file to use by clicking **Browse Amazon S3**.

6. Click **Infer schema**. You can then view the output schema by clicking on the **Output schema** tab.
7. Choose **Additional options** to enter a key-value pair.

Additional options [Info](#)

Enter additional key-value pairs for your data source connection.

Using Apache Hudi framework in data targets

Using Apache Hudi framework in Data Catalog data targets

1. From the **Target** menu, choose Amazon Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. Amazon Glue Studio displays the format type as Apache Hudi and the Amazon S3 URL.

Using Apache Hudi framework in Amazon S3 data targets

Enter values or select from the available options to configure Apache Hudi format. For more information on Apache Hudi, see [Apache Hudi documentation](#).

Browse S3

Data Catalog update options Info

Choose how you want to update the Data Catalog table's schema and partitions. These options will only apply if the Data Catalog table is an S3 backed source.

Do not update the Data Catalog

Create a table in the Data Catalog and on subsequent runs, update the schema and add new partitions

Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions

Partition keys - optional
Add partition keys.

- **Hudi Table Name** — this is the name of your hudi table.
- **Hudi Storage Type** — choose from two options:
 - **Copy on write** — recommended for optimizing read performance. This is the default Hudi storage type. Each update creates a new version of files during a write.
 - **Merge on read** — recommended for minimizing write latency. Updates are logged to row-based delta files and are compacted as needed to create new versions of the columnar files.
- **Hudi Write Operation** - choose from the following options:
 - **Upsert** — this is the default operation where the input records are first tagged as inserts or updates by looking up the index. Recommended where you are updating existing data.
 - **Insert** — this inserts records but doesn't check for existing records and may result in duplicates.
 - **Bulk Insert** — this inserts records and is recommended for large amounts of data.
- **Hudi Record Key Fields** — use the search bar to search for and choose primary record keys. Records in Hudi are identified by a primary key which is a pair of record key and partition path where the record belongs to.
- **Hudi Precombine Field** — this is the field used in preCombining before actual write. When two records have the same key value, Amazon Glue Studio will pick the one with the largest value for the precombine field. Set a field with incremental value (e.g. updated_at) belongs to.
- **Compression Type** — choose from one of the compression type options: Uncompressed, GZIP, LZO, or Snappy.
- **Amazon S3 Target Location** — choose the Amazon S3 target location by clicking **Browse S3**.
- **Data Catalog update options** — choose from the following options:
 - Do not update the Data Catalog: (Default) Choose this option if you don't want the job to update the Data Catalog, even if the schema changes or new partitions are added.
 - Create a table in the Data Catalog and on subsequent runs, update the schema and add new partitions: If you choose this option, the job creates the table in the Data Catalog on the first run of the job. On subsequent job runs, the job updates the Data Catalog table if the schema changes or new partitions are added.

You must also select a database from the Data Catalog and enter a table name.

- Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions: If you choose this option, the job creates the table in the Data Catalog on the first run of the job. On subsequent job runs, the job updates the Data Catalog table only to add new partitions.

You must also select a database from the Data Catalog and enter a table name.

- **Partition keys:** Choose which columns to use as partitioning keys in the output. To add more partition keys, choose Add a partition key.
- **Additional options** — enter a key-value pair as needed.

Generating code through Amazon Glue Studio

When the job is saved, the following job parameters are added to the job if a Hudi source or target are detected:

- `--datalake-formats` – a distinct list of data lake formats detected in the visual job (either directly by choosing a “Format” or indirectly by selecting a catalog table that is backed by a data lake).
- `--conf` – generated based on the value of `--datalake-formats`. For example, if the value for `--datalake-formats` is 'hudi', Amazon Glue generates a value of `spark.serializer=org.apache.spark.serializer.KryoSerializer` `--conf spark.sql.hive.convertMetastoreParquet=false` for this parameter.

Overriding Amazon Glue-provided libraries

To use a version of Hudi that Amazon Glue doesn't support, you can specify your own Hudi library JAR files. To use your own JAR file:

- use the `--extra-jars` job parameter. For example, `'--extra-jars': 's3pathtojarfile.jar'`. For more information, see [Amazon Glue job parameters](#).
- do not include `hudi` as a value for the `--datalake-formats` job parameter. Entering a blank string as a value ensures that no data lake libraries are provided for you by Amazon Glue automatically. For more information, see [Using the Hudi framework in Amazon Glue](#).

Using Delta Lake framework in Amazon Glue Studio

Using Delta Lake framework in data sources

Using Delta Lake framework in Amazon S3 data sources

1. From the Source menu, choose Amazon S3.

2. If you choose Data Catalog table as the Amazon S3 source type, choose a database and table.
3. Amazon Glue Studio displays the format as Delta Lake and the Amazon S3 URL.
4. Choose **Additional options** to enter a key-value pair. For example, a key-value pair could be: **key:** timestampAsOf and **value:** 2023-02-24 14:16:18.

Additional options [Info](#)

Enter additional key-value pairs for your data source connection.

Key	Value	
<input type="text"/>	<input type="text"/>	
<input type="button" value="Add new option"/>		

5. If you choose Amazon S3 location as the **Amazon S3 source type**, choose the Amazon S3 URL by clicking **Browse Amazon S3**.
6. In **Data format**, choose Delta Lake.

Note

If Amazon Glue Studio is unable to infer the schema from the Amazon S3 folder or file you selected, choose **Additional options** to select a new folder or file.

In **Additional options** choose from the following options under **Schema inference**:

- Let Amazon Glue Studio automatically choose a sample file — Amazon Glue Studio will choose a sample file in the Amazon S3 location so that the schema can be inferred. In the **Auto-sampled file** field, you can view the file that was automatically selected.
- Choose a sample file from Amazon S3 — choose the Amazon S3 file to use by clicking **Browse Amazon S3**.

7. Click **Infer schema**. You can then view the output schema by clicking on the **Output schema** tab.

Using Delta Lake framework in Data Catalog data sources

1. From the **Source** menu, choose Amazon Glue Studio Data Catalog.

2. In the **Data source properties** tab, choose a database and table.
3. Amazon Glue Studio displays the format type as Delta Lake and the Amazon S3 URL.

Note

If your Delta Lake source is not registered as the Amazon Glue Data Catalog table yet, you have two options:

1. Create a Amazon Glue crawler for the Delta Lake data store. For more information, see [How to specify configuration options for a Delta Lake data store](#).
2. Use an Amazon S3 data source to select your Delta Lake data source. See [Using Delta Lake framework in Amazon S3 data sources](#).

Using Delta Lake formats in data targets

Using Delta Lake formats in Data Catalog data targets

1. From the **Target** menu, choose Amazon Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. Amazon Glue Studio displays the format type as Delta Lake and the Amazon S3 URL.

Using Delta Lake formats in Amazon S3 data sources

Enter values or select from the available options to configure Delta Lake format.

- **Compression Type** — choose from one of the compression type options: Uncompressed or Snappy.
- **Amazon S3 Target Location** — choose the Amazon S3 target location by clicking **Browse S3**.
- **Data Catalog update options** — updating the Data Catalog is not supported for this format in the Glue Studio visual editor.
 - Do not update the Data Catalog: (Default) Choose this option if you don't want the job to update the Data Catalog, even if the schema changes or new partitions are added.
 - To update the Data Catalog after the Amazon Glue job execution, run or schedule a Amazon Glue crawler. For more information, see [How to specify configuration options for a Delta Lake data store](#).

- **Partition keys** — Choose which columns to use as partitioning keys in the output. To add more partition keys, choose **Add a partition key**.
- Optionally, choose **Additional options** to enter a key-value pair. For example, a key-value pair could be: **key:** timestampAsOf and **value:** 2023-02-24 14:16:18.

Using Apache Iceberg framework in Amazon Glue Studio

Using Apache Iceberg framework in data targets

Using Apache Iceberg framework in Data Catalog data targets

1. From the **Target** menu, choose Amazon Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. Amazon Glue Studio displays the format type as Apache Iceberg and the Amazon S3 URL.

Using Apache Iceberg framework in Amazon S3 data targets

Enter values or select from the available options to configure Apache Iceberg format.

- **Format** – choose **Apache Iceberg** from the drop-down menu.
- **Amazon S3 Target Location** – choose the Amazon S3 target location by clicking **Browse S3**.
- **Data Catalog update options** – **Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions** must be selected to proceed. Writing a new Iceberg table using Amazon Glue requires the Data Catalog to be configured as the catalog for the Iceberg table. To update an existing Iceberg table that has been registered in the Data Catalog, choose Data Catalog as the target.
 - **Database** – Choose the database from the Data Catalog.
 - **Table Name** – Enter the value for your table name. Apache Iceberg table names must be in all lower case. Use underscores if needed since spaces are not allowed. For example "data_lake_format_tables".

Node properties	Data target properties - S3	Output schema	Data preview	
-----------------	------------------------------------	---------------	--------------	---

Format

Apache Iceberg

Compression Type

GZIP

S3 Target Location

Choose an S3 location in the format `s3://bucket/prefix/object/` with a trailing slash (/).

Data Catalog update options

Choose how you want to update the Data Catalog table's schema and partitions. These options will only apply if the Data Catalog table is an S3 backed source.

- Do not update the Data Catalog
- Create a table in the Data Catalog and on subsequent runs, update the schema and add new partitions
- Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions

Database

Choose the database from the AWS Glue Data Catalog.

► **Use runtime parameters**

Table name

Enter a table name for the AWS Glue Data Catalog.

Using Apache Iceberg framework in Amazon S3 data sources

Using Apache Iceberg framework in Data Catalog data sources

1. From the **Source** menu, choose Amazon Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. Amazon Glue Studio displays the format type as Apache Iceberg and the Amazon S3 URL.

Node properties	Data source properties - S3	Output schema	Data preview
<p>S3 source type</p> <p><input type="radio"/> S3 location Choose a file or folder in an S3 bucket.</p> <p><input checked="" type="radio"/> Data Catalog table</p>			
<p>Database Choose a database.</p> <p>data_lake_format_tables ▼ ↻</p> <p>▶ Use runtime parameters</p>			
<p>Table</p> <p>source_iceberg ▼ ↻</p> <p>▶ Use runtime parameters</p>			
<p>Format Apache Iceberg</p>			
<p>S3 URL s3://data-lake-format-data/iceberg/ ↗</p>			
<p>Partition predicate - optional Enter a boolean expression supported by Spark SQL, using only partition columns.</p> <p><input type="text"/></p> <p>Partition predicate syntax for Spark SQL is <code>year == year(date_sub(current_date, 7)) AND month == month(date_sub(current_date, 7)) AND day == day(date_sub(current_date, 7))</code>.</p>			

Using Apache Iceberg framework in Amazon S3 data sources

Apache Iceberg is not available as a data option for Amazon S3 source nodes in Amazon Glue Studio.

Connecting to data sources using Visual ETL jobs

While creating a new job, you can use connections to connect to data when editing visual ETL jobs in Amazon Glue. You can do this by adding source nodes that use connectors to read in data, and target nodes to specify the location for writing out data.

Topics

- [Modifying properties of a data source node](#)
- [Using Data Catalog tables for the data source](#)
- [Using a connector for the data source](#)
- [Using files in Amazon S3 for the data source](#)
- [Using a streaming data source](#)
- [References](#)

Modifying properties of a data source node

To specify the data source properties, you first choose a data source node in the job diagram. Then, on the right side in the node details panel, you configure the node properties.

To modify the properties of a data source node

1. Go to the visual editor for a new or saved job.
2. Choose a data source node in the job diagram.
3. Choose the **Node properties** tab in the node details panel, and then enter the following information:
 - **Name:** (Optional) Enter a name to associate with the node in the job diagram. This name should be unique among all the nodes for this job.
 - **Node type:** The node type determines the action that is performed by the node. In the list of options for **Node type**, choose one of the values listed under the heading **Data source**.
4. Configure the **Data source properties** information. For more information, see the following sections:
 - [Using Data Catalog tables for the data source](#)
 - [Using a connector for the data source](#)
 - [Using files in Amazon S3 for the data source](#)
 - [Using a streaming data source](#)
5. (Optional) After configuring the node properties and data source properties, you can view the schema for your data source by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.

6. (Optional) After configuring the node properties and data source properties, you can preview the dataset from your data source by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

Using Data Catalog tables for the data source

For all data sources except Amazon S3 and connectors, a table must exist in the Amazon Glue Data Catalog for the source type that you choose. Amazon Glue does not create the Data Catalog table.

To configure a data source node based on a Data Catalog table

1. Go to the visual editor for a new or saved job.
2. Choose a data source node in the job diagram.
3. Choose the **Data source properties** tab, and then enter the following information:
 - **S3 source type:** (For Amazon S3 data sources only) Choose the option **Select a Catalog table** to use an existing Amazon Glue Data Catalog table.
 - **Database:** Choose the database in the Data Catalog that contains the source table you want to use for this job. You can use the search field to search for a database by its name.
 - **Table:** Choose the table associated with the source data from the list. This table must already exist in the Amazon Glue Data Catalog. You can use the search field to search for a table by its name.
 - **Partition predicate:** (For Amazon S3 data sources only) Enter a Boolean expression based on Spark SQL that includes only the partitioning columns. For example: "(year== '2020' and month== '04')"
 - **Temporary directory:** (For Amazon Redshift data sources only) Enter a path for the location of a working directory in Amazon S3 where your ETL job can write temporary intermediate results.
 - **Role associated with the cluster:** (For Amazon Redshift data sources only) Enter a role for your ETL job to use that contains permissions for Amazon Redshift clusters. For more information, see [the section called "Data source and data target permissions"](#).

Using a connector for the data source

If you select a connector for the **Node type**, follow the instructions at [Authoring jobs with custom connectors](#) to finish configuring the data source properties.

Using files in Amazon S3 for the data source

If you choose Amazon S3 as your data source, then you can choose either:

- A Data Catalog database and table.
- A bucket, folder, or file in Amazon S3.

If you use an Amazon S3 bucket as your data source, Amazon Glue detects the schema of the data at the specified location from one of the files, or by using the file you specify as a sample file. Schema detection occurs when you use the **Infer schema** button. If you change the Amazon S3 location or the sample file, then you must choose **Infer schema** again to perform the schema detection using the new information.

To configure a data source node that reads directly from files in Amazon S3

1. Go to the visual editor for a new or saved job.
2. Choose a data source node in the job diagram for an Amazon S3 source.
3. Choose the **Data source properties** tab, and then enter the following information:
 - **S3 source type:** (For Amazon S3 data sources only) Choose the option **S3 location**.
 - **S3 URL:** Enter the path to the Amazon S3 bucket, folder, or file that contains the data for your job. You can choose **Browse S3** to select the path from the locations available to your account.
 - **Recursive:** Choose this option if you want Amazon Glue to read data from files in child folders at the S3 location.

If the child folders contain partitioned data, Amazon Glue doesn't add any partition information that's specified in the folder names to the Data Catalog. For example, consider the following folders in Amazon S3:

```
S3://sales/year=2019/month=Jan/day=1
S3://sales/year=2019/month=Jan/day=2
```

If you choose **Recursive** and select the `sales` folder as your S3 location, then Amazon Glue reads the data in all the child folders, but doesn't create partitions for year, month or day.

- **Data format:** Choose the format that the data is stored in. You can choose JSON, CSV, or Parquet. The value you select tells the Amazon Glue job how to read the data from the source file.

 **Note**

If you don't select the correct format for your data, Amazon Glue might infer the schema correctly, but the job won't be able to correctly parse the data from the source file.

You can enter additional configuration options, depending on the format you choose.

- **JSON** (JavaScript Object Notation)
 - **JsonPath:** Enter a JSON path that points to an object that is used to define a table schema. JSON path expressions always refer to a JSON structure in the same way as XPath expressions are used in combination with an XML document. The "root member object" in the JSON path is always referred to as `$`, even if it's an object or array. The JSON path can be written in dot notation or bracket notation.

For more information about the JSON path, see [JsonPath](#) on the GitHub website.

- **Records in source files can span multiple lines:** Choose this option if a single record can span multiple lines in the CSV file.
- **CSV** (comma-separated values)
 - **Delimiter:** Enter a character to denote what separates each column entry in the row, for example, `;` or `,`.
 - **Escape character:** Enter a character that is used as an escape character. This character indicates that the character that immediately follows the escape character should be taken literally, and should not be interpreted as a delimiter.
 - **Quote character:** Enter the character that is used to group separate strings into a single value. For example, you would choose **Double quote (")** if you have values such as `"This is a single value"` in your CSV file.
 - **Records in source files can span multiple lines:** Choose this option if a single record can span multiple lines in the CSV file.

- **First line of source file contains column headers:** Choose this option if the first row in the CSV file contains column headers instead of data.

- **Parquet** (Apache Parquet columnar storage)

There are no additional settings to configure for data stored in Parquet format.

- **Apache Hudi**

There are no additional settings to configure for data stored in Apache Hudi format.

- **Delta Lake**

There are no additional settings to configure for data stored in Delta Lake format.

- **Excel**

There are no additional settings to configure for data stored in Excel format.

- **Partition predicate:** To partition the data that is read from the data source, enter a Boolean expression based on Spark SQL that includes only the partitioning columns. For example: `"(year=='2020' and month=='04')"`
- **Advanced options:** Expand this section if you want Amazon Glue to detect the schema of your data based on a specific file.
 - **Schema inference:** Choose the option **Choose a sample file from S3** if you want to use a specific file instead of letting Amazon Glue choose a file. Schema inference is not available for the Excel source.
 - **Auto-sampled file:** Enter the path to the file in Amazon S3 to use for inferring the schema.

If you're editing a data source node and change the selected sample file, choose **Reload schema** to detect the schema by using the new sample file.

4. Choose the **Infer schema** button to detect the schema from the sources files in Amazon S3. If you change the Amazon S3 location or the sample file, you must choose **Infer schema** again to infer the schema using the new information.

Using a streaming data source

You can create streaming extract, transform, and load (ETL) jobs that run continuously and consume data from streaming sources in Amazon Kinesis Data Streams, Apache Kafka, and Amazon [Managed Streaming for Apache Kafka \(Amazon MSK\)](#).

To configure properties for a streaming data source

1. Go to the visual graph editor for a new or saved job.
2. Choose a data source node in the graph for Kafka or Kinesis Data Streams.
3. Choose the **Data source properties** tab, and then enter the following information:

Kinesis

- **Kinesis source type:** Choose the option **Stream details** to use direct access to the streaming source or choose **Data Catalog table** to use the information stored there instead.

If you choose **Stream details**, specify the following additional information.

- **Location of data stream:** Choose whether the stream is associated with the current user, or if it is associated with a different user.
- **Region:** Choose the Amazon Web Services Region where the stream exists. This information is used to construct the ARN for accessing the data stream.
- **Stream ARN:** Enter the Amazon Resource Name (ARN) for the Kinesis data stream. If the stream is located within the current account, you can choose the stream name from the drop-down list. You can use the search field to search for a data stream by its name or ARN.
- **Data format:** Choose the format used by the data stream from the list.

Amazon Glue automatically detects the schema from the streaming data.

If you choose **Data Catalog table**, specify the following additional information.

- **Database:** (Optional) Choose the database in the Amazon Glue Data Catalog that contains the table associated with your streaming data source. You can use the search field to search for a database by its name.
- **Table:** (Optional) Choose the table associated with the source data from the list. This table must already exist in the Amazon Glue Data Catalog. You can use the search field to search for a table by its name.
- **Detect schema:** Choose this option to have Amazon Glue detect the schema from the streaming data, rather than using the schema information in a Data Catalog table. This option is enabled automatically if you choose the **Stream details** option.

- **Starting position:** By default, the ETL job uses the **Earliest** option, which means it reads data starting with the oldest available record in the stream. You can instead choose **Latest**, which indicates the ETL job should start reading from just after the most recent record in the stream.
- **Window size:** By default, your ETL job processes and writes out data in 100-second windows. This allows data to be processed efficiently and permits aggregations to be performed on data that arrives later than expected. You can modify this window size to increase timeliness or aggregation accuracy.

Amazon Glue streaming jobs use checkpoints rather than job bookmarks to track the data that has been read.

- **Connection options:** Expand this section to add key-value pairs to specify additional connection options. For information about what options you can specify here, see ["connectionType": "kinesis"](#) in the *Amazon Glue Developer Guide*.

Kafka

- **Apache Kafka source:** Choose the option **Stream details** to use direct access to the streaming source or choose **Data Catalog table** to use the information stored there instead.

If you choose **Data Catalog table**, specify the following additional information.

- **Database:** (Optional) Choose the database in the Amazon Glue Data Catalog that contains the table associated with your streaming data source. You can use the search field to search for a database by its name.
- **Table:** (Optional) Choose the table associated with the source data from the list. This table must already exist in the Amazon Glue Data Catalog. You can use the search field to search for a table by its name.
- **Detect schema:** Choose this option to have Amazon Glue detect the schema from the streaming data, rather than storing the schema information in a Data Catalog table. This option is enabled automatically if you choose the **Stream details** option.

If you choose **Stream details**, specify the following additional information.

- **Connection name:** Choose the Amazon Glue connection that contains the access and authentication information for the Kafka data stream. You must use a connection with

Kafka streaming data sources. If a connection doesn't exist, you can use the Amazon Glue console to create a connection for your Kafka data stream.

- **Topic name:** Enter the name of the topic to read from.
- **Data format:** Choose the format to use when reading data from the Kafka event stream.
- **Starting position:** By default, the ETL job uses the **Earliest** option, which means it reads data starting with the oldest available record in the stream. You can instead choose **Latest**, which indicates the ETL job should start reading from just after the most recent record in the stream.
- **Window size:** By default, your ETL job processes and writes out data in 100-second windows. This allows data to be processed efficiently and permits aggregations to be performed on data that arrives later than expected. You can modify this window size to increase timeliness or aggregation accuracy.

Amazon Glue streaming jobs use checkpoints rather than job bookmarks to track the data that has been read.

- **Connection options:** Expand this section to add key-value pairs to specify additional connection options. For information about what options you can specify here, see ["connectionType": "kafka"](#) in the *Amazon Glue Developer Guide*.

Note

Data previews are not currently supported for streaming data sources.

Configuring data target nodes

The data target is where the job writes the transformed data.

Overview of data target options

Your data target (also called a *data sink*) can be:

- **S3** – The job writes the data in a file in the Amazon S3 location you choose and in the format you specify.

If you configure partition columns for the data target, then the job writes the dataset to Amazon S3 into directories based on the partition key.

- **Amazon Glue Data Catalog** – The job uses the information associated with the table in the Data Catalog to write the output data to a target location.

You can create the table manually or with the crawler. You can also use Amazon CloudFormation templates to create tables in the Data Catalog.

- A connector – A connector is a piece of code that facilitates communication between your data store and Amazon Glue. The job uses the connector and associated connection to write the output data to a target location. You can either subscribe to a connector offered in Amazon Web Services Marketplace, or you can create your own custom connector. For more information, see [Adding connectors to Amazon Glue Studio](#)

You can choose to update the Data Catalog when your job writes to an Amazon S3 data target. Instead of requiring a crawler to update the Data Catalog when the schema or partitions change, this option makes it easy to keep your tables up to date. This option simplifies the process of making your data available for analytics by optionally adding new tables to the Data Catalog, updating table partitions, and updating the schema of your tables directly from the job.

Editing the data target node

The data target is where the job writes the transformed data.

To add or configure a data target node in your job diagram

1. (Optional) If you need to add a target node, choose **Target** in the toolbar at the top of the visual editor, and then choose either **S3** or **Glue Data Catalog**.
 - If you choose **S3** for the target, then the job writes the dataset to one or more files in the Amazon S3 location you specify.
 - If you choose **Amazon Glue Data Catalog** for the target, then the job writes to a location described by the table selected from the Data Catalog.
2. Choose a data target node in the job diagram. When you choose a node, the node details panel appears on the right-side of the page.
3. Choose the **Node properties** tab, and then enter the following information:
 - **Name:** Enter a name to associate with the node in the job diagram.
 - **Node type:** A value should already be selected, but you can change it as needed.
 - **Node parents:** The parent node is the node in the job diagram that provides the output data you want to write to the target location. For a pre-populated job diagram, the target node should already have the parent node selected. If there is no parent node displayed, then choose a parent node from the list.

A target node has a single parent node.
4. Configure the **Data target properties** information. For more information, see the following sections:
 - [Using Amazon S3 for the data target](#)
 - [Using Data Catalog tables for the data target](#)
 - [Using a connector for the data target](#)
5. (Optional) After configuring the data target node properties, you can view the output schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.

Using Amazon S3 for the data target

For all data sources except Amazon S3 and connectors, a table must exist in the Amazon Glue Data Catalog for the source type that you choose. Amazon Glue Studio does not create the Data Catalog table.

To configure a data target node that writes to Amazon S3

1. Go to the visual editor for a new or saved job.
2. Choose a data source node in the job diagram.
3. Choose the **Data source properties** tab, and then enter the following information:
 - **Format:** Choose a format from the list. The available format types for the data results are:
 - **JSON:** JavaScript Object Notation.
 - **CSV:** Comma-separated values.
 - **Avro:** Apache Avro JSON binary.
 - **Parquet:** A custom Parquet writer type that is optimized for `DynamicFrames` as the data format. Instead of requiring a precomputed schema for the data, it computes and modifies the schema dynamically.
 - **ORC:** Apache Optimized Row Columnar (ORC) format.
 - **Apache Hudi:** An open-source data lake storage framework that simplifies incremental data processing and data pipeline development.
 - **Apache Iceberg:** A high-performance table format that works just like an SQL table.
 - **Delta Lake:** An open-source data lake storage framework that helps you perform ACID transactions, scale metadata handling, and unify streaming and batch data processing.
 - **XML:** Extensible Markup Language (XML).
 - **Tableau Hyper:** Tableau's in-memory data engine technology.

To learn more about these format options, see [Format Options for ETL Inputs and Outputs in Amazon Glue](#) in the *Amazon Glue Developer Guide*.

- **Compression Type:** You can choose to optionally compress the data using the file types CSV, JSON, or Parquet. The default is no compression, or **None**.

File Type	Compressions
JSON/CSV/XML	GZIP, BZIP2, BROTLI, DEFLATE, LZ4, Snappy
Parquet	Snappy, LZ4, LZO, BROTLI, GZIP
ORC	Snappy, ZLIB, Uncompressed, LZO
Avro	GZIP, BZIP2, BROTLI, DEFLATE, LZ4, Snappy
Delta Lake	GZIP, BZIP2, BROTLI, DEFLATE, LZ4, Snappy
Apache Hudi	GZIP, LZO, Snappy
Apache Iceberg	GZIP, LZO, Snappy
Tableau Hyper	None

- **S3 Target Location:** The Amazon S3 bucket and location for the data output. You can choose the **Browse S3** button to see the Amazon S3 buckets that you have access to and choose one as the target destination.
- **Data catalog update options**
 - **Do not update the Data Catalog:** (Default) Choose this option if you don't want the job to update the Data Catalog, even if the schema changes or new partitions are added.
 - **Create a table in the Data Catalog and on subsequent runs, update the schema and add new partitions:** If you choose this option, the job creates the table in the Data Catalog on the first run of the job. On subsequent job runs, the job updates the Data Catalog table if the schema changes or new partitions are added.

You must also select a database from the Data Catalog and enter a table name.

- **Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions:** If you choose this option, the job creates the table in the Data Catalog on the first run of the job. On subsequent job runs, the job updates the Data Catalog table only to add new partitions.

You must also select a database from the Data Catalog and enter a table name.

- **File Partitioning:** Choose which type of partitioning you want to save the output in.

- **Autogenerate files (Recommended):** This is the default value for the number of generated files.
- **Multiple file output:** Specify the number of file outputs you want. For optimal performance, use the default auto-generated number of files value.
- **Partition keys:** Choose which columns to use as partitioning keys in the output. To add more partition keys, choose **Add a partition key**.

File partitioning is not supported for Tableau Hyper as a target format.

Using Data Catalog tables for the data target

For all data sources except Amazon S3 and connectors, a table must exist in the Amazon Glue Data Catalog for the target type that you choose. Amazon Glue Studio does not create the Data Catalog table.

To configure the data properties for a target that uses a Data Catalog table

1. Go to the visual editor for a new or saved job.
2. Choose a data target node in the job diagram.
3. Choose the **Data target properties** tab, and then enter the following information:
 - **Database:** Choose the database that contains the table you want to use as the target from the list. This database must already exist in the Data Catalog.
 - **Table:** Choose the table that defines the schema of your output data from the list. This table must already exist in the Data Catalog.

A table in the Data Catalog consists of the names of columns, data type definitions, partition information, and other metadata about the target dataset. Your job writes to a location described by this table in the Data Catalog.

For more information about creating tables in the Data Catalog, see [Defining Tables in the Data Catalog](#) in the *Amazon Glue Developer Guide*.

- **Data catalog update options**
 - **Do not change table definition:** (Default) Choose this option if you don't want the job to update the Data Catalog, even if the schema changes, or new partitions are added.

- **Update schema and add new partitions:** If you choose this option, the job updates the Data Catalog table if the schema changes or new partitions are added.
- **Keep existing schema and add new partitions:** If you choose this option, the job updates the Data Catalog table only to add new partitions.
- **Partition keys:** Choose which columns to use as partitioning keys in the output. To add more partition keys, choose **Add a partition key**.

Using a connector for the data target

If you select a connector for the **Node type**, follow the instructions at [Authoring jobs with custom connectors](#) to finish configuring the data target properties.

Editing or uploading a job script

Use the Amazon Glue Studio visual editor to edit the job script or upload your own script.

You can use the visual editor to edit job nodes only if the jobs were created with Amazon Glue Studio. If the job was created using the Amazon Glue console, through API commands, or with the command line interface (CLI), you can use the script editor in Amazon Glue Studio to edit the job script, parameters, and schedule. You can also edit the script for a job created in Amazon Glue Studio by converting the job to script-only mode.

To edit the job script or upload your own script

1. If creating a new job, on the **Jobs** page, choose the **Spark script editor** option to create a Spark job or choose the **Python Shell script editor** to create a Python shell job. You can either write a new script, or upload an existing script. If you choose **Spark script editor**, you can write or upload either a Scala or Python script. If you choose **Python Shell script editor**, you can only write or upload a Python script.

After choosing the option to create a new job, in the **Options** section that appears, you can choose to either start with a starter script (**Create a new script with boilerplate code**), or you can upload a local file to use as the job script.

If you chose **Spark script editor**, you can upload either Python or Scala script files. Scala scripts must have the file extension `.scala`. Python scripts must be recognized as files of type Python. If you chose **Python Shell script editor**, you can upload only Python script files.

When you are finished making your choices, choose **Create** to create the job and open the visual editor.

2. Go to the visual job editor for the new or saved job, and then choose the **Script** tab.
3. If you didn't create a new job using one of the script editor options, and you have never edited the script for an existing job, the **Script** tab displays the heading **Script (Locked)**. This means the script editor is in read-only mode. Choose **Edit script** to unlock the script for editing.

To make the script editable, Amazon Glue Studio converts your job from a visual job to a script-only job. If you unlock the script for editing, you can't use the visual editor anymore for this job after you save it.

In the confirmation window, choose **Confirm** to continue or **Cancel** to keep the job available for visual editing.

If you choose **Confirm**, the **Visual** tab no longer appears in the editor. You can use Amazon Glue Studio to modify the script using the script editor, modify the job details or schedule, or view job runs.

 **Note**

Until you save the job, the conversion to a script-only job is not permanent. If you refresh the console web page, or close the job before saving it and reopen it in the visual editor, you will still be able to edit the individual nodes in the visual editor.

4. Edit the script as needed.

When you are done editing the script, choose **Save** to save the job and permanently convert the job from visual to script-only.

5. (Optional) You can download the script from the Amazon Glue Studio console by choosing the **Download** button on the **Script** tab. When you choose this button, a new browser window opens, displaying the script from its location in Amazon S3. The **Script filename** and **Script path** parameters in the **Job details** tab of the job determine the name and location of the script file in Amazon S3.

- Job metrics [Info](#)
Enable the creation of CloudWatch metrics when this job runs.
- Continuous logging [Info](#)
Enable logs in CloudWatch.
- Spark UI [Info](#)
Enable using Spark UI for monitoring this job.

When you save the job, Amazon Glue save the job script at the location specified by these fields. If you modify the script file at this location within Amazon S3, Amazon Glue Studio will load the modified script the next time you edit the job.

Creating and editing Scala scripts in Amazon Glue Studio

When you choose the script editor for creating a job, by default, the job programming language is set to Python 3. If you choose to write a new script instead of uploading a script, Amazon Glue Studio starts a new script with boilerplate text written in Python. If you want to write a Scala script instead, you must first configure the script editor to use Scala.

Note

If you choose Scala as the programming language for the job and use the visual editor to design your job, the generated job script is written in Scala, and no further actions are needed.

To write a new Scala script in Amazon Glue Studio

1. Create a new job by choosing the **Spark script editor** option.
2. Under **Options**, choose **Create a new script with boilerplate code**.
3. Choose the **Job details** tab and set **Language** to Scala (instead of Python 3).

Note

The **Type** property for the job is automatically set to Spark when you choose the **Spark script editor** option to create a job.

4. Choose the **Script** tab.
5. Remove the Python boilerplate text. You can replace it with the following Scala boilerplate text.

```
import com.amazonaws.services.glue.{DynamicRecord, GlueContext}
import org.apache.spark.SparkContext
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job

object MyScript {
  def main(args: Array[String]): Unit = {
    val sc: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(sc)

  }
}
```

6. Write your Scala job script in the editor. Add additional import statements as needed.

Creating and editing Python shell jobs in Amazon Glue Studio

When you choose the Python shell script editor for creating a job, you can upload an existing Python script, or write a new one. If you choose to write a new script, boilerplate code is added to the new Python job script.

To create a new Python shell job

Refer to the instructions at [Starting jobs in Amazon Glue Studio](#).

The job properties that are supported for Python shell jobs are not the same as those supported for Spark jobs. The following list describes the changes to the available job parameters for Python shell jobs on the **Job details** tab.

- The **Type** property for the job is automatically set to `Python Shell` and can't be changed.
- Instead of **Language**, there is a **Python version** property for the job. Currently, Python shell jobs created in Amazon Glue Studio use Python 3.6.
- The **Glue version** property is not available, because it does not apply to Python shell jobs.
- Instead of **Worker type** and **Number of workers**, a **Data processing units** property is shown instead. This job property determines how many data processing units (DPUs) are consumed by the Python shell when running the job.
- The **Job bookmark** property is not available, because it is not supported for Python shell jobs.
- Under **Advanced properties**, the following properties are not available for Python shell jobs.
 - **Job metrics**
 - **Continuous logging**
 - **Spark UI** and **Spark UI logs path**
 - **Dependent jars path**, under the heading **Libraries**

Changing the parent nodes for a node in the job diagram

You can change a node's parents to move nodes within the job diagram or to change a data source for a node.

To change the parent node

1. Choose the node in the job diagram that you want to modify.
2. In the node details panel, on the **Node properties** tab, under the heading **Node parents** remove the current parent for the node.
3. Choose a new parent node from the list.
4. Modify the other properties of the node as needed to match the newly selected parent node.

If you modified a node by mistake, you can use the **Undo** button on the toolbar to reverse the action.

Deleting nodes from the job diagram

When working with Visual ETL jobs, you can remove nodes from the canvas without having to re-add or restructure any nodes that are connected to the removed node.

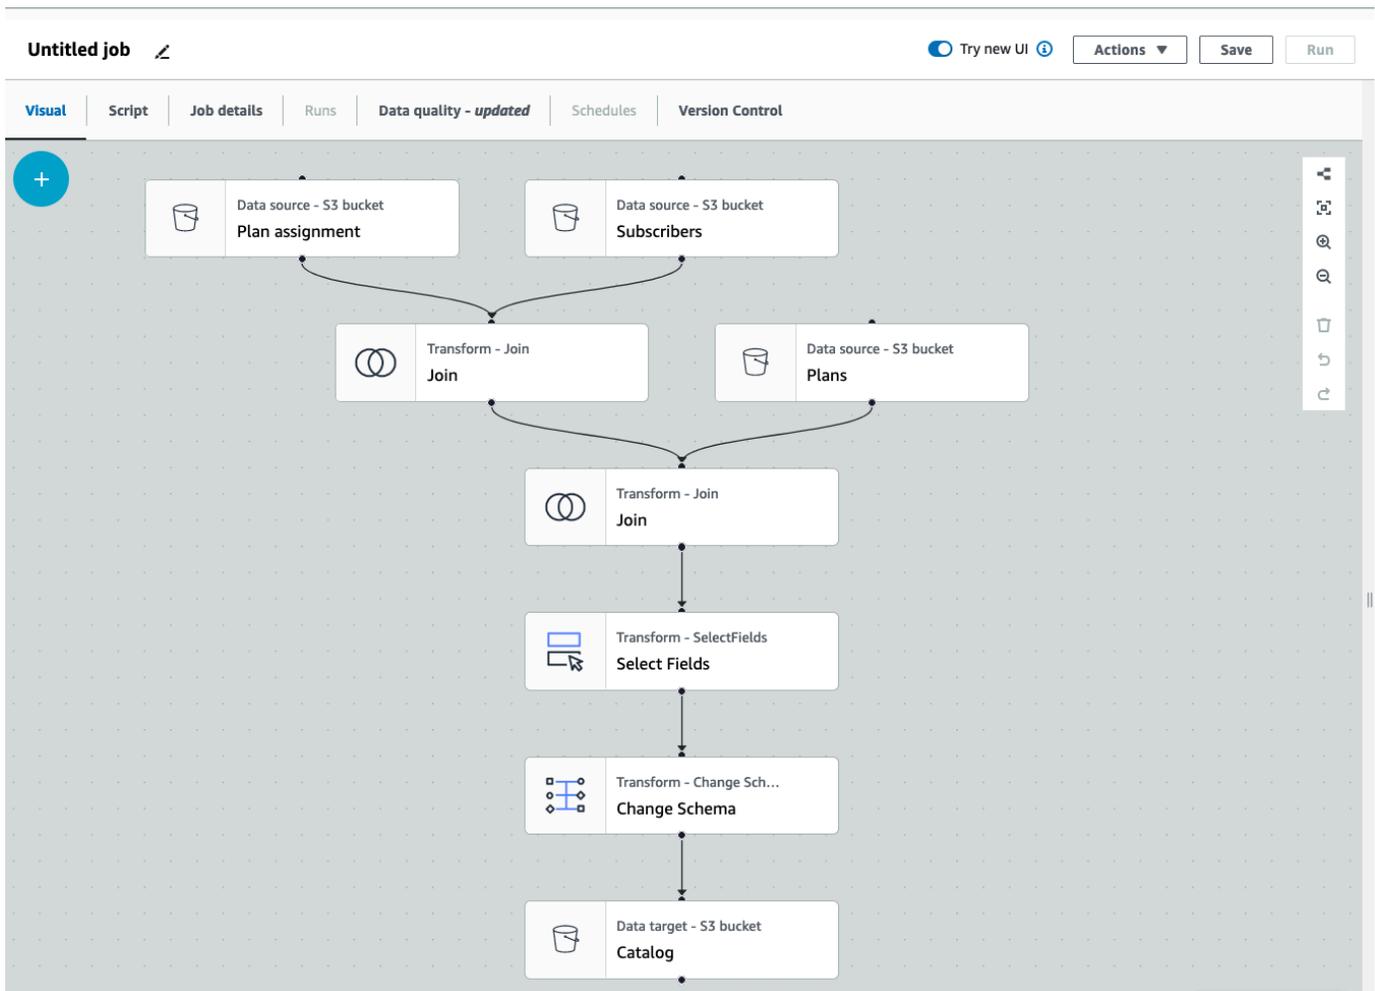

In the example below, you can follow along by choosing **ETL jobs > Visual ETL**, then in **Example jobs**, choosing **Visual ETL job to join multiple sources**. Choose **Create example job** to create a job and follow along with the steps below.

The screenshot shows the AWS Glue console interface. On the left is a navigation menu with 'Visual ETL' highlighted. The main content area shows the 'Create job' section with three options: 'Visual ETL', 'Notebook', and 'Script editor'. Below this is the 'Example jobs' section, where the 'Visual ETL job to join multiple sources' option is selected and highlighted with a red box. At the bottom, the 'Your jobs (1)' table shows a single job named 'job_101521'.

Job name	Type	Last modified	AWS Glue version
job_101521	Glue ETL	1/31/2022, 11:44:06 AM	2.0

To remove a node from the canvas

1. From the Amazon Glue console, choose **Visual ETL** from the navigation menu and choose an existing job. The job canvas displays the example job as depicted below.

- Choose the node you want to remove. The canvas will zoom in to the node. In the toolbar on the right side of the canvas, choose the **Trash** icon. This will remove the node and any node connected to the node will move to take its place in the workflow. In this example, the first **Join** node was deleted from the canvas.

If you delete a node in the workflow, Amazon Glue will re-arrange the nodes so that they are organized in a way that does not result in an invalid workflow. You may still need to correct a node's configuration.

In the example, the **Join** node beneath the **Subscribers** node was removed. As a result, the **Plans** source node has been moved to the top level and is still connected to the child **Join** node. The **Join** node now requires additional configuration since **Join** requires two parent source nodes with selected tables. The **Transform** tab to the right of the canvas displays the missing requirement under **Join conditions**.

The screenshot displays the Amazon Glue console interface for an "Untitled job". The workflow diagram shows three data sources: "Data source - S3 bucket Plan assignment", "Data source - S3 bucket Subscribers", and "Data source - S3 bucket Plans". These feed into a "Transform - Join" node, which then feeds into "Transform - SelectFields Select Fields", and finally "Transform - Change Sch... Change Schema".

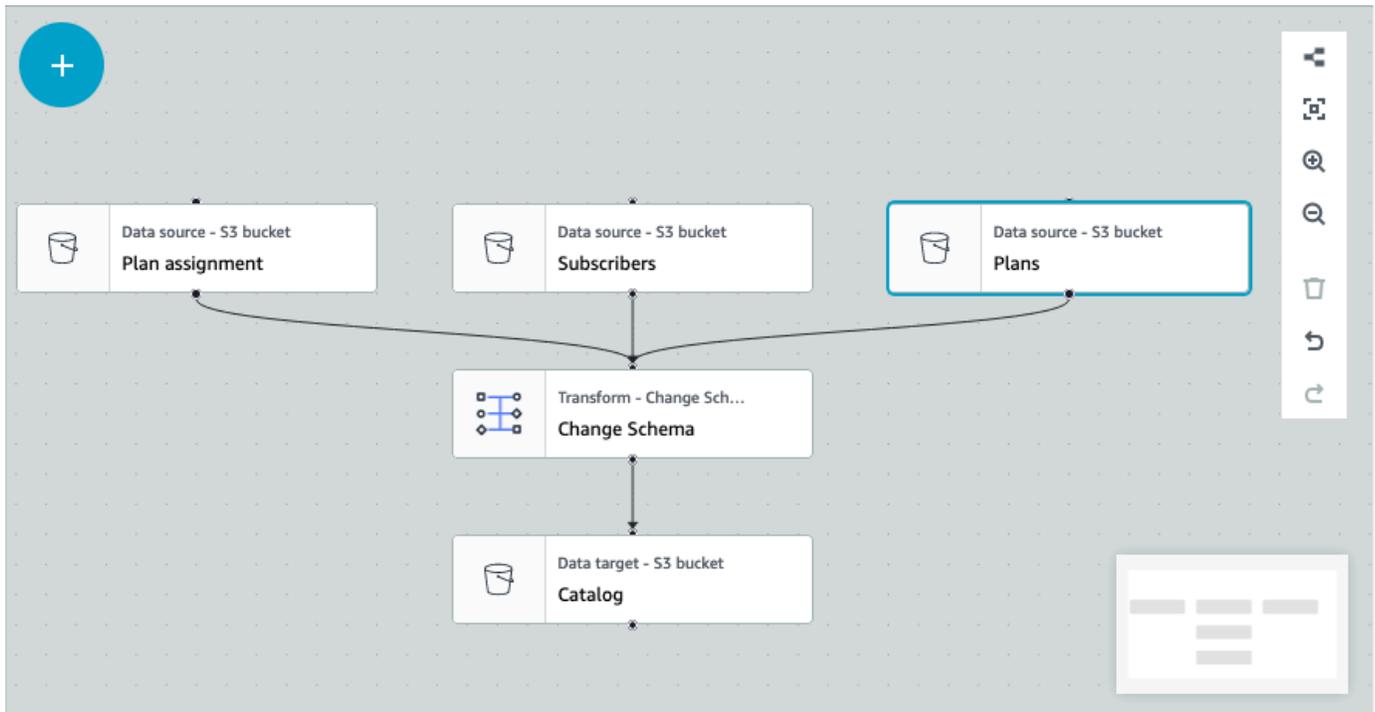

The "Transform" configuration panel on the right shows the following settings:

- Name:** Join
- Node parents:** Plan assignment, Subscribers, Plans
- Join type:** Inner join
- Join conditions:** Insufficient source nodes (The Join transform requires two parent source nodes with selected tables.)

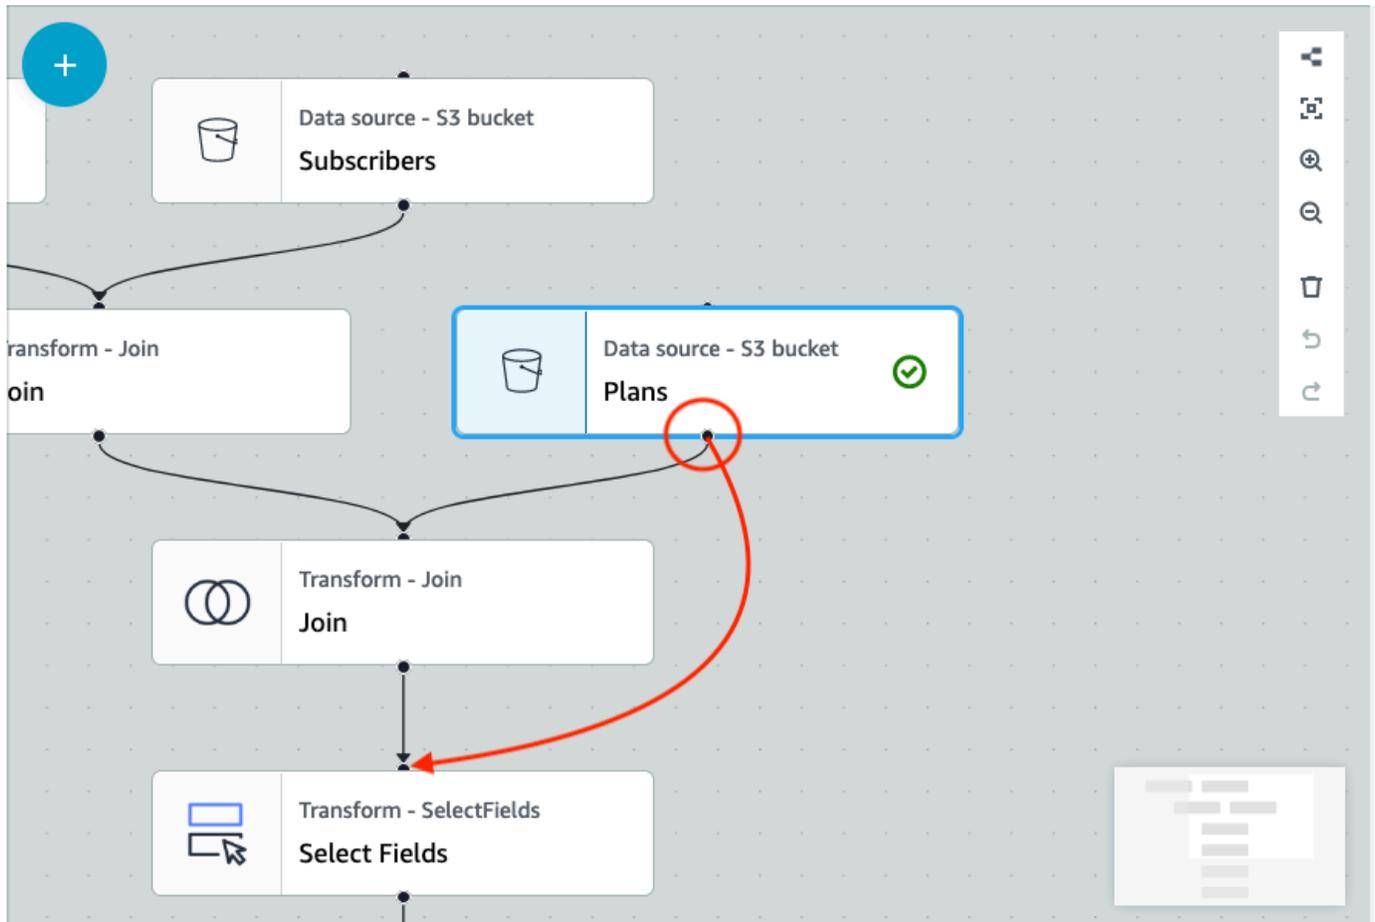

A warning message is displayed at the bottom of the workflow diagram:

Node is misconfigured
Data preview will be displayed when following node is correctly configured:
• Join

3. Delete the second **Join** node and **Select Fields** node. When the nodes have been deleted, the workflow will look like the example below.

4. To modify the node connections, click on the node's handle and drag the connection to a new node. This will allow you to delete nodes and rearrange the nodes in a logical flow. In the example, a new connection is being made by clicking the handle on the Plans node and dragging the connection to the Join node as depicted by the red arrow.

5. If you need to undo any action, choose the **Undo** icon directly beneath the **Trash** icon in the toolbar on the right side of the canvas.

Adding source and target parameters to the Amazon Glue Data Catalog node

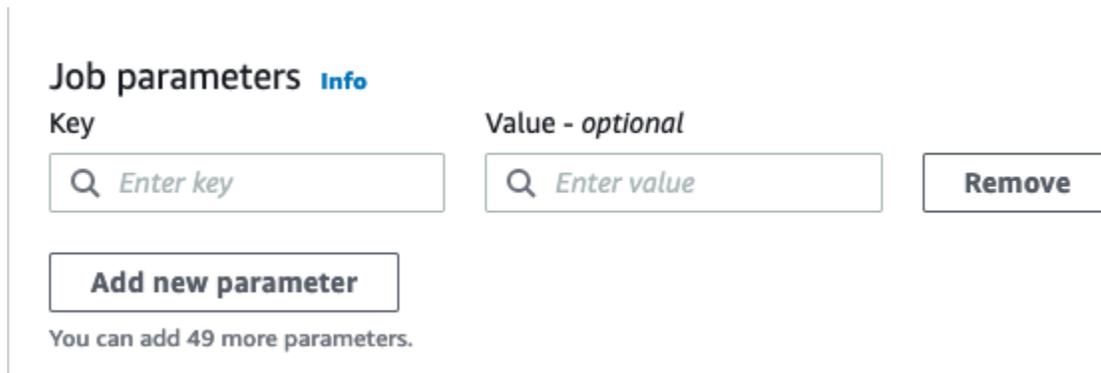

Amazon Glue Studio allows you to parameterize visual jobs. Since catalog table names in production and development environment may be different, you can define and select runtime parameters for databases and tables that will run when your job runs.

Job parameterization allows you to parameterize sources and targets, and save those parameters to the job when using the Amazon Glue Data Catalog node. When you specify sources and targets as parameters, you are enabling the reusability of jobs, particularly when using the same job in multiple environments. This is useful when promoting code across deployment environments by saving time and effort in managing your sources and targets. In addition, the custom parameters you specify will override any default arguments for specific runs of Amazon Glue jobs.

To add source and target parameters

Whether you are using the Amazon Glue Data Catalog node as a source or a target, you can define runtime parameters in the **Advanced properties** section on the **Job details** tab.

1. Choose the Amazon Glue Data Catalog node as either the source node or the target node.
2. Choose the **Job details** tab.
3. Choose **Advanced properties**.
4. In the Job parameters section, enter a key value. For example, `--db.source` would be the parameter for a database source. You can enter any name for the key, as long as the key name is followed by the 'dash dash'.

The screenshot shows the 'Job parameters' section of the Amazon Glue console. It features a table with two columns: 'Key' and 'Value - optional'. Below the table is an 'Add new parameter' button and a note: 'You can add 49 more parameters.'

Key	Value - optional	
<input type="text" value="Enter key"/>	<input type="text" value="Enter value"/>	<input type="button" value="Remove"/>

You can add 49 more parameters.

5. Enter the value. For example, `databaseName` would be the value for database being parameterized.
6. Choose **Add new parameter** if you want to add more parameters. Max 50 parameters is allowed. Once the key value pair has been defined, you can use the parameter in the Amazon Glue Data Catalog node.

To select a runtime parameter

Note

The process to select runtime parameters for databases and tables is the same whether the the Amazon Glue Data Catalog node is the source or the target.

1. Choose the Amazon Glue Data Catalog node as either the source node or the target node.
2. In the **Data source properties - Data Catalog** tab, under **Database**, choose **Use runtime parameters**.

▼ Use runtime parameters

Select runtime parameter

Runtime parameters can be configured in the **Advanced properties** section on the **Job details** tab

ApplyClear

3. Choose a parameter from the drop-down menu. For example, when you select a parameter you defined for a source database, the database will automatically populate in the database drop-down menu when you choose **Apply**.
4. In the Table section, choose a parameter you already defined as a source table. When you choose **Apply**, the table is automatically populated as the table to use.
5. When you save and run the job, Amazon Glue Studio will reference the selected parameters during the job run.

Using Git version control systems in Amazon Glue

Note

Notebooks are not currently supported for version control in Amazon Glue Studio. However, version control for Amazon Glue job scripts and visual ETL jobs are supported.

If you have remote repositories and want to manage your Amazon Glue jobs using your repositories, you can use Amazon Glue Studio or the Amazon CLI to sync changes to your repositories and your jobs in Amazon Glue. When you sync changes this way, you're pushing the job from Amazon Glue Studio to your repository, or pulling from the repository to Amazon Glue Studio.

With Git integration in Amazon Glue Studio, you can:

- Integrate with Git version control systems, such as Amazon CodeCommit, GitHub, GitLab, and Bitbucket

- Edit Amazon Glue jobs in Amazon Glue Studio whether you use visual jobs or script jobs and sync them to a repository
- Parameterize sources and targets in jobs
- Pull jobs from a repository and edit them in Amazon Glue Studio
- Test jobs by pulling from branches and/or pushing to branches utilizing multi-branch workflows in Amazon Glue Studio
- Download files from a repository and upload jobs into Amazon Glue Studio for cross-account job creation
- Use your automation tool of choice (for example, Jenkins, Amazon CodeDeploy, etc.)

This video demonstrates how you can integrate Amazon Glue with Git and build a continuous and collaborative code pipeline.

IAM permissions

Ensure the job has one of the following IAM permissions. For more information on how to set up IAM permissions, see [Set up IAM permissions for Amazon Glue Studio](#).

- `AWSGlueServiceRole`
- `AWSGlueConsoleFullAccess`

At minimum, the following actions are needed for Git integration:

- `glue:UpdateJobFromSourceControl` — to be able to update Amazon Glue with a job present in a version control system
- `glue:UpdateSourceControlFromJob` — to be able to update the version control system with a job stored in Amazon Glue
- `s3:GetObject` — to be able to retrieve the script for the job while pushing to version control system
- `s3:PutObject` — to be able to update the script when pulling a job from a source control system

Prerequisites

In order to push jobs to a source control repository, you will need:

- a repository that has already been created by your administrator
- a branch in the repository
- a personal access token (for Bitbucket, this is the Repository Access Token)
- the username of the repository owner
- set permissions in the repository to allow Amazon Glue Studio to read and write to the repository
 - **GitLab** – set token scopes to `api`, `read_repository`, and `write_repository`
 - **Bitbucket** – set permissions to:
 - **Workspace membership** – read, write
 - **Projects** – write, admin read
 - **Repositories** – read, write, admin, delete

Note

When using Amazon CodeCommit, personal access token and repository owner are not needed. See [Getting started with Git and Amazon CodeCommit](#).

Using jobs from your source control repository in Amazon Glue Studio

In order to pull a job from your source control repository that is not in Amazon Glue Studio, and to use that job in Amazon Glue Studio, the prerequisites will depend on the type of job.

For visual jobs:

- you need a folder and a JSON file of the job definition that matches the job name

For example, see the job definition below. The branch in your repository should contain a path `my-visual-job/my-visual-job.json` where both the folder and the JSON file match the job name

```
{
  "name" : "my-visual-job",
  "description" : "",
  "role" : "arn:aws:iam::aws_account_id:role/Rolename",
  "command" : {
    "name" : "glueetl",
```

```

    "scriptLocation" : "s3://foldername/scripts/my-visual-job.py",
    "pythonVersion" : "3"
  },
  "codegenConfigurationNodes" : "{\"node-nodeID\":{\"S3CsvSource\":
  {\"AdditionalOptions\":{\"EnableSamplePath\":false,\"SamplePath\":\"s3://notebook-
  test-input/netflix_titles.csv\"},\"Escaper\":\"\\\", \"Exclusions\": [], \"Name\": \"Amazon
  S3\", \"OptimizePerformance\":false, \"OutputSchemas\": [{\"Columns\": [{\"Name\":
  \"show_id\", \"Type\": \"string\"}, {\"Name\": \"type\", \"Type\": \"string\"}, {\"Name\":
  \"title\", \"Type\": \"choice\"}, {\"Name\": \"director\", \"Type\": \"string\"}, {\"Name\":
  \"cast\", \"Type\": \"string\"}, {\"Name\": \"country\", \"Type\": \"string\"}, {\"Name\":
  \"date_added\", \"Type\": \"string\"}, {\"Name\": \"release_year\", \"Type\": \"bigint\"},
  {\"Name\": \"rating\", \"Type\": \"string\"}, {\"Name\": \"duration\", \"Type\": \"string
  \"}, {\"Name\": \"listed_in\", \"Type\": \"string\"}, {\"Name\": \"description\", \"Type
  \": \"string\"}]}]}, \"Paths\": [\"s3://dalamgir-notebook-test-input/netflix_titles.csv
  \", \"QuoteChar\": \"quote\", \"Recurse\": true, \"Separator\": \"comma\", \"WithHeader
  \": true}}}"
}

```

For script jobs:

- you need a folder, a JSON file of the job definition, and the script
- the folder and JSON file should match the job name. The script name needs to match the `scriptLocation` in the job definition along with the file extension

For example, in the job definition below, the branch in your repository should contain a path `my-script-job/my-script-job.json` and `my-script-job/my-script-job.py`. The script name should match the name in the `scriptLocation` including the extension of the script

```

{
  "name" : "my-script-job",
  "description" : "",
  "role" : "arn:aws:iam::aws_account_id:role/Rolename",
  "command" : {
    "name" : "glueetl",
    "scriptLocation" : "s3://foldername/scripts/my-script-job.py",
    "pythonVersion" : "3"
  }
}

```

Limitations

- Amazon Glue currently does not support pushing/pulling from [GitLab-Groups](#).

Connecting version control repositories with Amazon Glue

You can enter your version control repository details and manage them in the **Version Control** tab in the Amazon Glue Studio job editor. To integrate with your Git repository, you must connect to your repository every time you log in to Amazon Glue Studio.

To connect a Git version control system:

1. In Amazon Glue Studio, start a new job and choose the **Version Control** tab.

Untitled job 

Visual | Script | Job details | Runs | Schedules | **Version Control**

 Your job has not been committed to version control. If you wish to do so, choose the **Push to repository** option from the **Actions** dropdown.

Version control configuration Reset

Configure the version control system you want to associate with your job.

Version control system
Choose a version control system.

None 

2. In **Version control system**, choose the Git Service from the available options by clicking on the drop-down menu.
 - Amazon CodeCommit
 - GitHub
 - GitLab
 - Bitbucket

3. Depending on the Git version control system you choose, you will have different fields to complete.

For Amazon CodeCommit:

Complete the repository configuration by selecting the repository and branch for your job:

- **Repository** — if you have set up repositories in Amazon CodeCommit, select the repository from the drop-down menu. Your repositories will automatically populate in the list
- **Branch** — select the branch from the drop-down menu
- **Folder** — *optional* - enter the name of the folder in which to save your job. If left empty, a folder is automatically created. The folder name defaults to the job name

For GitHub:

Complete the GitHub configuration by completing the fields:

- **Personal access token** — this is the token provided by the GitHub repository. For more information on personal access tokens, see [GitHub Docs](#)
- **Repository owner** — this is the owner of the GitHub repository.

Complete the repository configuration by selecting the repository and branch from GitHub.

- **Repository** — if you have set up repositories in GitHub, select the repository from the drop-down menu. Your repositories will automatically populate in the list
- **Branch** — select the branch from the drop-down menu
- **Folder** — *optional* - enter the name of the folder in which to save your job. If left empty, a folder is automatically created. The folder name defaults to the job name

For GitLab:

Note

Amazon Glue currently does not support pushing/pulling from [GitLab-Groups](#).

- **Personal access token** — this is the token provided by the GitLab repository. For more information on personal access tokens, see [GitLab Personal access tokens](#)
- **Repository owner** — this is the owner of the GitLab repository.

Complete the repository configuration by selecting the repository and branch from GitLab.

- **Repository** — if you have set up repositories in GitLab, select the repository from the drop-down menu. Your repositories will automatically populate in the list
- **Branch** — select the branch from the drop-down menu
- **Folder** — *optional* - enter the name of the folder in which to save your job. If left empty, a folder is automatically created. The folder name defaults to the job name

For Bitbucket:

- **App password** — Bitbucket uses App passwords and not Repository Access Tokens. For more information on App passwords, see [App passwords](#).
- **Repository owner** — this is the owner of the Bitbucket repository. In Bitbucket, the owner is the creator of the repository.

Complete the repository configuration by selecting the workspace, repository, branch, and folder from Bitbucket.

- **Workspace** – if you have workspaces set up in Bitbucket, select the workspace from the drop-down menu. Your workspaces are automatically populated
- **Repository** — if you have set up repositories in Bitbucket, select the repository from the drop-down menu. Your repositories are automatically populated
- **Branch** — select the branch from the drop-down menu. Your branches are automatically populated
- **Folder** — *optional* - enter the name of the folder in which to save your job. If left empty, a folder is automatically created with the job name.

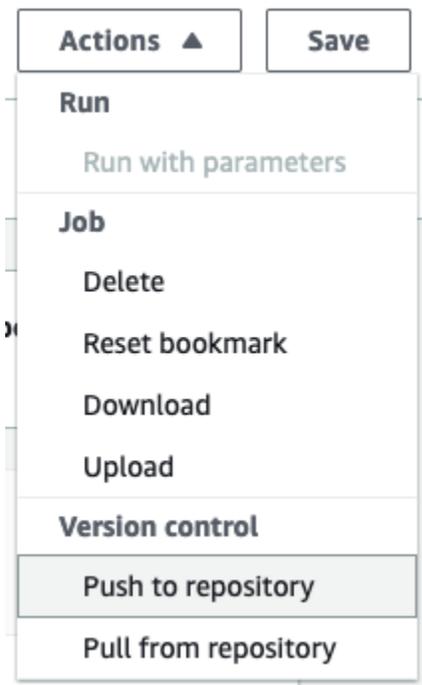

4. Choose **Save** at the top of the Amazon Glue Studio job

Pushing Amazon Glue jobs to the source repository

Once you've entered the details of your version control system, you can edit jobs in Amazon Glue Studio and push the jobs to your source repository. If you're unfamiliar with Git concepts such as pushing and pulling, see this tutorial on [Getting started with Git and Amazon CodeCommit](#).

In order to push your job to a repository, you need to enter the details of your version control system and save your job.

1. In the Amazon Glue Studio job, choose **Actions**. This will open additional menu options.

2. Choose **Push to repository**.

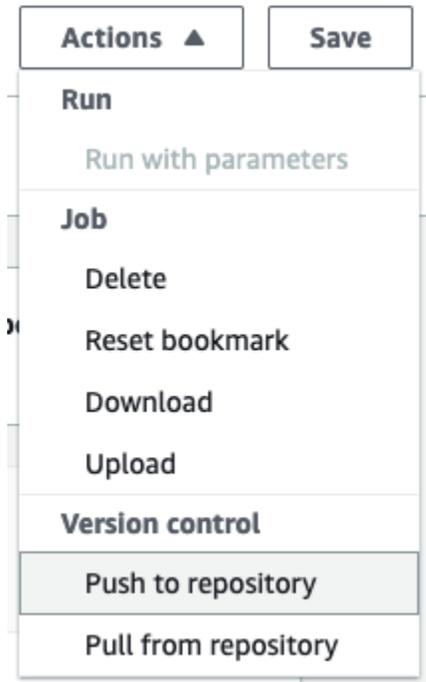

This action will save the job. When you push to repository, Amazon Glue Studio pushes the last saved change. If the job in the repository was modified by you or another user and is out of sync with the job in Amazon Glue Studio, the job in the repository is overwritten with the job saved in Amazon Glue Studio when you push the job from Amazon Glue Studio.

3. Choose **Confirm** to complete the action. This creates a new commit in the repository. If you are using Amazon CodeCommit, a confirmation message will display a link to the latest commit on Amazon CodeCommit.

Pulling Amazon Glue jobs from the source repository

Once you've entered details of your Git repository into the **Version control** tab, you can also pull jobs from your repository and edit them in Amazon Glue Studio.

1. In the Amazon Glue Studio job, choose **Actions**. This will open additional menu options.

2. Choose **Pull from repository**.
3. Choose **Confirm**. This takes the latest commit from the repository and updates your job in Amazon Glue Studio.
4. Edit your job in Amazon Glue Studio. If you make changes, you can sync your job to your repository by choosing **Push to repository** from the **Actions** drop-down menu.

Authoring code with Amazon Glue Studio notebooks

Data engineers can author Amazon Glue jobs faster and more easily than before using the interactive notebook interface in Amazon Glue Studio or interactive sessions in Amazon Glue.

Limitations

- Amazon Glue Studio notebooks do not support Scala.

Topics

- [Overview of using notebooks](#)
- [Creating an ETL job using notebooks in Amazon Glue Studio](#)
- [Notebook editor components](#)
- [Saving your notebook and job script](#)
- [Managing notebook sessions](#)
- [Using Amazon Q Developer with Amazon Glue Studio notebooks](#)

Overview of using notebooks

Amazon Glue Studio allows you to interactively author jobs in a notebook interface based on Jupyter Notebooks. Through notebooks in Amazon Glue Studio, you can edit job scripts and view the output without having to run a full job, and you can edit data integration code and view the output without having to run a full job, and you can add markdown and save notebooks as .ipynb files and job scripts. You can start a notebook without installing software locally or managing servers. When you are satisfied with your code, Amazon Glue Studio can convert your notebook to a Glue job with the click of a button.

Some benefits of using notebooks include:

- No cluster to provision or manage
- No idle clusters to pay for
- No up-front configuration required
- No installation of Jupyter notebooks required
- The same runtime/platform as Amazon Glue ETL

When you start a notebook through Amazon Glue Studio, all the configuration steps are done for you so that you can explore your data and start developing your job script after only a few seconds. Amazon Glue Studio configures a Jupyter notebook with the Amazon Glue Jupyter kernel. You don't have to configure VPCs, network connections, or development endpoints to use this notebook.

To create jobs using the notebook interface:

- configure the necessary IAM permissions.

- start a notebook session to create a job
- write code in the cells in the notebook
- run and test the code to view the output
- save the job

After your notebook is saved, your notebook is a full Amazon Glue job. You can manage all aspects of the job, such as scheduling jobs runs, setting job parameters, and viewing the job run history right along side your notebook.

Creating an ETL job using notebooks in Amazon Glue Studio

To start using notebooks in the Amazon Glue Studio console

1. Attach Amazon Identity and Access Management policies to the Amazon Glue Studio user and create an IAM role for your ETL job and notebook.
2. Configure additional IAM security for notebooks, as described in [Granting permissions for the IAM role](#).
3. Open the Amazon Glue Studio console at <https://console.amazonaws.cn/gluestudio/>.

Note

Check that your browser does not block third-party cookies. Any browser that blocks third party cookies either by default or as a user-enabled setting will prevent notebooks from launching. For more information on managing cookies, see:

- [Chrome](#)
 - [Firefox](#)
 - [Safari](#)
4. Choose the **Jobs** link in the left-side navigation menu.
 5. Choose **Jupyter notebook** and then choose **Create** to start a new notebook session.
 6. On the **Create job in Jupyter notebook** page, provide the job name, and choose the IAM role to use. Choose **Create job**.

After a short time period, the notebook editor appears.

7. After you add the code you must execute the cell to initiate a session. There are multiple ways to execute the cell:
 - Press the play button.
 - Use a keyboard shortcut:
 - On MacOS, **Command + Enter** to run the cell.
 - On Windows, **Shift + Enter** to run the cell.

For information about writing code using a Jupyter notebook interface, see [The Jupyter Notebook User Documentation](#) .

8. To test your script, run the entire script, or individual cells. Any command output will be displayed in the area beneath the cell.
9. After you have finished developing your notebook, you can save the job and then run it. You can find the script in the **Script** tab. Any magics you added to the notebook will be stripped away and won't be saved as part of the script of the generated Amazon Glue job. Amazon Glue Studio will auto-add a `job.commit()` to the end of your generated script from the notebook contents.

For more information about running jobs, see [Start a job run](#).

Notebook editor components

The notebook editor interface has the following main sections.

- Notebook interface (main panel) and toolbar
- Job editing tabs

The notebook editor

The Amazon Glue Studio notebook editor is based on the Jupyter Notebook Application. The Amazon Glue Studio notebook interface is similar to that provided by Jupyter Notebooks, which is described in the section [Notebook user interface](#) . The notebook used by interactive sessions is a Jupyter Notebook.

Although the Amazon Glue Studio notebook is similar to Jupyter Notebooks, it differs in a few key ways:

- currently, the Amazon Glue Studio notebook cannot install extensions
- you cannot use multiple tabs; there is a 1:1 relationship between a job and a notebook
- the Amazon Glue Studio notebook does not have the same top file menu that exists in Jupyter Notebooks
- currently, the Amazon Glue Studio notebook only runs with the Amazon Glue kernel. Note that you cannot update the kernel on your own.

Amazon Glue Studio job editing tabs

The tabs that you use to interact with the ETL job are at the top of the notebook page. They are similar to tabs that appear in the visual job editor of Amazon Glue Studio, and they perform the same actions.

- **Notebook** – Use this tab to view the job script using the notebook interface.
- **Job details** – Configure the environment and properties for the job runs.
- **Runs** – View information about previous runs of this job.
- **Schedules** – Configure a schedule for running your job at specific times.

Saving your notebook and job script

You can save your notebook and the job script you are creating at any time. Simply choose the **Save** button in the upper right corner, the same as if you were using the visual or script editor.

When you choose **Save**, the notebook file is saved in the default locations:

- By default, the job script is saved to the Amazon S3 location indicated in the **Job Details** tab, under **Advanced properties**, in the Job details property **Script path**. Job scripts are saved in a subfolder named **Scripts**.
- By default, the notebook file (.ipynb) is saved to the Amazon S3 location indicated in the **Job Details** tab, under **Advanced properties**, in the Job details **Script path**. Notebook files are saved in a subfolder named **Notebooks**.

Note

When you save the job, the job script contains only the code cells from the notebook. The Markdown cells and magics aren't included in the job script. However, the `.ipynb` file will contain any markdown and magics.

After you save the job, you can then run the job using the script that you created in the notebook.

Managing notebook sessions

Notebooks in Amazon Glue Studio are based on the interactive sessions feature of Amazon Glue. There is a cost for using interactive sessions. To help manage your costs, you can monitor the sessions created for your account, and configure the default settings for all sessions.

Change the default timeout for all notebook sessions

By default, the provisioned Amazon Glue Studio notebook times out after 12 hours if the notebook was launched and no cells have been executed. There is no cost associated to it and the timeout is not configurable.

Once you execute a cell this will start an interactive session. This session has a default timeout of 48 hours. This timeout can be configured by passing an `%idle_timeout` magic before executing a cell.

To modify the default session timeout for notebooks in Amazon Glue Studio

1. In the notebook, enter the `%idle_timeout` magic in a cell and specify the timeout value in minutes.
2. For example: `%idle_timeout 15` will change the default timeout to 15 minutes. If the session is not used in 15 minutes, the session is automatically stopped.

Installing additional Python modules

If you would like to install additional modules to your session using pip you can do so by using `%additional_python_modules` to add them to your session:

```
%additional_python_modules awswrangler, s3://amzn-s3-demo-bucket/mymodule.whl
```

All arguments to `additional_python_modules` are passed to `pip3 install -m <>`

For a list of available Python modules, see [Using Python libraries with Amazon Glue](#).

Changing Amazon Glue Configuration

You can use magics to control Amazon Glue job configuration values. If you want to change a job configuration value you have to use the proper magic in the notebook. See [Magics supported by Amazon Glue interactive sessions for Jupyter](#).

Note

Overriding properties for a running session is no longer available. In order to change the session's configurations, you can stop the session, set the new configurations and then start a new session.

Amazon Glue supports various worker types. You can set the worker type with `%worker_type`. For example: `%worker_type G.2X`. Available worker types include G.1X, G.2X, G.4X, G.8X, G.12X, G.16X, R.1X, R.2X, R.4X, and R.8X. The default is G.1X.

You can also specify the Number of workers with `%number_of_workers`. For example, to specify 40 workers: `%number_of_workers 40`.

For more information see [Defining Job Properties](#)

Stop a notebook session

To stop a notebook session, use the magic `%stop_session`.

If you navigate away from the notebook in the Amazon console, you will receive a warning message where you can choose to stop the session.

Using Amazon Q Developer with Amazon Glue Studio notebooks

Amazon Glue Studio allows you to interactively author jobs in a notebook interface based on Jupyter Notebooks. Using Amazon Q Developer improves the authoring experience within Amazon Glue Studio notebooks.

The Amazon Q Developer extension supports writing code by generating code recommendations and suggesting improvements related to code issues. Amazon Q Developer supports both Python and Scala, the two languages used for coding ETL scripts for Spark jobs in Amazon Glue Studio notebooks.

What is Amazon Q Developer?

Amazon Q Developer is a service powered by machine learning that helps improve developer productivity. Amazon Q Developer achieves this by generating code recommendations based on developers' comments in natural language and their code in the IDE. The service integrates with JupyterLab, Amazon SageMaker AI Studio, Amazon SageMaker AI notebook instances, and other integrated development environments (IDEs).

For more information, see [Using Amazon Q Developer with Amazon Glue Studio](#).

Amazon Glue job run statuses on the console

You can view the status of an Amazon Glue extract, transform, and load (ETL) job while it is running or after it has stopped. You can view the status using the Amazon Glue console.

Accessing the job monitoring dashboard

You access the job monitoring dashboard by choosing the **Job run monitoring** link in the Amazon Glue navigation pane under **ETL jobs**.

Overview of the job monitoring dashboard

The job monitoring dashboard provides an overall summary of the job runs, with totals for the jobs with a status of **Running**, **Canceled**, **Success**, or **Failed**. Additional tiles provide the overall job run success rate, the estimated DPU usage for jobs, a breakdown of the job status counts by job type, worker type, and by day.

The graphs in the tiles are interactive. You can choose any block in a graph to run a filter that displays only those jobs in the **Job runs** table at the bottom of the page.

You can change the date range for the information displayed on this page by using the **Date range** selector. When you change the date range, the information tiles adjust to show the values for the specified number of days before the current date. You can also use a specific date range if you choose **Custom** from the date range selector.

Job runs view

Note

Job run history is accessible for 90 days for your workflow and job run.

The **Job runs** resource list shows the jobs for the specified date range and filters.

You can filter the jobs on additional criteria, such as status, worker type, job type, and the job name. In the filter box at the top of the table, you can enter the text to use as a filter. The table results are updated with rows that contain matching text as you enter the text.

You can view a subset of the jobs by choosing elements from the graphs on the job monitoring dashboard. For example, if you choose the number of running jobs in the **Job runs summary** tile, then the **Job runs** list displays only the jobs that currently have a status of Running. If you choose one of the bars in the **Worker type breakdown** bar chart, then only job runs with the matching worker type and status are shown in the **Job runs** list.

The **Job runs** resource list displays the details for the job runs. You can sort the rows in the table by choosing a column heading. The table contains the following information:

Property	Description
Job name	The name of the job.
Type	The type of job environment: <ul style="list-style-type: none"> • Glue ETL: Runs in an Apache Spark environment managed by Amazon Glue. • Glue Streaming: Runs in an Apache Spark environment and performs ETL on data streams. • Python shell: Runs Python scripts as a shell.
Start time	The date and time at which this job run was started.
End time	The date and time that this job run completed.

Property	Description
Run status	<p>The current state of the job run. Values can be:</p> <ul style="list-style-type: none">• STARTING• RUNNING• STOPPING• STOPPED• SUCCEEDED• FAILED• TIMEOUT
Run time	<p>The amount of time that the job run consumed resources.</p>
Capacity	<p>The number of Amazon Glue data processing units (DPUs) that were allocated for this job run. For more information about capacity planning, see Monitoring for DPU Capacity Planning in the <i>Amazon Glue Developer Guide</i>.</p>

Property	Description
Worker type	<p>The type of predefined worker that was allocated when the job ran. Values can be G.1X, G.2X, G.4X or G.8X.</p> <ul style="list-style-type: none">• G.1X – When you choose this type, you also provide a value for Number of workers. Each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 84GB disk (approximately 34GB free). We recommend this worker type for memory-intensive jobs. This is the default Worker type for Amazon Glue Version 2.0 or later jobs.• G.2X – When you choose this type, you also provide a value for Number of workers. Each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 128GB disk (approximately 77GB free). We recommend this worker type for memory-intensive jobs and jobs that run machine learning transforms.• G.4X – When you choose this type, you also provide a value for Number of workers. Each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 235GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for Amazon Glue version 3.0 or later Spark ETL jobs in the following Amazon Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central),

Property	Description
	<p>Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).</p> <ul style="list-style-type: none"> • G.8X – When you choose this type, you also provide a value for Number of workers. Each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 487GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for Amazon Glue version 3.0 or later Spark ETL jobs, in the same Amazon Regions as supported for the G.4X worker type.
DPU hours	<p>The estimated number of DPUs used for the job run. A DPU is a relative measure of processing power. DPUs are used to determine the cost of running your job. For more information, see the Amazon Glue pricing page.</p>

You can choose any job run in the list and view additional information. Choose a job run, and then do one of the following:

- Choose the **Actions** menu and the **View job** option to view the job in the visual editor.
- Choose the **Actions** menu and the **Stop run** option to stop the current run of the job.
- Choose the **View CloudWatch logs** button to view the job run logs for that job.
- Choose **View details** to view the job run details page.

Viewing the job run logs

You can view the job logs in a variety of ways:

- On the **Monitoring** page, in the **Job runs** table, choose a job run, and then choose **View CloudWatch logs**.
- In the visual job editor, on the **Runs** tab for a job, choose the hyperlinks to view the logs:
 - **Logs** – Links to the Apache Spark job logs written when continuous logging is enabled for a job run. When you choose this link, it takes you to the Amazon CloudWatch logs in the `/aws-glue/jobs/logs-v2` log group. By default, the logs exclude non-useful Apache Hadoop YARN heartbeat and Apache Spark driver or executor log messages. For more information about continuous logging, see [Continuous Logging for Amazon Glue Jobs](#) in the *Amazon Glue Developer Guide*.
 - **Error logs** – Links to the logs written to `stderr` for this job run. When you choose this link, it takes you to the Amazon CloudWatch logs in the `/aws-glue/jobs/error` log group. You can use these logs to view details about any errors that were encountered during the job run.
 - **Output logs** – Links to the logs written to `stdout` for this job run. When you choose this link, it takes you to the Amazon CloudWatch logs in the `/aws-glue/jobs/output` log group. You can use these logs to see all the details about the tables that were created in the Amazon Glue Data Catalog and any errors that were encountered.

Viewing the details of a job run

You can choose a job in the **Job runs** list on the **Monitoring** page, and then choose **View run details** to see detailed information for that run of the job.

The information displayed on the job run detail page includes:

Property	Description
Job name	The name of the job.
Run Status	The current state of the job run. Values can be: <ul style="list-style-type: none"> • STARTING • RUNNING • STOPPING • STOPPED • SUCCEEDED • FAILED

Property	Description
	<ul style="list-style-type: none"> TIMEOUT
Glue version	The Amazon Glue version used by the job run.
Recent attempt	The number of automatic retry attempts for this job run.
Start time	The date and time at which this job run was started.
End time	The date and time that this job run completed.
Start-up time	The amount of time spent preparing to run the job.
Execution time	The amount of time spent running the job script.
Trigger name	The name of the trigger associated with the job.
Last modified on	The date when the job was last modified.
Security configuration	The security configuration for the job, which includes Amazon S3 encryption, CloudWatch encryption, and job bookmarks encryption settings.
Timeout	The job run timeout threshold value.
Allocated capacity	The number of Amazon Glue data processing units (DPUs) that were allocated for this job run. For more information about capacity planning, see Monitoring for DPU Capacity Planning in the <i>Amazon Glue Developer Guide</i> .
Max capacity	The maximum capacity available to the job run.

Property	Description
Number of workers	The number of workers used for the job run.
Worker type	<p>The type of predefined workers allocated for the job run. Values can be G.1X or G.2X.</p> <ul style="list-style-type: none"> • G.1X – When you choose this type, you also provide a value for Number of workers. Each worker maps to 1 DPU (4 vCPUs, 16 GB of memory, 64 GB disk), and provides 1 executor per worker. We recommend this worker type for memory-intensive jobs. This is the default Worker type for Amazon Glue Version 2.0 or later jobs. • G.2X – When you choose this type, you also provide a value for Number of workers. Each worker maps to 2 DPUs (8 vCPUs, 32 GB of memory, 128 GB disk), and provides 1 executor per worker. We recommend this worker type for memory-intensive jobs and jobs that run machine learning transforms.
Logs	A link to the job logs for continuous logging (<code>/aws-glue/jobs/logs-v2</code>).
Output Logs	A link to the job output log files (<code>/aws-glue/jobs/output</code>).
Error logs	A link to the job error log files (<code>/aws-glue/jobs/error</code>).

You can also view the following additional items, which are available when you view information for recent job runs. For more information, see [the section called “View information for recent job runs”](#).

- **Input arguments**

- **Continuous logs**
- **Metrics** – You can see visualizations of basic metrics. For more information on included metrics, see [the section called “Viewing Amazon CloudWatch metrics for a Spark job run”](#).
- **Spark UI** – You can visualize Spark logs for your job in the Spark UI. For more information about using the Spark Web UI, see [the section called “Monitoring with the Spark UI”](#). Enable this feature by following the procedure in [the section called “Enabling the Spark UI for jobs”](#).

Viewing Amazon CloudWatch metrics for a Spark job run

On the details page for a job run, below the **Run details** section, you can view the job metrics. Amazon Glue Studio sends job metrics to Amazon CloudWatch for every job run.

Amazon Glue reports metrics to Amazon CloudWatch every 30 seconds. The Amazon Glue metrics represent delta values from the previously reported values. Where appropriate, metrics dashboards aggregate (sum) the 30-second values to obtain a value for the entire last minute. However, the Apache Spark metrics that Amazon Glue passes on to Amazon CloudWatch are generally absolute values that represent the current state at the time they are reported.

Note

You must configure your account to access Amazon CloudWatch, .

The metrics provide information about your job run, such as:

- **ETL Data Movement** – The number of bytes read from or written to Amazon S3.
- **Memory Profile: Heap used** – The number of memory bytes used by the Java virtual machine (JVM) heap.
- **Memory Profile: heap usage** – The fraction of memory (scale: 0–1), shown as a percentage, used by the JVM heap.
- **CPU Load** – The fraction of CPU system load used (scale: 0–1), shown as a percentage.

Viewing Amazon CloudWatch metrics for a Ray job run

On the details page for a job run, below the **Run details** section, you can view the job metrics. Amazon Glue Studio sends job metrics to Amazon CloudWatch for every job run.

Amazon Glue reports metrics to Amazon CloudWatch every 30 seconds. The Amazon Glue metrics represent delta values from the previously reported values. Where appropriate, metrics dashboards aggregate (sum) the 30-second values to obtain a value for the entire last minute. However, the Apache Spark metrics that Amazon Glue passes on to Amazon CloudWatch are generally absolute values that represent the current state at the time they are reported.

Note

You must configure your account to access Amazon CloudWatch, as described in .

In Ray jobs, you can view the following aggregated metric graphs. With these, you can build a profile of your cluster and tasks, and can access detailed information about each node. The time-series data that back these graphs is available in CloudWatch for further analysis.

Task Profile: Task State

Shows the number of Ray tasks in the system. Each task lifecycle is given its own time series.

Task Profile: Task Name

Shows the number of Ray tasks in the system. Only pending and active tasks are shown. Each type of task (by name) is given its own time series.

Cluster Profile: CPUs in use

Shows the number of CPU cores that are used. Each node is given its own time series. Nodes are identified by IP addresses, which are ephemeral and only used for identification.

Cluster Profile: Object store memory use

Shows memory use by the Ray object cache. Each memory location (physical memory, cached on disk, and spilled in Amazon S3) is given its own time series. The object store manages data storage across all nodes in the cluster. For more information, see [Objects](#) in the Ray documentation.

Cluster Profile: Node count

Shows the number of nodes provisioned for the cluster.

Node Detail: CPU use

Shows CPU utilization on each node as a percentage. Each series shows an aggregated percentage of CPU usage across all cores on the node.

Node Detail: Memory use

Shows memory use on each node in GB. Each series shows memory aggregated between all processes on the node, including Ray tasks and the Plasma store process. This will not reflect objects stored to disk or spilled to Amazon S3.

Node Detail: Disk use

Shows disk use on each node in GB.

Node Detail: Disk I/O speed

Shows disk I/O on each node in KB/s.

Node Detail: Network I/O throughput

Shows network I/O on each node in KB/s.

Node Detail: CPU use by Ray component

Shows CPU use in fractions of a core. Each ray component on each node is given its own time series.

Node Detail: Memory use by Ray component

Shows memory use in GiB. Each ray component on each node is given its own time series.

Detect and process sensitive data

The Detect PII transform identifies Personal Identifiable Information (PII) in your data source. You choose the PII entity to identify, how you want the data to be scanned, and what to do with the PII entity that have been identified by the Detect PII transform.

The Detect PII transform provides the ability to detect, mask, or remove entities that you define, or are pre-defined by Amazon. This enables you to increase compliance and reduce liability. For example, you may want to ensure that no personally identifiable information exists in your data that can be read and want to mask social security numbers with a fixed string (such as xxx-xx-xxxx), phone numbers, or addresses.

To work with sensitive data outside of Amazon Glue Studio, see [Using Sensitive Data Detection outside Amazon Glue Studio](#)

Topics

- [Choosing how you want the data to be scanned](#)

- [Choosing the PII entities to detect](#)
- [Specifying the level of detection sensitivity](#)
- [Choosing what to do with identified PII data](#)
- [Adding fine-grained action overrides](#)

Choosing how you want the data to be scanned

When you scan your dataset for sensitive data like personally identifiable information (PII), you can choose to detect PII in each row or detect the columns that contain PII data.

<input type="radio"/> Detect PII in each cell Scan the entire data set, and act on each occurrence individually.	<input checked="" type="radio"/> Detect fields containing PII To reduce costs and improve performance, sample only a portion of the data and act on fields across all records.
--	--

Sample portion

The percentage of rows to sample out of the entire data set.

 %

Between 1 and 100.

Detection threshold

To consider a field as containing PII, set the minimum percentage of detected rows out of the sampled rows.

 %

Between 1 and 100.

When you choose **Detect PII in each cell**, you're choosing to scan all rows in the data source. This is a comprehensive scan to ensure that PII entities are identified.

When you choose **Detect fields containing PII**, you're choosing to scan a sample of rows for PII entities. This is a way to keep costs and resources low while also identifying the fields where PII entities are found.

When you choose to detect fields that contain PII, you can reduce costs and improve performance by sampling a portion of rows. Choosing this option will allow you to specify additional options:

- **Sample portion:** This allows you to specify the percentage of rows to sample. For example, if you enter '50', you're specifying that you want 50 percent of scanned rows for the PII entity.

- **Detection threshold:** This allows you to specify the percentage of rows that contain the PII entity in order for the entire column to be identified as having the PII entity. For example, if you enter '10', you're specifying that the number of the PII entity, US Phone, in the rows that are scanned must be 10 percent or greater in order for the field to be identified as having the PII entity, US Phone. If the percentage of rows that contain the PII entity is less than 10 percent, that field will not be labeled as having the PII entity, US Phone, in it.

Choosing the PII entities to detect

If you chose **Detect PII in each cell**, you can choose from one of three options:

- All available PII patterns - this includes Amazon entities.
- Select categories - when you select categories, PII patterns will automatically include patterns in the categories that you select.
- Select specific patterns - Only the patterns that you select will be detected.

For a full list of managed sensitive data types, see [Managed data types](#).

Choose from all available PII patterns

If you choose **All available PII patterns**, select entities pre-defined by Amazon. You can select one, more than one, or all entities.

Select entities to detect

Available entities (19)

Select all

All categories ▼

< 1 >

<input type="checkbox"/>	Entity name ▼	Category ▲
<input type="checkbox"/>	Person's name	Universal, HIPAA
<input type="checkbox"/>	Email (General)	Universal
<input type="checkbox"/>	Credit Card	Universal
<input type="checkbox"/>	IP Address	Networking
<input type="checkbox"/>	MAC Address	Networking
<input type="checkbox"/>	US Phone	United States, HIPAA
<input type="checkbox"/>	US Passport	United States
<input type="checkbox"/>	Social Security Number (SSN)	United States, HIPAA
<input type="checkbox"/>	US Individual Taxpayer Identification Number (ITIN)	United States, HIPAA
<input type="checkbox"/>	US/Canada bank account	United States, HIPAA
<input type="checkbox"/>	US driving license	HIPAA
<input type="checkbox"/>	Healthcare Common Procedure Coding System (HCPCS) code	HIPAA
<input type="checkbox"/>	National Drug Code (NDC)	HIPAA
<input type="checkbox"/>	National Provider Identifier (NPI)	HIPAA
<input type="checkbox"/>	Drug Enforcement Agency (DEA) Registration Number	HIPAA
<input type="checkbox"/>	Health Insurance Claim Number (HICN)	HIPAA
<input type="checkbox"/>	Medicare Beneficiary Identifier	HIPAA

Select categories

If you chose **Select categories** as the PII patterns to detect, you can select from the options in the drop-down menu. Note that some entities can belong to more than one category. For example, *Person's name* is an entity that belongs to the *Universal* and *HIPAA* categories.

- Universal (examples: Email, Credit Card)
- HIPAA (examples: US Driving License, Healthcare Common Procedure Coding System (HCPCS) code)
- Networking (examples: IP Address, MAC Address)
- Argentina
- Australia
- Austria
- Belgium
- Bosnia
- Bulgaria
- Canada
- Chile
- Colombia
- Croatia
- Cyprus
- Czechia
- Denmark
- Estonia
- Finland
- France
- Germany
- Greece
- Hungary
- Ireland
- Korea
- Japan

- Mexico
- Netherlands
- New Zealand
- Norway
- Portugal
- Romania
- Singapore
- Slovakia
- Slovenia
- Spain
- Sweden
- Switzerland
- Turkey
- Ukraine
- United States
- United Kingdom
- Venezuela

Select specific patterns

If you choose **Select specific patterns** as the PII patterns to detect, you can search or browse from a list of patterns you've already created, or create a new detection entity pattern.

The steps below describe how to create a new custom pattern for detecting sensitive data. You will create the custom pattern by entering a name for the custom pattern, add a regular expression, and optionally, define context words.

1. To create a new pattern, click the **Create new** button.

Select patterns

2. In the Create detection entity page, enter the entity name and a regular expression. The regular expression (Regex) is what Amazon Glue will use to match entities.
3. Click **Validate**. If the validation is successful, you will see a confirmation message stating that the string is a valid regular expression. If the validation is not successful, you will see a message stating that the string does not conform to proper formatting and accepted character literals, operators or constructs.
4. You can choose to add Context words in addition to the regular expression. Context words may increase the likelihood of a match. These can be useful in cases where field names are not descriptive of the entity. For example, social security numbers may be named 'SSN' or 'SS'. Adding these context words can help match the entity.
5. Click **Create** to create the detection entity. Any created entities are visible in the Amazon Glue Studio console. Click on **Detection entities** in the left-hand navigation menu.

You can edit, delete, or create detection entities from the **Detection entities** page. You can also search for a pattern using the search field.

Specifying the level of detection sensitivity

You can set the level of sensitivity when using detecting sensitive data.

- **High** – (Default) Detects more entities for use cases that require a higher level of sensitivity. All Amazon Glue jobs created after November 2023 are automatically opted-in to this setting.
- **Low** – Detects fewer entities and reduces false positives.

Select global detection sensitivity

Choose the level of detection sensitivity to apply to your data set.

- High (default)**
Detects more entities for use cases that require a higher level of sensitivity.
- Low**
Detects fewer entities and reduces false positives.

Choosing what to do with identified PII data

If you chose to detect PII in the entire data source, you can select a global action to apply:

- **Enrich data with detection results:** If you chose Detect PII in each cell, you can store the detected entities into a new column.
- **Redact detected text:** You can replace the detected PII value with a string that you specify in the optional Replacing text input field. If no string is specified, the detected PII entity is replaced with '*****'.
- **Partially redact detected text:** You can replace part of the detected PII value with a string you choose. There are two possible options: to either leave the ends unmasked or to mask by providing an explicit regex pattern. This feature is not available in Amazon Glue 2.0.
- **Apply cryptographic hash:** You can pass the detected PII value to a SHA-256 cryptographic hash function and replace the value with the function's output.

Select global action (required)

Choose an action to take on detected entities.

- DETECT. Enrich data with detection results.**
Create a new column that will contain any entity type detected in that row.
- REDACT. Redact detected text.**
Replace detected entity with a string you choose.
- PARTIAL_REDACT. Partially redact detected text.**
Replace part of a detected entity with a string you choose.
- SHA256_HASH. Apply cryptographic hash.**
Apply a SHA-256 cryptographic hash function to the input string.

Differences between Amazon Glue versions 2.0 and 3.0+

Amazon Glue 2.0 jobs will return a new DataFrame with the detected PII information for each column in a supplementary column. Any redaction or hash work is visible within the Amazon Glue script in the visual tab.

Amazon Glue 3.0 and 4.0 jobs will return a new DataFrame with this same supplementary column. A new key for "actionUsed" is present and can be one of DETECT, REDACT, PARTIAL_REDACT, or SHA256_HASH. If a masking action is selected, the DataFrame will return data with sensitive data masked.

Adding fine-grained action overrides

Additional detection and action settings can be added to the fine-grained actions overrides table. This allows you to:

- **Include or exclude certain columns from detection** – An inferred schema on the data source will populate the table with available columns.
- **Specify specific settings that are more fine-grained than using global actions** – For example, you can specify different redaction text settings for different entity types.
- **Specify a different action than the global action** – If a different action wants to be applied on a different sensitive data type, that can be done here. Note that two different edit-in-place actions (redaction and hashing) cannot be used on the same column, but detect can always be used.

Fine grained actions (overrides) (0)

Select entities to add a fine grained action different from the global action above.

< 1 >

<input type="checkbox"/>	Entity type ▲	Action ▼	Action options	Columns
No overrides				

Managing ETL jobs with Amazon Glue Studio

You can use the simple graphical interface in Amazon Glue Studio to manage your ETL jobs. Using the navigation menu, choose **Jobs** to view the **Jobs** page. On this page, you can see all the jobs that you have created either with Amazon Glue Studio or the Amazon Glue console. You can view, manage, and run your jobs on this page.

You can also perform the following tasks on this page:

- [Start a job run](#)
- [Schedule job runs](#)
- [Manage job schedules](#)
- [Stop job runs](#)
- [View your jobs](#)
- [View information for recent job runs](#)

- [View the job script](#)
- [Modify the job properties](#)
- [Save the job](#)
- [Clone a job](#)
- [Delete jobs](#)

Start a job run

In Amazon Glue Studio, you can run your jobs on demand. A job can run multiple times, and each time you run the job, Amazon Glue collects information about the job activities and performance. This information is referred to as a *job run* and is identified by a job run ID.

You can initiate a job run in the following ways in Amazon Glue Studio:

- On the **Jobs** page, choose the job you want to start, and then choose the **Run job** button.
- If you're viewing a job in the visual editor and the job has been saved, you can choose the **Run** button to start a job run.

For more information about job runs, see [Working with Jobs on the Amazon Glue Console](#) in the *Amazon Glue Developer Guide*.

Schedule job runs

In Amazon Glue Studio, you can create a schedule to have your jobs run at specific times. You can specify constraints, such as the number of times that the jobs run, which days of the week they run, and at what time. These constraints are based on `cron` and have the same limitations as `cron`. For example, if you choose to run your job on day 31 of each month, keep in mind that some months don't have 31 days. For more information about `cron`, see [Cron Expressions](#) in the *Amazon Glue Developer Guide*.

To run jobs according to a schedule

1. Create a job schedule using one of the following methods:
 - On the **Jobs** page, choose the job you want to create a schedule for, choose **Actions**, and then choose **Schedule job**.

- If you're viewing a job in the visual editor and the job has been saved, choose the **Schedules** tab. Then choose **Create Schedule**.
2. On the **Schedule job run** page, enter the following information:
 - **Name:** Enter a name for your job schedule.
 - **Frequency:** Enter the frequency for the job schedule. You can choose the following:
 - **Hourly:** The job will run every hour, starting at a specific minute. You can specify the **Minute** of the hour that the job should run. By default, when you choose hourly, the job runs at the beginning of the hour (minute 0).
 - **Daily:** The job will run every day, starting at a time. You can specify the **Minute** of the hour that the job should run and the **Start hour** for the job. Hours are specified using a 23-hour clock, where you use the numbers 13 to 23 for the afternoon hours. The default values for minute and hour are 0, which means that if you select **Daily**, the job by default will run at midnight.
 - **Weekly:** The job will run every week on one or more days. In addition to the same settings described previous for Daily, you can choose the days of the week on which the job will run. You can choose one or more days.
 - **Monthly:** The job will run every month on a specific day. In addition to the same settings described previous for Daily, you can choose the day of the month on which the job will run. Specify the day as a numeric value from 1 to 31. If you select a day that does not exist in a month, for example the 30th day of February, then the job does not run that month.
 - **Custom:** Enter an expression for your job schedule using the cron syntax. Cron expressions allow you to create more complicated schedules, such as the last day of the month (instead of a specific day of the month) or every third month on the 7th and 21st days of the month.

See [Cron Expressions](#) in the *Amazon Glue Developer Guide*

 - **Description:** You can optionally enter a description for your job schedule. If you plan to use the same schedule for multiple jobs, having a description makes it easier to determine what the job schedule does.
 3. Choose **Create schedule** to save the job schedule.
 4. After you create the schedule, a success message appears at the top of the console page. You can choose **Job details** in this banner to view the job details. This opens the visual job editor page, with the **Schedules** tab selected.

Manage job schedules

After you have created schedules for a job, you can open the job in the visual editor and choose the **Schedules** tab to manage the schedules.

On the **Schedules** tab of the visual editor, you can perform the following tasks:

- Create a new schedule.

Choose **Create schedule**, then enter the information for your schedule as described in [the section called "Schedule job runs"](#).

- Edit an existing schedule.

Choose the schedule you want to edit, then choose **Action** followed by **Edit schedule**. When you choose to edit an existing schedule, the **Frequency** shows as **Custom**, and the schedule is displayed as a cron expression. You can either modify the cron expression, or specify a new schedule using the **Frequency** button. When you finish with your changes, choose **Update schedule**.

- Pause an active schedule.

Choose an active schedule, and then choose **Action** followed by **Pause schedule**. The schedule is instantly deactivated. Choose the refresh (reload) button to see the updated job schedule status.

- Resume a paused schedule.

Choose a deactivated schedule, and then choose **Action** followed by **Resume schedule**. The schedule is instantly activated. Choose the refresh (reload) button to see the updated job schedule status.

- Delete a schedule.

Choose the schedule you want to remove, and then choose **Action** followed by **Delete schedule**. The schedule is instantly deleted. Choose the refresh (reload) button to see the updated job schedule list. The schedule will show a status of **Deleting** until it has been completely removed.

Stop job runs

You can stop a job before it has completed its job run. You might choose this option if you know that the job isn't configured correctly, or if the job is taking too long to complete.

On the **Monitoring** page, in the **Job runs** list, choose the job that you want to stop, choose **Actions**, and then choose **Stop run**.

View your jobs

You can view all your jobs on the **Jobs** page. You can access this page by choosing **Jobs** in the navigation pane.

On the **Jobs** page, you can see all the jobs that were created in your account. The **Your jobs** list shows the job name, its type, the status of the last run of that job, and the dates on which the job was created and last modified. You can choose the name of a job to see detailed information for that job.

You can also use the Monitoring dashboard to view all your jobs. You can access the dashboard by choosing **Monitoring** in the navigation pane.

Customize the job display

You can customize how the jobs are displayed in the **Your jobs** section of the **Jobs** page. Also, you can enter text in the search text field to display only jobs with a name that contains that text.

If you choose the settings icon

in the **Your jobs** section, you can customize how Amazon Glue Studio displays the information in the table. You can choose to wrap the lines of text in the display, change the number of jobs displayed on the page, and specify which columns to display.

View information for recent job runs

A job can run multiple times as new data is added at the source location. Each time a job runs, the job run is assigned a unique ID, and information about that job run is collected. You can view this information by using the following methods:

- Choose the **Runs** tab of the visual editor to view the job run information for the currently displayed job.

On the **Runs** tab (the **Recent job runs** page), there is a card for each job run. The information displayed on the **Runs** tab includes:

- Job run ID

- Number of attempts to run this job
 - Status of the job run
 - Start and end time for the job run
 - The runtime for the job run
 - A link to the job log files
 - A link to the job error log files
 - The error returned for failed jobs
- You can select a job run to view additional information about the job, including the following:
 - **Input arguments**
 - **Continuous logs**
 - **Metrics** – You can see visualizations of basic metrics. For more information on included metrics, see [the section called “Viewing Amazon CloudWatch metrics for a Spark job run”](#).
 - **Spark UI** – You can visualize Spark logs for your job in the Spark UI. For more information about using the Spark Web UI, see [the section called “Monitoring with the Spark UI”](#). Enable this feature by following the procedure in [the section called “Enabling the Spark UI for jobs”](#).

You can select **View details** to view similar information on the job run details page. Alternatively, you can navigate to the job run details page through the **Monitoring** page. In the navigation pane, choose **Monitoring**. Scroll down to the **Job runs** list. Choose the job and then choose **View run details**. The contents are described in [Viewing the details of a job run](#).

For more information about the job logs, see [Viewing the job run logs](#).

View the job script

After you provide information for all the nodes in the job, Amazon Glue Studio generates a script that is used by the job to read the data from the source, transform the data, and write the data in the target location. If you save the job, you can view this script at any time.

To view the generated script for your job

1. Choose **Jobs** in the navigation pane.
2. On the **Jobs** page, in the **Your Jobs** list, choose the name of the job you want to review. Alternatively, you can select a job in the list, choose the **Actions** menu, and then choose **Edit job**.

3. On the visual editor page, choose the **Script** tab at the top to view the job script.

If you want to edit the job script, see [Amazon Glue programming guide](#).

Modify the job properties

The nodes in the job diagram define the actions performed by the job, but there are several properties that you can configure for the job as well. These properties determine the environment that the job runs in, the resources it uses, the threshold settings, the security settings, and more.

To customize the job run environment

1. Choose **Jobs** in the navigation pane.
2. On the **Jobs** page, in the **Your Jobs** list, choose the name of the job you want to review.
3. On the visual editor page, choose the **Job details** tab at the top of the job editing pane.
4. Modify the job properties, as needed.

For more information about the job properties, see [Defining Job Properties](#) in the *Amazon Glue Developer Guide*.

5. Expand the **Advanced properties** section if you need to specify these additional job properties:
 - **Script filename** – The name of the file that stores the job script in Amazon S3.
 - **Script path** – The Amazon S3 location where the job script is stored.
 - **Job metrics** – (Not available for Python shell jobs) Turns on the creation of Amazon CloudWatch metrics when this job runs.
 - **Continuous logging** – (Not available for Python shell jobs) Turns on continuous logging to CloudWatch, so the logs are available for viewing before the job completes.
 - **Spark UI and Spark UI logs path** – (Not available for Python shell jobs) Turns on the use of Spark UI for monitoring this job and specifies the location for the Spark UI logs.
 - **Maximum concurrency** – Sets the maximum number of concurrent runs that are allowed for this job.
 - **Temporary path** – The location of a working directory in Amazon S3 where temporary intermediate results are written when Amazon Glue runs the job script.
 - **Delay notification threshold (minutes)** – Specify a delay threshold for the job. If the job runs for a longer time than that specified by the threshold, then Amazon Glue sends a delay notification for the job to CloudWatch.

- **Security configuration and Server-side encryption** – Use these fields to choose the encryption options for the job.
 - **Use Glue Data Catalog as the Hive metastore** – Choose this option if you want to use the Amazon Glue Data Catalog as an alternative to Apache Hive Metastore.
 - **Additional network connection** – For a data source in a VPC, you can specify a connection of type `Network` to ensure your job accesses your data through the VPC.
 - **Python library path, Dependent jars path** (Not available for Python shell jobs), or **Referenced files path** – Use these fields to specify the location of additional files used by the job when it runs the script.
 - **Job Parameters** – You can add a set of key-value pairs that are passed as named parameters to the job script. In Python calls to Amazon Glue APIs, it's best to pass parameters explicitly by name. For more information about using parameters in a job script, see [Passing and Accessing Python Parameters in Amazon Glue](#) in the *Amazon Glue Developer Guide*.
 - **Tags** – You can add tags to the job to help you organize and identify them.
6. After you have modified the job properties, save the job.

Store Spark shuffle files on Amazon S3

Some ETL jobs require reading and combining information from multiple partitions, for example, when using a join transform. This operation is referred to as *shuffling*. During a shuffle, data is written to disk and transferred across the network. With Amazon Glue version 3.0, you can configure Amazon S3 as a storage location for these files. Amazon Glue provides a shuffle manager which writes and reads shuffle files to and from Amazon S3. Writing and reading shuffle files from Amazon S3 is slower (by 5%-20%) compared to local disk (or Amazon EBS which is heavily optimized for Amazon EC2). However, Amazon S3 provides unlimited storage capacity, so you don't have to worry about "No space left on device" errors when running your job.

To configure your job to use Amazon S3 for shuffle files

1. On the **Jobs** page, in the **Your Jobs** list, choose the name of the job you want to modify.
2. On the visual editor page, choose the **Job details** tab at the top of the job editing pane.

Scroll down to the **Job parameters** section.

3. Specify the following key-value pairs.
 - `--write-shuffle-files-to-s3 — true`

This is the main parameter that configures the shuffle manager in Amazon Glue to use Amazon S3 buckets for writing and reading shuffle data. By default, this parameter has a value of `false`.

- (Optional) `--write-shuffle-spills-to-s3` — `true`

This parameter allows you to offload spill files to Amazon S3 buckets, which provides additional resiliency to your Spark job in Amazon Glue. This is only required for large workloads that spill a lot of data to disk. By default, this parameter has a value of `false`.

- (Optional) `--conf spark.shuffle.glue.s3ShuffleBucket` — `S3://<shuffle-bucket>`

This parameter specifies the Amazon S3 bucket to use when writing the shuffle files. If you do not set this parameter, the location is the `shuffle-data` folder in the location specified for **Temporary path** (`--TempDir`).

Note

Make sure the location of the shuffle bucket is in the same Amazon Web Services Region in which the job runs.

Also, the shuffle service does not clean the files after the job finishes running, so you should configure the Amazon S3 storage life cycle policies on the shuffle bucket location. For more information, see [Managing your storage lifecycle](#) in the *Amazon S3 User Guide*.

Save the job

A red **Job has not been saved** callout is displayed to the left of the **Save** button until you save the job.

Job has not been saved

 Save

To save your job

1. Provide all the required information in the **Visual** and **Job details** tabs.
2. Choose the **Save** button.

After you save the job, the 'not saved' callout changes to display the time and date that the job was last saved.

If you exit Amazon Glue Studio before saving your job, the next time you sign in to Amazon Glue Studio, a notification appears. The notification indicates that there is an unsaved job, and asks if you want to restore it. If you choose to restore the job, you can continue to edit it.

Troubleshooting errors when saving a job

If you choose the **Save** button, but your job is missing some required information, then a red callout appears on the tab where the information is missing. The number in the callout indicates how many missing fields were detected.

- If a node in the visual editor isn't configured correctly, the **Visual** tab shows a red callout, and the node with the error displays a warning symbol .
 1. Choose the node. In the node details panel, a red callout appears on the tab where the missing or incorrect information is located.
 2. Choose the tab in the node details panel that shows a red callout, and then locate the problem fields, which are highlighted. An error message below the fields provides additional information about the problem.

The screenshot displays the Amazon Glue console interface for an "Untitled job". At the top right, there is a red notification "Job has not been saved" and buttons for "Save" and "Run". The navigation tabs include "Visual 2", "Script", "Job details 1", "Runs", and "Schedules". The "Job details" tab is active, showing a toolbar with "Source", "Transform", "Target", "Undo", "Redo", and "Remove" buttons. The main workspace is a grid where a "Data source - S3 bucket" node is placed, with a red warning icon. The right-hand panel shows "Data source properties - S3 2" with the following configuration:

- Output schema**
- S3 source type** [Info](#)
 - Data Catalog table
 - S3 location
Choose a file or folder in an S3 bucket.
- Database**
 - Choose a database (dropdown menu)
 -
 - Database is required.**
- Table**
 - Choose a table (dropdown menu)
 - Table is required.**
- Partition predicate - optional**
Enter a Boolean expression supported by Spark SQL, using only partition columns.
(Text input field)

- If there is a problem with the job properties, the **Job details** tab shows a red callout. Choose that tab and locate the problem fields, which are highlighted. The error messages below the fields provide additional information about the problem.

Untitled job

Visual **2** | Script | **Job details 1** | Runs | Schedules

Basic properties [Info](#)

Name

Description - optional

Descriptions can be up to 2048 characters long.

IAM Role

Role assumed by the job with permission to access your data stores. Ensure that this role has permission to your Amazon S3 sources, targets, temporary directory, scripts, and any libraries used by the job.

 IAM Role is required.

Type

The type of ETL job. This is set automatically based on the types of data sources you have selected.

Clone a job

You can use the **Clone job** action to copy an existing job into a new job.

To create a new job by copying an existing job

1. On the **Jobs** page, in the **Your jobs** list, choose the job that you want to duplicate.
2. From the **Actions** menu, choose **Clone job**.
3. Enter a name for the new job. You can then save or edit the job.

Delete jobs

You can remove jobs that are no longer needed. You can delete one or more jobs in a single operation.

To remove jobs from Amazon Glue Studio

1. On the **Jobs** page, in the **Your jobs** list, choose the jobs that you want to delete.
2. From the **Actions** menu, choose **Delete job**.
3. Verify that you want to delete the job by entering **delete**.

You can also delete a saved job when you're viewing the **Job details** tab for that job in the visual editor.

Working with jobs in Amazon Glue

The following sections provide information on ETL and Ray jobs in Amazon Glue.

Topics

- [Amazon Glue versions](#)
- [Working with Spark jobs in Amazon Glue](#)
- [Working with Ray jobs in Amazon Glue](#)
- [Configuring job properties for Python shell jobs in Amazon Glue](#)
- [Monitoring Amazon Glue](#)

Amazon Glue versions

You can configure the Amazon Glue version parameter when you add or update a job. The Amazon Glue version determines the versions of Apache Spark and Python that Amazon Glue supports. The Python version indicates the version that's supported for jobs of type Spark. The following table lists the available Amazon Glue versions, the corresponding Spark and Python versions, and other changes in functionality.

You can use the [Generative AI upgrades for Apache Spark](#) to upgrade your Glue ETL jobs from older Glue versions (≥ 2.0) to the latest Glue version.

Amazon Glue versions

Amazon Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
Amazon Glue 5.1	<ul style="list-style-type: none">• Spark 3.5.6• Python 3.11• Scala 2.12.18	Java 17	In addition to the spark engine upgrade, there are optimizations and upgrades built into this Amazon Glue release, such as:

			<p>supports a writer option (using Amazon Glue version 1.0).</p> <p>Limitations</p> <p>The following are limitations with Amazon Glue 1.0:</p> <ul style="list-style-type: none"> Amazon Glue versions 0.9 and 1.0 are not available in the Asia Pacific (Jakarta) (ap-southeast-3), Middle East (UAE) (me-central-1), or other new Regions going forward.

Amazon Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
Amazon Glue 0.9 (end of life on April 1, 2026)	<ul style="list-style-type: none"> Spark 2.2.1 Python 2.7 	N/A	<p>Jobs that were created without specifying an Amazon Glue version default to Amazon Glue 0.9.</p> <p>Limitations</p> <p>The following are limitations with Amazon Glue 0.9:</p> <ul style="list-style-type: none"> Amazon Glue versions 0.9 and 1.0 are not available in the Asia Pacific (Jakarta) (ap-southeast-3), Middle East (UAE) (me-central-1), or other new Regions going forward.

Note

The following Glue versions support these versions of PythonShell:

- PythonShell v3.6 is supported in Glue version 1.0.
- PythonShell v3.9 is supported in Glue version 3.0.

Additionally, dev endpoints are supported only in Glue version 1.0, and 0.9.

Amazon Glue version support policy

Amazon Glue is a serverless data integration service that makes it easy to discover, prepare, and combine data for analytics, machine learning, and application development. An *Amazon Glue job* contains the business logic that performs the data integration work in Amazon Glue. There are three types of jobs in Amazon Glue: *Spark (batch and streaming)*, *Ray* and *Python shell*. When you define your job, you specify the Amazon Glue version, which configures versions in the underlying Spark, Ray or Python runtime environment. For example: an Amazon Glue version 5.0 Spark job supports Spark 3.5.4 and Python 3.11.

Support policy

Amazon Glue versions are built around a combination of operating system, programming language, and software libraries that are subject to maintenance and security updates. Amazon Glue's version support policy is to end support for a version when any major component of the version reaches the end of community long-term support (LTS) and security updates are no longer available. Amazon Glue's version support policy includes the following statuses:

End of Support (EOS) - When an Amazon Glue version reaches EOS:

- Amazon Glue will no longer apply security patches or other updates to EOS versions.
- Amazon Glue jobs on EOS versions are not eligible for technical support.
- Amazon Glue may not honor SLAs when jobs are run on EOS versions.

End of Life (EOL) - When an Amazon Glue version reaches EOL:

- You can no longer create new Amazon Glue jobs or interactive sessions on EOL versions.
- You can no longer start job runs on these Amazon Glue versions.
- Amazon Glue will stop existing job runs and interactive sessions on EOL versions.
- EOL versions will be removed from Amazon Glue SDKs and APIs.

The following Amazon Glue versions have reached end of support and will no longer be available after the end of life date. Changes to a version's support status start at midnight (Pacific time zone) on the specified date.

Type	Glue version	End of support	End of life
Spark	Glue version 0.9 (Spark 2.2, Scala 2, Python 2)	6/1/2022	4/1/2026
Spark	Glue version 1.0 (Spark 2.4, Python 2)	6/1/2022	4/1/2026
Spark	Glue version 1.0 (Spark 2.4, Scala 2, Python 3)	9/30/2022	4/1/2026
Spark	Glue version 2.0 (Spark 2.4, Python 3)	1/31/2024	4/1/2026
Type	Python version	End of support	End of life
Python shell	Python 2 (Amazon Glue Version 1.0)	6/1/2022	4/1/2026
Python shell	PythonShell 3.6 (Glue version 1.0)	3/31/2026	NA
Type	Notebook version	End of support	End of life
Development endpoint	Zeppelin notebook	9/30/2022	NA

Note

Creating new Amazon Glue Python Shell 3.6 jobs will not be allowed once end of support is reached on March 31, 2026, but you can continue to update and run existing jobs. However, jobs running on discontinued versions are not eligible for technical support. Amazon Glue

will not apply security patches or other updates to discontinued versions. Amazon Glue will also not honor SLAs when jobs are run on discontinued versions.

Amazon strongly recommends that you migrate your jobs to supported versions.

For information on migrating your Spark jobs to the latest Amazon Glue version, see [Migrating Amazon Glue jobs to Amazon Glue version 5.1](#).

For migrating your Python shell jobs to the latest Amazon Glue version:

- In the console, choose Python 3 (Glue Version 4.0).
- In the [CreateJob/UpdateJob](#) API, set the `GlueVersion` parameter to 2.0, and the `PythonVersion` to 3 under the `Command` parameter. The `GlueVersion` configuration does not affect the behavior of Python shell jobs, so there is no advantage to incrementing `GlueVersion`.
- You need to make your job script compatible with Python 3.

Migrating Amazon Glue for Spark jobs to Amazon Glue version 5.1

This topic describes the changes between Amazon Glue versions 0.9, 1.0, 2.0, 3.0, 4.0 and 5.0 to allow you to migrate your Spark applications and ETL jobs to Amazon Glue 5.1. It also describes the features in Amazon Glue 5.1 and the advantages of using it.

To use this feature with your Amazon Glue ETL jobs, choose **5.1** for the `Glue version` when creating your jobs.

Topics

- [New features](#)
- [Actions to migrate to Amazon Glue 5.1](#)
- [Migration checklist](#)
- [Migrating from Amazon Glue 5.0 to Amazon Glue 5.1](#)
- [Migrating from Older Amazon Glue Versions to Amazon Glue 5.1](#)
- [Connector and JDBC driver migration for Amazon Glue 5.1](#)

New features

This section describes new features and advantages of Amazon Glue version 5.1.

- Apache Spark update from 3.5.4 in Amazon Glue 5.0 to 3.5.6 in Amazon Glue 5.1.
- Open Table Formats (OTF) updated to Hudi 1.0.2, Iceberg 1.10.0, and Delta Lake 3.3.2
- **Iceberg Materialized Views** - Create and manage Iceberg Materialized Views (MV). For more information, see [blog post](#)
- **Iceberg format version 3.0** - Extends data types and existing metadata structures to add new capabilities. For more information, see the [Iceberg Table Spec](#).
- **Hudi Full Table Access** - Full Table Access (FTA) control for Apache Hudi in Apache Spark based on your policies defined in . This feature enables read and write operations from your Amazon Glue ETL jobs on registered tables when the job role has full table access.
- **Spark native fine-grained access control (FGAC) support using** - DDL/DML operations (like CREATE, ALTER, DELETE, DROP) with fine grained access control for Apache Hive, Apache Iceberg and Delta Lake tables registered in .
- **Audit context for Spark jobs** - Audit context for Amazon Glue ETL jobs with enabled jobs will be available for Amazon Glue and Amazon Lake Formation API calls in log

Known Issues and Limitations

Note the following known issues and limitations:

- Limited support for view SQL clause for creation of materialized views, query rewrite and incremental refresh. More details can be found in the [Iceberg Materialized Views feature documentation page](#)
- **Hudi FTA writes** require using `HoodieCredentialedHadoopStorage` for credential vending during job execution. Set the following configuration when running Hudi jobs:

```
hoodie.storage.class=org.apache.spark.sql.hudi.storage.HoodieCredentialedHadoopStorage
```

- Hudi FTA write support works only with the default Hudi configurations. Custom or non-default Hudi settings may not be fully supported and could result in unexpected behavior. Clustering for Hudi Merge-On-Read (MOR) tables is also not supported under FTA write mode.

Breaking changes

Note the following breaking changes:

- S3A filesystem has replaced EMRFS as the default S3 connector. For information on how to migrate, see [Migrating from Amazon Glue 5.0 to Amazon Glue 5.1](#).

Actions to migrate to Amazon Glue 5.1

For existing jobs, change the Glue version from the previous version to Glue 5.1 in the job configuration.

- In Amazon Glue Studio, choose Glue 5.1 - Supports Spark 3.5.6, Scala 2, Python 3 in Glue version.
- In the API, choose 5.1 in the GlueVersion parameter in the [UpdateJob](#) API operation.

For new jobs, choose Glue 5.1 when you create a job.

- In the console, choose Spark 3.5.6, Python 3 (Glue Version 5.1) or Spark 3.5.6, Scala 2 (Glue Version 5.1) in Glue version.
- In Amazon Glue Studio, choose Glue 5.1 - Supports Spark 3.5.6, Scala 2, Python 3 in Glue version.
- In the API, choose 5.1 in the GlueVersion parameter in the [CreateJob](#) API operation.

To view Spark event logs of Amazon Glue 5.1 coming from Amazon Glue 2.0 or earlier, [launch an upgraded Spark history server for Amazon Glue 5.1 using Amazon CloudFormation or Docker](#).

Migration checklist

Review this checklist for migration:

- [Python] Update boto references from 1.34 to 1.40.

Migrating from Amazon Glue 5.0 to Amazon Glue 5.1

All existing job parameters and major features that exist in Amazon Glue 5.0 will exist in Amazon Glue 5.1. Note the following changes when migrating:

- In Amazon Glue 5.1, S3A filesystem has replaced EMRFS as the default S3 connector. If both `spark.hadoop.fs.s3a.endpoint` and `spark.hadoop.fs.s3a.endpoint.region` are not set, the default region used by S3A is `us-east-2`. This can cause issues, such as S3 upload timeout errors, especially for VPC jobs. To mitigate the issues caused by this change, set the `spark.hadoop.fs.s3a.endpoint.region` Spark configuration when using the S3A file system in Amazon Glue 5.1.
- To continue using EMRFS instead of S3A, set the following spark configurations:

```
--conf spark.hadoop.fs.s3.impl=com.amazon.ws.emr.hadoop.fs.EmrFileSystem
--conf spark.hadoop.fs.s3n.impl=com.amazon.ws.emr.hadoop.fs.EmrFileSystem
--conf
spark.hadoop.fs.AbstractFileSystem.s3.impl=org.apache.hadoop.fs.s3.EMRFSDelegate
```

Refer to the Spark migration documentation:

- [Migration Guide: Structured Streaming](#)
- [Upgrading PySpark](#)

Migrating from Older Amazon Glue Versions to Amazon Glue 5.1

- For migration steps related to Amazon Glue 4.0 to Amazon Glue 5.0, see [Migrating from Amazon Glue 4.0 to Amazon Glue 5.0](#).
- For migration steps related to Amazon Glue 3.0 to Amazon Glue 5.0, see [Migrating from Amazon Glue 3.0 to Amazon Glue 5.0](#).
- For migration steps related to Amazon Glue 2.0 to Amazon Glue 5.0 and a list of migration differences between Amazon Glue version 2.0 and 4.0, see [Migrating from Amazon Glue 2.0 to Amazon Glue 5.0](#).

Connector and JDBC driver migration for Amazon Glue 5.1

For the versions of JDBC and data lake connectors that were upgraded, see:

- [Appendix B: JDBC driver upgrades](#)

- [Appendix C: Connector upgrades](#)
- [Appendix D: Open table format upgrades](#)

The following changes apply to the OTF version upgrades identified in [Appendix D: Open table format upgrades](#) for Amazon Glue 5.1.

Apache Hudi

Note the following changes:

- Support FTA read and write access on Lake Formation registered tables.

Apache Iceberg

Note the following changes:

- Support Iceberg format version 3. The following features are supported:
 - Multi-argument transforms for partitioning and sorting.
 - Row Lineage tracking.
 - Deletion vectors. Learn more in [blog post](#)
 - Table encryption keys.
- Support Spark-native FGAC writes on registered tables.
- Athena SQL compatibility - Cannot read Iceberg V3 tables created by EMR Spark due to error: `GENERIC_INTERNAL_ERROR: Cannot read unsupported version 3`

Delta Lake

Note the following changes:

- Support FTA read and write access on Lake Formation registered tables.

Appendix A: Notable dependency upgrades

The following are dependency upgrades:

Dependency	Version in Amazon Glue 5.1	Version in Amazon Glue 5.0	Version in Amazon Glue 4.0	Version in Amazon Glue 3.0	Version in Amazon Glue 2.0	Version in Amazon Glue 1.0
Java	17	17	8	8	8	8
Spark	3.5.6	3.5.4	3.3.0-amzn-1	3.1.1-amzn-0	2.4.3	2.4.3
Hadoop	3.4.1	3.4.1	3.3.3-amzn-0	3.2.1-amzn-3	2.8.5-amzn-5	2.8.5-amzn-1
Scala	2.12.18	2.12.18	2.12	2.12	2.11	2.11
Jackson	2.15.2	2.15.2	2.12	2.12	2.11	2.11
Hive	2.3.9-amzn-4	2.3.9-amzn-4	2.3.9-amzn-2	2.3.7-amzn-4	1.2	1.2
EMRFS	2.73.0	2.69.0	2.54.0	2.46.0	2.38.0	2.30.0
Json4s	3.7.0-M11	3.7.0-M11	3.7.0-M11	3.6.6	3.5.x	3.5.x
Arrow	12.0.1	12.0.1	7.0.0	2.0.0	0.10.0	0.10.0
Amazon Glue Data Catalog client	4.9.0	4.5.0	3.7.0	3.0.0	1.10.0	N/A
Amazon SDK for Java	2.35.5	2.29.52	1.12	1.12		
Python	3.11	3.11	3.10	3.7	2.7 & 3.6	2.7 & 3.6
Boto	1.40.61	1.34.131	1.26	1.18	1.12	N/A

Dependency	Version in Amazon Glue 5.1	Version in Amazon Glue 5.0	Version in Amazon Glue 4.0	Version in Amazon Glue 3.0	Version in Amazon Glue 2.0	Version in Amazon Glue 1.0
EMR DynamoDB connector	5.7.0	5.6.0	4.16.0			

Appendix B: JDBC driver upgrades

The following are JDBC driver upgrades:

Driver	JDBC driver version in Amazon Glue 5.1	JDBC driver version in Amazon Glue 5.0	JDBC driver version in Amazon Glue 4.0	JDBC driver version in Amazon Glue 3.0	JDBC driver version in past Amazon Glue versions
MySQL	8.0.33	8.0.33	8.0.23	8.0.23	5.1
Microsoft SQL Server	10.2.0	10.2.0	9.4.0	7.0.0	6.1.0
Oracle Databases	23.3.0.23.09	23.3.0.23.09	21.7	21.1	11.2
PostgreSQL	42.7.3	42.7.3	42.3.6	42.2.18	42.1.0
Amazon Redshift	redshift-jdbc42-2.1.0.29	redshift-jdbc42-2.1.0.29	redshift-jdbc42-2.1.0.16	redshift-jdbc41-1.2.12.1017	redshift-jdbc41-1.2.12.1017
SAP Hana	2.20.17	2.20.17	2.17.12		
Teradata	20.00.00.33	20.00.00.33	20.00.00.06		

Appendix C: Connector upgrades

The following are connector upgrades:

Driver	Connector version in Amazon Glue 5.1	Connector version in Amazon Glue 5.0	Connector version in Amazon Glue 4.0	Connector version in Amazon Glue 3.0
EMR DynamoDB connector	5.7.0	5.6.0	4.16.0	
Amazon Redshift	6.4.2	6.4.0	6.1.3	
OpenSearch	1.2.0	1.2.0	1.0.1	
MongoDB	10.3.0	10.3.0	10.0.4	3.0.0
Snowflake	3.1.1	3.0.0	2.12.0	
Google BigQuery	0.32.2	0.32.2	0.32.2	
AzureCosmos	4.33.0	4.33.0	4.22.0	
AzureSQL	1.3.0	1.3.0	1.3.0	
Vertica	3.3.5	3.3.5	3.3.5	

Appendix D: Open table format upgrades

The following are open table format upgrades:

OTF	Connector version in Amazon Glue 5.1	Connector version in Amazon Glue 5.0	Connector version in Amazon Glue 4.0	Connector version in Amazon Glue 3.0
Hudi	1.0.2	0.15.0	0.12.1	0.10.1

OTF	Connector version in Amazon Glue 5.1	Connector version in Amazon Glue 5.0	Connector version in Amazon Glue 4.0	Connector version in Amazon Glue 3.0
Delta Lake	3.3.2	3.3.0	2.1.0	1.0.0
Iceberg	1.10.0	1.7.1	1.0.0	0.13.1

Migrating Amazon Glue for Spark jobs to Amazon Glue version 5.0

This topic describes the changes between Amazon Glue versions 0.9, 1.0, 2.0, 3.0, and 4.0 to allow you to migrate your Spark applications and ETL jobs to Amazon Glue 5.0. It also describes the features in Amazon Glue 5.0 and the advantages of using it.

To use this feature with your Amazon Glue ETL jobs, choose **5.0** for the Glue version when creating your jobs.

Topics

- [New features](#)
- [Actions to migrate to Amazon Glue 5.0](#)
- [Migration checklist](#)
- [Amazon Glue 5.0 features](#)
- [Migrating from Amazon Glue 4.0 to Amazon Glue 5.0](#)
- [Migrating from Amazon Glue 3.0 to Amazon Glue 5.0](#)
- [Migrating from Amazon Glue 2.0 to Amazon Glue 5.0](#)
- [Logging behavior changes in Amazon Glue 5.0](#)
- [Connector and JDBC driver migration for Amazon Glue 5.0](#)

New features

This section describes new features and advantages of Amazon Glue version 5.0.

- Apache Spark update from 3.3.0 in Amazon Glue 4.0 to 3.5.4 in Amazon Glue 5.0. See [Major enhancements from Spark 3.3.0 to Spark 3.5.4](#).

- Spark-native fine-grained access control (FGAC) using Lake Formation. This includes FGAC for Iceberg, Delta and Hudi tables. For more information, see [Using Amazon Glue with Amazon Lake Formation for fine-grained access control](#).

Note the following considerations or limitations for Spark-native FGAC:

- Currently data writes are not supported
- Writing into Iceberg through `GlueContext` using Lake Formation requires use of IAM access control instead

For a complete list of limitations and considerations when using Spark-native FGAC, see [the section called "Considerations"](#).

- Support for Amazon S3 Access Grants as a scalable access control solution to your Amazon S3 data from Amazon Glue. For more information, see [Using Amazon S3 Access Grants with Amazon Glue](#).
- Open Table Formats (OTF) updated to Hudi 0.15.0, Iceberg 1.7.1, and Delta Lake 3.3.0
- Amazon SageMaker Unified Studio support.
- Amazon SageMaker Lakehouse and data abstraction integration. For more information, see [Querying metastore data catalogs from Amazon Glue ETL](#).
- Support to install additional Python libraries using `requirements.txt`. For more information, see [Installing additional Python libraries in Amazon Glue 5.0 or above using requirements.txt](#).
- Amazon Glue 5.0 supports data lineage in Amazon DataZone. You can configure Amazon Glue to automatically collect lineage information during Spark job runs and send the lineage events to be visualized in Amazon DataZone. For more information, see [Data lineage in Amazon DataZone](#).

To configure this on the Amazon Glue console, turn on **Generate lineage events**, and enter your Amazon DataZone domain ID on the **Job details** tab.

The screenshot shows the Amazon Glue console interface with the 'Job details' tab selected. Under the 'Generate lineage events' section, the checkbox is checked, indicating that AWS Glue will capture Spark lineage events and send them to Amazon DataZone or the next generation of Amazon SageMaker for visualization. Below this, the 'Domain ID' field is populated with the value 'dzd_test_domain'.

Alternatively, you can provide the following job parameter (provide your DataZone domain ID):

- Key: --conf
- Value:

```
extraListeners=io.openlineage.spark.agent.OpenLineageSparkListener
--conf spark.openlineage.transport.type=amazon_datazone_api
--conf spark.openlineage.transport.domainId=<your-domain-ID>
```

- Connector and JDBC driver updates. For more information, see [Appendix B: JDBC driver upgrades](#) and [Appendix C: Connector upgrades](#).
- Java update from 8 to 17.
- Increased storage for Amazon Glue G.1X and G.2X workers with disk space increasing to 94GB and 138GB respectively. Additionally, new worker types G.12X, G.16X, and memory-optimized R.1X, R.2X, R.4X, R.8X are available in Amazon Glue 4.0 and later versions. For more information, see [Jobs](#)
- **Support for Amazon SDK for Java, version 2** - Amazon Glue 5.0 jobs can use the for Java versions [1.12.569](#) or [2.28.8](#) if the job supports v2. The Amazon SDK for Java 2.x is a major rewrite of the version 1.x code base. It's built on top of Java 8+ and adds several frequently requested features. These include support for non-blocking I/O, and the ability to plug in a different HTTP implementation at runtime. For more information, including a Migration Guide from SDK for Java v1 to v2, see the [Amazon SDK for Java, version 2](#) guide.

Breaking changes

Note the following breaking changes:

- In Amazon Glue 5.0, when using the S3A file system and if both `fs.s3a.endpoint` and fs.s3a.endpoint.region` are not set, the default region used by S3A is us-east-2`. This can cause issues, such as S3 upload timeout errors, especially for VPC jobs. To mitigate the issues caused by this change, set the fs.s3a.endpoint.region` Spark configuration when using the S3A file system in Amazon Glue 5.0.`
- Lake Formation Fine-grained Access Control (FGAC)
 - Amazon Glue 5.0 only supports the new Spark-native FGAC using Spark DataFrames. It does not support FGAC using Amazon Glue DynamicFrames.
 - Use of FGAC in 5.0 requires migrating from Amazon Glue DynamicFrames to Spark DataFrames

- If you don't need FGAC, then it is not necessary to migrate to Spark DataFrame and GlueContext features, like job bookmarks and push down predicates, will continue to work.
- Jobs with Spark-native FGAC require a minimum of 4 workers: one user driver, one system driver, one system executor, and one standby user executor.
- For more information, see [Using Amazon Glue with Amazon Lake Formation for fine-grained access control](#).
- Lake Formation Full Table Access (FTA)
 - Amazon Glue 5.0 supports FTA with Spark-native DataFrames (new) and GlueContext DynamicFrames (legacy, with limitations)
 - Spark-native FTA
 - If 4.0 script uses GlueContext, migrate to using native spark.
 - This feature is limited to hive and iceberg tables
 - For more info on configuring a 5.0 job to use Spark native FTA, see
 - GlueContext DynamicFrame FTA
 - No code change necessary
 - This feature is limited to non-OTF tables - it will not work with Iceberg, Delta Lake, and Hudi.
- [Vectorized SIMD CSV reader](#) is not supported.
- [Continuous logging](#) to output log group is not supported. Use `error` log group instead.
- The Amazon Glue job run insights `job-insights-rule-driver` has been deprecated. The `job-insights-rca-driver` log stream is now located in the error log group.
- Athena-based custom/marketplace connectors are not supported.
- Adobe Marketo Engage, Facebook Ads, Google Ads, Google Analytics 4, Google Sheets, Hubspot, Instagram Ads, Intercom, Jira Cloud, Oracle NetSuite, Salesforce, Salesforce Marketing Cloud, Salesforce Marketing Cloud Account Engagement, SAP OData, ServiceNow, Slack, Snapchat Ads, Stripe, Zendesk and Zoho CRM connectors are not supported.
- Custom log4j properties are not supported in Amazon Glue 5.0.

Major enhancements from Spark 3.3.0 to Spark 3.5.4

Note the following enhancements:

- Python client for Spark Connect ([SPARK-39375](#)).
- Implement support for DEFAULT values for columns in tables ([SPARK-38334](#)).

- Support "Lateral Column Alias References" ([SPARK-27561](#)).
- Harden SQLSTATE usage for error classes ([SPARK-41994](#)).
- Enable Bloom filter Joins by default ([SPARK-38841](#)).
- Better Spark UI scalability and driver stability for large applications ([SPARK-41053](#)).
- Async Progress Tracking in Structured Streaming ([SPARK-39591](#)).
- Python arbitrary stateful processing in structured streaming ([SPARK-40434](#)).
- Pandas API coverage improvements ([SPARK-42882](#)) and NumPy input support in PySpark ([SPARK-39405](#)).
- Provide a memory profiler for PySpark user-defined functions ([SPARK-40281](#)).
- Implement PyTorch distributor ([SPARK-41589](#)).
- Publish SBOM artifacts ([SPARK-41893](#)).
- Support IPv6-only environment ([SPARK-39457](#)).
- Customized K8s scheduler (Apache YuniKorn and Volcano) GA ([SPARK-42802](#)).
- Scala and Go client support in Spark Connect ([SPARK-42554](#)) and ([SPARK-43351](#)).
- PyTorch-based distributed ML Support for Spark Connect ([SPARK-42471](#)).
- Structured streaming support for Spark Connect in Python and Scala ([SPARK-42938](#)).
- Pandas API support for the Python Spark Connect Client ([SPARK-42497](#)).
- Introduce Arrow Python UDFs ([SPARK-40307](#)).
- Support Python user-defined table functions ([SPARK-43798](#)).
- Migrate PySpark errors onto error classes ([SPARK-42986](#)).
- PySpark test framework ([SPARK-44042](#)).
- Add support for Dataskeches HllSketch ([SPARK-16484](#)).
- Built-in SQL function improvement ([SPARK-41231](#)).
- IDENTIFIER clause ([SPARK-43205](#)).
- Add SQL functions into Scala, Python and R API ([SPARK-43907](#)).
- Add named argument support for SQL functions ([SPARK-43922](#)).
- Avoid unnecessary task rerun on decommissioned executor lost if shuffle data migrated ([SPARK-41469](#)).
- Distributed ML <> spark connect ([SPARK-42471](#)).

- DeepSpeed distributor ([SPARK-44264](#)).
- Implement changelog checkpointing for RocksDB state store ([SPARK-43421](#)).
- Introduce watermark propagation among operators ([SPARK-42376](#)).
- Introduce dropDuplicatesWithinWatermark ([SPARK-42931](#)).
- RocksDB state store provider memory management enhancements ([SPARK-43311](#)).

Actions to migrate to Amazon Glue 5.0

For existing jobs, change the Glue version from the previous version to Glue 5.0 in the job configuration.

- In Amazon Glue Studio, choose Glue 5.0 - Supports Spark 3.5.4, Scala 2, Python 3 in Glue version.
- In the API, choose 5.0 in the GlueVersion parameter in the [UpdateJob](#) API operation.

For new jobs, choose Glue 5.0 when you create a job.

- In the console, choose Spark 3.5.4, Python 3 (Glue Version 5.0) or Spark 3.5.4, Scala 2 (Glue Version 5.0) in Glue version.
- In Amazon Glue Studio, choose Glue 5.0 - Supports Spark 3.5.4, Scala 2, Python 3 in Glue version.
- In the API, choose 5.0 in the GlueVersion parameter in the [CreateJob](#) API operation.

To view Spark event logs of Amazon Glue 5.0 coming from Amazon Glue 2.0 or earlier, [launch an upgraded Spark history server for Amazon Glue 5.0 using Amazon CloudFormation or Docker](#).

Migration checklist

Review this checklist for migration:

- Java 17 updates
- [Scala] Upgrade Amazon SDK calls from v1 to v2
- Python 3.10 to 3.11 migration
- [Python] Update boto references from 1.26 to 1.34

Amazon Glue 5.0 features

This section describes Amazon Glue features in more detail.

Querying metastore data catalogs from Amazon Glue ETL

You can register your Amazon Glue job to access the Amazon Glue Data Catalog, which makes tables and other metastore resources available to disparate consumers. The Data Catalog supports a multi-catalog hierarchy, which unifies all your data across Amazon S3 data lakes. It also provides both a Hive metastore API and an open-source Apache Iceberg API for accessing the data. These features are available to Amazon Glue and other data-oriented services like Amazon EMR, Amazon Athena and Amazon Redshift.

When you create resources in the Data Catalog, you can access them from any SQL engine that supports the Apache Iceberg REST API. Amazon Lake Formation manages permissions. Following configuration, you can leverage Amazon Glue's capabilities to query disparate data by querying these metastore resources with familiar applications. These include Apache Spark and Trino.

How metadata resources are organized

Data is organized in a logical hierarchy of catalogs, databases and tables, using the Amazon Glue Data Catalog:

- Catalog – A logical container that holds objects from a data store, such as schemas or tables.
- Database – Organizes data objects such as tables and views in a catalog.
- Tables and views – Data objects in a database that provide an abstraction layer with an understandable schema. They make it easy to access underlying data, which could be in various formats and in various locations.

Migrating from Amazon Glue 4.0 to Amazon Glue 5.0

All existing job parameters and major features that exist in Amazon Glue 4.0 will exist in Amazon Glue 5.0, except machine learning transforms.

The following new parameters were added:

- `--enable-lakeformation-fine-grained-access`: Enables the fine-grained access control (FGAC) feature in Amazon Lake Formation tables.

Refer to the Spark migration documentation:

- [Migration Guide: Spark Core](#)
- [Migration Guide: SQL, Datasets and DataFrame](#)
- [Migration Guide: Structured Streaming](#)
- [Upgrading PySpark](#)

Migrating from Amazon Glue 3.0 to Amazon Glue 5.0

Note

For migration steps related to Amazon Glue 4.0, see [Migrating from Amazon Glue 3.0 to Amazon Glue 4.0](#).

All existing job parameters and major features that exist in Amazon Glue 3.0 will exist in Amazon Glue 5.0, except machine learning transforms.

Migrating from Amazon Glue 2.0 to Amazon Glue 5.0

Note

For migration steps related to Amazon Glue 4.0 and a list of migration differences between Amazon Glue version 3.0 and 4.0, see [Migrating from Amazon Glue 3.0 to Amazon Glue 4.0](#).

Also note the following migration differences between Amazon Glue versions 3.0 and 2.0:

- All existing job parameters and major features that exist in Amazon Glue 2.0 will exist in Amazon Glue 5.0, except machine learning transforms.
- Several Spark changes alone may require revision of your scripts to ensure removed features are not being referenced. For example, Spark 3.1.1 and later does not enable Scala-untyped UDFs but Spark 2.4 does allow them.
- Python 2.7 is not supported.
- Any extra jars supplied in existing Amazon Glue 2.0 jobs may bring in conflicting dependencies since there were upgrades in several dependencies. You can avoid classpath conflicts with the `--user-jars-first` job parameter.

- Changes to the behavior of loading/saving of timestamps from/to parquet files. For more details, see [Upgrading from Spark SQL 3.0 to 3.1](#).
- Different Spark task parallelism for driver/executor configuration. You can adjust task parallelism by passing the `--executor-cores` job argument.

Logging behavior changes in Amazon Glue 5.0

The following are changes in logging behavior in Amazon Glue 5.0. For more information, see [Logging for Amazon Glue jobs](#).

- All logs (system logs, Spark daemon logs, user logs, and Glue Logger logs) are now written to the `/aws-glue/jobs/error` log group by default.
- The `/aws-glue/jobs/logs-v2` log group used for continuous logging in previous versions is no longer used.
- You can no longer rename or customize the log group or log stream names using the removed continuous logging arguments. Instead, see the new job arguments in Amazon Glue 5.0.

Two new job arguments are introduced in Amazon Glue 5.0

- `--custom-logGroup-prefix`: Allows you to specify a custom prefix for the `/aws-glue/jobs/error` and `/aws-glue/jobs/output` log groups.
- `--custom-logStream-prefix`: Allows you to specify a custom prefix for the log stream names within the log groups.

Validation rules and limitations for custom prefixes include:

- The entire log stream name must be between 1 and 512 characters.
- The custom prefix for log stream names is limited to 400 characters.
- Allowed characters in prefixes include alphanumeric characters, underscores (`_``), hyphens (`-``), and forward slashes (`/``).

Deprecated continuous logging arguments in Amazon Glue 5.0

The following job arguments for continuous logging have been deprecated in Amazon Glue 5.0

- `--enable-continuous-cloudwatch-log`
- `--continuous-log-logGroup`

- `--continuous-log-logStreamPrefix`
- `--continuous-log-conversionPattern`
- `--enable-continuous-log-filter`

Connector and JDBC driver migration for Amazon Glue 5.0

For the versions of JDBC and data lake connectors that were upgraded, see:

- [Appendix B: JDBC driver upgrades](#)
- [Appendix C: Connector upgrades](#)
- [Appendix D: Open table format upgrades](#)

The following changes apply to the connector or driver versions identified in the appendices for Glue 5.0.

Amazon Redshift

Note the following changes:

- Adds support for three-part table names to allow connector to query Redshift data sharing tables.
- Corrects mapping of Spark `ShortType` to use Redshift `SMALLINT` instead of `INTEGER` to better match expected data size.
- Added support for Custom Cluster Names (CNAME) for Amazon Redshift Serverless.

Apache Hudi

Note the following changes:

- Support record level index.
- Support auto generation of record keys. Now you don't have to specify the record key field.

Apache Iceberg

Note the following changes:

- Support fine-grained access control with Amazon Lake Formation.

- Support branching and tagging which are named references to snapshots with their own independent lifecycles.
- Added a changelog view procedure which generates a view that contains the changes made to a table over a specified period or between specific snapshots.

Delta Lake

Note the following changes:

- Support Delta Universal Format (UniForm) which enables seamless access through Apache Iceberg and Apache Hudi.
- Support Deletion Vectors that implements a Merge-on-Read paradigm.

AzureCosmos

Note the following changes:

- Added hierarchical partition key support.
- Added option to use custom Schema with StringType (raw json) for a nested property.
- Added config option `spark.cosmos.auth.aad.clientCertPemBase64` to allow using SPN (ServicePrincipal name) authentication with certificate instead of client secret.

For more information, see the [Azure Cosmos DB Spark connector change log](#).

Microsoft SQL Server

Note the following changes:

- TLS encryption is enabled by default.
- When `encrypt = false` but the server requires encryption, the certificate is validated based on the `trustServerCertificate` connection setting.
- `aadSecurePrincipalId` and `aadSecurePrincipalSecret` deprecated.
- `getAADSecretPrincipalId` API removed.
- Added CNAME resolution when realm is specified.

MongoDB

Note the following changes:

- Support for micro-batch mode with Spark Structured Streaming.
- Support for BSON data types.
- Added support for reading multiple collections when using micro-batch or continuous streaming modes.
 - If the name of a collection used in your `collection` configuration option contains a comma, the Spark Connector treats it as two different collections. To avoid this, you must escape the comma by preceding it with a backslash (\).
 - If the name of a collection used in your `collection` configuration option is "*", the Spark Connector interprets it as a specification to scan all collections. To avoid this, you must escape the asterisk by preceding it with a backslash (\).
 - If the name of a collection used in your `collection` configuration option contains a backslash (\), the Spark Connector treats the backslash as an escape character, which might change how it interprets the value. To avoid this, you must escape the backslash by preceding it with another backslash.

For more information, see the [MongoDB connector for Spark release notes](#).

Snowflake

Note the following changes:

- Introduced a new `trim_space` parameter that you can use to trim values of `StringType` columns automatically when saving to a Snowflake table. Default: `false`.
- Disabled the `abort_detached_query` parameter at the session level by default.
- Removed the requirement of the `SFUSER` parameter when using `OAUTH`.
- Removed the Advanced Query Pushdown feature. Alternatives to the feature are available. For example, instead of loading data from Snowflake tables, users can directly load data from Snowflake SQL queries.

For more information, see the [Snowflake Connector for Spark release notes](#).

Appendix A: Notable dependency upgrades

The following are dependency upgrades:

Dependency	Version in Amazon Glue 5.0	Version in Amazon Glue 4.0	Version in Amazon Glue 3.0	Version in Amazon Glue 2.0	Version in Amazon Glue 1.0
Java	17	8	8	8	8
Spark	3.5.4	3.3.0-amzn-1	3.1.1-amzn-0	2.4.3	2.4.3
Hadoop	3.4.1	3.3.3-amzn-0	3.2.1-amzn-3	2.8.5-amzn-5	2.8.5-amzn-1
Scala	2.12.18	2.12	2.12	2.11	2.11
Jackson	2.15.2	2.12	2.12	2.11	2.11
Hive	2.3.9-amzn-4	2.3.9-amzn-2	2.3.7-amzn-4	1.2	1.2
EMRFS	2.69.0	2.54.0	2.46.0	2.38.0	2.30.0
Json4s	3.7.0-M11	3.7.0-M11	3.6.6	3.5.x	3.5.x
Arrow	12.0.1	7.0.0	2.0.0	0.10.0	0.10.0
Amazon Glue Data Catalog client	4.5.0	3.7.0	3.0.0	1.10.0	N/A
Amazon SDK for Java	2.29.52	1.12	1.12		
Python	3.11	3.10	3.7	2.7 & 3.6	2.7 & 3.6
Boto	1.34.131	1.26	1.18	1.12	N/A
EMR DynamoDB connector	5.6.0	4.16.0			

Appendix B: JDBC driver upgrades

The following are JDBC driver upgrades:

Driver	JDBC driver version in Amazon Glue 5.0	JDBC driver version in Amazon Glue 4.0	JDBC driver version in Amazon Glue 3.0	JDBC driver version in past Amazon Glue versions
MySQL	8.0.33	8.0.23	8.0.23	5.1
Microsoft SQL Server	10.2.0	9.4.0	7.0.0	6.1.0
Oracle Databases	23.3.0.23.09	21.7	21.1	11.2
PostgreSQL	42.7.3	42.3.6	42.2.18	42.1.0
Amazon Redshift	redshift-jdbc42-2.1.0.29	redshift-jdbc42-2.1.0.16	redshift-jdbc41-1.2.12.1017	redshift-jdbc41-1.2.12.1017
SAP Hana	2.20.17	2.17.12		
Teradata	20.00.00.33	20.00.00.06		

Appendix C: Connector upgrades

The following are connector upgrades:

Driver	Connector version in Amazon Glue 5.0	Connector version in Amazon Glue 4.0	Connector version in Amazon Glue 3.0
EMR DynamoDB connector	5.6.0	4.16.0	
Amazon Redshift	6.4.0	6.1.3	
OpenSearch	1.2.0	1.0.1	
MongoDB	10.3.0	10.0.4	3.0.0

Driver	Connector version in Amazon Glue 5.0	Connector version in Amazon Glue 4.0	Connector version in Amazon Glue 3.0
Snowflake	3.0.0	2.12.0	
Google BigQuery	0.32.2	0.32.2	
AzureCosmos	4.33.0	4.22.0	
AzureSQL	1.3.0	1.3.0	
Vertica	3.3.5	3.3.5	

Appendix D: Open table format upgrades

The following are open table format upgrades:

OTF	Connector version in Amazon Glue 5.0	Connector version in Amazon Glue 4.0	Connector version in Amazon Glue 3.0
Hudi	0.15.0	0.12.1	0.10.1
Delta Lake	3.3.0	2.1.0	1.0.0
Iceberg	1.7.1	1.0.0	0.13.1

Migrating Amazon Glue for Spark jobs to Amazon Glue version 4.0

This topic describes the changes between Amazon Glue versions 0.9, 1.0, 2.0, and 3.0 to allow you to migrate your Spark applications and ETL jobs to Amazon Glue 4.0. It also describes the features in Amazon Glue 4.0 and the advantages of using it.

To use this feature with your Amazon Glue ETL jobs, choose **4.0** for the Glue version when creating your jobs.

Topics

- [New features supported](#)
- [Actions to migrate to Amazon Glue 4.0](#)

- [Migration checklist](#)
- [Migrating from Amazon Glue 3.0 to Amazon Glue 4.0](#)

- [Appendix A: Notable dependency upgrades](#)
- [Appendix B: JDBC driver upgrades](#)
- [Appendix C: Connector upgrades](#)

New features supported

This section describes new features and advantages of Amazon Glue version 4.0.

- It is based on Apache Spark 3.3.0, but includes optimizations in Amazon Glue, and Amazon EMR, such as adaptive query runs, vectorized readers, and optimized shuffles and partition coalescing.
- Upgraded JDBC drivers for all Amazon Glue native sources including MySQL, Microsoft SQL Server, Oracle, PostgreSQL, MongoDB, and upgraded Spark libraries and dependencies brought in by Spark 3.3.0.
- Updated with a new Amazon Redshift connector and JDBC driver.
- Optimized Amazon S3 access with upgraded EMR File System (EMRFS) and enabled Amazon S3-optimized output committers, by default.
- Optimized Data Catalog access with partition indexes, pushdown predicates, partition listing, and an upgraded Hive metastore client.
- Integration with Lake Formation for governed catalog tables with cell-level filtering and data lake transactions.
- Reduced startup latency to improve overall job completion times and interactivity.
- Spark jobs are billed in 1-second increments with a 10x lower minimum billing duration—from a 10-minute minimum to a 1-minute minimum.
- Native support for open-data lake frameworks with Apache Hudi, Delta Lake, and Apache Iceberg.
- Native support for the Amazon S3-based Cloud Shuffle Storage Plugin (an Apache Spark plugin) to use Amazon S3 for shuffling and elastic storage capacity.

Major enhancements from Spark 3.1.1 to Spark 3.3.0

Note the following enhancements:

- Row-level runtime filtering ([SPARK-32268](#)).
- ANSI enhancements ([SPARK-38860](#)).
- Error message improvements ([SPARK-38781](#)).
- Support complex types for Parquet vectorized reader ([SPARK-34863](#)).
- Hidden file metadata support for Spark SQL ([SPARK-37273](#)).
- Provide a profiler for Python/Pandas UDFs ([SPARK-37443](#)).
- Introduce Trigger.AvaliableNow for running streaming queries like Trigger.Once in multiple batches ([SPARK-36533](#)).
- More comprehensive Datasource V2 pushdown capabilities ([SPARK-38788](#)).
- Migrating from log4j 1 to log4j 2 ([SPARK-37814](#)).

Other notable changes

Note the following changes:

- Breaking changes
 - Drop references to Python 3.6 support in docs and Python/docs ([SPARK-36977](#)).
 - Remove named tuple hack by replacing built-in pickle to cloudpickle ([SPARK-32079](#)).
 - Bump minimum pandas version to 1.0.5 ([SPARK-37465](#)).

Actions to migrate to Amazon Glue 4.0

For existing jobs, change the Glue version from the previous version to Glue 4.0 in the job configuration.

- In Amazon Glue Studio, choose Glue 4.0 - Supports Spark 3.3, Scala 2, Python 3 in Glue version.
- In the API, choose 4.0 in the GlueVersion parameter in the [UpdateJob](#) API operation.

For new jobs, choose Glue 4.0 when you create a job.

- In the console, choose Spark 3.3, Python 3 (Glue Version 4.0) or Spark 3.3, Scala 2 (Glue Version 3.0) in Glue version.
- In Amazon Glue Studio, choose Glue 4.0 - Supports Spark 3.3, Scala 2, Python 3 in Glue version.
- In the API, choose 4.0 in the GlueVersion parameter in the [CreateJob](#) API operation.

To view Spark event logs of Amazon Glue 4.0 coming from Amazon Glue 2.0 or earlier, [launch an upgraded Spark history server for Amazon Glue 4.0 using Amazon CloudFormation or Docker](#).

Migration checklist

- Do your job's external Python libraries depend on Python 2.7/3.6?
 - Update the dependent libraries from Python 2.7/3.6 to Python 3.10 as Spark 3.3.0 completely removed Python 2.7 and 3.6 support.

Migrating from Amazon Glue 3.0 to Amazon Glue 4.0

Note the following changes when migrating:

- All existing job parameters and major features that exist in Amazon Glue 3.0 will exist in Amazon Glue 4.0.
- Amazon Glue 3.0 uses Amazon EMR-optimized Spark 3.1.1, and Amazon Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.

Several Spark changes alone might require revision of your scripts to ensure that removed features are not being referenced.

- Amazon Glue 4.0 also features an update to EMRFS and Hadoop. For the specific version, see [Appendix A: Notable dependency upgrades](#).
- The Amazon SDK provided in ETL jobs is now upgraded from 1.11 to 1.12.
- All Python jobs will be using Python version 3.10. Previously, Python 3.7 was used in Amazon Glue 3.0.

As a result, some pymodules brought out-of-the-box by Amazon Glue are upgraded.

- Log4j has been upgraded to Log4j2.
 - For information on the Log4j2 migration path, see the [Log4j documentation](#).

- You must rename any custom `log4j.properties` file as a `log4j2.properties` file instead, with the appropriate `log4j2` properties.
- For migrating certain connectors, see [Connector and JDBC driver migration for Amazon Glue 4.0](#).
- The Amazon Encryption SDK is upgraded from 1.x to 2.x. Amazon Glue jobs using Amazon Glue security configurations and jobs dependent on the Amazon Encryption SDK dependency provided in runtime are affected. See the instructions for Amazon Glue job migration.

You can safely upgrade an Amazon Glue 2.0/3.0 job to an Amazon Glue 4.0 job because Amazon Glue 2.0/3.0 already contains the Amazon Encryption SDK bridge version.

Refer to the Spark migration documentation:

- [Upgrading from Spark SQL 3.1 to 3.2](#)
- [Upgrading from Spark SQL 3.2 to 3.3](#)

Migrating from Amazon Glue 2.0 to Amazon Glue 4.0

Note the following changes when migrating:

Note

For migration steps related to Amazon Glue 3.0, see [Migrating from Amazon Glue 3.0 to Amazon Glue 4.0](#).

- All existing job parameters and major features that exist in Amazon Glue 2.0 will exist in Amazon Glue 4.0.
- The EMRFS S3-optimized committer for writing Parquet data into Amazon S3 is enabled by default since Amazon Glue 3.0. However, you can still disable it by setting `--enable-s3-parquet-optimized-committer` to `false`.
- Amazon Glue 2.0 uses open-source Spark 2.4 and Amazon Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.
 - Several Spark changes alone may require revision of your scripts to ensure that removed features are not being referenced.
 - For example, Spark 3.3.0 does not enable Scala-untyped UDFs, but Spark 2.4 does allow them.

- The Amazon SDK provided in ETL jobs is now upgraded from 1.11 to 1.12.
- Amazon Glue 4.0 also features an update to EMRFS, updated JDBC drivers, and inclusions of additional optimizations onto Spark itself provided by Amazon Glue.
- Scala is updated to 2.12 from 2.11, and Scala 2.12 is not backward compatible with Scala 2.11.
- Python 3.10 is the default version used for Python scripts, as Amazon Glue 2.0 was only using Python 3.7 and 2.7.
 - Python 2.7 is not supported with Spark 3.3.0. Any job requesting Python 2 in the job configuration will fail with an `IllegalArgumentException`.
 - A new mechanism of installing additional Python modules is available since Amazon Glue 2.0.
- Several dependency updates, highlighted in [Appendix A: Notable dependency upgrades](#).
- Any extra JAR files supplied in existing Amazon Glue 2.0 jobs might bring in conflicting dependencies because there were upgrades in several dependencies in 4.0 from 2.0. You can avoid classpath conflicts in Amazon Glue 4.0 with the `--user-jars-first` Amazon Glue job parameter.
- Amazon Glue 4.0 uses Spark 3.3. Starting with Spark 3.1, there was a change in the behavior of loading/saving of timestamps from/to parquet files. For more details, see [Upgrading from Spark SQL 3.0 to 3.1](#).

We recommend to set the following parameters when reading/writing parquet data that contains timestamp columns. Setting those parameters can resolve the calendar incompatibility issue that occurs during the Spark 2 to Spark 3 upgrade, for both the Amazon Glue Dynamic Frame and Spark Data Frame. Use the `CORRECTED` option to read the datetime value as it is; and the `LEGACY` option to rebase the datetime values with regard to the calendar difference during reading.

```
- Key: --conf
- Value: spark.sql.legacy.parquet.int96RebaseModeInRead=[CORRECTED|LEGACY] --
conf spark.sql.legacy.parquet.int96RebaseModeInWrite=[CORRECTED|LEGACY] --conf
spark.sql.legacy.parquet.datetimeRebaseModeInRead=[CORRECTED|LEGACY]
```

- For migrating certain connectors, see [Connector and JDBC driver migration for Amazon Glue 4.0](#).
- The Amazon Encryption SDK is upgraded from 1.x to 2.x. Amazon Glue jobs using Amazon Glue security configurations and jobs dependent on the Amazon Encryption SDK dependency provided in runtime are affected. See these instructions for Amazon Glue job migration:
 - You can safely upgrade an Amazon Glue 2.0 job to an Amazon Glue 4.0 job because Amazon Glue 2.0 already contains the Amazon Encryption SDK bridge version.

Refer to the Spark migration documentation:

- [Upgrading from Spark SQL 2.4 to 3.0](#)
- [Upgrading from Spark SQL 3.1 to 3.2](#)
- [Upgrading from Spark SQL 3.2 to 3.3](#)
- [Changes in Datetime behavior to be expected since Spark 3.0.](#)

Migrating from Amazon Glue 1.0 to Amazon Glue 4.0

Note the following changes when migrating:

- Amazon Glue 1.0 uses open-source Spark 2.4 and Amazon Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.
 - Several Spark changes alone may require revision of your scripts to ensure that removed features are not being referenced.
 - For example, Spark 3.3.0 does not enable Scala-untyped UDFs, but Spark 2.4 does allow them.
- All jobs in Amazon Glue 4.0 will be run with significantly improved startup times. Spark jobs will be billed in 1-second increments with a 10x lower minimum billing duration since startup latency will go from 10 minutes maximum to 1 minute maximum.
- Logging behavior has changed significantly in Amazon Glue 4.0, Spark 3.3.0 has a minimum requirement of Log4j2.
- Several dependency updates, highlighted in the appendix.
- Scala is also updated to 2.12 from 2.11, and Scala 2.12 is not backward compatible with Scala 2.11.
- Python 3.10 is also the default version used for Python scripts, as Amazon Glue 0.9 was only using Python 2.

Python 2.7 is not supported with Spark 3.3.0. Any job requesting Python 2 in the job configuration will fail with an `IllegalArgumentException`.

- A new mechanism of installing additional Python modules through pip is available since Amazon Glue 2.0. For more information, see [Installing additional Python modules with pip in Amazon Glue 2.0+](#).
- Amazon Glue 4.0 does not run on Apache YARN, so YARN settings do not apply.
- Amazon Glue 4.0 does not have a Hadoop Distributed File System (HDFS).

- Any extra JAR files supplied in existing Amazon Glue 1.0 jobs might bring in conflicting dependencies because there were upgrades in several dependencies in 4.0 from 1.0. We enable Amazon Glue 4.0 with the `--user-jars-first` Amazon Glue job parameter by default, to avoid this problem.
- Amazon Glue 4.0 supports auto scaling. Therefore, the `ExecutorAllocationManager` metric will be available when auto scaling is enabled.
- In Amazon Glue version 4.0 jobs, you specify the number of workers and worker type, but do not specify a `maxCapacity`.
- Amazon Glue 4.0 does not yet support machine learning transforms.
- For migrating certain connectors, see [Connector and JDBC driver migration for Amazon Glue 4.0](#).
- The Amazon Encryption SDK is upgraded from 1.x to 2.x. Amazon Glue jobs using Amazon Glue security configurations and jobs dependent on the Amazon Encryption SDK dependency provided in runtime are affected. See these instructions for Amazon Glue job migration.
 - You cannot migrate an Amazon Glue 0.9/1.0 job to an Amazon Glue 4.0 job directly. This is because when upgrading directly to version 2.x or later and enabling all new features immediately, the Amazon Encryption SDK won't be able to decrypt the ciphertext encrypted under earlier versions of the Amazon Encryption SDK.
 - To safely upgrade, we first recommend that you migrate to an Amazon Glue 2.0/3.0 job that contains the Amazon Encryption SDK bridge version. Run the job once to utilize the Amazon Encryption SDK bridge version.
 - Upon completion, you can safely migrate the Amazon Glue 2.0/3.0 job to Amazon Glue 4.0.

Refer to the Spark migration documentation:

- [Upgrading from Spark SQL 2.4 to 3.0](#)
- [Upgrading from Spark SQL 3.0 to 3.1](#)
- [Upgrading from Spark SQL 3.1 to 3.2](#)
- [Upgrading from Spark SQL 3.2 to 3.3](#)
- [Changes in Datetime behavior to be expected since Spark 3.0](#).

Migrating from Amazon Glue 0.9 to Amazon Glue 4.0

Note the following changes when migrating:

- Amazon Glue 0.9 uses open-source Spark 2.2.1 and Amazon Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.
 - Several Spark changes alone might require revision of your scripts to ensure that removed features are not being referenced.
 - For example, Spark 3.3.0 does not enable Scala-untyped UDFs, but Spark 2.2 does allow them.
- All jobs in Amazon Glue 4.0 will be run with significantly improved startup times. Spark jobs will be billed in 1-second increments with a 10x lower minimum billing duration because startup latency will go from 10 minutes maximum to 1 minute maximum.
- Logging behavior has changed significantly since Amazon Glue 4.0, Spark 3.3.0 has a minimum requirement of Log4j2 as mentioned here (<https://spark.apache.org/docs/latest/core-migration-guide.html#upgrading-from-core-32-to-33>).
- Several dependency updates, highlighted in the appendix.
- Scala is also updated to 2.12 from 2.11, and Scala 2.12 is not backward compatible with Scala 2.11.
- Python 3.10 is also the default version used for Python scripts, as Amazon Glue 0.9 was only using Python 2.
 - Python 2.7 is not supported with Spark 3.3.0. Any job requesting Python 2 in the job configuration will fail with an `IllegalArgumentException`.
 - A new mechanism of installing additional Python modules through pip is available.
- Amazon Glue 4.0 does not run on Apache YARN, so YARN settings do not apply.
- Amazon Glue 4.0 does not have a Hadoop Distributed File System (HDFS).
- Any extra JAR files supplied in existing Amazon Glue 0.9 jobs might bring in conflicting dependencies because there were upgrades in several dependencies in 3.0 from 0.9. You can avoid classpath conflicts in Amazon Glue 3.0 with the `--user-jars-first` Amazon Glue job parameter.
- Amazon Glue 4.0 supports auto scaling. Therefore, the `ExecutorAllocationManager` metric will be available when auto scaling is enabled.
- In Amazon Glue version 4.0 jobs, you specify the number of workers and worker type, but do not specify a `maxCapacity`.
- Amazon Glue 4.0 does not yet support machine learning transforms.
- For migrating certain connectors, see [Connector and JDBC driver migration for Amazon Glue 4.0](#).

- The Amazon Encryption SDK is upgraded from 1.x to 2.x. Amazon Glue jobs using Amazon Glue security configurations and jobs dependent on the Amazon Encryption SDK dependency provided in runtime are affected. See these instructions for Amazon Glue job migration.
- You cannot migrate an Amazon Glue 0.9/1.0 job to an Amazon Glue 4.0 job directly. This is because when upgrading directly to version 2.x or later and enabling all new features immediately, the Amazon Encryption SDK won't be able to decrypt the ciphertext encrypted under earlier versions of the Amazon Encryption SDK.
- To safely upgrade, we first recommend that you migrate to an Amazon Glue 2.0/3.0 job that contains the Amazon Encryption SDK bridge version. Run the job once to utilize the Amazon Encryption SDK bridge version.
- Upon completion, you can safely migrate the Amazon Glue 2.0/3.0 job to Amazon Glue 4.0.

Refer to the Spark migration documentation:

- [Upgrading from Spark SQL 2.2 to 2.3](#)
- [Upgrading from Spark SQL 2.3 to 2.4](#)
- [Upgrading from Spark SQL 2.4 to 3.0](#)
- [Upgrading from Spark SQL 3.0 to 3.1](#)
- [Upgrading from Spark SQL 3.1 to 3.2](#)
- [Upgrading from Spark SQL 3.2 to 3.3](#)
- [Changes in Datetime behavior to be expected since Spark 3.0.](#)

Connector and JDBC driver migration for Amazon Glue 4.0

For the versions of JDBC and data lake connectors that were upgraded, see:

- [Appendix B: JDBC driver upgrades](#)
- [Appendix C: Connector upgrades](#)

Hudi

- Spark SQL support improvements:
 - Through the `Call Procedure` command, there is added support for upgrade, downgrade, bootstrap, clean, and repair. `Create/Drop/Show/Refresh Index` syntax is possible in Spark SQL.

- A performance gap has been closed between usage through a Spark DataSource as opposed to Spark SQL. Datasource writes in the past used to be faster than SQL.
- All built-in key generators implement more performant Spark-specific API operations.
- Replaced UDF transformation in the bulk `insert` operation with RDD transformations to cut down on costs of using SerDe.
- Spark SQL with Hudi requires a `primaryKey` to be specified by `tblproperties` or options in the SQL statement. For update and delete operations, the `preCombineField` is required as well.
- Any Hudi table created before version 0.10.0 without a `primaryKey` needs to be recreated with a `primaryKey` field since version 0.10.0.

PostgreSQL

- Several vulnerabilities (CVEs) were addressed.
- Java 8 is natively supported.
- If the job is using Arrays of Arrays, with the exception of byte arrays, this scenario can be treated as multidimensional arrays.

MongoDB

- The current MongoDB connector supports Spark version 3.1 or later and MongoDB version 4.0 or later.
- Due to the connector upgrade, a few property names changed. For example, the URI property name changed to `connection.uri`. For more information on the current options, see the [MongoDB Spark Connector blog](#).
- Using MongoDB 4.0 hosted by Amazon DocumentDB has some functional differences. For more information, see these topics:
 - [Functional Differences: Amazon DocumentDB and MongoDB](#)
 - [Supported MongoDB APIs, Operations, and Data Types](#).
- The "partitioner" option is restricted to `ShardedPartitioner`, `PaginateIntoPartitionsPartitioner`, and `SinglePartitionPartitioner`. It cannot use default `SamplePartitioner` and `PaginateBySizePartitioner` for Amazon DocumentDB because the stage operator does not support the MongoDB API. For more information, see [Supported MongoDB APIs, Operations, and Data Types](#).

Delta Lake

- Delta Lake now supports [time travel in SQL](#) to query older data easily. With this update, time travel is now available both in Spark SQL and through the DataFrame API. Support has been added for the current version of `TIMESTAMP` in SQL.
- Spark 3.3 introduces [Trigger.AvailableNow](#) for running streaming queries as an equivalent to `Trigger.Once` for batch queries. This support is also available when using Delta tables as a streaming source.
- Support for `SHOW COLUMNS` to return the list of columns in a table.
- Support for [DESCRIBE DETAIL](#) in the Scala and Python DeltaTable API. It retrieves detailed information about a Delta table using either the DeltaTable API or Spark SQL.
- Support for returning operation metrics from SQL [Delete](#), [Merge](#), and [Update](#) commands. Previously these SQL commands returned an empty DataFrame, now they return a DataFrame with useful metrics about the operation performed.
- Optimize performance improvements:
 - Set the configuration option `spark.databricks.delta.optimize.repartition.enabled=true` to use `repartition(1)` instead of `coalesce(1)` in the `Optimize` command for better performance when compacting many small files.
 - [Improved performance](#) by using a queue-based approach to parallelize compaction jobs.
- Other notable changes:
 - [Support for using variables](#) in the `VACUUM` and `OPTIMIZE` SQL commands.
 - Improvements for `CONVERT TO DELTA` with catalog tables including:
 - [Autofill the partition schema](#) from the catalog when it's not provided.
 - [Use partition information](#) from the catalog to find the data files to commit instead of doing a full directory scan. Instead of committing all data files in the table directory, only data files under the directories of active partitions will be committed.
 - [Support for Change Data Feed \(CDF\) batch reads](#) on column mapping enabled tables when `DROP COLUMN` and `RENAME COLUMN` have not been used. For more information, see the [Delta Lake documentation](#).
 - [Improve Update command performance](#) by enabling schema pruning in the first pass.

Apache Iceberg

- Added several [performance improvements](#) for scan planning and Spark queries.
- Added a common REST catalog client that uses change-based commits to resolve commit conflicts on the service side.
- AS OF syntax for SQL time travel queries is supported.
- Added merge-on-read support for MERGE and UPDATE queries.
- Added support to rewrite partitions using Z-order.
- Added a spec and implementation for Puffin, a format for large stats and index blobs, like [Theta sketches](#) or bloom filters.
- Added new interfaces for consuming data incrementally (both append and changelog scans).
- Added support for bulk operations and ranged reads to FileIO interfaces.
- Added more metadata tables to show delete files in the metadata tree.
- The drop table behavior changed. In Iceberg 0.13.1, running DROP TABLE removes the table from the catalog and deletes the table contents as well. In Iceberg 1.0.0, DROP TABLE only removes the table from the catalog. To delete the table contents use DROP TABLE PURGE.
- Parquet vectorized reads are enabled by default in Iceberg 1.0.0. If you want to disable vectorized reads, set `read.parquet.vectorization.enabled` to `false`.

Oracle

Changes are minor.

MySQL

Changes are minor.

Amazon Redshift

Amazon Glue 4.0 features a new Amazon Redshift connector with a new JDBC driver. For information about the enhancements and how to migrate from previous Amazon Glue versions, see [the section called "Redshift connections"](#).

Appendix A: Notable dependency upgrades

The following are dependency upgrades:

Dependency	Version in Amazon Glue 4.0	Version in Amazon Glue 3.0	Version in Amazon Glue 2.0	Version in Amazon Glue 1.0
Spark	3.3.0-amzn-1	3.1.1-amzn-0	2.4.3	2.4.3
Hadoop	3.3.3-amzn-0	3.2.1-amzn-3	2.8.5-amzn-5	2.8.5-amzn-1
Scala	2.12	2.12	2.11	2.11
Jackson	2.13.3	2.10.x	2.7.x	2.7.x
Hive	2.3.9-amzn-2	2.3.7-amzn-4	1.2	1.2
EMRFS	2.54.0	2.46.0	2.38.0	2.30.0
Json4s	3.7.0-M11	3.6.6	3.5.x	3.5.x
Arrow	7.0.0	2.0.0	0.10.0	0.10.0
Amazon Glue Data Catalog client	3.7.0	3.0.0	1.10.0	N/A
Python	3.10	3.7	2.7 & 3.6	2.7 & 3.6
Boto	1.26	1.18	1.12	N/A

Appendix B: JDBC driver upgrades

The following are JDBC driver upgrades:

Driver	JDBC driver version in past Amazon Glue versions	JDBC driver version in Amazon Glue 3.0	JDBC driver version in Amazon Glue 4.0
MySQL	5.1	8.0.23	8.0.23
Microsoft SQL Server	6.1.0	7.0.0	9.4.0

Driver	JDBC driver version in past Amazon Glue versions	JDBC driver version in Amazon Glue 3.0	JDBC driver version in Amazon Glue 4.0
Oracle Databases	11.2	21.1	21.7
PostgreSQL	42.1.0	42.2.18	42.3.6
MongoDB	2.0.0	4.0.0	4.7.2
Amazon Redshift	redshift-jdbc41-1.2.12.1017	redshift-jdbc41-1.2.12.1017	redshift-jdbc42-2.1.0.16

Appendix C: Connector upgrades

The following are connector upgrades:

Driver	Connector version in Amazon Glue 3.0	Connector version in Amazon Glue 4.0
MongoDB	3.0.0	10.0.4
Hudi	0.10.1	0.12.1
Delta Lake	1.0.0	2.1.0
Iceberg	0.13.1	1.0.0
DynamoDB	1.11	1.12

Generative AI upgrades for Apache Spark in Amazon Glue

Spark Upgrades in Amazon Glue enables data engineers and developers to upgrade and migrate their existing Amazon Glue Spark jobs to the latest Spark releases using generative AI. Data engineers can use it to scan their Amazon Glue Spark jobs, generate upgrade plans, execute plans, and validate outputs. It reduces the time and cost of Spark upgrades by automating the undifferentiated work of identifying and updating Spark scripts, configurations, dependencies, methods, and features.

The screenshot displays the AWS Glue Studio interface. On the left is a navigation sidebar. The main area is titled 'AWS Glue Studio' and contains several sections:

- Create job:** Three options are shown: 'Visual ETL' (Author in a visual interface focused on data flow.), 'Notebook' (Author using an interactive code notebook.), and 'Script editor' (Author code with a script editor.).
- Example jobs:** A section with a 'Create example job' button.
- Your jobs (39):** A table listing jobs with the following columns: Job name, Type, Created by, Last modified, and AWS Glue version. The table contains 10 rows of job entries.

Job name	Type	Created by	Last modified	AWS Glue version
books-review-analytics	Glue ETL	Script	11/21/2024, 3:13:51 PM	2.0
book-reviews-daily-analytics-job	Glue ETL	Script	11/21/2024, 3:11:33 PM	2.0
Tests4S3ToGDCToS3-copy	Glue ETL	Script	11/21/2024, 3:10:40 PM	2.0
Tests4Rag	Glue ETL	Script	11/21/2024, 8:33:42 AM	2.0
Tests4S3ToGDCToS3	Glue ETL	Script	11/20/2024, 6:31:08 PM	2.0
Tests4GDCToS3ToGDC	Glue ETL	Script	11/20/2024, 5:05:47 PM	2.0
Tests2S3ToGDC	Glue ETL	Script	11/15/2024, 5:58:51 PM	2.0
Tests6S3ToS3	Glue ETL	Script	11/15/2024, 4:38:18 AM	2.0
Tests3S3ToS3	Glue ETL	Script	11/15/2024, 4:38:17 AM	2.0
Tests3GDCToS3ToGDC	Glue ETL	Script	11/15/2024, 4:38:16 AM	2.0

How it works

When you use upgrade analysis, Amazon Glue identifies differences between versions and configurations in your job's code to generate an upgrade plan. The upgrade plan details all code changes, and required migration steps. Next, Amazon Glue builds and runs the upgraded application in an environment to validate changes and generates a list of code changes for you to migrate your job. You can view the updated script along with the summary that details the proposed changes. After running your own tests, accept the changes and the Amazon Glue job will be updated automatically to the latest version with the new script.

The upgrade analysis process can take some time to complete, depending on the complexity of the job and the workload. The results of the upgrade analysis will be stored in the specified Amazon S3 path, which can be reviewed to understand the upgrade and any potential compatibility issues. After reviewing the upgrade analysis results, you can decide whether to proceed with the actual upgrade or make any necessary changes to the job before upgrading.

Prerequisites

The following prerequisites are required to use generative AI to upgrade jobs in Amazon Glue:

- Amazon Glue 2 PySpark jobs – only Amazon Glue 2 jobs can be upgraded to Amazon Glue 5.
- IAM permissions are required to start the analysis, review the results and upgrade your job. For more information, see the examples in the [Permissions](#) section below.
- If using Amazon KMS to encrypt analysis artifacts, then additional Amazon Amazon KMS permissions are needed. For more information, see the examples in the [Amazon KMS policy](#) section below.

Permissions

To start a new upgrade analysis, you need the following permissions:

1. Update the IAM policy of the caller with the following permission:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartJobUpgradeAnalysis",
        "glue:StartJobRun",
        "glue:GetJobRun",
        "glue:GetJob",
        "glue:BatchStopJobRun"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:job/jobName"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/script-location/*"
      ]
    },
    {
      "Effect": "Allow",
```

```

        "Action": [
            "s3:PutObject",
            "s3:GetObject"
        ],
        "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket/results/*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "kms:Decrypt",
            "kms:GenerateDataKey"
        ],
        "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-id"
    }
]
}

```

2. Update the Execution role of the job you are upgrading to include the following in-line policy:

```

{
  "Effect": "Allow",
  "Action": ["s3:GetObject"],
  "Resource": [
    "ARN of the Amazon S3 path provided on API",
    "ARN of the Amazon S3 path provided on API/*"
  ]
}

```

For example, if you are using the Amazon S3 path `s3://amzn-s3-demo-bucket/upgraded-result`, then the policy will be:

```

{
  "Effect": "Allow",
  "Action": ["s3:GetObject"],
  "Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket/upgraded-result/",
    "arn:aws:s3:::amzn-s3-demo-bucket/upgraded-result/*"
  ]
}

```

To retrieve the details of an analysis, you need the following permissions:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:GetJobUpgradeAnalysis"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:job/jobName"
      ]
    }
  ]
}
```

To stop an in-progress analysis, you need the following permissions:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StopJobUpgradeAnalysis",
        "glue:BatchStopJobRun"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:job/jobName"
      ]
    }
  ]
}
```

To list all the analyses submitted on a specific job, you need the following permissions:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:ListJobUpgradeAnalyses"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:job/jobName"
      ]
    }
  ]
}
```

To accept the changes from an analysis and upgrade a job, you need the following permissions:

Amazon KMS policy

To pass your own custom Amazon KMS key when starting an analysis, please refer to the following section to configure appropriate permissions on the Amazon KMS keys.

Configuring the result artifact encryption using a Amazon KMS key:

This policy ensures that you have both the encryption and decryption permissions on the Amazon KMS key.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "<IAM Customer caller ARN>"
  },
  "Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey",
  ],
  "Resource": "<key-arn-passed-on-start-api>"
}
```

}

Running an upgrade analysis and applying the upgrade script

You can run an upgrade analysis, which will generate an upgrade plan on a job you select from the **Jobs** view.

1. From **Jobs**, select a Amazon Glue 2.0 job, then choose **Run upgrade analysis** from the **Actions** menu.

The screenshot shows the AWS Glue Studio interface. At the top, there's a navigation bar with 'AWS Glue > Jobs'. Below that, there are three options to create a job: 'Visual ETL', 'Notebook', and 'Script editor'. Under 'Example jobs', there's a 'Create example job' button. The main section is 'Your jobs (3)', which has a search bar and a filter 'glue2'. A table lists the jobs:

Job name	Type	Created by	Last modified
glue2-migrate-demo	Glue ETL	Script	11/6/2024, 2:14:49 AM
glue2-migration	Glue ETL	Script	11/4/2024, 9:56:12 PM
<input checked="" type="checkbox"/> glue2-count	Glue ETL	Script	11/1/2024, 12:51:39 AM

An 'Actions' menu is open over the selected 'glue2-count' job, showing options: 'Edit job', 'Clone job', 'Schedule job', 'Delete job(s)', 'Reset job bookmark', and 'Run upgrade analysis with AI - preview'.

2. In the modal, select a path to store your generated upgrade plan in the **Result path**. This must be an Amazon S3 bucket you can access and write to.

Run upgrade analysis with AI - preview

Spark upgrades analyzes your Spark application to generate an upgrade plan. It runs up to 10 iterations, executing the upgraded application in a Glue environment to validate changes. This process incurs compute costs. You can monitor progress and stop the upgrade anytime. It provides a detailed summary of changes for your review before final application. [Learn more](#)

Job name
book-reviews-daily-analytics-job

Target Glue version
Glue 4.0 - Support Spark 3.3, Scala 2, Python 3

Result path
s3://glue-upgrades-demo-bucket/upgraded-script/

Run configuration
AWS Glue use defaults from your job configurations. You can override them below.

Worker type
Set the type of predefined worker that is allowed when a job runs.
G 1X (4vCPU and 16GB RAM)

Requested number of workers
The number of workers you want AWS Glue to allocate to this job.
2

Job timeout (minutes)
Set the execution time. The default is 2,880 minutes (48 hours) for a Glue ETL job.
2880

Security configuration
None

Job parameters

Key	Value - optional
--enable-glue-datacatalog	true
--enable-job-insights	true
--job-language	python

[Add new parameter](#)
You can add 47 more parameters.

[Cancel](#) [Run](#)

3. Configure additional options, if needed:

- **Run configuration** – optional: The run configuration is an optional setting that allows you to customize various aspects of the validation runs performed during the upgrade analysis. This configuration is utilized to execute the upgraded script and allows you to select the compute environment properties (worker type, number of workers, etc). Note you should use your non-production developer accounts to run the validations on sample datasets before reviewing, accepting the changes and applying them to production environments. The run configuration includes the following customizable parameters:
 - **Worker type:** You can specify the type of worker to be used for the validation runs, allowing you to choose appropriate compute resources based on your requirements.
 - **Number of workers:** You can define the number of workers to be provisioned for the validation runs, enabling you to scale resources according to your workload needs.

- **Job timeout (in minutes):** This parameter allows you to set a time limit for the validation runs, ensuring that the jobs terminate after a specified duration to prevent excessive resource consumption.
- **Security configuration:** You can configure security settings, such as encryption and access control, to ensure the protection of your data and resources during the validation runs.
- **Additional job parameters:** If needed, you can add new job parameters to further customize the execution environment for the validation runs.

By leveraging the run configuration, you can tailor the validation runs to suit your specific requirements. For example, you can configure the validation runs to use a smaller dataset, which allows the analysis to complete more quickly and optimizes costs. This approach ensures that the upgrade analysis is performed efficiently while minimizing resource utilization and associated costs during the validation phase.

- **Encryption configuration – optional:**
 - **Enable upgrade artifacts encryption:** Enable at-rest encryption when writing data to the result path. If you don't want to encrypt your upgrade artifacts, leave this option unchecked.
4. Choose **Run** to start the upgrade analysis. While the analysis is running, you can view the results on the **Upgrade analysis** tab. The analysis details window will show you information about the analysis as well as links to the upgrade artifacts.
 - **Result path** – this is where the results summary and upgrade script are stored.
 - **Upgraded script in Amazon S3** – the location of the upgrade script in Amazon S3. You can view the script prior to applying the upgrade.
 - **Upgrade summary in Amazon S3** – the location of the upgrade summary in Amazon S3. You can view the upgrade summary prior to applying the upgrade.
 5. When the upgrade analysis is completed successfully, you can apply the upgrade script to automatically upgrade your job by choosing **Apply upgraded script**.

Once applied, the Amazon Glue version will be updated to 4.0. You can view the new script in the **Script** tab.

Understanding your upgrade summary

This example demonstrates the process of upgrading a Amazon Glue job from version 2.0 to version 4.0. The sample job reads product data from an Amazon S3 bucket, applies several transformations to the data using Spark SQL, and then saves the transformed results back to an Amazon S3 bucket.

Original code (Amazon Glue 2.0) - before upgrade

```
from awsglue.transforms import *
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from pyspark.sql.types import *
from pyspark.sql.functions import *
from awsglue.job import Job
import json
from pyspark.sql.types import StructType

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
```

```
gdc_database = "s3://aws-glue-scripts-us-east-1-gamma/demo-database/"
schema_location = (
    "s3://aws-glue-scripts-us-east-1-gamma/DataFiles/"
)

products_schema_string = spark.read.text(
    f"{schema_location}schemas/products_schema"
).first()[0]

product_schema = StructType.fromJson(json.loads(products_schema_string))

products_source_df = (
    spark.read.option("header", "true")
    .schema(product_schema)
    .option(
        "path",
        f"{gdc_database}products/",
    )
    .csv(f"{gdc_database}products/")
)

products_source_df.show()
products_temp_view_name = "spark_upgrade_demo_product_view"
products_source_df.createOrReplaceTempView(products_temp_view_name)

query = f"select {products_temp_view_name}.*, format_string('%0$s-%0$s', category,
    subcategory) as unique_category from {products_temp_view_name}"
products_with_combination_df = spark.sql(query)
products_with_combination_df.show()

products_with_combination_df.createOrReplaceTempView(products_temp_view_name)
product_df_attribution = spark.sql(
    f"""
SELECT *,
unbase64(split(product_name, ' ')[0]) as product_name_decoded,
unbase64(split(unique_category, '-')[1]) as subcategory_decoded
FROM {products_temp_view_name}
"""
)
product_df_attribution.show()

product_df_attribution.write.mode("overwrite").option("header", "true").option(
```

```
    "path", f"{gdc_database}spark_upgrade_demo_product_agg/"
).saveAsTable("spark_upgrade_demo_product_agg", external=True)

spark_upgrade_demo_product_agg_table_df = spark.sql(
    f"SHOW TABLE EXTENDED in default like 'spark_upgrade_demo_product_agg'"
)
spark_upgrade_demo_product_agg_table_df.show()
job.commit()
```

New code (Glue 4.0) - after upgrade

```
from awsglue.transforms import *
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from pyspark.sql.types import *
from pyspark.sql.functions import *
from awsglue.job import Job
import json
from pyspark.sql.types import StructType

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
# change 1
spark.conf.set("spark.sql.adaptive.enabled", "false")
# change 2
spark.conf.set("spark.sql.legacy.pathOptionBehavior.enabled", "true")
job = Job(glueContext)

gdc_database = "s3://aws-glue-scripts-us-east-1-gamma/demo-database/"
schema_location = (
    "s3://aws-glue-scripts-us-east-1-gamma/DataFiles/"
)

products_schema_string = spark.read.text(
    f"{schema_location}schemas/products_schema"
).first()[0]

product_schema = StructType.fromJson(json.loads(products_schema_string))

products_source_df = (
    spark.read.option("header", "true")
    .schema(product_schema)
```

```
.option(
    "path",
    f"{gdc_database}products/",
)
.csv(f"{gdc_database}products/")
)

products_source_df.show()
products_temp_view_name = "spark_upgrade_demo_product_view"
products_source_df.createOrReplaceTempView(products_temp_view_name)

# change 3
query = f"select {products_temp_view_name}.*, format_string('%1$s-%1$s', category,
    subcategory) as unique_category from {products_temp_view_name}"
products_with_combination_df = spark.sql(query)
products_with_combination_df.show()

products_with_combination_df.createOrReplaceTempView(products_temp_view_name)
# change 4
product_df_attribution = spark.sql(
    f"""
SELECT *,
try_to_binary(split(product_name, ' ')[0], 'base64') as product_name_decoded,
try_to_binary(split(unique_category, '-')[1], 'base64') as subcategory_decoded
FROM {products_temp_view_name}
"""
)
product_df_attribution.show()

product_df_attribution.write.mode("overwrite").option("header", "true").option(
    "path", f"{gdc_database}spark_upgrade_demo_product_agg/"
).saveAsTable("spark_upgrade_demo_product_agg", external=True)

spark_upgrade_demo_product_agg_table_df = spark.sql(
    f"SHOW TABLE EXTENDED in default like 'spark_upgrade_demo_product_agg'"
)
spark_upgrade_demo_product_agg_table_df.show()
job.commit()
```

Explanation of analysis summary

In Spark 3.2, `spark.sql.adaptive.enabled` is enabled by default. To restore the behavior before Spark 3.2, you can set `spark.sql.adaptive.enabled` to `false`.

In Spark 3.1, `path` option cannot coexist when the following methods are called with `path` parameter(s): `DataFrameReader.load()`, `DataFrameWriter.save()`, `DataStreamReader.load()`, or `DataStreamWriter.start()`. In addition, `paths` option cannot coexist for `DataFrameReader.load()`. For example, `spark.read.format(csv).option(path, /tmp).load(/tmp2)` or `spark.read.option(path, /tmp).csv(/tmp2)` will throw `org.apache.spark.sql.AnalysisException`. In Spark version 3.0 and below, `path` option is overwritten if one `path` parameter is passed to above methods; `path` option is added to the overall paths if multiple `path` parameters are passed to `DataFrameReader.load()`. To restore the behavior before Spark 3.1, you can set `spark.sql.legacy.pathOptionBehavior.enabled` to `true`.

Since Spark 3.3, the ``strfmt`` in ``format_string(strfmt, obj, ...)`` and ``printf(strfmt, obj, ...)`` will no longer support to use `0$` to specify the first argument, the first argument should always reference by `1$` when use argument index to indicating the position of the argument in the argument list.

Since Spark 3.3, the `unbase64` function throws error for a malformed `str` input. Use `try_to_binary(<str>, 'base64')` to tolerate malformed input and return `NULL` instead. In Spark 3.2 and earlier, the `unbase64` function returns a best-efforts result for a malformed `str` input.

Based on the summary, there are four changes proposed by Amazon Glue in order to successfully upgrade the script from Amazon Glue 2.0 to Amazon Glue 4.0:

- 1. Spark SQL configuration (`spark.sql.adaptive.enabled`):** This change is to restore the application behavior as a new feature for Spark SQL adaptive query execution is introduced starting Spark 3.2. You can inspect this configuration change and can further enable or disable it as per their preference.
- 2. DataFrame API change:** The `path` option cannot coexist with other `DataFrameReader` operations like `load()`. To retain the previous behavior, Amazon Glue updated the script to add a new SQL configuration (`spark.sql.legacy.pathOptionBehavior.enabled`).
- 3. Spark SQL API change:** The behavior of `strfmt` in `format_string(strfmt, obj, ...)` has been updated to disallow `0$` as the first argument. To ensure compatibility, Amazon Glue has modified the script to use `1$` as the first argument instead.
- 4. Spark SQL API change:** The `unbase64` function does not allow malformed string inputs. To retain the previous behavior, Amazon Glue updated the script to use the `try_to_binary` function.

Stopping an upgrade analysis in progress

You can cancel an upgrade analysis in progress or just stop the analysis.

1. Choose the **Upgrade Analysis** tab.
2. Select the job that is running, then choose **Stop**. This will stop the analysis. You can then run another upgrade analysis on the same job.

The screenshot shows the Amazon Glue console interface for a job named 'glue2-migrate-demo'. The 'Upgrade Analysis - preview' tab is active. At the top right, there are buttons for 'Load JSON', 'Dev Utils', 'Actions', 'Save', and 'Run'. Below the navigation tabs, the 'Analysis (1/1)' section is visible, showing a search bar and a 'Stop' button. A table lists the analysis details:

Analysis ID	Status	Target Glue version	Start time (Local)	End time (Local)	Duration
ja-254c2a32-7fa6-48a3-a93c-62bb110a74b9	Running	4.0	11/05/2024 14:14:06		1 m 56 s

Considerations

As you begin using Spark Upgrades, there are several important aspects to consider for optimal usage of the service.

- **Service Scope and Limitations:** The current release focuses on PySpark code upgrades from Amazon Glue versions 2.0 to version 5.0. At this time, the service handles PySpark code that doesn't rely on additional library dependencies. You can run automated upgrades for up to 10 jobs concurrently in an Amazon account, allowing you to efficiently upgrade multiple jobs while maintaining system stability.
 - Only PySpark jobs are supported.
 - Upgrade analysis will time out after 24 hours.
 - Only one active upgrade analysis can be run at a time for one job. On the account-level, up to 10 active upgrade analysis can be run at the same time.
- **Optimizing Costs During Upgrade Process:** Since Spark Upgrades use generative AI to validate the upgrade plan through multiple iterations, with each iteration running as a Amazon Glue job in your account, it's essential to optimize the validation job run configurations for cost efficiency. To achieve this, we recommend specifying a Run Configuration when starting an Upgrade Analysis as follows:
 - Use non-production developer accounts and select sample mock datasets that represent your production data but are smaller in size for validation with Spark Upgrades.

- Using right-sized compute resources, such as G.1X workers, and selecting an appropriate number of workers for processing your sample data.
- Enabling Amazon Glue job auto-scaling when applicable to automatically adjust resources based on workload.

For example, if your production job processes terabytes of data with 20 G.2X workers, you might configure the upgrade job to process a few gigabytes of representative data with 2 G.2X workers and auto-scaling enabled for validation.

- **Best Practices:** We strongly recommend starting your upgrade journey with non-production jobs. This approach allows you to familiarize yourself with the upgrade workflow, and understand how the service handles different types of Spark code patterns.
- **Alarms and notifications:** When utilizing the Generative AI upgrades feature on a job, ensure that alarms/notifications for failed job runs are turned off. During the upgrade process, there may be up to 10 failed job runs in your account before the upgraded artifacts are provided.
- **Anomaly detection rules:** Turn off any anomaly detection rules on the Job that is being upgraded as well, as the data written to output folders during intermediate job runs might not be in the expected format while the upgrade validation is in progress.
- **Use upgrade analysis with idempotent jobs:** Use upgrade analysis with idempotent jobs to ensure each subsequent validation job run attempt is similar to the previous one, and doesn't run into issues. Idempotent jobs are jobs that can be run multiple times with the same input data, and they will produce the same output each time. When using the Generative AI upgrades for Apache Spark in Amazon Glue, the service will run multiple iterations of your job as part of the validation process. During each iteration, it will make changes to your Spark code and configurations to validate the upgrade plan. If your Spark job is not idempotent, running it multiple times with the same input data could lead to issues.

Supported regions

Generative AI upgrades for Apache Spark is available in the following regions:

- **Asia Pacific:** Tokyo (ap-northeast-1), Seoul (ap-northeast-2), Mumbai (ap-south-1), Singapore (ap-southeast-1), and Sydney (ap-southeast-2)
- **North America:** Canada (ca-central-1)
- **Europe:** Frankfurt (eu-central-1), Stockholm (eu-north-1), Ireland (eu-west-1), London (eu-west-2), and Paris (eu-west-3)

- **South America:** São Paulo (sa-east-1)
- **United States:** North Virginia (us-east-1), Ohio (us-east-2), and Oregon (us-west-2)

Cross-region inference in Spark Upgrades

Spark Upgrades is powered by Amazon Bedrock and leverages cross-region inference (CRIS). With CRIS, Spark Upgrades will automatically select the optimal region within your geography (as described in more detail [here](#)) to process your inference request, maximizing available compute resources and model availability, and providing the best customer experience. There's no additional cost for using cross-region inference.

Cross-region inference requests are kept within the Amazon Regions that are part of the geography where the data originally resides. For example, a request made within the US is kept within the Amazon Regions in the US. Although the data remains stored only in the primary region, when using cross-region inference, your input prompts and output results may move outside of your primary region. All data will be transmitted encrypted across Amazon's secure network.

Working with Spark jobs in Amazon Glue

Provides information on Amazon Glue for Spark ETL jobs.

Topics

- [Using job parameters in Amazon Glue jobs](#)
- [Amazon Glue Spark and PySpark jobs](#)
- [Amazon Glue worker types](#)
- [Streaming ETL jobs in Amazon Glue](#)
- [Record matching with Amazon Lake Formation FindMatches](#)
- [Migrate Apache Spark programs to Amazon Glue](#)

Using job parameters in Amazon Glue jobs

When creating a Amazon Glue job, you set some standard fields, such as `Role` and `WorkerType`. You can provide additional configuration information through the `Argument` fields (**Job Parameters** in the console). In these fields, you can provide Amazon Glue jobs with the arguments (parameters) listed in this topic.

For more information about the Amazon Glue Job API, see [the section called “Jobs”](#).

Note

Job arguments have a maximum size limit of 260KB. A validation check will raise an error if the argument size is greater than 260KB.

Setting job parameters

You can configure a job through the console on the **Job details** tab, under the **Job Parameters** heading. You can also configure a job through the Amazon CLI by setting `DefaultArguments` or `NonOverridableArguments` on a job, or setting `Arguments` on a job run. Arguments set on the job will be passed in every time the job is run, while arguments set on the job run will only be passed in for that individual run.

For example, the following is the syntax for running a job using `--arguments` to set a job parameter.

```
$ aws glue start-job-run --job-name "CSV to CSV" --arguments='--scriptLocation="s3://my_glue/libraries/test_lib.py"'
```

Accessing job parameters

When writing Amazon Glue scripts, you may want to access job parameter values to alter the behavior of your own code. We provide helper methods to do so in our libraries. These methods resolve job run parameter values that override job parameter values. When resolving parameters set in multiple places, job `NonOverridableArguments` will override job run `Arguments`, which will override job `DefaultArguments`.

In Python:

In Python jobs, we provide a function named `getResolvedParameters`. For more information, see [the section called “getResolvedOptions”](#). Job parameters are available in the `sys.argv` variable.

In Scala:

In Scala jobs, we provide an object named `GlueArgParser`. For more information, see [the section called “GlueArgParser”](#). Job parameters are available in the `sysArgs` variable.

Job parameter reference

Amazon Glue recognizes the following argument names that you can use to set up the script environment for your jobs and job runs:

--additional-python-modules

A comma delimited list representing a set of Python packages to be installed. You can install packages from PyPI or provide a custom distribution. A PyPI package entry will be in the format *package==version*, with the PyPI name and version of your target package. A custom distribution entry is the S3 path to the distribution.

Entries use Python version matching to match package and version. This means you will need to use two equals signs, such as `==`. There are other version matching operators, for more information see [PEP 440](#).

To pass module installation options to `pip3`, use the [--python-modules-installer-option](#) parameter.

--auto-scale-within-microbatch

The default value is true. This parameter can only be used for Amazon Glue streaming jobs, which process the streaming data in a series of micro batches, and auto scaling must be enabled. When setting this value to false, it computes the exponential moving average of batch duration for completed micro-batches and compares this value with the window size to determine whether to scale up or scale down the number of executors. Scaling only happens when a micro batch is completed. When setting this value to true, during a micro-batch, it scales up when the number of Spark tasks remains the same for 30 seconds, or the current batch processing is greater than the window size. The number of executors will drop if an executor has been idle for more than 60 seconds, or the exponential moving average of batch duration is low.

--class

The Scala class that serves as the entry point for your Scala script. This applies only if your `--job-language` is set to `scala`.

--continuous-log-conversionPattern

Specifies a custom conversion log pattern for a job enabled for continuous logging. The conversion pattern applies only to driver logs and executor logs. It does not affect the Amazon Glue progress bar.

--continuous-log-logGroup

Specifies a custom Amazon CloudWatch log group name for a job enabled for continuous logging.

--continuous-log-logStreamPrefix

Specifies a custom CloudWatch log stream prefix for a job enabled for continuous logging.

--customer-driver-env-vars and --customer-executor-env-vars

These parameters set environment variables on the operating system respectively for each worker (driver or executor). You can use these parameters when building platforms and custom frameworks on top of Amazon Glue, to let your users write jobs on top of it. Enabling these two flags will allow you to set different environment variables on the driver and executor respectively without having to inject the same logic in the job script itself.

Example usage

The following is an example of using these parameters:

```
"--customer-driver-env-vars", "CUSTOMER_KEY1=VAL1,CUSTOMER_KEY2=\"val2,val2 val2\"",  
"--customer-executor-env-vars", "CUSTOMER_KEY3=VAL3,KEY4=VAL4"
```

Setting these in the job run argument is equivalent to running the following commands:

In the driver:

- export CUSTOMER_KEY1=VAL1
- export CUSTOMER_KEY2="val2,val2 val2"

In the executor:

- export CUSTOMER_KEY3=VAL3

Then, in the job script itself, you can retrieve the environment variables using `os.environ.get("CUSTOMER_KEY1")` or `System.getenv("CUSTOMER_KEY1")`.

Enforced syntax

Observe the following standards when defining environment variables:

- Each key must have the `CUSTOMER_` prefix.

For example: for `"CUSTOMER_KEY3=VAL3,KEY4=VAL4"`, `KEY4=VAL4` will be ignored and not set.

- Each key and value pair must be delineated with a single comma.

For example: "CUSTOMER_KEY3=VAL3,CUSTOMER_KEY4=VAL4"

- If the "value" has spaces or commas, then it must be defined within quotations.

For example: CUSTOMER_KEY2=\"val2, val2 val2\"

This syntax closely models the standards of setting bash environment variables.

--datalake-formats

Supported in Amazon Glue 3.0 and later versions.

Specifies the data lake framework to use. Amazon Glue adds the required JAR files for the frameworks that you specify into the `classpath`. For more information, see [Using data lake frameworks with Amazon Glue ETL jobs](#).

You can specify one or more of the following values, separated by a comma:

- `hudi`
- `delta`
- `iceberg`

For example, pass the following argument to specify all three frameworks.

```
'--datalake-formats': 'hudi,delta,iceberg'
```

--disable-proxy-v2

Disable the service proxy to allow Amazon service calls to Amazon S3, CloudWatch, and Amazon Glue originating from your script through your VPC. For more information, see [Configuring Amazon calls to go through your VPC](#). To disable the service proxy, set the value of this parameter to `true`.

--enable-auto-scaling

Turns on auto scaling and per-worker billing when you set the value to `true`.

--enable-continuous-cloudwatch-log

Enables real-time continuous logging for Amazon Glue jobs. You can view real-time Apache Spark job logs in CloudWatch.

--enable-continuous-log-filter

Specifies a standard filter (`true`) or no filter (`false`) when you create or edit a job enabled for continuous logging. Choosing the standard filter prunes out non-useful Apache Spark driver/executor and Apache Hadoop YARN heartbeat log messages. Choosing no filter gives you all the log messages.

--enable-glue-datacatalog

Enables you to use the Amazon Glue Data Catalog as an Apache Spark Hive metastore. To enable this feature, set the value to `true`.

--enable-job-insights

Enables additional error analysis monitoring with Amazon Glue job run insights. For details, see [the section called “Monitoring with Amazon Glue job run insights”](#). By default, the value is set to `true` and job run insights are enabled.

This option is available for Amazon Glue version 2.0 and 3.0.

--enable-lakeformation-fine-grained-access

Enables fine-grained access control for Amazon Glue jobs. For more information, see [the section called “Lake Formation for FGAC”](#).

--enable-metrics

Enables the collection of metrics for job profiling for this job run. These metrics are available on the Amazon Glue console and the Amazon CloudWatch console. The value of this parameter is not relevant. To enable this feature, you can provide this parameter with any value, but `true` is recommended for clarity. To disable this feature, remove this parameter from your job configuration.

--enable-observability-metrics

Enables a set of Observability metrics to generate insights into what is happening inside each job run on Job Runs Monitoring page under Amazon Glue console and the Amazon CloudWatch console. To enable this feature, set the value of this parameter to `true`. To disable this feature, set it to `false` or remove this parameter from your job configuration.

--enable-rename-algorithm-v2

Sets the EMRFS rename algorithm version to version 2. When a Spark job uses dynamic partition overwrite mode, there is a possibility that a duplicate partition is created. For instance,

you can end up with a duplicate partition such as `s3://bucket/table/location/p1=1/p1=1`. Here, P1 is the partition that is being overwritten. Rename algorithm version 2 fixes this issue.

This option is only available on Amazon Glue version 1.0.

--enable-s3-parquet-optimized-committer

Enables the EMRFS S3-optimized committer for writing Parquet data into Amazon S3. You can supply the parameter/value pair via the Amazon Glue console when creating or updating an Amazon Glue job. Setting the value to `true` enables the committer. By default, the flag is turned on in Amazon Glue 3.0 and off in Amazon Glue 2.0.

For more information, see [Using the EMRFS S3-optimized Committer](#).

--enable-spark-ui

When set to `true`, turns on the feature to use the Spark UI to monitor and debug Amazon Glue ETL jobs.

--executor-cores

Number of spark tasks that can run in parallel. This option is supported on Amazon Glue 3.0+. The value should not exceed 2x the number of vCPUs on the worker type, which is 8 on G.1X, 16 on G.2X, 32 on G.4X, 64 on G.8X, 96 on G.12X, 128 on G.16X, and 8 on R.1X, 16 on R.2X, 32 on R.4X, 64 on R.8X. You should exercise caution while updating this configuration as it could impact job performance because increased task parallelism causes memory, disk pressure as well as it could throttle the source and target systems (for example: it would cause more concurrent connections on Amazon RDS).

--extra-files

The Amazon S3 paths to additional files, such as configuration files that Amazon Glue copies to the working directory of your script on the driver node before running it. Multiple values must be complete paths separated by a comma (,). The value can be individual files or directory locations. This option is not supported for Python Shell job types.

--extra-jars

The Amazon S3 paths to additional files that Amazon Glue copies to the driver and executors. Amazon Glue also adds these files to the Java classpath before executing your script. Multiple values must be complete paths separated by a comma (,). The extension need not be `.jar`

--extra-py-files

The Amazon S3 paths to additional Python modules that Amazon Glue adds to the Python path on the driver node before running your script. Multiple values must be complete paths separated by a comma (,). Only individual files are supported, not a directory path.

--job-bookmark-option

Controls the behavior of a job bookmark. The following option values can be set.

--job-bookmark-option value	Description
job-bookmark-enable	Keep track of previously processed data. When a job runs, process new data since the last checkpoint.
job-bookmark-disable	Always process the entire dataset. You are responsible for managing the output from previous job runs.
job-bookmark-pause	<p>Process incremental data since the last successful run or the data in the range identified by the following suboptions, without updating the state of the last bookmark. You are responsible for managing the output from previous job runs. The two suboptions are as follows:</p> <ul style="list-style-type: none"> • job-bookmark-from <from-value> is the run ID that represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input is ignored. • job-bookmark-to <to-value> is the run ID that represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input excluding the input identified by the <from-value> is processed by the job. Any input later than this input is also excluded for processing. <p>The job bookmark state is not updated when this option set is specified.</p>

--job-bookmark-option value	Description
	The suboptions are optional. However, when used, both suboptions must be provided.

For example, to enable a job bookmark, pass the following argument.

```
'--job-bookmark-option': 'job-bookmark-enable'
```

--job-language

The script programming language. This value must be either `scala` or `python`. If this parameter is not present, the default is `python`.

--python-modules-installer-option

A plaintext string that defines options to be passed to `pip3` when installing modules with [--additional-python-modules](#). Provide options as you would in the command line, separated by spaces and prefixed by dashes. For more information about usage, see [the section called “Installing additional Python modules with pip in Amazon Glue 2.0 or later”](#).

Note

This option is not supported for Amazon Glue jobs when you use Python 3.9.

--scriptLocation

The Amazon Simple Storage Service (Amazon S3) location where your ETL script is located (in the form `s3://path/to/my/script.py`). This parameter overrides a script location set in the `JobCommand` object.

--spark-event-logs-path

Specifies an Amazon S3 path. When using the Spark UI monitoring feature, Amazon Glue flushes the Spark event logs to this Amazon S3 path every 30 seconds to a bucket that can be used as a temporary directory for storing Spark UI events.

--TempDir

Specifies an Amazon S3 path to a bucket that can be used as a temporary directory for the job.

For example, to set a temporary directory, pass the following argument.

```
'--TempDir': 's3-path-to-directory'
```

Note

Amazon Glue creates a temporary bucket for jobs if a bucket doesn't already exist in a Region. This bucket might permit public access. You can either modify the bucket in Amazon S3 to set the public access block, or delete the bucket later after all jobs in that Region have completed.

--use-postgres-driver

When setting this value to `true`, it prioritizes the Postgres JDBC driver in the class path to avoid a conflict with the Amazon Redshift JDBC driver. This option is only available in Amazon Glue version 2.0.

--user-jars-first

When setting this value to `true`, it prioritizes the customer's extra JAR files in the classpath. This option is only available in Amazon Glue version 2.0 or later.

--conf

Controls Spark config parameters. It is for advanced use cases.

--encryption-type

Legacy parameter. The corresponding behavior should be configured using security configurations. For more information about security configurations, see [the section called "Encrypting data written by Amazon Glue"](#).

Amazon Glue uses the following arguments internally and you should never use them:

- `--debug` — Internal to Amazon Glue. Do not set.
- `--mode` — Internal to Amazon Glue. Do not set.
- `--JOB_NAME` — Internal to Amazon Glue. Do not set.
- `--endpoint` — Internal to Amazon Glue. Do not set.

Amazon Glue supports bootstrapping an environment with Python's `site` module using `sitecustomize` to perform site-specific customizations. Bootstrapping your own initialization functions is recommended for advanced use cases only and is supported on a best-effort basis on Amazon Glue 4.0.

The environment variable prefix, `GLUE_CUSTOMER`, is reserved for customer use.

Amazon Glue Spark and PySpark jobs

Amazon Glue support Spark and PySpark jobs. A Spark job is run in an Apache Spark environment managed by Amazon Glue. It processes data in batches. A streaming ETL job is similar to a Spark job, except that it performs ETL on data streams. It uses the Apache Spark Structured Streaming framework. Some Spark job features are not available to streaming ETL jobs.

The following sections provide information on Amazon Glue Spark and PySpark jobs.

Topics

- [Configuring job properties for Spark jobs in Amazon Glue](#)
- [Editing Spark scripts in the Amazon Glue console](#)
- [Jobs \(legacy\)](#)
- [Tracking processed data using job bookmarks](#)
- [Storing Spark shuffle data](#)

- [Generative AI troubleshooting for Apache Spark in Amazon Glue](#)
- [Using materialized views with Amazon Glue](#)

Configuring job properties for Spark jobs in Amazon Glue

When you define your job on the Amazon Glue console, you provide values for properties to control the Amazon Glue runtime environment.

Defining job properties for Spark jobs

The following list describes the properties of a Spark job. For the properties of a Python shell job, see [Defining job properties for Python shell jobs](#). For properties of a streaming ETL job, see [the section called “Defining job properties for a streaming ETL job”](#).

The properties are listed in the order in which they appear on the **Add job** wizard on Amazon Glue console.

Name

Provide a UTF-8 string with a maximum length of 255 characters.

Description

Provide an optional description of up to 2048 characters.

IAM Role

Specify the IAM role that is used for authorization to resources used to run the job and access data stores. For more information about permissions for running jobs in Amazon Glue, see [Identity and access management for Amazon Glue](#).

Type

The type of ETL job. This is set automatically based on the type of data sources you select.

- **Spark** runs an Apache Spark ETL script with the job command `glueetl`.
- **Spark Streaming** runs a Apache Spark streaming ETL script with the job command `gluestreaming`. For more information, see [the section called "Streaming ETL jobs"](#).
- **Python shell** run a Python script with the job command `pythonshell`. For more information, see [Configuring job properties for Python shell jobs in Amazon Glue](#).

Amazon Glue version

Amazon Glue version determines the versions of Apache Spark and Python that are available to the job, as specified in the following table.

Amazon Glue version	Supported Spark and Python versions
5.1	<ul style="list-style-type: none"> • Spark 3.5.6 • Python 3.11
5.0	<ul style="list-style-type: none"> • Spark 3.5.4 • Python 3.11
4.0	<ul style="list-style-type: none"> • Spark 3.3.0 • Python 3.10

Amazon Glue version	Supported Spark and Python versions
3.0	<ul style="list-style-type: none"> • Spark 3.1.1 • Python 3.7

Language

The code in the ETL script defines your job's logic. The script can be coded in Python or Scala. You can choose whether the script that the job runs is generated by Amazon Glue or provided by you. You provide the script name and location in Amazon Simple Storage Service (Amazon S3). Confirm that there isn't a file with the same name as the script directory in the path. To learn more about writing scripts, see [Amazon Glue programming guide](#).

Worker type

The following worker types are available:

The resources available on Amazon Glue workers are measured in DPUs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory.

- **G.025X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk (approximately 34GB free). We recommend this worker type for low volume streaming jobs. This worker type is only available for Amazon Glue version 3.0 or later streaming jobs.
- **G.1X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 94GB disk (approximately 44GB free). We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- **G.2X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 138GB disk (approximately 78GB free). We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- **G.4X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 230GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries.

- **G. 8X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 485GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries.
- **G. 12X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 12 DPU (48 vCPUs, 192 GB of memory) with 768GB disk (approximately 741GB free). We recommend this worker type for jobs with very large and resource-intensive workloads that require significant compute capacity.
- **G. 16X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 16 DPU (64 vCPUs, 256 GB of memory) with 1024GB disk (approximately 996GB free). We recommend this worker type for jobs with the largest and most resource-intensive workloads that require maximum compute capacity.
- **R. 1X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 1 DPU with memory-optimized configuration. We recommend this worker type for memory-intensive workloads that frequently encounter out-of-memory errors or require high memory-to-CPU ratios.
- **R. 2X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 2 DPU with memory-optimized configuration. We recommend this worker type for memory-intensive workloads that frequently encounter out-of-memory errors or require high memory-to-CPU ratios.
- **R. 4X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 4 DPU with memory-optimized configuration. We recommend this worker type for large memory-intensive workloads that frequently encounter out-of-memory errors or require high memory-to-CPU ratios.
- **R. 8X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 8 DPU with memory-optimized configuration. We recommend this worker type for very large memory-intensive workloads that frequently encounter out-of-memory errors or require high memory-to-CPU ratios.

Worker Type Specifications

The following table provides detailed specifications for all available G worker types:

G Worker Type Specifications

Worker Type	DPU per Node	vCPU	Memory (GB)	Disk (GB)	Free Disk Space (GB)	Spark Executors per Node
G.025X	0.25	2	4	84	34	1
G.1X	1	4	16	94	44	1
G.2X	2	8	32	138	78	1
G.4X	4	16	64	256	230	1
G.8X	8	32	128	512	485	1
G.12X	12	48	192	768	741	1
G.16X	16	64	256	1024	996	1

Important: G.12X and G.16X worker types, as well as all R worker types (R.1X through R.8X), have higher startup latency.

You are charged an hourly rate based on the number of DPUs used to run your ETL jobs. For more information, see the [Amazon Glue pricing page](#).

For Amazon Glue version 1.0 or earlier jobs, when you configure a job using the console and specify a **Worker type** of **Standard**, the **Maximum capacity** is set and the **Number of workers** becomes the value of **Maximum capacity** - 1. If you use the Amazon Command Line Interface (Amazon CLI) or Amazon SDK, you can specify the **Max capacity** parameter, or you can specify both **Worker type** and the **Number of workers**.

For Amazon Glue version 2.0 or later jobs, you cannot specify a **Maximum capacity**. Instead, you should specify a **Worker type** and the **Number of workers**.

G.4X and **G.8X** worker types are available only for Amazon Glue version 3.0 or later Spark ETL jobs in the following Amazon Regions: US East (Ohio), US East (N. Virginia), US West (N. California), US West (Oregon), Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt),

Europe (Ireland), Europe (London), Europe (Spain), Europe (Stockholm), and South America (São Paulo).

G . 12X, **G . 16X**, and **R . 1X** through **R . 8X** worker types are available only for Amazon Glue version 4.0 or later Spark ETL jobs in the following Amazon Regions: US East (N. Virginia), US West (Oregon), US East (Ohio), Europe (Ireland), and Europe (Frankfurt). Additional regions will be supported in future releases.

Requested number of workers

For most worker types, you must specify the number of workers that are allocated when the job runs.

Job bookmark

Specify how Amazon Glue processes state information when the job runs. You can have it remember previously processed data, update state information, or ignore state information. For more information, see [the section called “Tracking processed data using job bookmarks”](#).

Job run queuing

Specifies whether job runs are queued to run later when they cannot run immediately due to service quotas.

When checked, job run queuing is enabled for the job runs. If not populated, the job runs will not be considered for queueing.

If this setting does not match the value set in the job run, then the value from the job run field will be used.

Flex execution

When you configure a job using Amazon Studio or the API you may specify a standard or flexible job execution class. Your jobs may have varying degrees of priority and time sensitivity. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for non-urgent jobs such as pre-production jobs, testing, and one-time data loads. Flexible job runs are supported for jobs using Amazon Glue version 3.0 or later and G . 1X or G . 2X worker types. The new worker types (G . 12X, G . 16X, and R . 1X through R . 8X) do not support flexible execution.

Flex job runs are billed based on the number of workers running at any point in time. Number of workers may be added or removed for a running flexible job run. Instead of billing as a

simple calculation of `Max Capacity * Execution Time`, each worker will contribute for the time it ran during the job run. The bill is the sum of (`Number of DPUs per worker * time each worker ran`).

For more information, see the help panel in Amazon Studio, or [Jobs](#) and [Job runs](#).

Number of retries

Specify the number of times, from 0 to 10, that Amazon Glue should automatically restart the job if it fails. Jobs that reach the timeout limit are not restarted.

Job timeout

Sets the maximum execution time in minutes. The maximum is 7 days or 10,080 minutes. Otherwise, the jobs will throw an exception.

When the value is left blank, the timeout is defaulted to 2880 minutes.

Any existing Amazon Glue jobs that had a timeout value greater than 7 days will be defaulted to 7 days. For instance if you specified a timeout of 20 days for a batch job, it will be stopped on the 7th day.

Best practices for job timeouts

Jobs are billed based on execution time. To avoid unexpected charges, configure timeout values appropriate for the expected execution time of your job.

Advanced Properties

Script filename

A unique script name for your job. Cannot be named **Untitled job**.

Script path

The Amazon S3 location of the script. The path must be in the form `s3://bucket/prefix/path/`. It must end with a slash (/) and not include any files.

Job metrics

Turn on or turn off the creation of Amazon CloudWatch metrics when this job runs. To see profiling data, you must enable this option. For more information about how to turn on and visualize metrics, see [Job monitoring and debugging](#).

Job observability metrics

Turn on the creation of additional observability CloudWatch metrics when this job runs. For more information, see [the section called “Monitoring with Amazon Glue Observability metrics”](#).

Continuous logging

Turn on continuous logging to Amazon CloudWatch. If this option is not enabled, logs are available only after the job completes. For more information, see [the section called “Logging for Amazon Glue jobs”](#).

Spark UI

Turn on the use of Spark UI for monitoring this job. For more information, see [Enabling the Apache Spark web UI for Amazon Glue jobs](#).

Spark UI logs path

The path to write logs when Spark UI is enabled.

Spark UI logging and monitoring configuration

Choose one of the following options:

- *Standard*: write logs using the Amazon Glue job run ID as the filename. Turn on Spark UI monitoring in the Amazon Glue console.
- *Legacy*: write logs using 'spark-application-{timestamp}' as the filename. Do not turn on Spark UI monitoring.
- *Standard and legacy*: write logs to both the standard and legacy locations. Turn on Spark UI monitoring in the Amazon Glue console.

Maximum concurrency

Sets the maximum number of concurrent runs that are allowed for this job. The default is 1. An error is returned when this threshold is reached. The maximum value you can specify is controlled by a service limit. For example, if a previous run of a job is still running when a new instance is started, you might want to return an error to prevent two instances of the same job from running concurrently.

Temporary path

Provide the location of a working directory in Amazon S3 where temporary intermediate results are written when Amazon Glue runs the script. Confirm that there isn't a file with the

same name as the temporary directory in the path. This directory is used when Amazon Glue reads and writes to Amazon Redshift and by certain Amazon Glue transforms.

Note

Amazon Glue creates a temporary bucket for jobs if a bucket doesn't already exist in a region. This bucket might permit public access. You can either modify the bucket in Amazon S3 to set the public access block, or delete the bucket later after all jobs in that region have completed.

Delay notification threshold (minutes)

Sets the threshold (in minutes) before a delay notification is sent. You can set this threshold to send notifications when a RUNNING, STARTING, or STOPPING job run takes more than an expected number of minutes.

Security configuration

Choose a security configuration from the list. A security configuration specifies how the data at the Amazon S3 target is encrypted: no encryption, server-side encryption with Amazon KMS-managed keys (SSE-KMS), or Amazon S3-managed encryption keys (SSE-S3).

Server-side encryption

If you select this option, when the ETL job writes to Amazon S3, the data is encrypted at rest using SSE-S3 encryption. Both your Amazon S3 data target and any data that is written to an Amazon S3 temporary directory is encrypted. This option is passed as a job parameter. For more information, see [Protecting Data Using Server-Side Encryption with Amazon S3-Managed Encryption Keys \(SSE-S3\)](#) in the *Amazon Simple Storage Service User Guide*.

Important

This option is ignored if a security configuration is specified.

Use Glue data catalog as the Hive metastore

Select to use the Amazon Glue Data Catalog as the Hive metastore. The IAM role used for the job must have the `glue:CreateDatabase` permission. A database called "default" is created in the Data Catalog if it does not exist.

Connections

Choose a VPC configuration to access Amazon S3 data sources located in your virtual private cloud (VPC). You can create and manage Network connection in Amazon Glue. For more information, see [Connecting to data](#).

Libraries

Python library path, Dependent JARs path, and Referenced files path

Specify these options if your script requires them. You can define the comma-separated Amazon S3 paths for these options when you define the job. You can override these paths when you run the job. For more information, see [Providing your own custom scripts](#).

Job parameters

A set of key-value pairs that are passed as named parameters to the script. These are default values that are used when the script is run, but you can override them in triggers or when you run the job. You must prefix the key name with --; for example: --myKey. You pass job parameters as a map when using the Amazon Command Line Interface.

For examples, see Python parameters in [Passing and accessing Python parameters in Amazon Glue](#).

Tags

Tag your job with a **Tag key** and an optional **Tag value**. After tag keys are created, they are read-only. Use tags on some resources to help you organize and identify them. For more information, see [Amazon tags in Amazon Glue](#).

Restrictions for jobs that access Lake Formation managed tables

Keep in mind the following notes and restrictions when creating jobs that read from or write to tables managed by Amazon Lake Formation:

- The following features are not supported in jobs that access tables with cell-level filters:
 - [Job bookmarks](#) and [bounded execution](#)
 - [Push-down predicates](#)
 - [Server-side catalog partition predicates](#)
 - [enableUpdateCatalog](#)

Editing Spark scripts in the Amazon Glue console

A script contains the code that extracts data from sources, transforms it, and loads it into targets. Amazon Glue runs a script when it starts a job.

Amazon Glue ETL scripts can be coded in Python or Scala. Python scripts use a language that is an extension of the PySpark Python dialect for extract, transform, and load (ETL) jobs. The script contains *extended constructs* to deal with ETL transformations. When you automatically generate the source code logic for your job, a script is created. You can edit this script, or you can provide your own script to process your ETL work.

For information about defining and editing scripts in Amazon Glue, see [Amazon Glue programming guide](#).

Additional libraries or files

If your script requires additional libraries or files, you can specify them as follows:

Python library path

Comma-separated Amazon Simple Storage Service (Amazon S3) paths to Python libraries that are required by the script.

Note

Only pure Python libraries can be used. Libraries that rely on C extensions, such as the pandas Python Data Analysis Library, are not yet supported.

Dependent jars path

Comma-separated Amazon S3 paths to JAR files that are required by the script.

Note

Currently, only pure Java or Scala (2.11) libraries can be used.

Referenced files path

Comma-separated Amazon S3 paths to additional files (for example, configuration files) that are required by the script.

Jobs (legacy)

A script contains the code that performs extract, transform, and load (ETL) work. You can provide your own script, or Amazon Glue can generate a script with guidance from you. For information about creating your own scripts, see [Providing your own custom scripts](#).

You can edit a script in the Amazon Glue console. When you edit a script, you can add sources, targets, and transforms.

To edit a script

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>. Then choose the **Jobs** tab.
2. Choose a job in the list, and then choose **Action, Edit script** to open the script editor.

You can also access the script editor from the job details page. Choose the **Script** tab, and then choose **Edit script**.

Script editor

The Amazon Glue script editor lets you insert, modify, and delete sources, targets, and transforms in your script. The script editor displays both the script and a diagram to help you visualize the flow of data.

To create a diagram for the script, choose **Generate diagram**. Amazon Glue uses annotation lines in the script beginning with **##** to render the diagram. To correctly represent your script in the diagram, you must keep the parameters in the annotations and the parameters in the Apache Spark code in sync.

The script editor lets you add code templates wherever your cursor is positioned in the script. At the top of the editor, choose from the following options:

- To add a source table to the script, choose **Source**.
- To add a target table to the script, choose **Target**.
- To add a target location to the script, choose **Target location**.
- To add a transform to the script, choose **Transform**. For information about the functions that are called in your script, see [Program Amazon Glue ETL scripts in PySpark](#).
- To add a Spigot transform to the script, choose **Spigot**.

In the inserted code, modify the parameters in both the annotations and Apache Spark code. For example, if you add a **Spigot** transform, verify that the path is replaced in both the @args annotation line and the output code line.

The **Logs** tab shows the logs that are associated with your job as it runs. The most recent 1,000 lines are displayed.

The **Schema** tab shows the schema of the selected sources and targets, when available in the Data Catalog.

Tracking processed data using job bookmarks

Amazon Glue tracks data that has already been processed during a previous run of an ETL job by persisting state information from the job run. This persisted state information is called a *job bookmark*. Job bookmarks help Amazon Glue maintain state information and prevent the reprocessing of old data. With job bookmarks, you can process new data when rerunning on a scheduled interval. A job bookmark is composed of the states for various elements of jobs, such as sources, transformations, and targets. For example, your ETL job might read new partitions in an Amazon S3 file. Amazon Glue tracks which partitions the job has processed successfully to prevent duplicate processing and duplicate data in the job's target data store.

Job bookmarks are implemented for JDBC data sources, the Relationalize transform, and some Amazon Simple Storage Service (Amazon S3) sources. The following table lists the Amazon S3 source formats that Amazon Glue supports for job bookmarks.

Amazon Glue version	Amazon S3 source formats
Version 0.9	JSON, CSV, Apache Avro, XML
Version 1.0 and later	JSON, CSV, Apache Avro, XML, Parquet, ORC

For information about Amazon Glue versions, see [Defining job properties for Spark jobs](#).

The job bookmarks feature has additional functionalities when accessed through Amazon Glue scripts. When browsing your generated script, you may see transformation contexts, which are related to this feature. For more information, see [the section called "Using job bookmarks"](#).

Topics

- [Using job bookmarks in Amazon Glue](#)

- [Operational details of the job bookmarks feature](#)

Using job bookmarks in Amazon Glue

The job bookmark option is passed as a parameter when the job is started. The following table describes the options for setting job bookmarks on the Amazon Glue console.

Job bookmark	Description
Enable	Causes the job to update the state after a run to keep track of previously processed data. If your job has a source with job bookmark support, it will keep track of processed data, and when a job runs, it processes new data since the last checkpoint.
Disable	Job bookmarks are not used, and the job always processes the entire dataset. You are responsible for managing the output from previous job runs. This is the default.
Pause	<p>Process incremental data since the last successful run or the data in the range identified by the following sub-options, without updating the state of last bookmark. You are responsible for managing the output from previous job runs. The two sub-options are:</p> <ul style="list-style-type: none"> • job-bookmark-from <from-value> is the run ID which represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input is ignored. • job-bookmark-to <to-value> is the run ID which represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input excluding the input identified by the <from-value> is processed by the job. Any input later than this input is also excluded for processing. <p>The job bookmark state is not updated when this option set is specified .</p> <p>The sub-options are optional, however when used both the sub-options needs to be provided.</p>

For details about the parameters passed to a job on the command line, and specifically for job bookmarks, see [Using job parameters in Amazon Glue jobs](#).

For Amazon S3 input sources, Amazon Glue job bookmarks check the last modified time of the objects to verify which objects need to be reprocessed. If your input source data has been modified since your last job run, the files are reprocessed when you run the job again.

For JDBC sources, the following rules apply:

- For each table, Amazon Glue uses one or more columns as bookmark keys to determine new and processed data. The bookmark keys combine to form a single compound key.
- Amazon Glue by default uses the primary key as the bookmark key, provided that it is sequentially increasing or decreasing (with no gaps).
- You can specify the columns to use as bookmark keys in your Amazon Glue script. For more information about using Job bookmarks in Amazon Glue scripts, see [the section called “Using job bookmarks”](#).
- Amazon Glue doesn't support using columns with case-sensitive names as job bookmark keys.

You can rewind your job bookmarks for your Amazon Glue Spark ETL jobs to any previous job run. You can support data backfilling scenarios better by rewinding your job bookmarks to any previous job run, resulting in the subsequent job run reprocessing data only from the bookmarked job run.

If you intend to reprocess all the data using the same job, reset the job bookmark. To reset the job bookmark state, use the Amazon Glue console, the [ResetJobBookmark action \(Python: `reset_job_bookmark`\)](#) API operation, or the Amazon CLI. For example, enter the following command using the Amazon CLI:

```
aws glue reset-job-bookmark --job-name my-job-name
```

When you rewind or reset a bookmark, Amazon Glue does not clean the target files because there could be multiple targets and targets are not tracked with job bookmarks. Only source files are tracked with job bookmarks. You can create different output targets when rewinding and reprocessing the source files to avoid duplicate data in your output.

Amazon Glue keeps track of job bookmarks by job. If you delete a job, the job bookmark is deleted.

In some cases, you might have enabled Amazon Glue job bookmarks but your ETL job is reprocessing data that was already processed in an earlier run. For information about resolving common causes of this error, see [Troubleshooting Glue common setup errors](#).

Operational details of the job bookmarks feature

This section describes more of the operational details of using job bookmarks.

Job bookmarks store the states for a job. Each instance of the state is keyed by a job name and a version number. When a script invokes `job.init`, it retrieves its state and always gets the latest version. Within a state, there are multiple state elements, which are specific to each source, transformation, and sink instance in the script. These state elements are identified by a transformation context that is attached to the corresponding element (source, transformation, or sink) in the script. The state elements are saved atomically when `job.commit` is invoked from the user script. The script gets the job name and the control option for the job bookmarks from the arguments.

The state elements in the job bookmark are source, transformation, or sink-specific data. For example, suppose that you want to read incremental data from an Amazon S3 location that is being constantly written to by an upstream job or process. In this case, the script must determine what has been processed so far. The job bookmark implementation for the Amazon S3 source saves information so that when the job runs again, it can filter only the new objects using the saved information and recompute the state for the next run of the job. A timestamp is used to filter the new files.

In addition to the state elements, job bookmarks have a *run number*, an *attempt number*, and a *version number*. The run number tracks the run of the job, and the attempt number records the attempts for a job run. The job run number is a monotonically increasing number that is incremented for every successful run. The attempt number tracks the attempts for each run, and is only incremented when there is a run after a failed attempt. The version number increases monotonically and tracks the updates to a job bookmark.

In the Amazon Glue service database, the bookmark states for all the transformations are stored together as key-value pairs:

```
{
  "job_name" : ...,
  "run_id": ...,
  "run_number": ..,
  "attempt_number": ...
```

```
"states": {
  "transformation_ctx1" : {
    bookmark_state1
  },
  "transformation_ctx2" : {
    bookmark_state2
  }
}
```

Best practices

The following are best practices for using job bookmarks.

- *Do not change the data source property with the bookmark enabled.* For example, there is a `datasource0` pointing to an Amazon S3 input path A, and the job has been reading from a source which has been running for several rounds with the bookmark enabled. If you change the input path of `datasource0` to Amazon S3 path B without changing the `transformation_ctx`, the Amazon Glue job will use the old bookmark state stored. That will result in missing or skipping files in the input path B as Amazon Glue would assume that those files had been processed in previous runs.
- *Use a catalog table with bookmarks for better partition management.* Bookmarks works both for data sources from the Data Catalog or from options. However, it's difficult to remove/add new partitions with the from options approach. Using a catalog table with crawlers can provide better automation to track the newly added [partitions](#) and give you the flexibility to select particular partitions with a [pushdown predicate](#).
- *Use the [Amazon Glue Amazon S3 file lister](#) for large datasets.* A bookmark will list all files under each input partition and do the filtering, so if there are too many files under a single partition the bookmark can run into driver OOM. Use the Amazon Glue Amazon S3 file lister to avoid listing all files in memory at once.

Storing Spark shuffle data

Shuffling is an important step in a Spark job whenever data is rearranged between partitions. This is required because wide transformations such as `join`, `groupByKey`, `reduceByKey`, and `repartition` require information from other partitions to complete processing. Spark gathers the required data from each partition and combines it into a new partition. During a shuffle, data is written to disk and transferred across the network. As a result, the shuffle

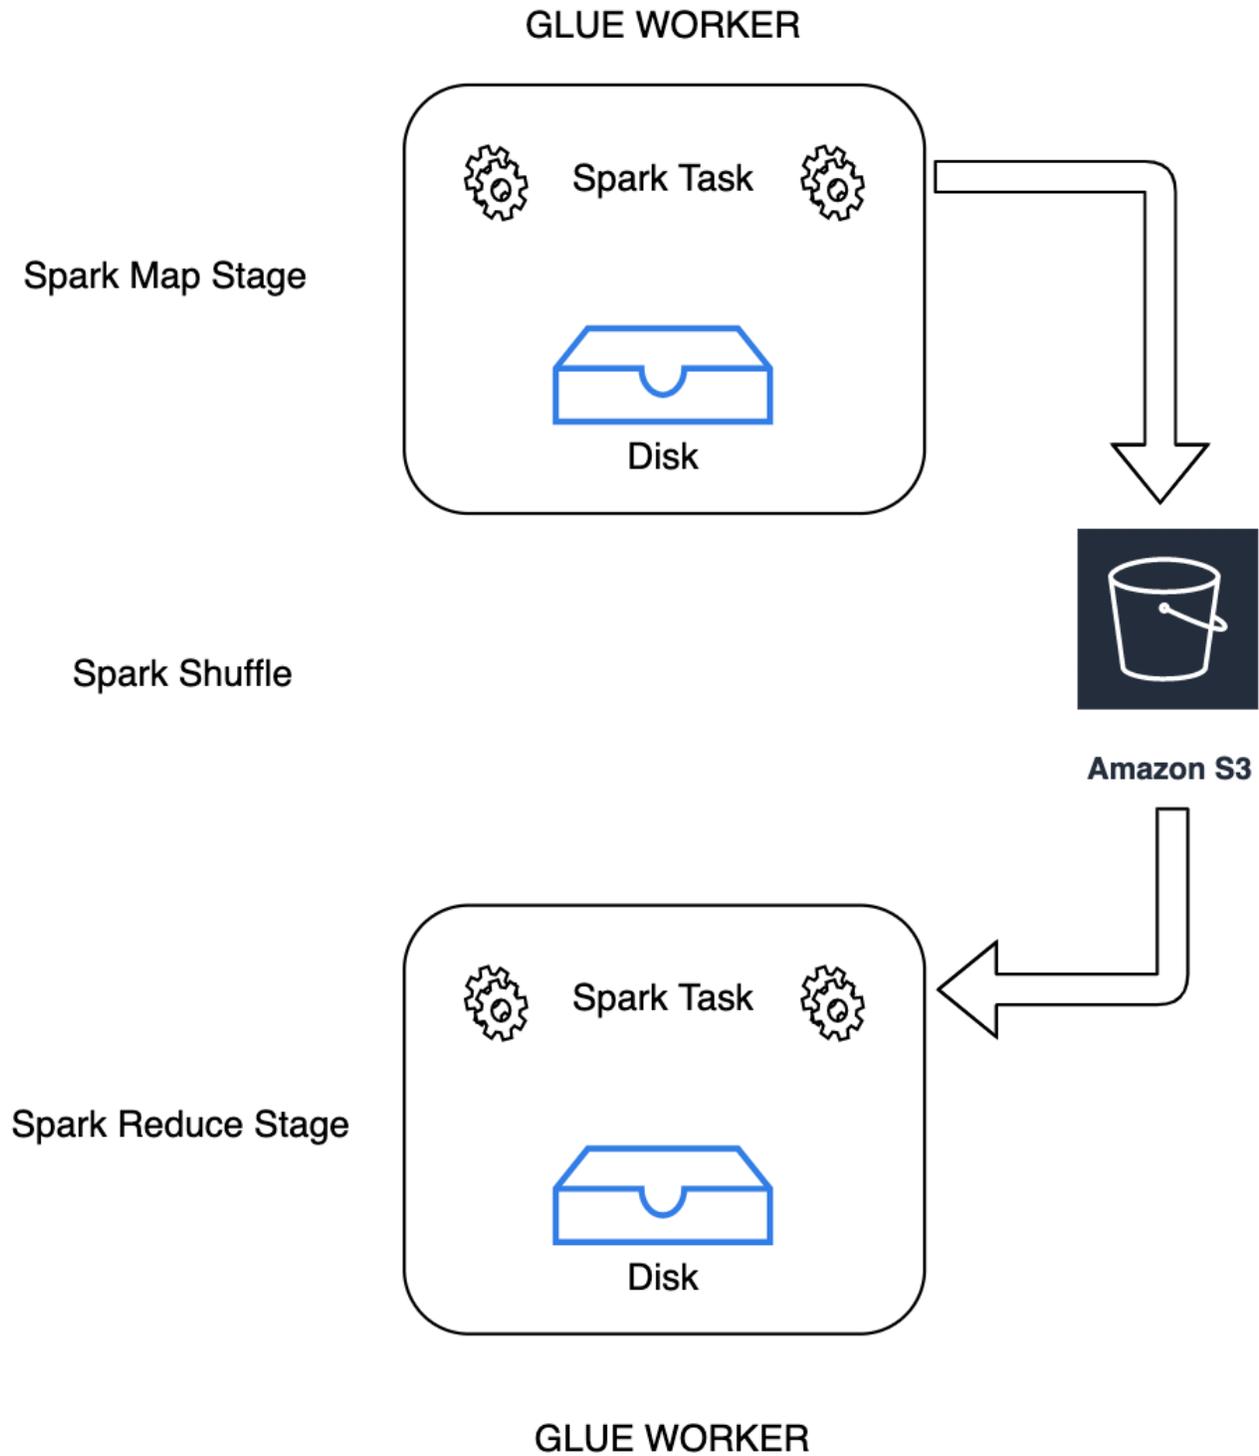

operation is bound to local disk capacity. Spark throws a `No space left on device` or `MetadataFetchFailedException` error when there is not enough disk space left on the executor and there is no recovery.

 **Note**

Amazon Glue Spark shuffle plugin with Amazon S3 is only supported for Amazon Glue ETL jobs.

Solution

With Amazon Glue, you can now use Amazon S3 to store Spark shuffle data. Amazon S3 is an object storage service that offers industry-leading scalability, data availability, security, and performance. This solution disaggregates compute and storage for your Spark jobs, and gives complete elasticity and low-cost shuffle storage, allowing you to run your most shuffle-intensive workloads reliably.

We are introducing a new Cloud Shuffle Storage Plugin for Apache Spark to use Amazon S3. You can turn on Amazon S3 shuffling to run your Amazon Glue jobs reliably without failures if they are known to be bound by the local disk capacity for large shuffle operations. In some cases, shuffling

to Amazon S3 is marginally slower than local disk (or EBS) if you have a large number of small partitions or shuffle files written out to Amazon S3.

Prerequisites for using Cloud Shuffle Storage Plugin

In order to use the Cloud Shuffle Storage Plugin with Amazon Glue ETL jobs, you need the following:

- An Amazon S3 bucket located in the same region as your job run, for storing the intermediate shuffle and spilled data. The Amazon S3 prefix of shuffle storage can be specified with `--conf spark.shuffle.glue.s3ShuffleBucket=s3://shuffle-bucket/prefix/`, as in the following example:

```
--conf spark.shuffle.glue.s3ShuffleBucket=s3://glue-shuffle-123456789-us-east-1/glue-shuffle-data/
```

- Set the Amazon S3 storage lifecycle policies on the *prefix* (such as `glue-shuffle-data`) as the shuffle manager does not clean the files after the job is done. The intermediate shuffle and spilled data should be deleted after a job is finished. Users can set a short lifecycle policies on the prefix. Instructions for setting up an Amazon S3 lifecycle policy are available at [Setting lifecycle configuration on a bucket](#) in the Amazon Simple Storage Service User Guide.

Using Amazon Glue Spark shuffle manager from the Amazon console

To set up the Amazon Glue Spark shuffle manager using the Amazon Glue console or Amazon Glue Studio when configuring a job: choose the `--write-shuffle-files-to-s3` job parameter to turn on Amazon S3 shuffling for the job.

Job parameters

Key	Value - optional	
<input type="text" value="Q --write-shuffle-files- X"/>	<input type="text" value="Q"/>	<input type="button" value="Remove"/>

You can add 49 more parameters.

Using Amazon Glue Spark shuffle plugin

The following job parameters turn on and tune the Amazon Glue shuffle manager. These parameters are flags, so any values provided are not considered.

- `--write-shuffle-files-to-s3` — The main flag, which enables the Amazon Glue Spark shuffle manager to use Amazon S3 buckets for writing and reading shuffle data. When the flag is not specified, the shuffle manager is not used.
- `--write-shuffle-spills-to-s3` — (Supported only on Amazon Glue version 2.0). An optional flag that allows you to offload spill files to Amazon S3 buckets, which provides additional resiliency to your Spark job. This is only required for large workloads that spill a lot of data to disk. When the flag is not specified, no intermediate spill files are written.
- `--conf spark.shuffle.glue.s3ShuffleBucket=s3://<shuffle-bucket>` — Another optional flag that specifies the Amazon S3 bucket where you write the shuffle files. By default, `--TempDir/shuffle-data`. Amazon Glue 3.0+ supports writing shuffle files to multiple buckets by specifying buckets with comma delimiter, as in `--conf spark.shuffle.glue.s3ShuffleBucket=s3://shuffle-bucket-1/prefix,s3://shuffle-bucket-2/prefix/`. Using multiple buckets improves performance.

You need to provide security configuration settings to enable encryption at-rest for the shuffle data. For more information about security configurations, see [the section called “Setting up encryption”](#). Amazon Glue supports all other shuffle related configurations provided by Spark.

Software binaries for the Cloud Shuffle Storage plugin

You can also download the software binaries of the Cloud Shuffle Storage Plugin for Apache Spark under the Apache 2.0 license and run it on any Spark environment. The new plugin comes with out-of-the box support for Amazon S3, and can also be easily configured to use other forms of cloud storage such as [Google Cloud Storage and Microsoft Azure Blob Storage](#). For more information, see [Cloud Shuffle Storage Plugin for Apache Spark](#).

Notes and limitations

The following are notes or limitations for the Amazon Glue shuffle manager:

- Amazon Glue shuffle manager doesn't automatically delete the (temporary) shuffle data files stored in your Amazon S3 bucket after a job is completed. To ensure data protection, follow the

instructions in [Prerequisites for using Cloud Shuffle Storage Plugin](#) before enabling the Cloud Shuffle Storage Plugin.

- You can use this feature if your data is skewed.

Cloud Shuffle Storage Plugin for Apache Spark

The Cloud Shuffle Storage Plugin is an Apache Spark plugin compatible with the [ShuffleDataIO API](#) which allows storing shuffle data on cloud storage systems (such as Amazon S3). It helps you to supplement or replace local disk storage capacity for large shuffle operations, commonly triggered by transformations such as `join`, `reduceByKey`, `groupByKey` and `repartition` in your Spark applications, thereby reducing common failures or price/performance dislocation of your serverless data analytics jobs and pipelines.

Amazon Glue

Amazon Glue versions 3.0 and 4.0 comes with the plugin pre-installed and ready to enable shuffling to Amazon S3 without any extra steps. For more information, see [Amazon Glue Spark shuffle plugin with Amazon S3](#) to enable the feature for your Spark applications.

Other Spark environments

The plugin requires the following Spark configurations to be set on other Spark environments:

- `--conf spark.shuffle.sort.io.plugin.class=com.amazonaws.spark.shuffle.io.cloud.Chopped`
This informs Spark to use this plugin for Shuffle IO.
- `--conf spark.shuffle.storage.path=s3://bucket-name/shuffle-file-dir`: The path where your shuffle files will be stored.

Note

The plugin overwrites one Spark core class. As a result, the plugin jar needs to be loaded before Spark jars. You can do this using `userClassPathFirst` in on-prem YARN environments if the plugin is used outside Amazon Glue.

Bundling the plugin with your Spark applications

You can bundle the plugin with your Spark applications and Spark distributions (versions 3.1 and above) by adding the plugin dependency in your Maven pom.xml while developing your Spark applications locally. For more information on the plugin and Spark versions, see [Plugin versions](#).

```
<repositories>
  ...
  <repository>
    <id>aws-glue-etl-artifacts</id>
    <url>https://aws-glue-etl-artifacts.s3.amazonaws.com/release/ </url>
  </repository>
</repositories>
...
<dependency>
  <groupId>com.amazonaws</groupId>
  <artifactId>chopper-plugin</artifactId>
  <version>3.1-amzn-LATEST</version>
</dependency>
```

You can alternatively download the binaries from Amazon Glue Maven artifacts directly and include them in your Spark application as follows.

```
#!/bin/bash
sudo wget -v https://aws-glue-etl-artifacts.s3.amazonaws.com/release/com.amazonaws/
chopper-plugin/3.1-amzn-LATEST/chopper-plugin-3.1-amzn-LATEST.jar -P /usr/lib/spark/
jars/
```

Example spark-submit

```
spark-submit --deploy-mode cluster \
--conf spark.shuffle.storage.s3.path=s3://<ShuffleBucket>/<shuffle-dir> \
--conf spark.driver.extraClassPath=<Path to plugin jar> \
--conf spark.executor.extraClassPath=<Path to plugin jar> \
--class <your test class name> s3://<ShuffleBucket>/<Your application jar> \
```

Optional configurations

These are optional configuration values that control Amazon S3 shuffle behavior.

- `spark.shuffle.storage.s3.enableServerSideEncryption`: Enable/disable S3 SSE for shuffle and spill files. Default value is `true`.

- `spark.shuffle.storage.s3.serverSideEncryption.algorithm`: The SSE algorithm to be used. Default value is AES256.
- `spark.shuffle.storage.s3.serverSideEncryption.kms.key`: The KMS key ARN when SSE aws:kms is enabled.

Along with these configurations, you may need to set configurations such as `spark.hadoop.fs.s3.enableServerSideEncryption` and **other environment-specific configurations** to ensure appropriate encryption is applied for your use case.

Plugin versions

This plugin is supported for the Spark versions associated with each Amazon Glue version. The following table shows the Amazon Glue version, Spark version and associated plugin version with Amazon S3 location for the plugin's software binary.

Amazon Glue version	Spark version	Plugin version	Amazon S3 location
3.0	3.1	3.1-amzn-LATEST	s3://aws-glue-etl-artifacts/release/com/amazonaws/chopper-plugin/3.1-amzn-0/chopper-plugin-3.1-amzn-LATEST.jar
4.0	3.3	3.3-amzn-LATEST	s3://aws-glue-etl-artifacts/release/com/amazonaws/chopper-plugin/3.3-amzn-0/chopper-plugin-3.3-amzn-LATEST.jar

License

The software binary for this plugin is licensed under the Apache-2.0 License.

Monitoring Amazon Glue Spark jobs

Topics

- [Spark Metrics available in Amazon Glue Studio](#)
- [Monitoring jobs using the Apache Spark web UI](#)
- [Monitoring with Amazon Glue job run insights](#)
- [Monitoring with Amazon CloudWatch](#)
- [Job monitoring and debugging](#)

Spark Metrics available in Amazon Glue Studio

The **Metrics** tab shows metrics collected when a job runs and profiling is turned on. The following graphs are shown in Spark jobs:

- ETL Data Movement
- Memory Profile: Driver and Executors

Choose **View additional metrics** to show the following graphs:

- ETL Data Movement
- Memory Profile: Driver and Executors
- Data Shuffle Across Executors
- CPU Load: Driver and Executors
- Job Execution: Active Executors, Completed Stages & Maximum Needed Executors

Data for these graphs is pushed to CloudWatch metrics if the job is configured to collect metrics. For more information about how to turn on metrics and interpret the graphs, see [Job monitoring and debugging](#).

Example ETL data movement graph

The ETL Data Movement graph shows the following metrics:

- The number of bytes read from Amazon S3 by all executors
—[glue.ALL.s3.filesystem.read_bytes](#)

- The number of bytes written to Amazon S3 by all executors—[glue.ALL.s3.filesystem.write_bytes](#)

Jobs > e2e-straggler

Detailed job metrics

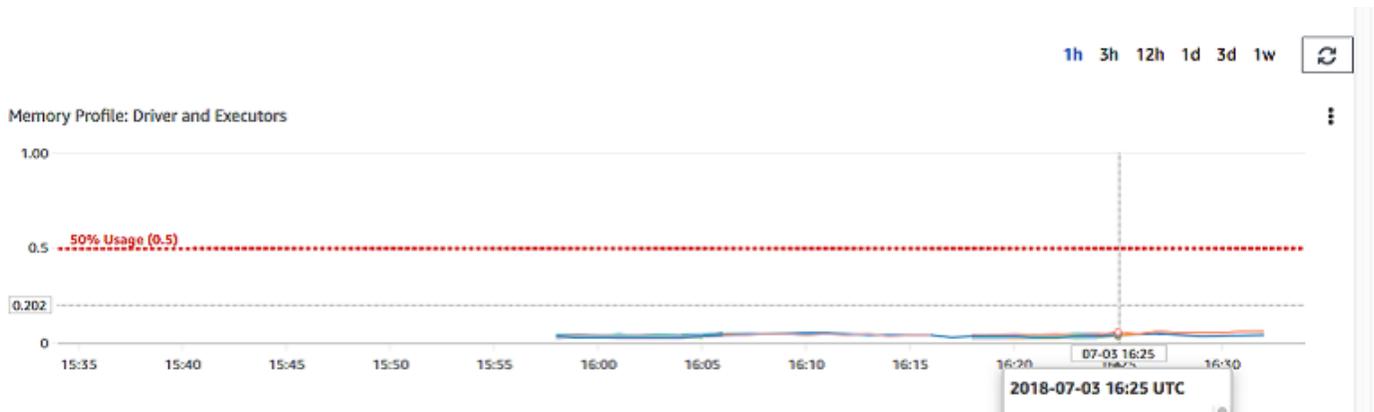

ETL Data Movement

Example Memory profile graph

The Memory Profile graph shows the following metrics:

- The fraction of memory used by the JVM heap for this driver (scale: 0–1) by the driver, an executor identified by *executorId*, or all executors—
 - [glue.driver.jvm.heap.usage](#)
 - [glue.executorId.jvm.heap.usage](#)
 - [glue.ALL.jvm.heap.usage](#)

Example Data shuffle across executors graph

The Data Shuffle Across Executors graph shows the following metrics:

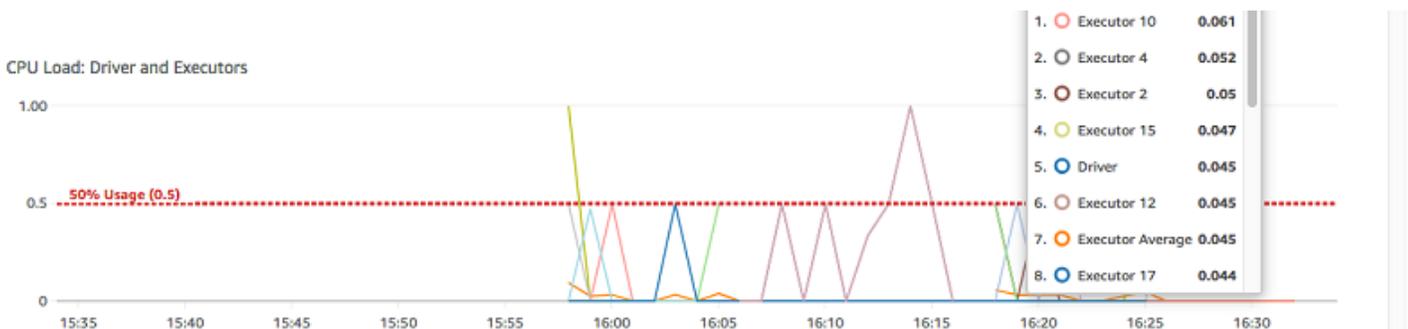

- The number of bytes read by all executors to shuffle data between them
—[glue.driver.aggregate.shuffleLocalBytesRead](#)
- The number of bytes written by all executors to shuffle data between them
—[glue.driver.aggregate.shuffleBytesWritten](#)

Example CPU load graph

The CPU Load graph shows the following metrics:

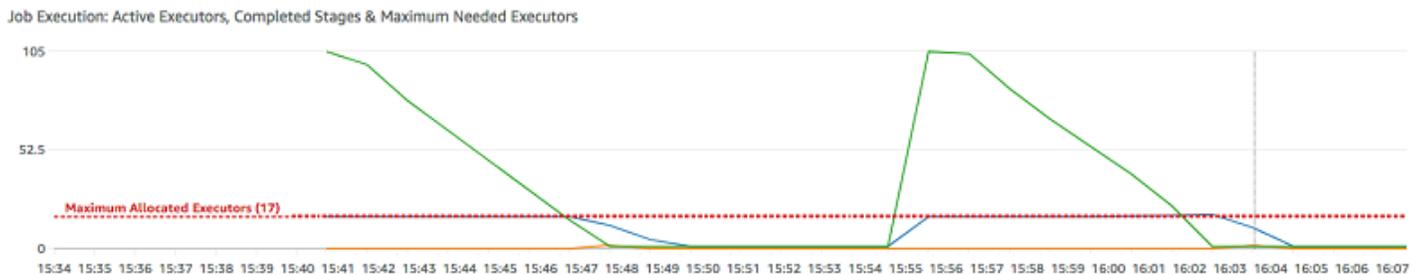

- The fraction of CPU system load used (scale: 0–1) by the driver, an executor identified by *executorId*, or all executors—
 - [glue.driver.system.cpuSystemLoad](#)
 - [glue.executorId.system.cpuSystemLoad](#)
 - [glue.ALL.system.cpuSystemLoad](#)

Example Job execution graph

The Job Execution graph shows the following metrics:

- The number of actively running executors
—[glue.driver.ExecutorAllocationManager.executors.numberAllExecutors](#)
- The number of completed stages—[glue.aggregate.numCompletedStages](#)
- The number of maximum needed executors
—[glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors](#)

Monitoring jobs using the Apache Spark web UI

You can use the Apache Spark web UI to monitor and debug Amazon Glue ETL jobs running on the Amazon Glue job system, and also Spark applications running on Amazon Glue development endpoints. The Spark UI enables you to check the following for each job:

- The event timeline of each Spark stage
- A directed acyclic graph (DAG) of the job
- Physical and logical plans for SparkSQL queries
- The underlying Spark environmental variables for each job

For more information about using the Spark Web UI, see [Web UI](#) in the Spark documentation. For guidance on how to interpret Spark UI results to improve the performance of your job, see [Best practices for performance tuning Amazon Glue for Apache Spark jobs](#) in Amazon Prescriptive Guidance.

You can see the Spark UI in the Amazon Glue console. This is available when an Amazon Glue job runs on Amazon Glue 3.0 or later versions with logs generated in the Standard (rather than

legacy) format, which is the default for newer jobs. If you have log files greater than 0.5 GB, you can enable rolling log support for job runs on Amazon Glue 4.0 or later versions to simplify log archiving, analysis, and troubleshooting.

You can enable the Spark UI by using the Amazon Glue console or the Amazon Command Line Interface (Amazon CLI). When you enable the Spark UI, Amazon Glue ETL jobs and Spark applications on Amazon Glue development endpoints can back up Spark event logs to a location that you specify in Amazon Simple Storage Service (Amazon S3). You can use the backed up event logs in Amazon S3 with the Spark UI, both in real time as the job is operating and after the job is complete. While the logs remain in Amazon S3, the Spark UI in the Amazon Glue console can view them.

Permissions

In order to use the Spark UI in the Amazon Glue console, you can use `UseGlueStudio` or add all the individual service APIs. All APIs are needed to use the Spark UI completely, however users can access SparkUI features by adding its service APIs in their IAM permission for fine-grained access.

`RequestLogParsing` is the most critical as it performs the parsing of logs. The remaining APIs are for reading the respective parsed data. For example, `GetStages` provides access to the data about all stages of a Spark job.

The list of Spark UI service APIs mapped to `UseGlueStudio` are below in the sample policy. The policy below provides access to use only Spark UI features. To add more permissions like Amazon S3 and IAM see [Creating Custom IAM Policies for Amazon Glue Studio](#).

The list of Spark UI service APIs mapped to `UseGlueStudio` is below in the sample policy. When using a Spark UI service API, use the following namespace: `glue:<ServiceAPI>`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGlueStudioSparkUI",
      "Effect": "Allow",
      "Action": [
        "glue:RequestLogParsing",
```

```

    "glue:GetLogParsingStatus",
    "glue:GetEnvironment",
    "glue:GetJobs",
    "glue:GetJob",
    "glue:GetStage",
    "glue:GetStages",
    "glue:GetStageFiles",
    "glue:BatchGetStageFiles",
    "glue:GetStageAttempt",
    "glue:GetStageAttemptTaskList",
    "glue:GetStageAttemptTaskSummary",
    "glue:GetExecutors",
    "glue:GetExecutorsThreads",
    "glue:GetStorage",
    "glue:GetStorageUnit",
    "glue:GetQueries",
    "glue:GetQuery"
  ],
  "Resource": [
    "*"
  ]
}
]
}

```

Limitations

- Spark UI in the Amazon Glue console is not available for job runs that occurred before 20 Nov 2023 because they are in the legacy log format.
- Spark UI in the Amazon Glue console supports rolling logs for Amazon Glue 4.0, such as those generated by default in streaming jobs. The maximum sum of all generated rolled log event files is 2 GB. For Amazon Glue jobs without rolled log support, the maximum log event file size supported for SparkUI is 0.5 GB.
- Serverless Spark UI is not available for Spark event logs stored in an Amazon S3 bucket that can only be accessed by your VPC.

Example: Apache Spark web UI

This example shows you how to use the Spark UI to understand your job performance. Screen shots show the Spark web UI as provided by a self-managed Spark history server. Spark UI in the Amazon

Glue console provides similar views. For more information about using the Spark Web UI, see [Web UI](#) in the Spark documentation.

The following is an example of a Spark application that reads from two data sources, performs a join transform, and writes it out to Amazon S3 in Parquet format.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from pyspark.sql.functions import count, when, expr, col, sum, isnull
from pyspark.sql.functions import countDistinct
from awsglue.dynamicframe import DynamicFrame

args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

job = Job(glueContext)
job.init(args['JOB_NAME'])

df_persons = spark.read.json("s3://awsglue-datasets/examples/us-legislators/all/
persons.json")
df_memberships = spark.read.json("s3://awsglue-datasets/examples/us-legislators/all/
memberships.json")

df_joined = df_persons.join(df_memberships, df_persons.id == df_memberships.person_id,
'fullouter')
df_joined.write.parquet("s3://aws-glue-demo-sparkui/output/")

job.commit()
```

The following DAG visualization shows the different stages in this Spark job.

Enabling the Apache Spark web UI for Amazon Glue jobs

You can use the Apache Spark web UI to monitor and debug Amazon Glue ETL jobs running on the Amazon Glue job system. You can configure the Spark UI using the Amazon Glue console or the Amazon Command Line Interface (Amazon CLI).

Every 30 seconds, Amazon Glue backs up the Spark event logs to the Amazon S3 path that you specify.

Topics

- [Configuring the Spark UI \(console\)](#)
- [Configuring the Spark UI \(Amazon CLI\)](#)
- [Configuring the Spark UI for sessions using Notebooks](#)
- [Enable rolling logs](#)

Configuring the Spark UI (console)

Follow these steps to configure the Spark UI by using the Amazon Web Services Management Console. When creating an Amazon Glue job, Spark UI is enabled by default.

To turn on the Spark UI when you create or edit a job

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, choose **Jobs**.
3. Choose **Add job**, or select an existing one.
4. In **Job details**, open the **Advanced properties**.
5. Under the **Spark UI** tab, choose **Write Spark UI logs to Amazon S3**.
6. Specify an Amazon S3 path for storing the Spark event logs for the job. Note that if you use a security configuration in the job, the encryption also applies to the Spark UI log file. For more information, see [Encrypting data written by Amazon Glue](#).
7. Under **Spark UI logging and monitoring configuration**:

- Select **Standard** if you are generating logs to view in the Amazon Glue console.
- Select **Legacy** if you are generating logs to view on a Spark history server.
- You can also choose to generate both.

Configuring the Spark UI (Amazon CLI)

To generate logs for viewing with Spark UI, in the Amazon Glue console, use the Amazon CLI to pass the following job parameters to Amazon Glue jobs. For more information, see [the section called “Job parameters”](#).

```
'--enable-spark-ui': 'true',  
'--spark-event-logs-path': 's3://s3-event-log-path'
```

To distribute logs to their legacy locations, set the `--enable-spark-ui-legacy-path` parameter to `"true"`. If you do not want to generate logs in both formats, remove the `--enable-spark-ui` parameter.

Configuring the Spark UI for sessions using Notebooks

Warning

Amazon Glue interactive sessions do not currently support Spark UI in the console. Configure a Spark history server.

If you use Amazon Glue notebooks, set up SparkUI config before starting the session. To do this, use the `%%configure` cell magic:

```
%%configure { "--enable-spark-ui": "true", "--spark-event-logs-path": "s3://path" }
```

Enable rolling logs

Enabling SparkUI and rolling log event files for Amazon Glue jobs provides several benefits:

- **Rolling Log Event Files** – With rolling log event files enabled, Amazon Glue generates separate log files for each step of the job execution, making it easier to identify and troubleshoot issues specific to a particular stage or transformation.

- **Better Log Management** – Rolling log event files help in managing log files more efficiently. Instead of having a single, potentially large log file, the logs are split into smaller, more manageable files based on the job execution stages. This can simplify log archiving, analysis, and troubleshooting.
- **Improved Fault Tolerance** – If a Amazon Glue job fails or is interrupted, the rolling log event files can provide valuable information about the last successful stage, making it easier to resume the job from that point rather than starting from scratch.
- **Cost Optimization** – By enabling rolling log event files, you can save on storage costs associated with log files. Instead of storing a single, potentially large log file, you store smaller, more manageable log files, which can be more cost-effective, especially for long-running or complex jobs.

In a new environment, users can explicitly enable rolling logs through:

```
'-conf': 'spark.eventLog.rolling.enabled=true'
```

or

```
'-conf': 'spark.eventLog.rolling.enabled=true -conf  
spark.eventLog.rolling.maxFileSize=128m'
```

When rolling logs are activated, `spark.eventLog.rolling.maxFileSize` specifies the maximum size of the event log file before it rolls over. The default value of this optional parameter if not specified is 128 MB. Minimum is 10 MB.

The maximum sum of all generated rolled log event files is 2 GB. For Amazon Glue jobs without rolling log support, the maximum log event file size supported for SparkUI is 0.5 GB.

You can turn off rolling logs for a streaming job by passing an additional configuration. Note that very large log files may be costly to maintain.

To turn off rolling logs, provide the following configuration:

```
'--spark-ui-event-logs-path': 'true',  
'-conf': 'spark.eventLog.rolling.enabled=false'
```

Launching the Spark history server

You can use a Spark history server to visualize Spark logs on your own infrastructure. You can see the same visualizations in the Amazon Glue console for Amazon Glue job runs on Amazon Glue 4.0 or later versions with logs generated in the Standard (rather than legacy) format. For more information, see [the section called “Monitoring with the Spark UI”](#).

You can launch the Spark history server using a Amazon CloudFormation template that hosts the server on an EC2 instance, or launch locally using Docker.

Topics

- [Launching the Spark history server and viewing the Spark UI using Amazon CloudFormation](#)
- [Launching the Spark history server and viewing the Spark UI using Docker](#)

Launching the Spark history server and viewing the Spark UI using Amazon CloudFormation

You can use an Amazon CloudFormation template to start the Apache Spark history server and view the Spark web UI. These templates are samples that you should modify to meet your requirements.

To start the Spark history server and view the Spark UI using Amazon CloudFormation

1. Choose one of the **Launch Stack** buttons in the following table. This launches the stack on the Amazon CloudFormation console.

Region	Launch
US East (Ohio)	
US East (N. Virginia)	
US West (N. California)	
US West (Oregon)	
Africa (Cape Town)	

Region	Launch
Asia Pacific (Hong Kong)	Launch Stack 
Asia Pacific (Mumbai)	Launch Stack 
Asia Pacific (Osaka)	Launch Stack 
Asia Pacific (Seoul)	Launch Stack 
Asia Pacific (Singapore)	Launch Stack 
Asia Pacific (Sydney)	Launch Stack 
Asia Pacific (Tokyo)	Launch Stack 
Canada (Central)	Launch Stack 
Europe (Frankfurt)	Launch Stack 
Europe (Ireland)	Launch Stack 
Europe (London)	Launch Stack 
Europe (Milan)	Launch Stack 
Europe (Paris)	Launch Stack 
Europe (Stockholm)	Launch Stack 
Middle East (Bahrain)	Launch Stack 

Region	Launch
South America (São Paulo)	

2. On the **Specify template** page, choose **Next**.
3. On the **Specify stack details** page, enter the **Stack name**. Enter additional information under **Parameters**.

a. **Spark UI configuration**

Provide the following information:

- **IP address range** — The IP address range that can be used to view the Spark UI. If you want to restrict access from a specific IP address range, you should use a custom value.
- **History server port** — The port for the Spark UI. You can use the default value.
- **Event log directory** — Choose the location where Spark event logs are stored from the Amazon Glue job or development endpoints. You must use **s3a://** for the event logs path scheme.
- **Spark package location** — You can use the default value.
- **Keystore path** — SSL/TLS keystore path for HTTPS. If you want to use a custom keystore file, you can specify the S3 path **s3://path_to_your_keystore_file** here. If you leave this parameter empty, a self-signed certificate based keystore is generated and used.
- **Keystore password** — Enter a SSL/TLS keystore password for HTTPS.

b. **EC2 instance configuration**

Provide the following information:

- **Instance type** — The type of Amazon EC2 instance that hosts the Spark history server. Because this template launches Amazon EC2 instance in your account, Amazon EC2 cost will be charged in your account separately.
- **Latest AMI ID** — The AMI ID of Amazon Linux 2 for the Spark history server instance. You can use the default value.
- **VPC ID** — The virtual private cloud (VPC) ID for the Spark history server instance. You can use any of the VPCs available in your account Using a default VPC with a [default](#)

[Network ACL](#) is not recommended. For more information, see [Default VPC and Default Subnets](#) and [Creating a VPC](#) in the *Amazon VPC User Guide*.

- **Subnet ID** — The ID for the Spark history server instance. You can use any of the subnets in your VPC. You must be able to reach the network from your client to the subnet. If you want to access via the internet, you must use a public subnet that has the internet gateway in the route table.
- c. Choose **Next**.
 4. On the **Configure stack options** page, to use the current user credentials for determining how CloudFormation can create, modify, or delete resources in the stack, choose **Next**. You can also specify a role in the **Permissions** section to use instead of the current user permissions, and then choose **Next**.
 5. On the **Review** page, review the template.

Select **I acknowledge that Amazon CloudFormation might create IAM resources**, and then choose **Create stack**.

6. Wait for the stack to be created.
7. Open the **Outputs** tab.
 - a. Copy the URL of **SparkUiPublicUrl** if you are using a public subnet.
 - b. Copy the URL of **SparkUiPrivateUrl** if you are using a private subnet.
8. Open a web browser, and paste in the URL. This lets you access the server using HTTPS on the specified port. Your browser may not recognize the server's certificate, in which case you have to override its protection and proceed anyway.

Launching the Spark history server and viewing the Spark UI using Docker

If you prefer local access (not to have an EC2 instance for the Apache Spark history server), you can also use Docker to start the Apache Spark history server and view the Spark UI locally. This Dockerfile is a sample that you should modify to meet your requirements.

Prerequisites

For information about how to install Docker on your laptop see the [Docker Engine community](#).

To start the Spark history server and view the Spark UI locally using Docker

1. Download files from GitHub.

Download the Dockerfile and pom.xml from [Amazon Glue code samples](#).

2. Determine if you want to use your user credentials or federated user credentials to access Amazon.
 - To use the current user credentials for accessing Amazon, get the values to use for `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` in the `docker run` command. For more information, see [Managing access keys for IAM users](#) in the *IAM User Guide*.
 - To use SAML 2.0 federated users for accessing Amazon, get the values for `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, and `AWS_SESSION_TOKEN`. For more information, see [Requesting temporary security credentials](#)
3. Determine the location of your event log directory, to use in the `docker run` command.
4. Build the Docker image using the files in the local directory, using the name `glue/sparkui`, and the tag `latest`.

```
$ docker build -t glue/sparkui:latest .
```

5. Create and start the docker container.

In the following commands, use the values obtained previously in steps 2 and 3.

- a. To create the docker container using your user credentials, use a command similar to the following

```
docker run -itd -e SPARK_HISTORY_OPTS="$SPARK_HISTORY_OPTS -
Dspark.history.fs.logDirectory=s3a://path_to_eventlog
-Dspark.hadoop.fs.s3a.access.key=AWS_ACCESS_KEY_ID -
Dspark.hadoop.fs.s3a.secret.key=AWS_SECRET_ACCESS_KEY"
-p 18080:18080 glue/sparkui:latest "/opt/spark/bin/spark-class
org.apache.spark.deploy.history.HistoryServer"
```

- b. To create the docker container using temporary credentials, use `org.apache.hadoop.fs.s3a.TemporaryAWSCredentialsProvider` as the provider, and provide the credential values obtained in step 2. For more information, see [Using Session Credentials with TemporaryAWSCredentialsProvider](#) in the *Hadoop: Integration with Amazon Web Services* documentation.

```
docker run -itd -e SPARK_HISTORY_OPTS="$SPARK_HISTORY_OPTS -
Dspark.history.fs.logDirectory=s3a://path_to_eventlog
```

```
-Dspark.hadoop.fs.s3a.access.key=AWS_ACCESS_KEY_ID -  
Dspark.hadoop.fs.s3a.secret.key=AWS_SECRET_ACCESS_KEY  
-Dspark.hadoop.fs.s3a.session.token=AWS_SESSION_TOKEN  
-  
Dspark.hadoop.fs.s3a.aws.credentials.provider=org.apache.hadoop.fs.s3a.TemporaryAWSCred  
-p 18080:18080 glue/sparkui:latest "/opt/spark/bin/spark-class  
org.apache.spark.deploy.history.HistoryServer"
```

Note

These configuration parameters come from the [Hadoop-AWS Module](#). You may need to add specific configuration based on your use case. For example: users in isolated regions will need to configure the `spark.hadoop.fs.s3a.endpoint`.

6. Open `http://localhost:18080` in your browser to view the Spark UI locally.

Monitoring with Amazon Glue job run insights

Amazon Glue job run insights is a feature in Amazon Glue that simplifies job debugging and optimization for your Amazon Glue jobs. Amazon Glue provides [Spark UI](#), and [CloudWatch logs and metrics](#) for monitoring your Amazon Glue jobs. With this feature, you get this information about your Amazon Glue job's execution:

- Line number of your Amazon Glue job script that had a failure.
- Spark action that executed last in the Spark query plan just before the failure of your job.
- Spark exception events related to the failure presented in a time-ordered log stream.
- Root cause analysis and recommended action (such as tuning your script) to fix the issue.
- Common Spark events (log messages relating to a Spark action) with a recommended action that addresses the root cause.

All these insights are available to you using two new log streams in the CloudWatch logs for your Amazon Glue jobs.

Requirements

The Amazon Glue job run insights feature is available for Amazon Glue versions 2.0 and above. You can follow the [migration guide](#) for your existing jobs to upgrade them from older Amazon Glue versions.

Enabling job run insights for an Amazon Glue ETL job

You can enable job run insights through Amazon Glue Studio or the CLI.

Amazon Glue Studio

When creating a job via Amazon Glue Studio, you can enable or disable job run insights under the **Job Details** tab. Check that the **Generate job insights** box is selected.

Requested number of workers

The number of workers you want Glue to allocate to this job.

The maximums are 299 for G.1X and 149 for G.2X, and the minimum is 2.

Generate job insights

Glue will analyze your job runs and provide insights on how to optimize your jobs and the reasons for job failures.

Command line

If creating a job via the CLI, you can start a job run with a single new [job parameter](#): `--enable-job-insights = true`.

By default, the job run insights log streams are created under the same default log group used by [Amazon Glue continuous logging](#), that is, `/aws-glue/jobs/logs-v2/`. You may set up custom log group name, log filters and log group configurations using the same set of arguments for continuous logging. For more information, see [Enabling Continuous Logging for Amazon Glue Jobs](#).

Accessing the job run insights log streams in CloudWatch

With the job run insights feature enabled, there may be two log streams created when a job run fails. When a job finishes successfully, neither of the streams are generated.

1. *Exception analysis log stream*: `<job-run-id>-job-insights-rca-driver`. This stream provides the following:

- Line number of your Amazon Glue job script that caused the failure.
- Spark action that executed last in the Spark query plan (DAG).
- Concise time-ordered events from the Spark driver and executors that are related to the exception. You can find details such as complete error messages, the failed Spark task and its executors ID that help you to focus on the specific executor's log stream for a deeper investigation if needed.

2. *Rule-based insights stream:*

- Root cause analysis and recommendations on how to fix the errors (such as using a specific job parameter to optimize the performance).
- Relevant Spark events serving as the basis for root cause analysis and a recommended action.

Note

The first stream will exist only if any exception Spark events are available for a failed job run, and the second stream will exist only if any insights are available for the failed job run. For example, if your job finishes successfully, neither of the streams will be generated; if your job fails but there isn't a service-defined rule that can match with your failure scenario, then only the first stream will be generated.

If the job is created from Amazon Glue Studio, the links to the above streams are also available under the job run details tab (Job run insights) as "Concise and consolidated error logs" and "Error analysis and guidance".

Job run - jr_ [REDACTED]

Run details [Info](#)

An error occurred while calling o134.pyWriteDynamicFrame. No such file or directory 's3://[REDACTED]'

Example for Amazon Glue job run insights

In this section we present an example of how the job run insights feature can help you resolve an issue in your failed job. In this example, a user forgot to import the required module (tensorflow) in an Amazon Glue job to analyze and build a machine learning model on their data.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from pyspark.sql.types import *
from pyspark.sql.functions import udf,col

args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
```

```
job.init(args['JOB_NAME'], args)

data_set_1 = [1, 2, 3, 4]
data_set_2 = [5, 6, 7, 8]

scoresDf = spark.createDataFrame(data_set_1, IntegerType())

def data_multiplier_func(factor, data_vector):
    import tensorflow as tf
    with tf.compat.v1.Session() as sess:
        x1 = tf.constant(factor)
        x2 = tf.constant(data_vector)
        result = tf.multiply(x1, x2)
        return sess.run(result).tolist()

data_multiplier_udf = udf(lambda x:data_multiplier_func(x, data_set_2),
    ArrayType(IntegerType(),False))
factoredDf = scoresDf.withColumn("final_value", data_multiplier_udf(col("value")))
print(factoredDf.collect())
```

Without the job run insights feature, as the job fails, you only see this message thrown by Spark:

```
An error occurred while calling o111.collectToPython. Traceback (most recent call last):
```

The message is ambiguous and limits your debugging experience. In this case, this feature provides with you additional insights in two CloudWatch log streams:

1. The `job-insights-rca-driver` log stream:

- *Exception events*: This log stream provides you the Spark exception events related to the failure collected from the Spark driver and different distributed workers. These events help you understand the time-ordered propagation of the exception as faulty code executes across Spark tasks, executors, and stages distributed across the Amazon Glue workers.
- *Line numbers*: This log stream identifies line 21, which made the call to import the missing Python module that caused the failure; it also identifies line 24, the call to Spark Action `collect()`, as the last executed line in your script.

Monitoring with Amazon CloudWatch

You can monitor Amazon Glue using Amazon CloudWatch, which collects and processes raw data from Amazon Glue into readable, near-real-time metrics. These statistics are recorded for a period of two weeks so that you can access historical information for a better perspective on how your web application or service is performing. By default, Amazon Glue metrics data is sent to

CloudWatch automatically. For more information, see [What Is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*, and [Amazon Glue metrics](#).

Continuous logging

Amazon Glue also supports real-time continuous logging for Amazon Glue jobs. When continuous logging is enabled for a job, you can view the real-time logs on the Amazon Glue console or the CloudWatch console dashboard. For more information, see [Logging for Amazon Glue jobs](#).

Observability metrics

When **Job observability metrics** is enabled, additional Amazon CloudWatch metrics are generated when the job is run. Use Amazon Glue Observability metrics to generate insights into what is happening inside your Amazon Glue to improve triaging and analysis of issues.

Topics

- [Monitoring Amazon Glue using Amazon CloudWatch metrics](#)
- [Setting up Amazon CloudWatch alarms on Amazon Glue job profiles](#)
- [Logging for Amazon Glue jobs](#)
- [Monitoring with Amazon Glue Observability metrics](#)

Monitoring Amazon Glue using Amazon CloudWatch metrics

You can profile and monitor Amazon Glue operations using Amazon Glue job profiler. It collects and processes raw data from Amazon Glue jobs into readable, near real-time metrics stored in Amazon CloudWatch. These statistics are retained and aggregated in CloudWatch so that you can access historical information for a better perspective on how your application is performing.

Note

You may incur additional charges when you enable job metrics and CloudWatch custom metrics are created. For more information, see [Amazon CloudWatch pricing](#).

Amazon Glue metrics overview

When you interact with Amazon Glue, it sends metrics to CloudWatch. You can view these metrics using the Amazon Glue console (the preferred method), the CloudWatch console dashboard, or the Amazon Command Line Interface (Amazon CLI).

To view metrics using the Amazon Glue console dashboard

You can view summary or detailed graphs of metrics for a job, or detailed graphs for a job run.

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, choose **Job run monitoring**.
3. In **Job runs** choose **Actions** to stop a job that is currently running, view a job, or rewind job bookmark.
4. Select a job, then choose **View run details** to view additional information about the job run.

To view metrics using the CloudWatch console dashboard

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. In the navigation pane, choose **Metrics**.
3. Choose the **Glue** namespace.

To view metrics using the Amazon CLI

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace Glue
```

Amazon Glue reports metrics to CloudWatch every 30 seconds, and the CloudWatch metrics dashboards are configured to display them every minute. The Amazon Glue metrics represent delta values from the previously reported values. Where appropriate, metrics dashboards aggregate (sum) the 30-second values to obtain a value for the entire last minute.

Amazon Glue metrics behavior for Spark jobs

Amazon Glue metrics are enabled at initialization of a `GlueContext` in a script and are generally updated only at the end of an Apache Spark task. They represent the aggregate values across all completed Spark tasks so far.

However, the Spark metrics that Amazon Glue passes on to CloudWatch are generally absolute values representing the current state at the time they are reported. Amazon Glue reports them to CloudWatch every 30 seconds, and the metrics dashboards generally show the average across the data points received in the last 1 minute.

Amazon Glue metrics names are all preceded by one of the following types of prefix:

- `glue.driver.` – Metrics whose names begin with this prefix either represent Amazon Glue metrics that are aggregated from all executors at the Spark driver, or Spark metrics corresponding to the Spark driver.
- `glue.executorId.` – The *executorId* is the number of a specific Spark executor. It corresponds with the executors listed in the logs.
- `glue.ALL.` – Metrics whose names begin with this prefix aggregate values from all Spark executors.

Amazon Glue metrics

Amazon Glue profiles and sends the following metrics to CloudWatch every 30 seconds, and the Amazon Glue Metrics Dashboard report them once a minute:

Metric	Description
<code>glue.driver.aggregate.bytes</code> Read	<p>The number of bytes read from all data sources by all completed Spark tasks running in all executors.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Bytes</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"> • Bytes read.

Metric	Description
	<ul style="list-style-type: none"> • Job progress. • JDBC data sources. • Job Bookmark Issues. • Variance across Job Runs. <p>This metric can be used the same way as the <code>glue.ALL.s3.filesystem.read_bytes</code> metric, with the difference that this metric is updated at the end of a Spark task and captures non-S3 data sources as well.</p>
<code>glue.driver.aggregate.elapsedTime</code>	<p>The ETL elapsed time in milliseconds (does not include the job bootstrap times).</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Milliseconds</p> <p>Can be used to determine how long it takes a job run to run on average.</p> <p>Some ways to use the data:</p> <ul style="list-style-type: none"> • Set alarms for stragglers. • Measure variance across job runs.

Metric	Description
glue.driver.aggregate.numCompletedStages	<p>The number of completed stages in the job.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Job progress.• Per-stage timeline of job execution,when correlated with other metrics. <p>Some ways to use the data:</p> <ul style="list-style-type: none">• Identify demanding stages in the execution of a job.• Set alarms for correlated spikes (demanding stages) across job runs.

Metric	Description
<code>glue.driver.aggregate.numCompletedTasks</code>	<p>The number of completed tasks in the job.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Job progress.• Parallelism within a stage.

Metric	Description
<code>glue.driver.aggregate.numFailedTasks</code>	<p>The number of failed tasks.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Data abnormalities that cause job tasks to fail.• Cluster abnormalities that cause job tasks to fail.• Script abnormalities that cause job tasks to fail. <p>The data can be used to set alarms for increased failures that might suggest abnormalities in data, cluster or scripts.</p>

Metric	Description
<code>glue.driver.aggregate.numKilledTasks</code>	<p>The number of tasks killed.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Abnormalities in Data Skew that result in exceptions (OOMs) that kill tasks.• Script abnormalities that result in exceptions (OOMs) that kill tasks. <p>Some ways to use the data:</p> <ul style="list-style-type: none">• Set alarms for increased failures indicating data abnormalities.• Set alarms for increased failures indicating cluster abnormalities.• Set alarms for increased failures indicating script abnormalities.

Metric	Description
<code>glue.driver.aggregate.recordsRead</code>	<p>The number of records read from all data sources by all completed Spark tasks running in all executors.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Records read.• Job progress.• JDBC data sources.• Job Bookmark Issues.• Skew in Job Runs over days. <p>This metric can be used in a similar way to the <code>glue.ALL.s3.filesystem.read_bytes</code> metric, with the difference that this metric is updated at the end of a Spark task.</p>

Metric	Description
<code>glue.driver.aggregate.shuffleBytesWritten</code>	<p>The number of bytes written by all executors to shuffle data between them since the previous report (aggregated by the Amazon Glue Metrics Dashboard as the number of bytes written for this purpose during the previous minute).</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Bytes</p> <p>Can be used to monitor: Data shuffle in jobs (large joins, groupBy, repartition, coalesce).</p> <p>Some ways to use the data:</p> <ul style="list-style-type: none">• Repartition or decompress large input files before further processing.• Repartition data more uniformly to avoid hot keys.• Pre-filter data before joins or groupBy operations.

Metric	Description
<code>glue.driver.aggregate.shuffleLocalBytesRead</code>	<p>The number of bytes read by all executors to shuffle data between them since the previous report (aggregated by the Amazon Glue Metrics Dashboard as the number of bytes read for this purpose during the previous minute).</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Bytes</p> <p>Can be used to monitor: Data shuffle in jobs (large joins, groupBy, repartition, coalesce).</p> <p>Some ways to use the data:</p> <ul style="list-style-type: none">• Repartition or decompress large input files before further processing.• Repartition data more uniformly using hot keys.• Pre-filter data before joins or groupBy operations.

Metric	Description
<code>glue.driver.BlockManager.disk.diskSpaceUsed_MB</code>	<p>The number of megabytes of disk space used across all executors.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p> <p>Valid Statistics: Average. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Megabytes</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Disk space used for blocks that represent cached RDD partitions.• Disk space used for blocks that represent intermediate shuffle outputs.• Disk space used for blocks that represent broadcasts. <p>Some ways to use the data:</p> <ul style="list-style-type: none">• Identify job failures due to increased disk usage.• Identify large partitions resulting in spilling or shuffling.• Increase provisioned DPU capacity to correct these issues.

Metric	Description
<code>glue.driver.ExecutorAllocationManager.executors.numberAllExecutors</code>	<p>The number of actively running job executors.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p> <p>Valid Statistics: Average. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Job activity.• Straggling executors (with a few executors running only)• Current executor-level parallelism. <p>Some ways to use the data:</p> <ul style="list-style-type: none">• Repartition or decompress large input files beforehand if cluster is under-utilized.• Identify stage or job execution delays due to straggler scenarios.• Compare with <code>numberMaxNeededExecutors</code> to understand backlog for provisioning more DPUs.

Metric	Description
<code>glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors</code>	<p>The number of maximum (actively running and pending) job executors needed to satisfy the current load.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p> <p>Valid Statistics: Maximum. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Job activity.• Current executor-level parallelism and backlog of pending tasks not yet scheduled because of unavailable executors due to DPU capacity or killed/failed executors. <p>Some ways to use the data:</p> <ul style="list-style-type: none">• Identify pending/backlog of scheduling queue.• Identify stage or job execution delays due to straggler scenarios.• Compare with <code>numberAllExecutors</code> to understand backlog for provisioning more DPUs.• Increase provisioned DPU capacity to correct the pending executor backlog.

Metric	Description
<code>glue.driver.jvm.heap.usage</code>	The fraction of memory used by the JVM heap for this driver (scale: 0-1) for driver, executor identified by <code>executorId</code> , or ALL executors.
<code>glue.executorId.jvm.heap.usage</code>	Valid dimensions: <code>JobName</code> (the name of the Amazon Glue Job), <code>JobRunId</code> (the JobRun ID. or ALL), and <code>Type</code> (gauge).
<code>glue.ALL.jvm.heap.usage</code>	<p>Valid Statistics: Average. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Percentage</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"> • Driver out-of-memory conditions (OOM) using <code>glue.driver.jvm.heap.usage</code> . • Executor out-of-memory conditions (OOM) using <code>glue.ALL.jvm.heap.usage</code> . <p>Some ways to use the data:</p> <ul style="list-style-type: none"> • Identify memory-consuming executor ids and stages. • Identify stragglers executor ids and stages. • Identify a driver out-of-memory condition (OOM). • Identify an executor out-of-memory condition (OOM) and obtain the corresponding executor ID so as to be able to get a stack trace from the executor log. • Identify files or partitions that may have data skew resulting in stragglers or out-of-memory conditions (OOMs).

Metric	Description
<p><code>glue.driver.jvm.heap.used</code></p> <p><code>glue.executorId.jvm.heap.used</code></p> <p><code>glue.ALL.jvm.heap.used</code></p>	<p>The number of memory bytes used by the JVM heap for the driver, the executor identified by <i>executorId</i>, or ALL executors.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p> <p>Valid Statistics: Average. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Bytes</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"> • Driver out-of-memory conditions (OOM). • Executor out-of-memory conditions (OOM). <p>Some ways to use the data:</p> <ul style="list-style-type: none"> • Identify memory-consuming executor ids and stages. • Identify stragglers executor ids and stages. • Identify a driver out-of-memory condition (OOM). • Identify an executor out-of-memory condition (OOM) and obtain the corresponding executor ID so as to be able to get a stack trace from the executor log. • Identify files or partitions that may have data skew resulting in stragglers or out-of-memory conditions (OOMs).

Metric	Description
<code>glue.driver.s3.filesystem.read_bytes</code>	<p>The number of bytes read from Amazon S3 by the driver, an executor identified by <i>executorId</i>, or ALL executors since the previous report (aggregated by the Amazon Glue Metrics Dashboard as the number of bytes read during the previous minute).</p>
<code>glue.executorId.s3.filesystem.read_bytes</code>	<p>Valid dimensions: JobName, JobRunId, and Type (gauge).</p>
<code>glue.ALL.s3.filesystem.read_bytes</code>	<p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard a SUM statistic is used for aggregation. The area under the curve on the Amazon Glue Metrics Dashboard can be used to visually compare bytes read by two different job runs.</p> <p>Unit: Bytes.</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• ETL data movement.• Job progress.• Job bookmark issues (data processed, reprocessed, and skipped).• Comparison of reads to ingestion rate from external data sources.• Variance across job runs. <p>Resulting data can be used for:</p> <ul style="list-style-type: none">• DPU capacity planning.• Setting alarms for large spikes or dips in data read for job runs and job stages.

Metric	Description
<code>glue.driver.s3.filesystem.write_bytes</code>	<p>The number of bytes written to Amazon S3 by the driver, an executor identified by <i>executorId</i>, or ALL executors since the previous report (aggregated by the Amazon Glue Metrics Dashboard as the number of bytes written during the previous minute).</p>
<code>glue.executorId.s3.filesystem.write_bytes</code>	<p>Valid dimensions: JobName, JobRunId, and Type (gauge).</p>
<code>glue.ALL.s3.filesystem.write_bytes</code>	<p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the Amazon Glue Metrics Dashboard a SUM statistic is used for aggregation. The area under the curve on the Amazon Glue Metrics Dashboard can be used to visually compare bytes written by two different job runs.</p> <p>Unit: Bytes</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"> • ETL data movement. • Job progress. • Job bookmark issues (data processed, reprocessed, and skipped). • Comparison of reads to ingestion rate from external data sources. • Variance across job runs. <p>Some ways to use the data:</p> <ul style="list-style-type: none"> • DPU capacity planning. • Setting alarms for large spikes or dips in data read for job runs and job stages.

Metric	Description
<code>glue.driver.streaming.numRecords</code>	<p>The number of records that are received in a micro-batch. This metric is only available for Amazon Glue streaming jobs with Amazon Glue version 2.0 and above.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: Sum, Maximum, Minimum, Average, Percentile</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Records read.• Job progress.
<code>glue.driver.streaming.batchProcessingTimeInMs</code>	<p>The time it takes to process the batches in milliseconds. This metric is only available for Amazon Glue streaming jobs with Amazon Glue version 2.0 and above.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: Sum, Maximum, Minimum, Average, Percentile</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none">• Job progress.• Script performance.

Metric	Description
<code>glue.driver.system.cpuSystemLoad</code>	<p>The fraction of CPU system load used (scale: 0-1) by the driver, an executor identified by <i>executorId</i>, or ALL executors.</p>
<code>glue.executorId.system.cpuSystemLoad</code>	<p>Valid dimensions: JobName (the name of the Amazon Glue job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p>
<code>glue.ALL.system.cpuSystemLoad</code>	<p>Valid Statistics: Average. This metric is reported as an absolute value.</p> <p>Unit: Percentage</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"> • Driver CPU load. • Executor CPU load. • Detecting CPU-bound or IO-bound executors or stages in a Job. <p>Some ways to use the data:</p> <ul style="list-style-type: none"> • DPU capacity Planning along with IO Metrics (Bytes Read/Shuffle Bytes, Task Parallelism) and the number of maximum needed executors metric. • Identify the CPU/IO-bound ratio. This allows for repartitioning and increasing provisioned capacity for long-running jobs with splittable datasets having lower CPU utilization.

Dimensions for Amazon Glue Metrics

Amazon Glue metrics use the Amazon Glue namespace and provide metrics for the following dimensions:

Dimension	Description
JobName	This dimension filters for metrics of all job runs of a specific Amazon Glue job.
JobRunId	This dimension filters for metrics of a specific Amazon Glue job run by a JobRun ID, or ALL.
Type	This dimension filters for metrics by either count (an aggregate number) or gauge (a value at a point in time).

For more information, see the [Amazon CloudWatch User Guide](#).

Setting up Amazon CloudWatch alarms on Amazon Glue job profiles

Amazon Glue metrics are also available in Amazon CloudWatch. You can set up alarms on any Amazon Glue metric for scheduled jobs.

A few common scenarios for setting up alarms are as follows:

- Jobs running out of memory (OOM): Set an alarm when the memory usage exceeds the normal average for either the driver or an executor for an Amazon Glue job.
- Stragglers: Set an alarm when the number of executors falls below a certain threshold for a large duration of time in an Amazon Glue job.
- Data backlog or reprocessing: Compare the metrics from individual jobs in a workflow using a CloudWatch math expression. You can then trigger an alarm on the resulting expression value (such as the ratio of bytes written by a job and bytes read by a following job).

For detailed instructions on setting alarms, see [Create or Edit a CloudWatch Alarm](#) in the [Amazon CloudWatch Events User Guide](#).

For monitoring and debugging scenarios using CloudWatch, see [Job monitoring and debugging](#).

Logging for Amazon Glue jobs

In Amazon Glue 5.0, all jobs have real-time logging capabilities. Additionally, you can specify custom configuration options to tailor the logging behavior. These options include setting the

Amazon CloudWatch log group name, the Amazon CloudWatch log stream prefix (which will precede the Amazon Glue job run ID and driver/executor ID), and the log conversion pattern for log messages. These configurations allow you to aggregate logs in custom Amazon CloudWatch log groups with different expiration policies. Furthermore, you can analyze the logs more effectively by using custom log stream prefixes and conversion patterns. This level of customization enables you to optimize log management and analysis according to your specific requirements.

Logging behavior in Amazon Glue 5.0

By default, system logs, Spark daemon logs, and user Amazon Glue Logger logs are written to the `/aws-glue/jobs/error` log group in Amazon CloudWatch. On the other hand, user stdout (standard output) and stderr (standard error) logs are written to the `/aws-glue/jobs/output` log group by default.

Custom logging

You can customize the default log group and log stream prefixes using the following job arguments:

- `--custom-logGroup-prefix`: Allows you to specify a custom prefix for the `/aws-glue/jobs/error` and `/aws-glue/jobs/output` log groups. If you provide a custom prefix, the log group names will be in the following format:
 - `/aws-glue/jobs/error` will be `<customer prefix>/error`
 - `/aws-glue/jobs/output` will be `<customer prefix>/output`
- `--custom-logStream-prefix`: Allows you to specify a custom prefix for the log stream names within the log groups. If you provide a custom prefix, the log stream names will be in the following format:
 - `jobrunid-driver` will be `<customer log stream>-driver`
 - `jobrunid-executorNum` will be `<customer log stream>-executorNum`

Validation rules and limitations for custom prefixes:

- The entire log stream name must be between 1 and 512 characters long.
- The custom prefix itself is restricted to 400 characters.
- The custom prefix must match the regular expression pattern ``[^:]*`` (special characters allowed are `'_'`, `'-'`, and `'/'`).

Logging application-specific messages using the custom script logger

You can use the Amazon Glue logger to log any application-specific messages in the script that are sent in real time to the driver log stream.

The following example shows a Python script.

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)
logger = glueContext.get_logger()
logger.info("info message")
logger.warn("warn message")
logger.error("error message")
```

The following example shows a Scala script.

```
import com.amazonaws.services.glue.log.GlueLogger

object GlueApp {
  def main(sysArgs: Array[String]) {
    val logger = new GlueLogger
    logger.info("info message")
    logger.warn("warn message")
    logger.error("error message")
  }
}
```

Enabling the progress bar to show job progress

Amazon Glue provides a real-time progress bar under the `JOB_RUN_ID-progress-bar` log stream to check Amazon Glue job run status. Currently it supports only jobs that initialize `glueContext`. If you run a pure Spark job without initializing `glueContext`, the Amazon Glue progress bar does not appear.

The progress bar shows the following progress update every 5 seconds.

```
Stage Number (Stage Name): > (numCompletedTasks + numActiveTasks) /
totalNumOfTasksInThisStage]
```

Security configuration with Amazon CloudWatch logging

When a security configuration is enabled for Amazon CloudWatch logs, Amazon Glue creates log groups with specific naming patterns that incorporate the security configuration name.

Log group naming with security configuration

The default and custom log groups will be as follows:

- **Default error log group:** `/aws-glue/jobs/Security-Configuration-Name-role/glue-job-role/error`
- **Default output log group:** `/aws-glue/jobs/Security-Configuration-Name-role/glue-job-role/output`
- **Custom error log group (Amazon Glue 5.0):** `custom-log-group-prefix/Security-Configuration-Name-role/glue-job-role/error`
- **Custom output log group (Amazon Glue 5.0):** `custom-log-group-prefix/Security-Configuration-Name-role/glue-job-role/output`

Required IAM Permissions

You need to add the `logs:AssociateKmsKey` permission to your IAM role permissions, if you enable a security configuration with Amazon CloudWatch Logs. If that permission is not included, continuous logging will be disabled.

Also, to configure the encryption for the Amazon CloudWatch Logs, follow the instructions at [Encrypt Log Data in Amazon CloudWatch Logs Using Amazon Key Management Service](#) in the Amazon Amazon CloudWatch Logs User Guide.

Additional Information

For more information on creating security configurations, see [Managing security configurations on the Amazon Glue console](#).

Topics

- [Enabling continuous logging for Amazon Glue 4.0 and earlier jobs](#)
- [Viewing logs for Amazon Glue jobs](#)

Enabling continuous logging for Amazon Glue 4.0 and earlier jobs

Note

In Amazon Glue 4.0 and earlier versions, continuous logging was an available feature. However, with the introduction of Amazon Glue 5.0, all jobs have real-time logging capability. For more details on the logging capabilities and configuration options in Amazon Glue 5.0, see [Logging for Amazon Glue jobs](#).

You can enable continuous logging using the Amazon Glue console or through the Amazon Command Line Interface (Amazon CLI).

You can enable continuous logging when you create a new job, edit an existing job, or enable it through the Amazon CLI.

You can also specify custom configuration options such as the Amazon CloudWatch log group name, CloudWatch log stream prefix before the Amazon Glue job run ID driver/executor ID, and log conversion pattern for log messages. These configurations help you to set aggregate logs in custom CloudWatch log groups with different expiration policies, and analyze them further with custom log stream prefixes and conversions patterns.

Topics

- [Using the Amazon Web Services Management Console](#)
- [Logging application-specific messages using the custom script logger](#)
- [Enabling the progress bar to show job progress](#)
- [Security configuration with continuous logging](#)

Using the Amazon Web Services Management Console

Follow these steps to use the console to enable continuous logging when creating or editing an Amazon Glue job.

To create a new Amazon Glue job with continuous logging

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.

2. In the navigation pane, choose **ETL jobs**.
3. Choose **Visual ETL**.
4. In the **Job details** tab, expand the **Advanced properties** section.
5. Under **Continuous logging** select **Enable logs in CloudWatch**.

To enable continuous logging for an existing Amazon Glue job

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, choose **Jobs**.
3. Choose an existing job from the **Jobs** list.
4. Choose **Action, Edit job**.
5. In the **Job details** tab, expand the **Advanced properties** section.
6. Under **Continuous logging** select **Enable logs in CloudWatch**.

Using the Amazon CLI

To enable continuous logging, you pass in job parameters to an Amazon Glue job. Pass the following special job parameters similar to other Amazon Glue job parameters. For more information, see [Using job parameters in Amazon Glue jobs](#).

```
'--enable-continuous-cloudwatch-log': 'true'
```

You can specify a custom Amazon CloudWatch log group name. If not specified, the default log group name is `/aws-glue/jobs/logs-v2`.

```
'--continuous-log-logGroup': 'custom_log_group_name'
```

You can specify a custom Amazon CloudWatch log stream prefix. If not specified, the default log stream prefix is the job run ID.

```
'--continuous-log-logStreamPrefix': 'custom_log_stream_prefix'
```

You can specify a custom continuous logging conversion pattern. If not specified, the default conversion pattern is `%d{yy/MM/dd HH:mm:ss} %p %c{1}: %m%n`. Note that the conversion

pattern only applies to driver logs and executor logs. It does not affect the Amazon Glue progress bar.

```
'--continuous-log-conversionPattern': 'custom_log_conversion_pattern'
```

Logging application-specific messages using the custom script logger

You can use the Amazon Glue logger to log any application-specific messages in the script that are sent in real time to the driver log stream.

The following example shows a Python script.

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)
logger = glueContext.get_logger()
logger.info("info message")
logger.warn("warn message")
logger.error("error message")
```

The following example shows a Scala script.

```
import com.amazonaws.services.glue.log.GlueLogger

object GlueApp {
  def main(sysArgs: Array[String]) {
    val logger = new GlueLogger
    logger.info("info message")
    logger.warn("warn message")
    logger.error("error message")
  }
}
```

Enabling the progress bar to show job progress

Amazon Glue provides a real-time progress bar under the `JOB_RUN_ID-progress-bar` log stream to check Amazon Glue job run status. Currently it supports only jobs that initialize `glueContext`. If you run a pure Spark job without initializing `glueContext`, the Amazon Glue progress bar does not appear.

The progress bar shows the following progress update every 5 seconds.

```
Stage Number (Stage Name): > (numCompletedTasks + numActiveTasks) /  
totalNumOfTasksInThisStage]
```

Security configuration with continuous logging

If a security configuration is enabled for CloudWatch logs, Amazon Glue will create a log group named as follows for continuous logs:

```
<Log-Group-Name>-<Security-Configuration-Name>
```

The default and custom log groups will be as follows:

- The default continuous log group will be `/aws-glue/jobs/error-<Security-Configuration-Name>`
- The custom continuous log group will be `<custom-log-group-name>-<Security-Configuration-Name>`

You need to add the `logs:AssociateKmsKey` to your IAM role permissions, if you enable a security configuration with CloudWatch Logs. If that permission is not included, continuous logging will be disabled. Also, to configure the encryption for the CloudWatch Logs, follow the instructions at [Encrypt Log Data in CloudWatch Logs Using Amazon Key Management Service](#) in the *Amazon CloudWatch Logs User Guide*.

For more information on creating security configurations, see [Managing security configurations on the Amazon Glue console](#).

Note

You may incur additional charges when you enable logging and additional CloudWatch log events are created. For more information, see [Amazon CloudWatch pricing](#).

Viewing logs for Amazon Glue jobs

You can view real-time logs using the Amazon Glue console or the Amazon CloudWatch console.

To view real-time logs using the Amazon Glue console dashboard

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, choose **Jobs**.
3. Add or start an existing job. Choose **Action, Run job**.

When you start running a job, you navigate to a page that contains information about the running job:

- The **Logs** tab shows the older aggregated application logs.
 - The **Logs** tab shows a real-time progress bar when the job is running with `glueContext` initialized.
 - The **Logs** tab also contains the **Driver logs**, which capture real-time Apache Spark driver logs, and application logs from the script logged using the Amazon Glue application logger when the job is running.
4. For older jobs, you can also view the real-time logs under the **Job History** view by choosing **Logs**. This action takes you to the CloudWatch console that shows all Spark driver, executor, and progress bar log streams for that job run.

To view real-time logs using the CloudWatch console dashboard

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. In the navigation pane, choose **Log**.
3. Choose the `/aws-glue/jobs/error/` log group.
4. In the **Filter** box, paste the job run ID.

You can view the driver logs, executor logs, and progress bar (if using the **Standard filter**).

Monitoring with Amazon Glue Observability metrics

Note

Amazon Glue Observability metrics is available on Amazon Glue 4.0 and later versions.

Use Amazon Glue Observability metrics to generate insights into what is happening inside your Amazon Glue for Apache Spark jobs to improve triaging and analysis of issues. Observability metrics are visualized through Amazon CloudWatch dashboards and can be used to help perform root cause analysis for errors and for diagnosing performance bottlenecks. You can reduce the time spent debugging issues at scale so you can focus on resolving issues faster and more effectively.

Amazon Glue Observability provides Amazon CloudWatch metrics categorized in following four groups:

- **Reliability (i.e., Errors Classes)** – easily identify the most common failure reasons at given time range that you may want to address.
- **Performance (i.e., Skewness)** – identify a performance bottleneck and apply tuning techniques. For example, when you experience degraded performance due to job skewness, you may want to enable Spark Adaptive Query Execution and fine-tune the skew join threshold.
- **Throughput (i.e., per source/sink throughput)** – monitor trends of data reads and writes. You can also configure Amazon CloudWatch alarms for anomalies.
- **Resource Utilization (i.e., workers, memory and disk utilization)** – efficiently find the jobs with low capacity utilization. You may want to enable Amazon Glue auto-scaling for those jobs.

Getting started with Amazon Glue Observability metrics

Note

The new metrics are enabled by default in the Amazon Glue Studio console.

To configure observability metrics in Amazon Glue Studio:

1. Log in to the Amazon Glue console and choose **ETL jobs** from the console menu.
2. Choose a job by clicking on the job name in the **Your jobs** section.
3. Choose the **Job details** tab.
4. Scroll to the bottom and choose **Advanced properties**, then **Job observability metrics**.

obs-test Last modified on 10/10/2023, 2:04:44 PM [Try new UI](#) [Load JSON](#) [De](#)

Visual | Script | **Job details** | Runs | Data quality *New* | Schedules | Version Control

▼ **Advanced properties**

Script filename
obs-test.py

Script path
S3 location of the script. Path must be in the form s3://bucket/prefix/path/. It must end with a slash (/) and not include any files.
s3://aws-glue-assets-590186200215-us-east-1/scripts/ [View](#) [Browse S3](#)

Job metrics [Info](#)
 Enable the creation of CloudWatch metrics when this job runs.

Job observability metrics [Info](#)
 Enable the creation of additional observability CloudWatch metrics when this job runs.

Continuous logging [Info](#)
 Enable logs in CloudWatch.

Spark UI [Info](#)
 Enable using Spark UI for monitoring this job.

Serverless Spark UI [Info](#)
 Enable using Serverless Spark UI for monitoring this job.

Spark UI logs path
s3://aws-glue-assets-590186200215-us-east-1/sparkHistoryLogs/ [View](#) [Browse S3](#)

Maximum concurrency
Sets the maximum number of concurrent runs that are allowed for this job. An error is returned when this threshold is reached.
1

Temporary path
Working directory. Path must be in the form s3://bucket/prefix/path/. It must end with a slash (/) and not include any files.

Delay notification threshold (minutes) | 5

To enable Amazon Glue Observability metrics using Amazon CLI:

- Add to the `--default-arguments` map the following key-value in the input JSON file:

```
--enable-observability-metrics, true
```

Using Amazon Glue observability

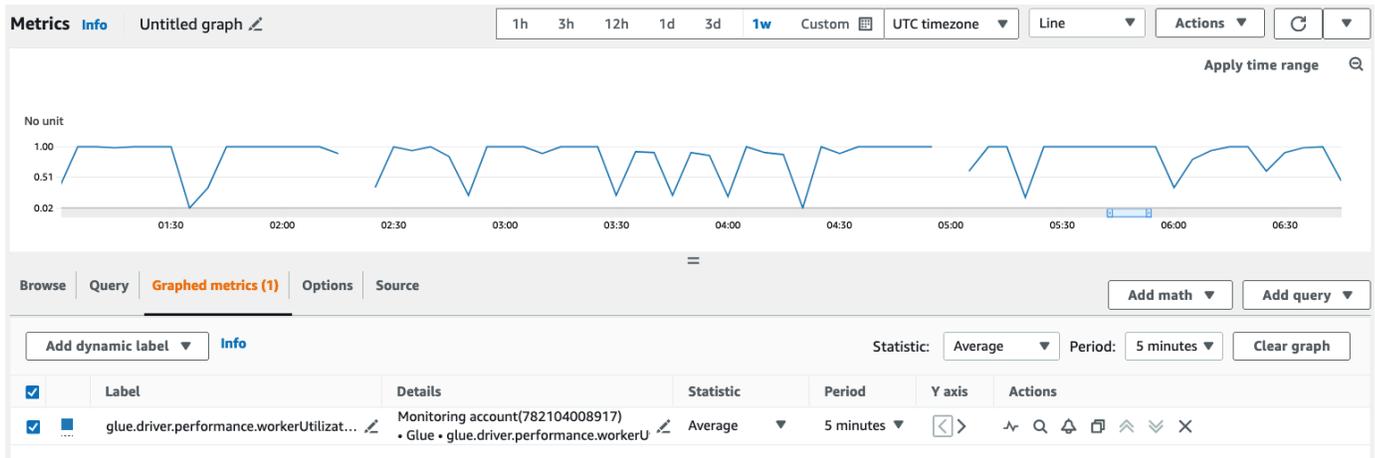

Because the Amazon Glue observability metrics is provided through Amazon CloudWatch, you can use the Amazon CloudWatch console, Amazon CLI, SDK or API to query the observability metrics

datapoints. See [Using Glue Observability for monitoring resource utilization to reduce cost](#) for an example use case when to use Amazon Glue observability metrics.

Using Amazon Glue observability in the Amazon CloudWatch console

To query and visualize metrics in the Amazon CloudWatch console:

1. Open the Amazon CloudWatch console and choose **All metrics**.
2. Under custom namespaces, choose **Amazon Glue**.
3. Choose **Job Observability Metrics, Observability Metrics Per Source, or Observability Metrics Per Sink**.
4. Search for the specific metric name, job name, job run ID, and select them.
5. Under the **Graphed metrics** tab, configure your preferred statistic, period, and other options.

To query an Observability metric using Amazon CLI:

1. Create a metric definition JSON file and replace your `-Glue-job-name` and your `-Glue-job-run-id` with yours.

```
$ cat multiplequeries.json
[
  {
    "Id": "avgWorkerUtil_0",
    "MetricStat": {
      "Metric": {
        "Namespace": "Glue",
        "MetricName": "glue.driver.workerUtilization",
        "Dimensions": [
```

```

        {
            "Name": "JobName",
            "Value": "<your-Glue-job-name-A>"
        },
        {
            "Name": "JobRunId",
            "Value": "<your-Glue-job-run-id-A>"
        },
        {
            "Name": "Type",
            "Value": "gauge"
        },
        {
            "Name": "ObservabilityGroup",
            "Value": "resource_utilization"
        }
    ]
},
"Period": 1800,
"Stat": "Minimum",
"Unit": "None"
}
},
{
    "Id": "avgWorkerUtil_1",
    "MetricStat": {
        "Metric": {
            "Namespace": "Glue",
            "MetricName": "glue.driver.workerUtilization",
            "Dimensions": [
                {
                    "Name": "JobName",
                    "Value": "<your-Glue-job-name-B>"
                },
                {
                    "Name": "JobRunId",
                    "Value": "<your-Glue-job-run-id-B>"
                },
                {
                    "Name": "Type",
                    "Value": "gauge"
                }
            ],
            {
                "Name": "ObservabilityGroup",

```

```

        "Value": "resource_utilization"
      }
    ]
  },
  "Period": 1800,
  "Stat": "Minimum",
  "Unit": "None"
}
]

```

2. Run the get-metric-data command:

```

$ aws cloudwatch get-metric-data --metric-data-queries file://multiplequeries.json \
\
  --start-time '2023-10-28T18: 20' \
  --end-time '2023-10-28T19: 10' \
  --region us-east-1
{
  "MetricDataResults": [
    {
      "Id": "avgWorkerUtil_0",
      "Label": "<your-label-for-A>",
      "Timestamps": [
        "2023-10-28T18:20:00+00:00"
      ],
      "Values": [
        0.06718750000000001
      ],
      "StatusCode": "Complete"
    },
    {
      "Id": "avgWorkerUtil_1",
      "Label": "<your-label-for-B>",
      "Timestamps": [
        "2023-10-28T18:50:00+00:00"
      ],
      "Values": [

      ],
      "StatusCode": "Complete"
    }
  ]
}

```

```

    ],
    "Messages": []
  }

```

Observability metrics

Amazon Glue Observability profiles and sends the following metrics to Amazon CloudWatch every 30 seconds, and some of these metrics can be visible in the Amazon Glue Studio Job Runs Monitoring Page.

Metric	Description	Category
glue.driver.skewness.stage	<p>Metric Category: job_performance</p> <p>The spark stages execution Skewness: this metric is an indicator of how long the maximum task duration time in a certain stage is compared to the median task duration in this stage. It captures execution skewness, which might be caused by input data skewness or by a transformation (e.g., skewed join). The values of this metric falls into the range of [0, infinity[, where 0 means the ratio of the maximum to median tasks' execution time, among all tasks in the stage is less than a certain stage skewness factor. The default stage skewness factor is `5` and it can be overwritten via</p>	job_performance

Metric	Description	Category
	<p>spark conf: spark.metrics.conf .driver.source.glue.jobPerformance.skewnessFactor</p> <p>A stage skewness value of 1 means the ratio is twice the stage skewness factor.</p> <p>The value of stage skewness is updated every 30 seconds to reflect the current skewness. The value at the end of the stage reflects the final stage skewness.</p> <p>This stage-level metric is used to calculate the job-level metric <code>glue.driver.skewness.job</code>.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (job_performance)</p> <p>Valid Statistics: Average, Maximum, Minimum, Percentile</p> <p>Unit: Count</p>	

Metric	Description	Category
glue.driver.skewness.job	<p>Metric Category: job_performance</p> <p>Job skewness is the maximum of weighted skewness of all stages. The stage skewness (glue.driver.skewness.stage) is weighted with stage duration. This is to avoid the corner case when a very skewed stage is actually running for very short time relative to other stages (and thus its skewness is not significant for the overall job performance and does not worth the effort to try to address its skewness)</p> <p>.</p> <p>This metric is updated upon completion of each stage, and thus the last value reflects the actual overall job skewness.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (job_performance)</p> <p>Valid Statistics: Average, Maximum, Minimum, Percentile</p> <p>Unit: Count</p>	job_performance

Metric	Description	Category
glue.succeed.ALL	<p>Metric Category: error</p> <p>Total number of successful job runs, to complete the picture of failures categories</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), Type (count), and ObservabilityGroup (error)</p> <p>Valid Statistics: SUM</p> <p>Unit: Count</p>	error
glue.error.ALL	<p>Metric Category: error</p> <p>Total number of job run errors, to complete the picture of failures categories</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), Type (count), and ObservabilityGroup (error)</p> <p>Valid Statistics: SUM</p> <p>Unit: Count</p>	error

Metric	Description	Category
glue.error.[error category]	<p>Metric Category: error</p> <p>This is actually a set of metrics, that are updated only when a job run fails. The error categorization helps with triaging and debugging. When a job run fails, the error causing the failure is categorized and the corresponding error category metric is set to 1. This helps to perform over time failures analysis, as well as over all jobs error analysis to identify most common failure categories to start addressing them. Amazon Glue has 28 error categories, including OUT_OF_MEMORY (driver and executor), PERMISSION, SYNTAX and THROTTLING error categories. Error categories also include COMPILATION, LAUNCH and TIMEOUT error categories.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), Type (count), and ObservabilityGroup (error)</p> <p>Valid Statistics: SUM</p>	error

Metric	Description	Category
	Unit: Count	
glue.driver.workerUtilization	<p>Metric Category: resource_utilization</p> <p>The percentage of the allocated workers which are actually used. If not good, auto scaling can help.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization)</p> <p>Valid Statistics: Average, Maximum, Minimum, Percentile</p> <p>Unit: Percentage</p>	resource_utilization

Metric	Description	Category
glue.driver.memory.heap.[available used]	<p data-bbox="591 226 980 308">Metric Category: resource_utilization</p> <p data-bbox="591 352 1008 768">The driver's available / used heap memory during the job run. This helps to understand memory usage trends, especially over time, which can help avoid potential failures, in addition to debugging memory related failures.</p> <p data-bbox="591 814 992 1136">Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization)</p> <p data-bbox="591 1182 938 1218">Valid Statistics: Average</p> <p data-bbox="591 1264 751 1299">Unit: Bytes</p>	resource_utilization

glue.driver.[recordsWritten filesWritten]	<p>Metric Category: throughput</p> <p>The number of records/files written per output sink in this job run, as well as well as for ALL sinks. This helps understand the data volume and how it evolves over time, which helps addressing issues such as processing skewness.</p> <p>Valid dimensions: JobName (the name of the Amazon Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), ObservabilityGroup (resource_utilization), and Sink (sink data location)</p> <p>Valid Statistics: Average</p> <p>Unit: Count</p>	throughput

Error categories

Error categories	Description
COMPILATION_ERROR	Errors arise during the compilation of Scala code.
CONNECTION_ERROR	Errors arise during connecting to a service/remote host/database service, etc.
DISK_NO_SPACE_ERROR	Errors arise when there is no space left in disk on driver/executor.

Error categories	Description
OUT_OF_MEMORY_ERROR	Errors arise when there is no space left in memory on driver/executor.
IMPORT_ERROR	Errors arise when import dependencies.
INVALID_ARGUMENT_ERROR	Errors arise when the input arguments are invalid/illegal.
PERMISSION_ERROR	Errors arise when lacking the permission to service, data, etc.
RESOURCE_NOT_FOUND_ERROR	Errors arise when data, location, etc does not exist.
QUERY_ERROR	Errors arise from Spark SQL query execution.
SYNTAX_ERROR	Errors arise when there is syntax error in the script.
THROTTLING_ERROR	Errors arise when hitting service concurrency limitation or exceeding service quota limitaion .
DATA_LAKE_FRAMEWORK_ERROR	Errors arise from Amazon Glue native-supported data lake framework like Hudi, Iceberg, etc.
UNSUPPORTED_OPERATION_ERROR	Errors arise when making unsupported operation.
RESOURCES_ALREADY_EXISTS_ERROR	Errors arise when a resource to be created or added already exists.
GLUE_INTERNAL_SERVICE_ERROR	Errors arise when there is a Amazon Glue internal service issue.
GLUE_OPERATION_TIMEOUT_ERROR	Errors arise when a Amazon Glue operation is timeout.

Error categories	Description
GLUE_VALIDATION_ERROR	Errors arise when a required value could not be validated for Amazon Glue job.
GLUE_JOB_BOOKMARK_VERSION_MISMATCH_ERROR	Errors arise when same job exon the same source bucket and write to the same/different destination concurrently (concurrency >1)
LAUNCH_ERROR	Errors arise during the Amazon Glue job launch phase.
DYNAMODB_ERROR	Generic errors arise from Amazon DynamoDB service.
GLUE_ERROR	Generic Errors arise from Amazon Glue service.
LAKEFORMATION_ERROR	Generic Errors arise from Amazon Lake Formation service.
REDSHIFT_ERROR	Generic Errors arise from Amazon Redshift service.
S3_ERROR	Generic Errors arise from Amazon S3 service.
SYSTEM_EXIT_ERROR	Generic system exit error.
TIMEOUT_ERROR	Generic errors arise when job failed by operation time out.
UNCLASSIFIED_SPARK_ERROR	Generic errors arise from Spark.
UNCLASSIFIED_ERROR	Default error category.

Limitations

Note

`glueContext` must be initialized to publish the metrics.

In the Source Dimension, the value is either Amazon S3 path or table name, depending on the source type. In addition, if the source is JDBC and the query option is used, the query string is set in the source dimension. If the value is longer than 500 characters, it is trimmed within 500 characters. The following are limitations in the value:

- Non-ASCII characters will be removed.
- If the source name doesn't contain any ASCII character, it is converted to <non-ASCII input>.

Limitations and considerations for throughput metrics

- DataFrame and DataFrame-based DynamicFrame (e.g. JDBC, reading from parquet on Amazon S3) are supported, however, RDD-based DynamicFrame (e.g. reading csv, json on Amazon S3, etc.) is not supported. Technically, all reads and writes visible on Spark UI are supported.
- The `recordsRead` metric will be emitted if the data source is catalog table and the format is JSON, CSV, text, or Iceberg.
- `glue.driver.throughput.recordsWritten`, `glue.driver.throughput.bytesWritten`, and `glue.driver.throughput.filesWritten` metrics are not available in JDBC and Iceberg tables.
- Metrics may be delayed. If the job finishes in about one minute, there may be no throughput metrics in Amazon CloudWatch Metrics.

Job monitoring and debugging

You can collect metrics about Amazon Glue jobs and visualize them on the Amazon Glue and Amazon CloudWatch consoles to identify and fix issues. Profiling your Amazon Glue jobs requires the following steps:

1. Enable metrics:
 - a. Enable the **Job metrics** option in the job definition. You can enable profiling in the Amazon Glue console or as a parameter to the job. For more information see [Defining job properties for Spark jobs](#) or [Using job parameters in Amazon Glue jobs](#).
 - b. Enable the **Amazon Glue Observability metrics** option in the job definition. You can enable Observability in the Amazon Glue console or as a parameter to the job. For more information see [Monitoring with Amazon Glue Observability metrics](#).

2. Confirm that the job script initializes a GlueContext. For example, the following script snippet initializes a GlueContext and shows where profiled code is placed in the script. This general format is used in the debugging scenarios that follow.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
import time

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

...
...
code-to-profile
...
...

job.commit()
```

3. Run the job.
4. Visualize the metrics:
 - a. Visualize job metrics on the Amazon Glue console and identify abnormal metrics for the driver or an executor.
 - b. Check observability metrics in the Job run monitoring page, job run details page, or on Amazon CloudWatch. For more information, see [Monitoring with Amazon Glue Observability metrics](#).
5. Narrow down the root cause using the identified metric.
6. Optionally, confirm the root cause using the log stream of the identified driver or job executor.

Use cases for Amazon Glue observability metrics

- [Debugging OOM exceptions and job abnormalities](#)
- [Debugging demanding stages and straggler tasks](#)
- [Monitoring the progress of multiple jobs](#)
- [Monitoring for DPU capacity planning](#)
- [Using Amazon Glue Observability for monitoring resource utilization to reduce cost](#)

Debugging OOM exceptions and job abnormalities

You can debug out-of-memory (OOM) exceptions and job abnormalities in Amazon Glue. The following sections describe scenarios for debugging out-of-memory exceptions of the Apache Spark driver or a Spark executor.

- [Debugging a driver OOM exception](#)
- [Debugging an executor OOM exception](#)

Debugging a driver OOM exception

In this scenario, a Spark job is reading a large number of small files from Amazon Simple Storage Service (Amazon S3). It converts the files to Apache Parquet format and then writes them out to Amazon S3. The Spark driver is running out of memory. The input Amazon S3 data has more than 1 million files in different Amazon S3 partitions.

The profiled code is as follows:

```
data = spark.read.format("json").option("inferSchema", False).load("s3://input_path")
data.write.format("parquet").save(output_path)
```

Visualize the profiled metrics on the Amazon Glue console

The following graph shows the memory usage as a percentage for the driver and executors. This usage is plotted as one data point that is averaged over the values reported in the last minute. You can see in the memory profile of the job that the [driver memory](#) crosses the safe threshold of 50 percent usage quickly. On the other hand, the [average memory usage](#) across all executors is still less than 4 percent. This clearly shows abnormality with driver execution in this Spark job.

The job run soon fails, and the following error appears in the **History** tab on the Amazon Glue console: Command Failed with Exit Code 1. This error string means that the job failed due to a systemic error—which in this case is the driver running out of memory.

e2e-metrics python ... 7 June 2018 7:37 PM UTC-7 Disable

[History](#) [Details](#) [Script](#) [Metrics](#)

Run ID	Retry attempt	Run status	Error	Logs	Error logs	Execution time	Timeout	Delay	Triggered by	Start time
jr_651bfc34...	-	Failed	!	Logs	Error logs	2 mins	2880 mins			7 June :
jr_5731b225...	-	Failed	Command failed with exit code 1					2880 mins		7 June :

On the console, choose the **Error logs** link on the **History** tab to confirm the finding about driver OOM from the CloudWatch Logs. Search for "**Error**" in the job's error logs to confirm that it was indeed an OOM exception that failed the job:

```
# java.lang.OutOfMemoryError: Java heap space
# -XX:OnOutOfMemoryError="kill -9 %p"
# Executing /bin/sh -c "kill -9 12039"...
```

On the **History** tab for the job, choose **Logs**. You can find the following trace of driver execution in the CloudWatch Logs at the beginning of the job. The Spark driver tries to list all the files in all the directories, constructs an `InMemoryFileIndex`, and launches one task per file. This in turn results in the Spark driver having to maintain a large amount of state in memory to track all the tasks. It caches the complete list of a large number of files for the in-memory index, resulting in a driver OOM.

Fix the processing of multiple files using grouping

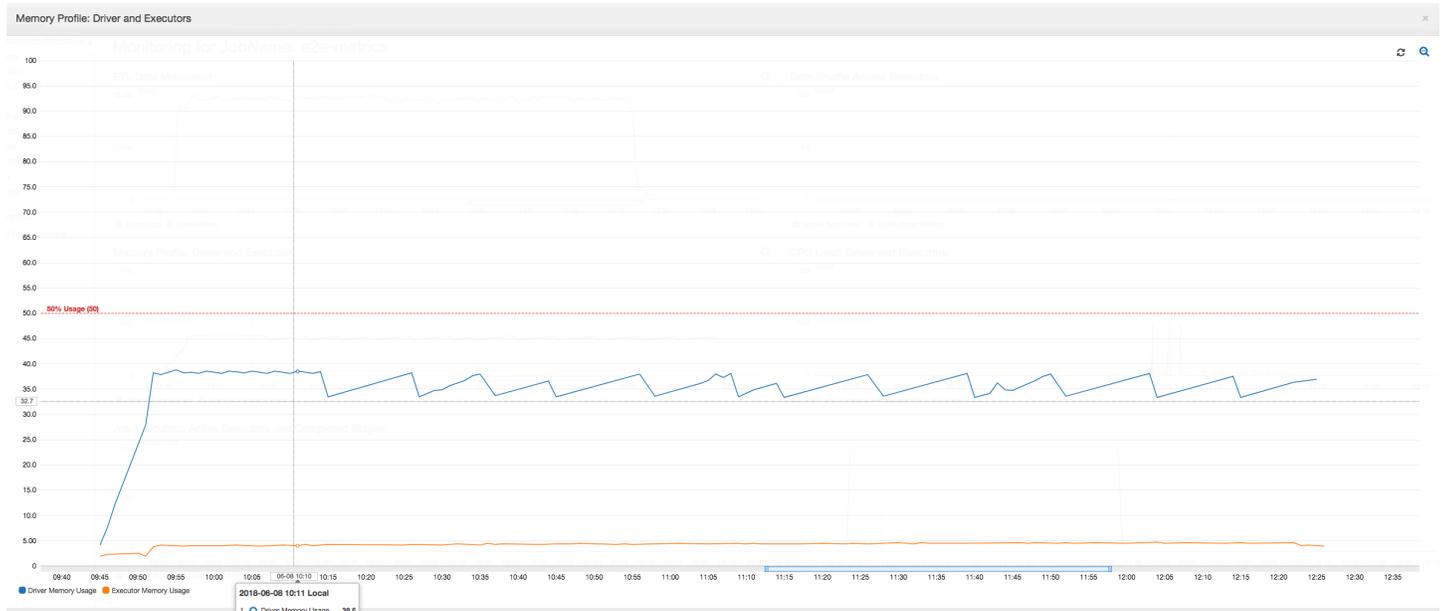

You can fix the processing of the multiple files by using the *grouping* feature in Amazon Glue. Grouping is automatically enabled when you use dynamic frames and when the input dataset has a large number of files (more than 50,000). Grouping allows you to coalesce multiple files together into a group, and it allows a task to process the entire group instead of a single file. As a result, the Spark driver stores significantly less state in memory to track fewer tasks. For more information about manually enabling grouping for your dataset, see [Reading input files in larger groups](#).

To check the memory profile of the Amazon Glue job, profile the following code with grouping enabled:

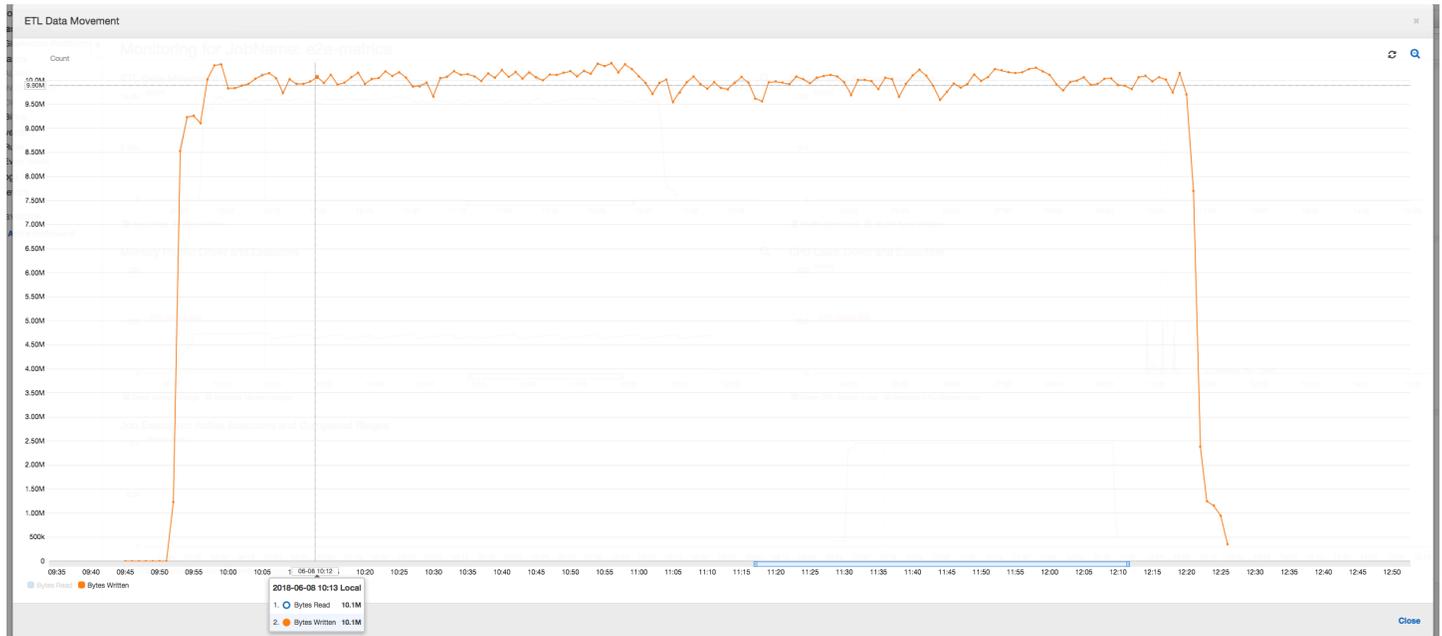

```
df = glueContext.create_dynamic_frame_from_options("s3", {'paths': ["s3://input_path"],
  "recurse":True, 'groupFiles': 'inPartition'}, format="json")
datasink = glueContext.write_dynamic_frame.from_options(frame = df, connection_type
  = "s3", connection_options = {"path": output_path}, format = "parquet",
  transformation_ctx = "datasink")
```

You can monitor the memory profile and the ETL data movement in the Amazon Glue job profile.

The driver runs below the threshold of 50 percent memory usage over the entire duration of the Amazon Glue job. The executors stream the data from Amazon S3, process it, and write it out to Amazon S3. As a result, they consume less than 5 percent memory at any point in time.

The data movement profile below shows the total number of Amazon S3 bytes that are [read](#) and [written](#) in the last minute by all executors as the job progresses. Both follow a similar pattern as the data is streamed across all the executors. The job finishes processing all one million files in less than three hours.

Debugging an executor OOM exception

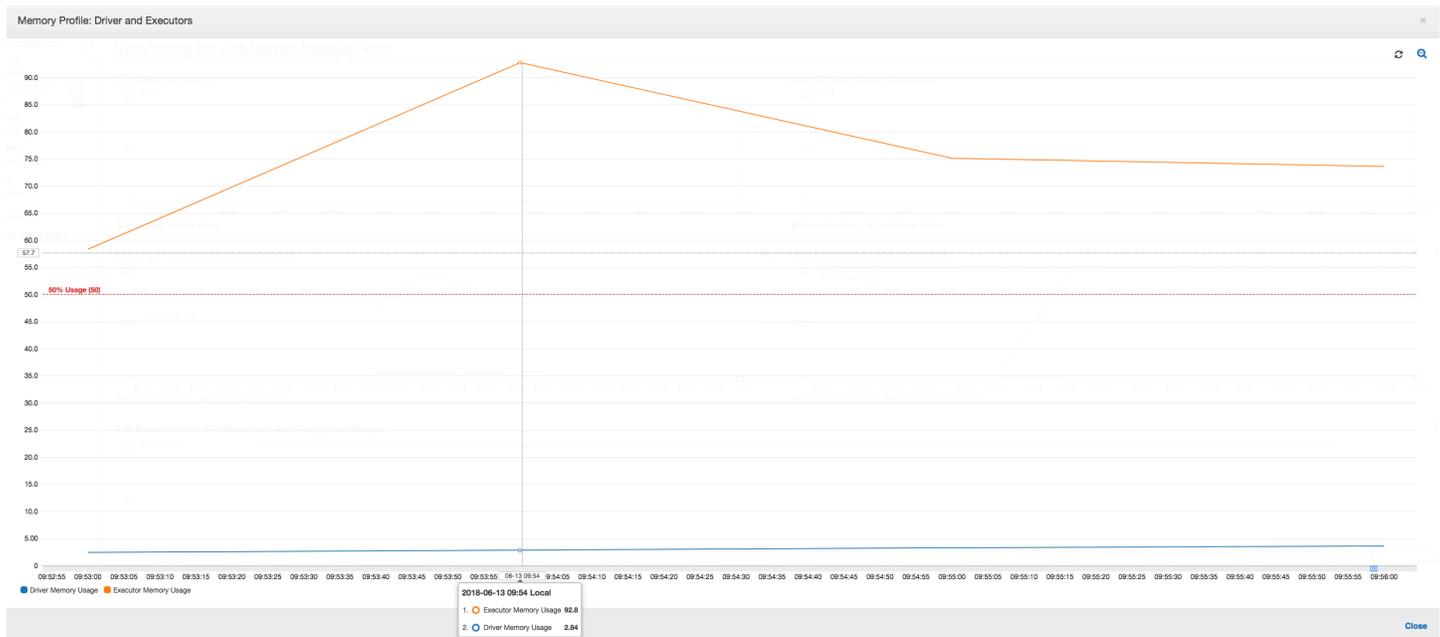

In this scenario, you can learn how to debug OOM exceptions that could occur in Apache Spark executors. The following code uses the Spark MySQL reader to read a large table of about 34

million rows into a Spark dataframe. It then writes it out to Amazon S3 in Parquet format. You can provide the connection properties and use the default Spark configurations to read the table.

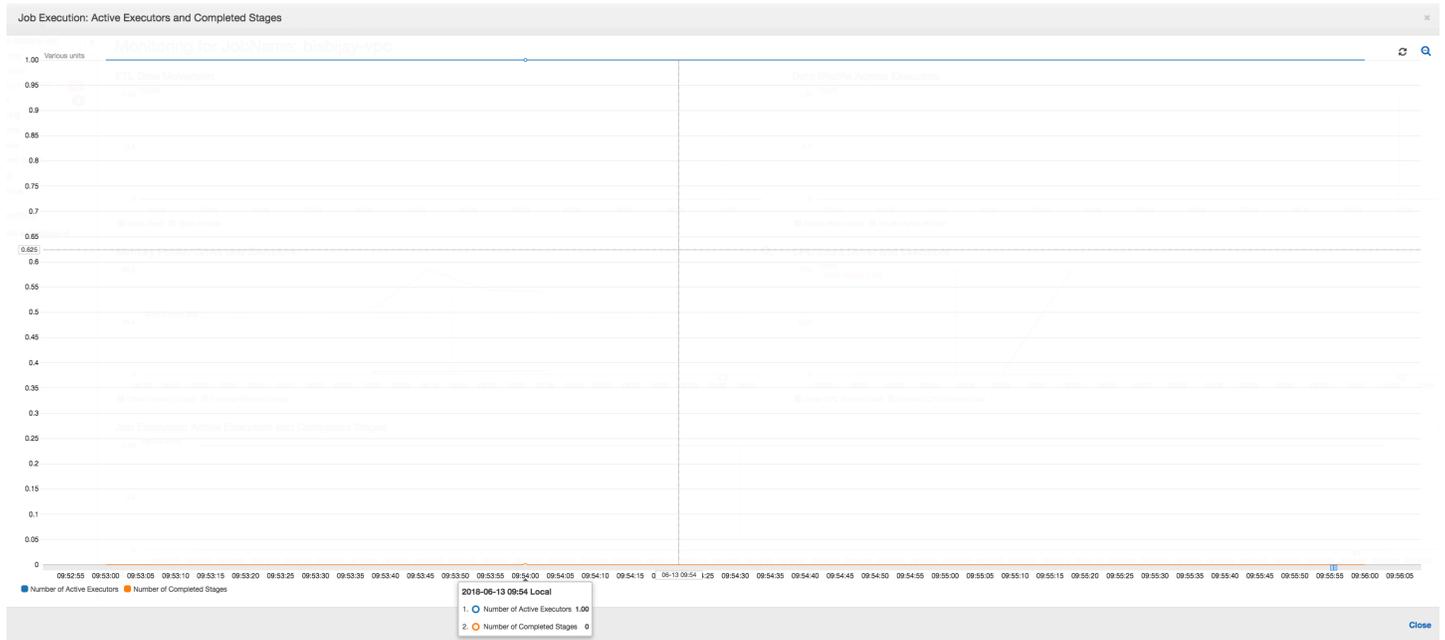

```
val connectionProperties = new Properties()
connectionProperties.put("user", user)
connectionProperties.put("password", password)
connectionProperties.put("Driver", "com.mysql.jdbc.Driver")
val sparkSession = glueContext.sparkSession
val dfSpark = sparkSession.read.jdbc(url, tableName, connectionProperties)
dfSpark.write.format("parquet").save(output_path)
```

Visualize the profiled metrics on the Amazon Glue console

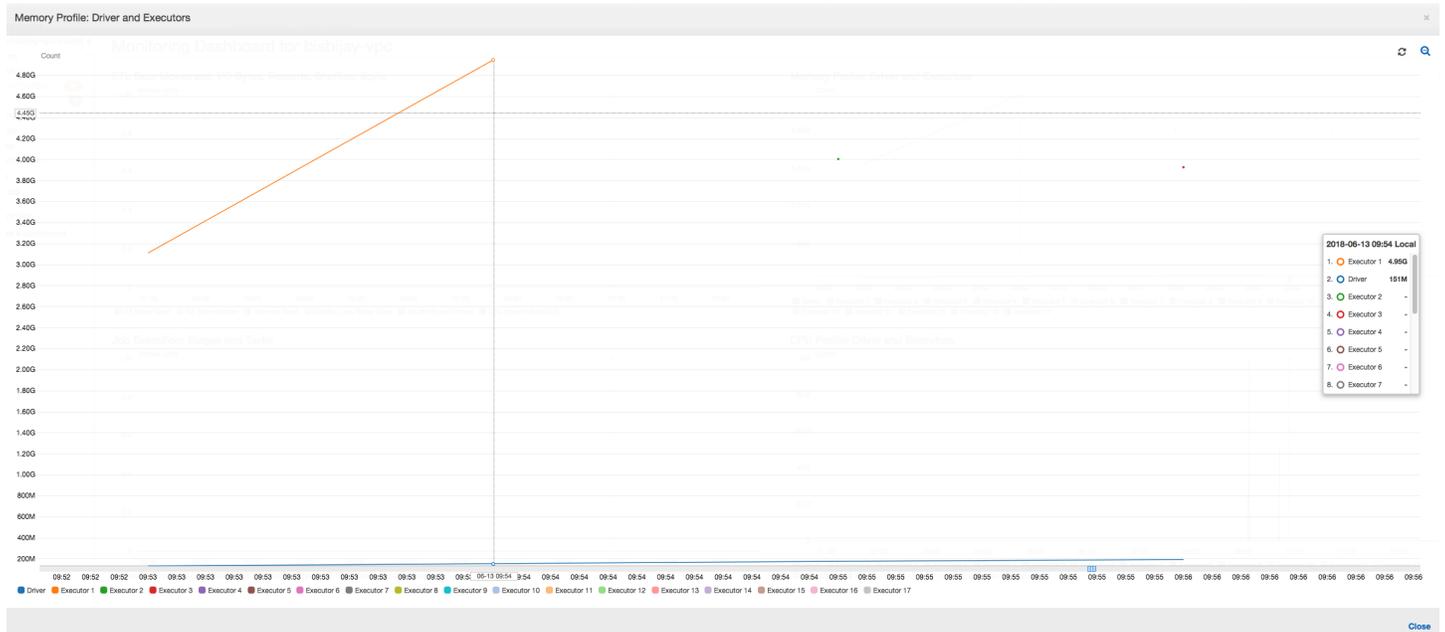

If the slope of the memory usage graph is positive and crosses 50 percent, then if the job fails before the next metric is emitted, then memory exhaustion is a good candidate for the cause. The following graph shows that within a minute of execution, the [average memory usage](#) across all executors spikes up quickly above 50 percent. The usage reaches up to 92 percent and the container running the executor is stopped by Apache Hadoop YARN.

As the following graph shows, there is always a [single executor](#) running until the job fails. This is because a new executor is launched to replace the stopped executor. The JDBC data source reads are not parallelized by default because it would require partitioning the table on a column and opening multiple connections. As a result, only one executor reads in the complete table sequentially.

As the following graph shows, Spark tries to launch a new task four times before failing the job. You can see the [memory profile](#) of three executors. Each executor quickly uses up all of its memory. The fourth executor runs out of memory, and the job fails. As a result, its metric is not reported immediately.

You can confirm from the error string on the Amazon Glue console that the job failed due to OOM exceptions, as shown in the following image.

Run ID	Retry attempt	Run status	Error	Logs	Error logs	Execution time	Timeout	Delay	Triggered by	Start time	End time

Job output logs: To further confirm your finding of an executor OOM exception, look at the CloudWatch Logs. When you search for **Error**, you find the four executors being stopped in roughly the same time windows as shown on the metrics dashboard. All are terminated by YARN as they exceed their memory limits.

```

Fix the fetch size setting using Amazon Glue dynamic frames

The executor ran out of memory while reading the JDBC table because the default configuration for the Spark JDBC fetch size is zero. This means that the JDBC driver on the Spark executor tries to fetch the 34 million rows from the database together and cache them, even though Spark streams through the rows one at a time. With Spark, you can avoid this scenario by setting the fetch size parameter to a non-zero default value.

You can also fix this issue by using Amazon Glue dynamic frames instead. By default, dynamic frames use a fetch size of 1,000 rows that is a typically sufficient value. As a result, the executor does not take more than 7 percent of its total memory. The Amazon Glue job finishes in less than two minutes with only a single executor. While using Amazon Glue dynamic frames is the recommended approach, it is also possible to set the fetch size using the Apache Spark `fetchsize` property. See the [Spark SQL, DataFrames and Datasets Guide](#).

```
val (url, database, tableName) = {
  ("jdbc_url", "db_name", "table_name")
}
val source = glueContext.getSource(format, sourceJson)
val df = source.getDynamicFrame
glueContext.write_dynamic_frame.from_options(frame = df, connection_type = "s3",
  connection_options = {"path": output_path}, format = "parquet", transformation_ctx =
  "datasink")
```

Normal profiled metrics: The [executor memory](#) with Amazon Glue dynamic frames never exceeds the safe threshold, as shown in the following image. It streams in the rows from the database and caches only 1,000 rows in the JDBC driver at any point in time. An out of memory exception does not occur.

Debugging demanding stages and straggler tasks

You can use Amazon Glue job profiling to identify demanding stages and straggler tasks in your extract, transform, and load (ETL) jobs. A straggler task takes much longer than the rest of the tasks in a stage of an Amazon Glue job. As a result, the stage takes longer to complete, which also delays the total execution time of the job.

Coalescing small input files into larger output files

A straggler task can occur when there is a non-uniform distribution of work across the different tasks, or a data skew results in one task processing more data.

You can profile the following code—a common pattern in Apache Spark—to coalesce a large number of small files into larger output files. For this example, the input dataset is 32 GB of JSON Gzip compressed files. The output dataset has roughly 190 GB of uncompressed JSON files.

The profiled code is as follows:

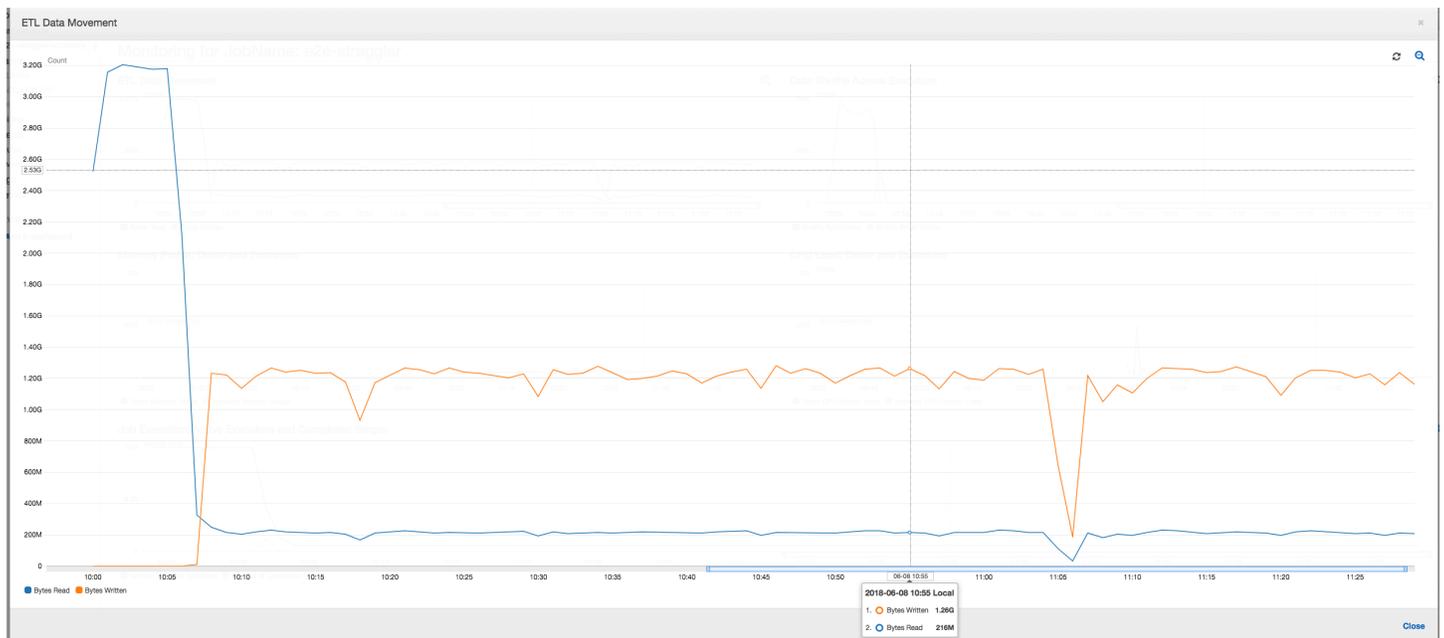

```
datasource0 = spark.read.format("json").load("s3://input_path")
df = datasource0.coalesce(1)
df.write.format("json").save(output_path)
```

Visualize the profiled metrics on the Amazon Glue console

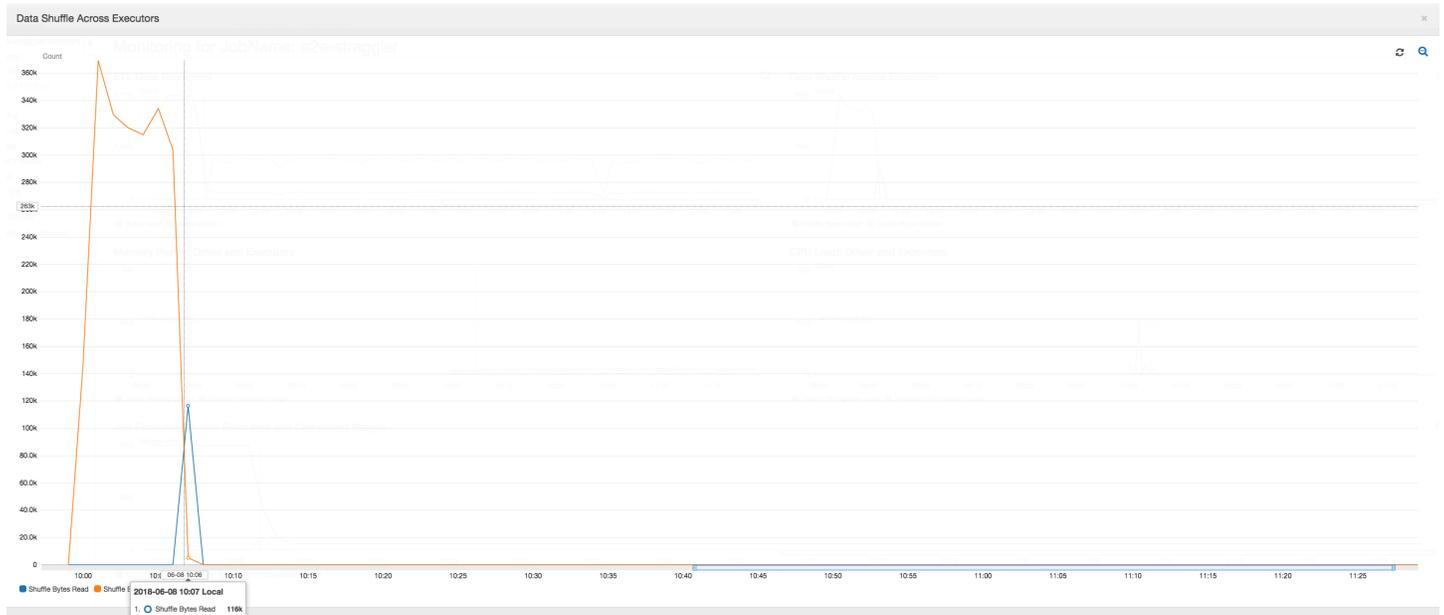

You can profile your job to examine four different sets of metrics:

- ETL data movement
- Data shuffle across executors
- Job execution
- Memory profile

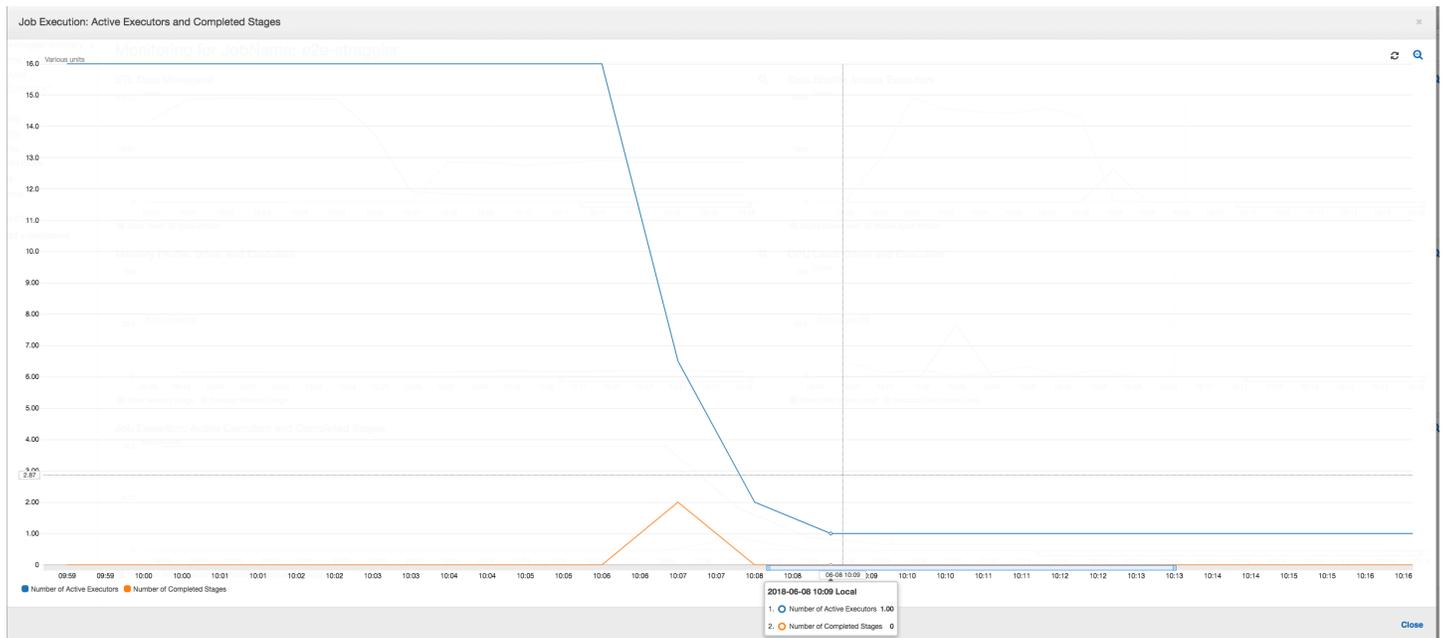

ETL data movement: In the **ETL Data Movement** profile, the bytes are [read](#) fairly quickly by all the executors in the first stage that completes within the first six minutes. However, the total job execution time is around one hour, mostly consisting of the data [writes](#).

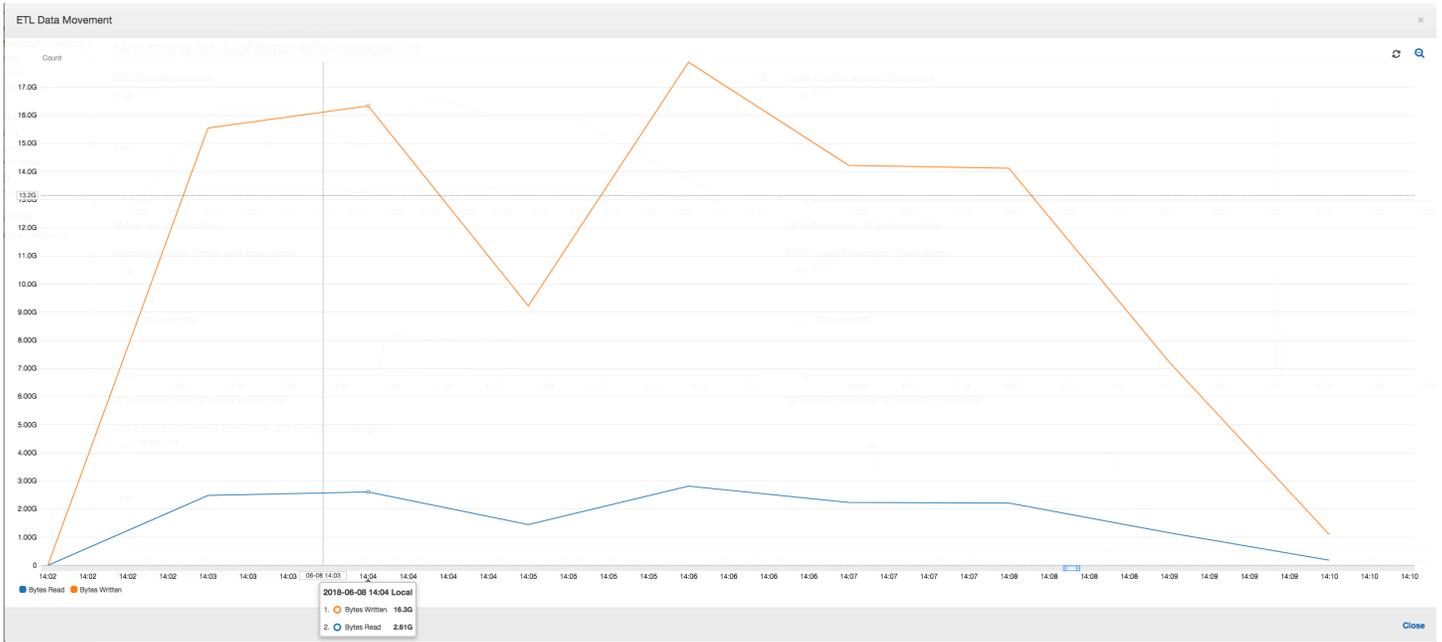

Data shuffle across executors: The number of bytes [read](#) and [written](#) during shuffling also shows a spike before Stage 2 ends, as indicated by the **Job Execution** and **Data Shuffle** metrics. After the data shuffles from all executors, the reads and writes proceed from executor number 3 only.

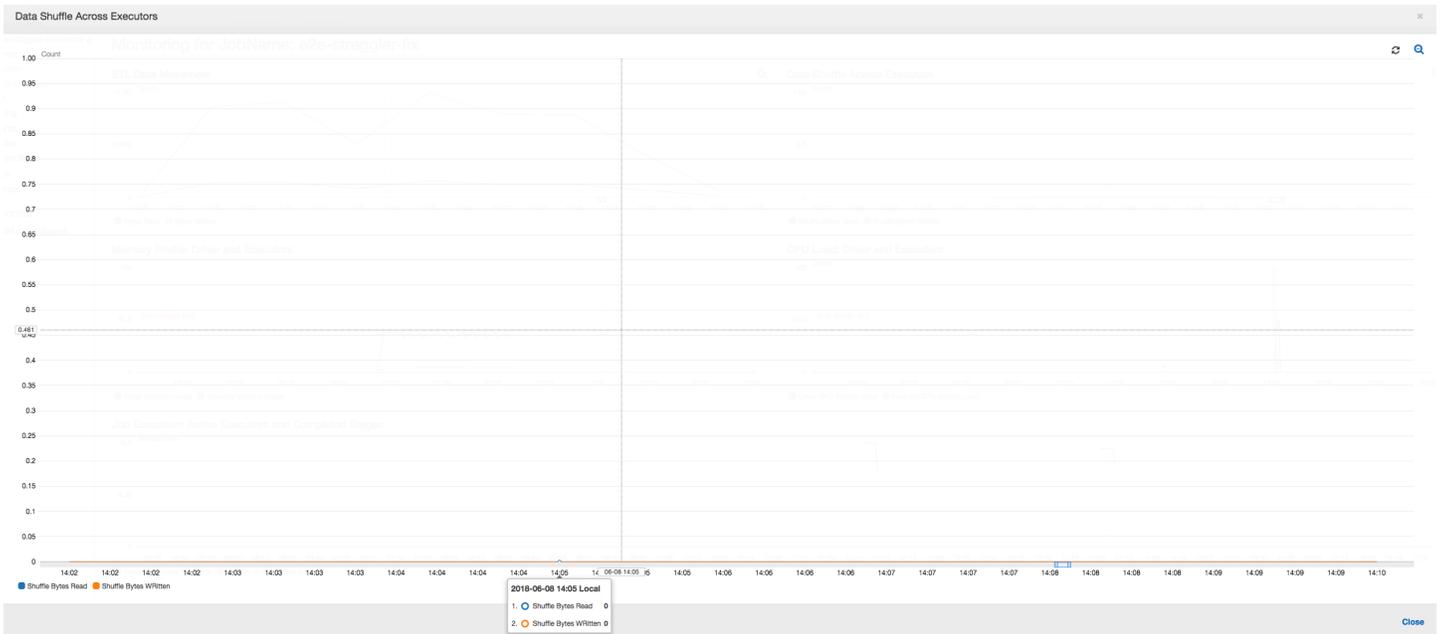

Job execution: As shown in the graph below, all other executors are idle and are eventually relinquished by the time 10:09. At that point, the total number of executors decreases to only one. This clearly shows that executor number 3 consists of the straggler task that is taking the longest execution time and is contributing to most of the job execution time.

Memory profile: After the first two stages, only [executor number 3](#) is actively consuming memory to process the data. The remaining executors are simply idle or have been relinquished shortly after the completion of the first two stages.

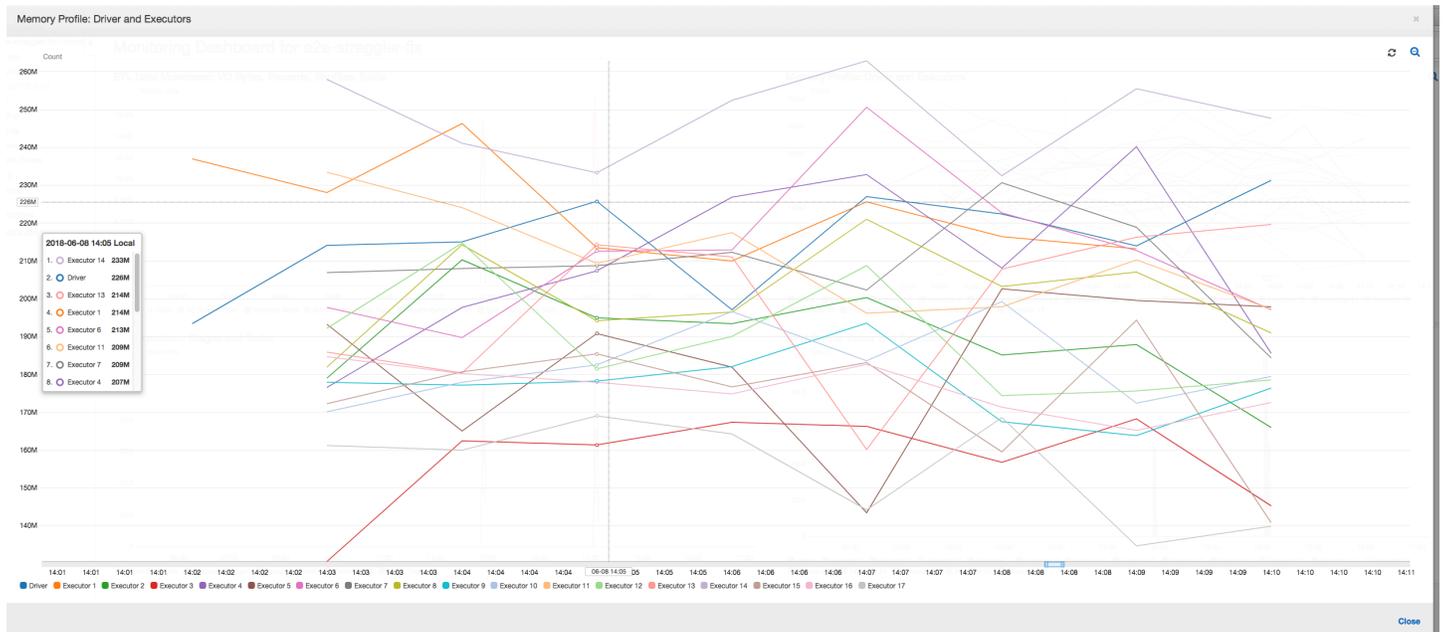

Data shuffle across executors: As the input files are coalesced during the reads using the grouping feature, there is no costly data shuffle after the data reads.

Job execution: The job execution metrics show that the total number of active executors running and processing data remains fairly constant. There is no single straggler in the job. All executors are active and are not relinquished until the completion of the job. Because there is no intermediate shuffle of data across the executors, there is only a single stage in the job.

Memory profile: The metrics show the [active memory consumption](#) across all executors—reconfirming that there is activity across all executors. As data is streamed in and written out in parallel, the total memory footprint of all executors is roughly uniform and well below the safe threshold for all executors.

Monitoring the progress of multiple jobs

You can profile multiple Amazon Glue jobs together and monitor the flow of data between them. This is a common workflow pattern, and requires monitoring for individual job progress, data processing backlog, data reprocessing, and job bookmarks.

Topics

- [Profiled code](#)
- [Visualize the profiled metrics on the Amazon Glue console](#)
- [Fix the processing of files](#)

Profiled code

In this workflow, you have two jobs: an Input job and an Output job. The Input job is scheduled to run every 30 minutes using a periodic trigger. The Output job is scheduled to run after each successful run of the Input job. These scheduled jobs are controlled using job triggers.

Triggers A trigger starts a job when it fires.

Trigger name	Trigger type	Trigger status	Trigger parameters	Jobs to trigger
<input type="checkbox"/> e2e-bookmark-input	Schedule	ACTIVATED	Every 15 minutes	e2ebookmark-input
<input type="checkbox"/> e2e-bookmark-output	Job events	ACTIVATED	Job events: e2ebookmark-input	e2e-bookmark

Input job: This job reads in data from an Amazon Simple Storage Service (Amazon S3) location, transforms it using ApplyMapping, and writes it to a staging Amazon S3 location. The following code is profiled code for the Input job:

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
  connection_options = {"paths": ["s3://input_path"],
  "useS3ListImplementation":True,"recurse":True}, format="json")
applymapping1 = ApplyMapping.apply(frame = datasource0, mappings = [map_spec])
datasink2 = glueContext.write_dynamic_frame.from_options(frame = applymapping1,
  connection_type = "s3", connection_options = {"path": staging_path, "compression":
  "gzip"}, format = "json")
```

Output job: This job reads the output of the Input job from the staging location in Amazon S3, transforms it again, and writes it to a destination:

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
  connection_options = {"paths": [staging_path],
  "useS3ListImplementation":True,"recurse":True}, format="json")
```

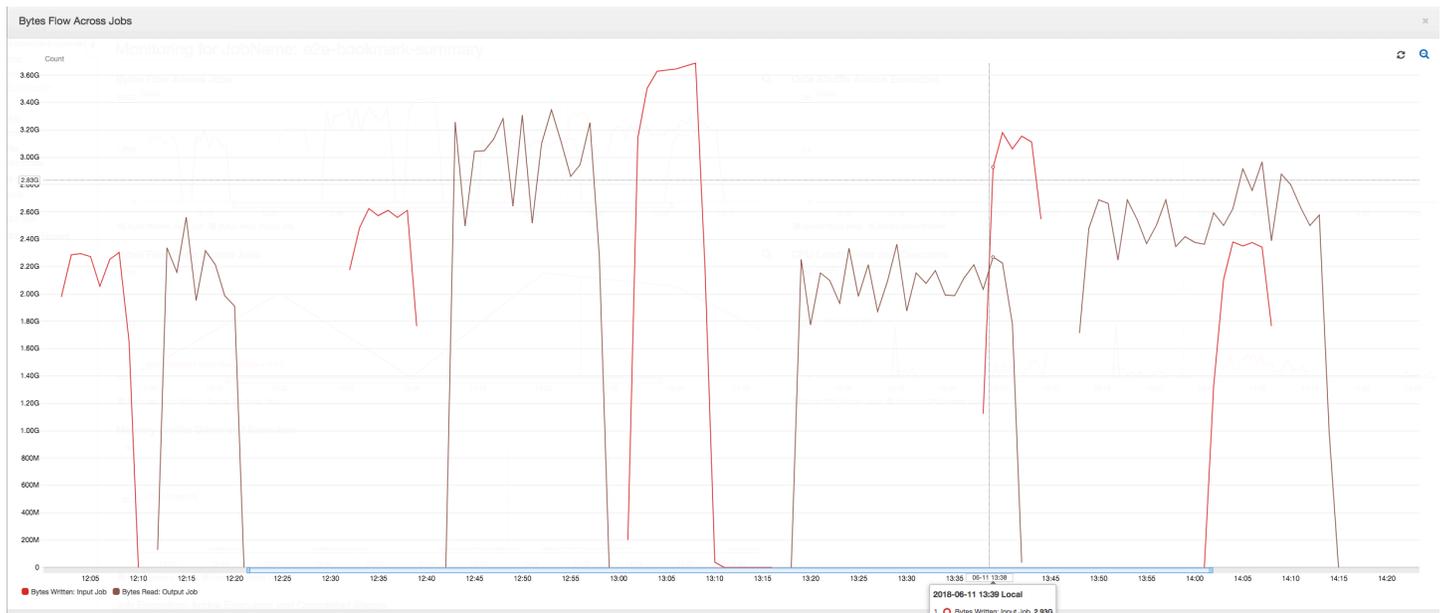

```

appliedmapping1 = ApplyMapping.apply(frame = datasource0, mappings = [map_spec])
datasink2 = glueContext.write_dynamic_frame.from_options(frame = appliedmapping1,
  connection_type = "s3", connection_options = {"path": output_path}, format = "json")

```

Visualize the profiled metrics on the Amazon Glue console

The following dashboard superimposes the Amazon S3 bytes written metric from the Input job onto the Amazon S3 bytes read metric on the same timeline for the Output job. The timeline shows different job runs of the Input and Output jobs. The Input job (shown in red) starts every 30 minutes. The Output Job (shown in brown) starts at the completion of the Input Job, with a Max Concurrency of 1.

In this example, [job bookmarks](#) are not enabled. No transformation contexts are used to enable job bookmarks in the script code.

Job History: The Input and Output jobs have multiple runs, as shown on the **History** tab, starting from 12:00 PM.

The Input job on the Amazon Glue console looks like this:

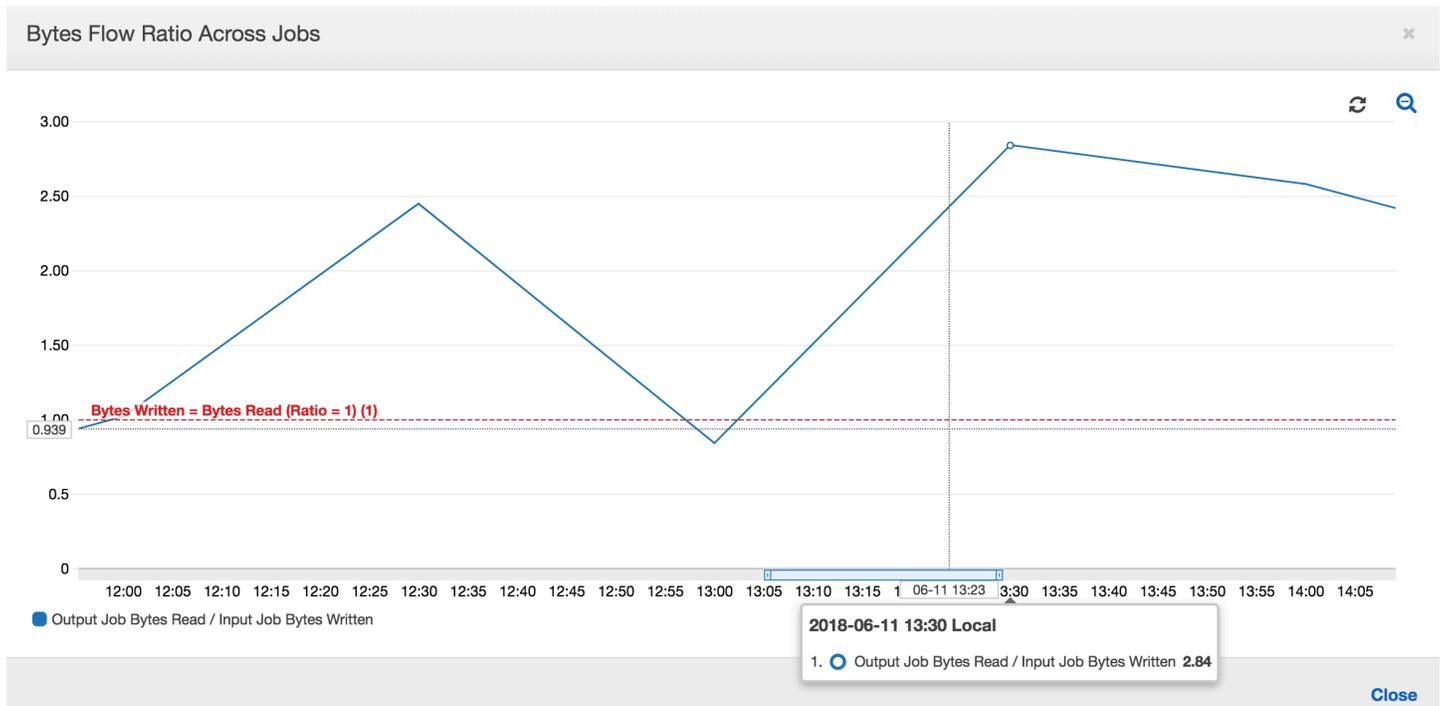

Run ID	Retry attempt	Run status	Error	Logs	Error logs	Execution time	Timeout	Delay	Triggered by	Start time	End time
jx_0ce47b1a581051f6c9ae96e...	-	Succeeded		Logs		8 mins	2880 mins		e2e-bookmark-input	11 June 2018 2:30 PM UT...	11 June 2018 2:40 PM UT...

First job runs: As shown in the Data Bytes Read and Written graph below, the first job runs of the Input and Output jobs between 12:00 and 12:30 show roughly the same area under the curves. Those areas represent the Amazon S3 bytes written by the Input job and the Amazon S3 bytes read by the Output job. This data is also confirmed by the ratio of Amazon S3 bytes written (summed over 30 minutes – the job trigger frequency for the Input job). The data point for the ratio for the Input job run that started at 12:00PM is also 1.

The following graph shows the data flow ratio across all the job runs:

Second job runs: In the second job run, there is a clear difference in the number of bytes read by the Output job compared to the number of bytes written by the Input job. (Compare the area under the curve across the two job runs for the Output job, or compare the areas in the second run of the Input and Output jobs.) The ratio of the bytes read and written shows that the Output Job read about 2.5x the data written by the Input job in the second span of 30 minutes from 12:30 to 13:00. This is because the Output Job reprocessed the output of the first job run of the Input job because job bookmarks were not enabled. A ratio above 1 shows that there is an additional backlog of data that was processed by the Output job.

Third job runs: The Input job is fairly consistent in terms of the number of bytes written (see the area under the red curves). However, the third job run of the Input job ran longer than expected (see the long tail of the red curve). As a result, the third job run of the Output job started late. The third job run processed only a fraction of the data accumulated in the staging location in the remaining 30 minutes between 13:00 and 13:30. The ratio of the bytes flow shows that it only processed 0.83 of data written by the third job run of the Input job (see the ratio at 13:00).

Overlap of Input and Output jobs: The fourth job run of the Input job started at 13:30 as per the schedule, before the third job run of the Output job finished. There is a partial overlap between these two job runs. However, the third job run of the Output job captures only the files that it listed in the staging location of Amazon S3 when it began around 13:17. This consists of all data output from the first job runs of the Input job. The actual ratio at 13:30 is around 2.75. The third job run of the Output job processed about 2.75x of data written by the fourth job run of the Input job from 13:30 to 14:00.

As these images show, the Output job is reprocessing data from the staging location from all prior job runs of the Input job. As a result, the fourth job run for the Output job is the longest and overlaps with the entire fifth job run of the Input job.

Fix the processing of files

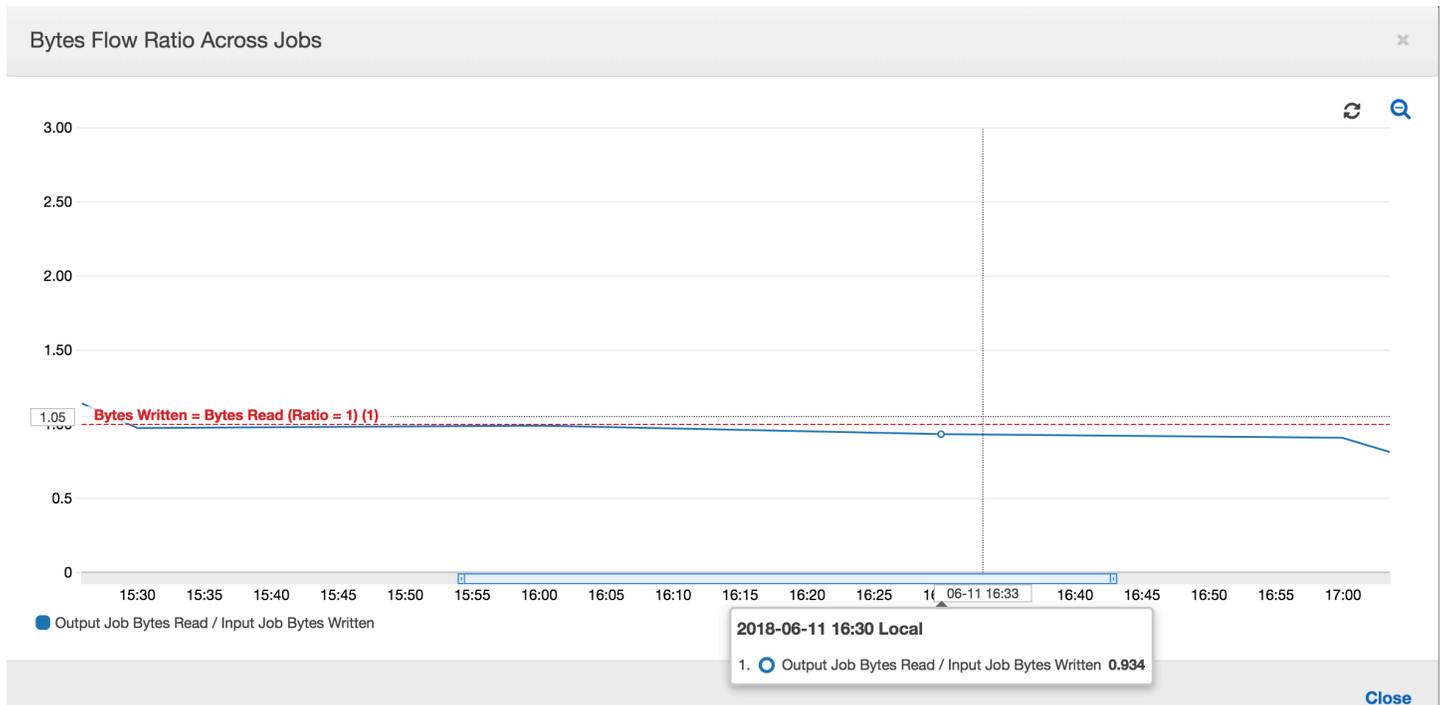

You should ensure that the Output job processes only the files that haven't been processed by previous job runs of the Output job. To do this, enable job bookmarks and set the transformation context in the Output job, as follows:

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
  connection_options = {"paths": [staging_path],
  "useS3ListImplementation":True,"recurse":True}, format="json", transformation_ctx =
  "bookmark_ctx")
```

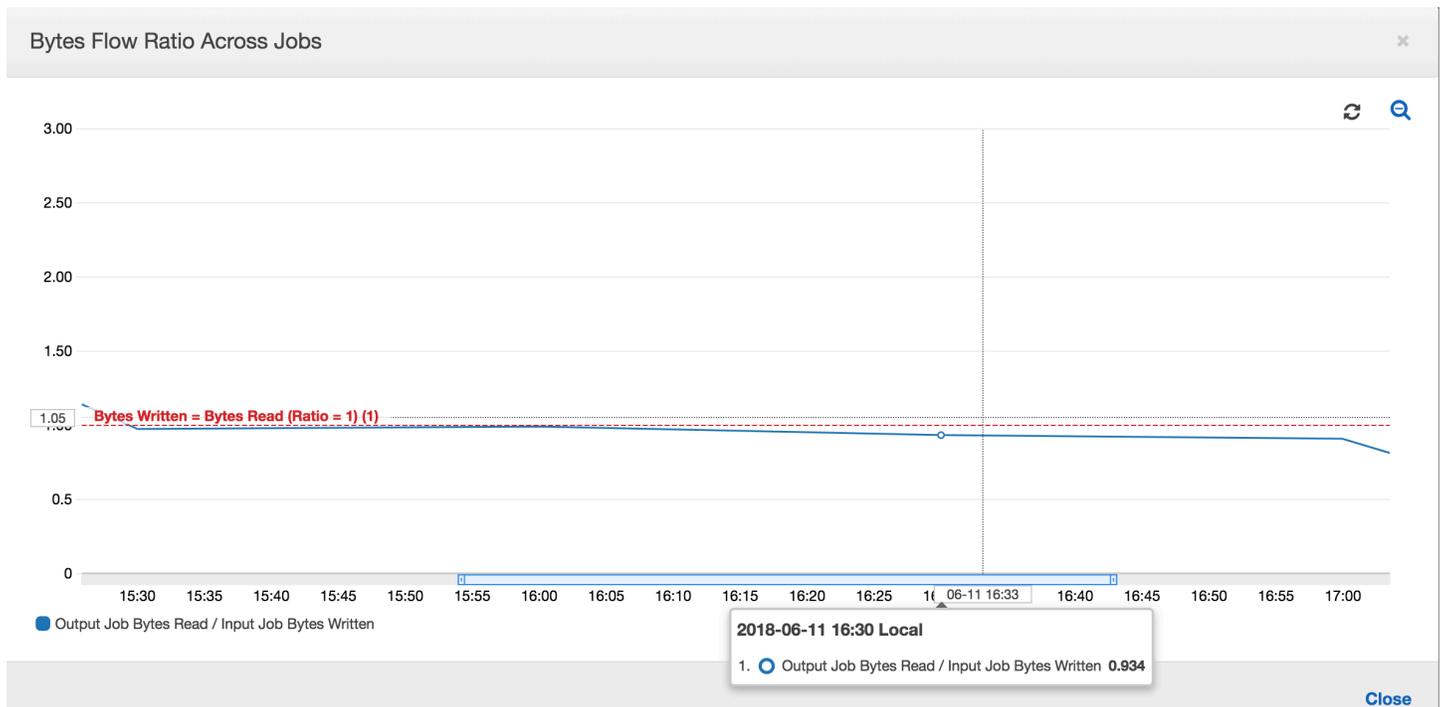

With job bookmarks enabled, the Output job doesn't reprocess the data in the staging location from all the previous job runs of the Input job. In the following image showing the data read and written, the area under the brown curve is fairly consistent and similar with the red curves.

The ratios of byte flow also remain roughly close to 1 because there is no additional data processed.

A job run for the Output job starts and captures the files in the staging location before the next Input job run starts putting more data into the staging location. As long as it continues to do this, it processes only the files captured from the previous Input job run, and the ratio stays close to 1.

Suppose that the Input job takes longer than expected, and as a result, the Output job captures files in the staging location from two Input job runs. The ratio is then higher than 1 for that Output job run. However, the following job runs of the Output job don't process any files that are already processed by the previous job runs of the Output job.

Monitoring for DPU capacity planning

You can use job metrics in Amazon Glue to estimate the number of data processing units (DPUs) that can be used to scale out an Amazon Glue job.

Note

This page is only applicable to Amazon Glue versions 0.9 and 1.0. Later versions of Amazon Glue contain cost-saving features that introduce additional considerations when capacity planning.

Topics

- [Profiled code](#)
- [Visualize the profiled metrics on the Amazon Glue console](#)
- [Determine the optimal DPU capacity](#)

Profiled code

The following script reads an Amazon Simple Storage Service (Amazon S3) partition containing 428 gzipped JSON files. The script applies a mapping to change the field names, and converts and writes them to Amazon S3 in Apache Parquet format. You provision 10 DPUs as per the default and run this job.

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
  connection_options = {"paths": [input_path],
  "useS3ListImplementation":True,"recurse":True}, format="json")
applymapping1 = ApplyMapping.apply(frame = datasource0, mappings = [(map_spec)])
datasink2 = glueContext.write_dynamic_frame.from_options(frame = applymapping1,
  connection_type = "s3", connection_options = {"path": output_path}, format =
  "parquet")
```

Visualize the profiled metrics on the Amazon Glue console

Job run 1: In this job run we show how to find if there are under-provisioned DPUs in the cluster. The job execution functionality in Amazon Glue shows the total [number of actively running executors](#), the [number of completed stages](#), and the [number of maximum needed executors](#).

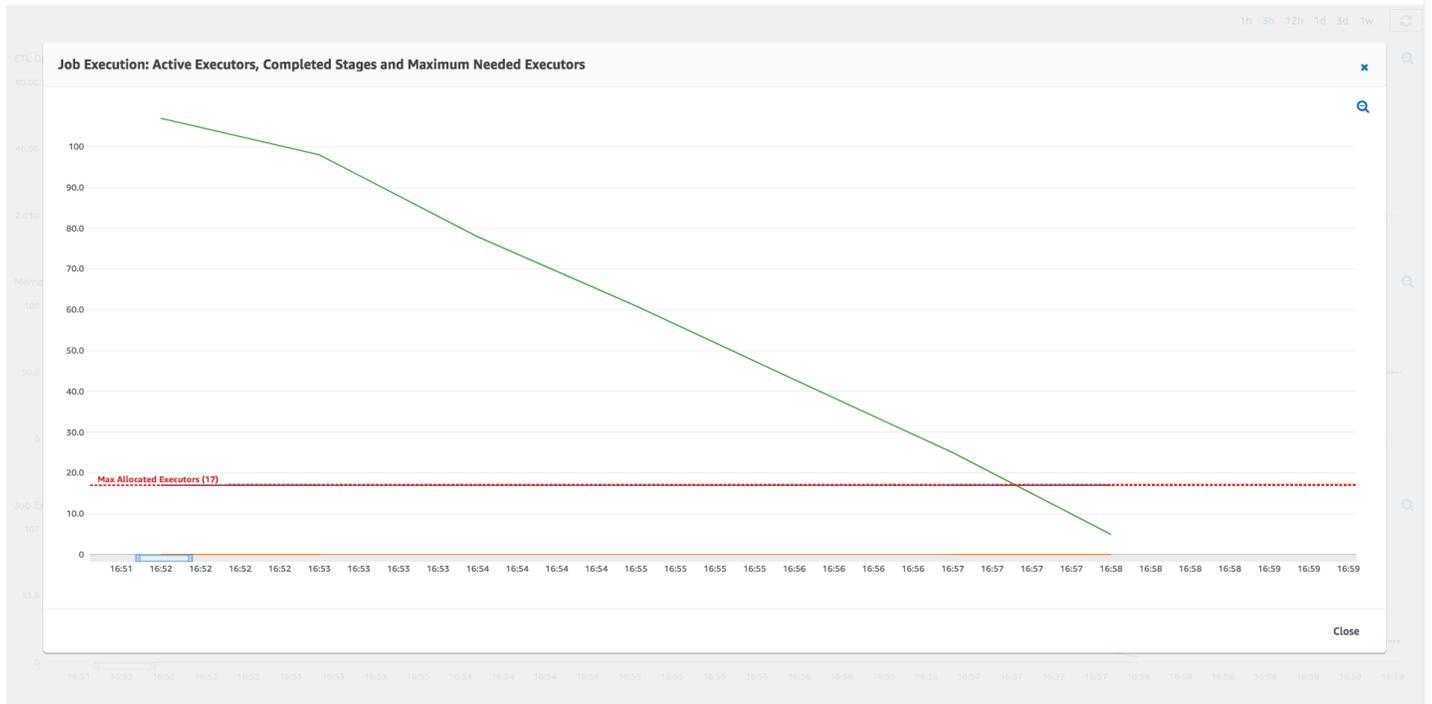

The number of maximum needed executors is computed by adding the total number of running tasks and pending tasks, and dividing by the tasks per executor. This result is a measure of the total number of executors required to satisfy the current load.

In contrast, the number of actively running executors measures how many executors are running active Apache Spark tasks. As the job progresses, the maximum needed executors can change and typically goes down towards the end of the job as the pending task queue diminishes.

The horizontal red line in the following graph shows the number of maximum allocated executors, which depends on the number of DPUs that you allocate for the job. In this case, you allocate 10 DPUs for the job run. One DPU is reserved for management. Nine DPUs run two executors each and one executor is reserved for the Spark driver. The Spark driver runs inside the primary application. So, the number of maximum allocated executors is $2 \times 9 - 1 = 17$ executors.

Jobs > e2e-dpus

Detailed job metrics

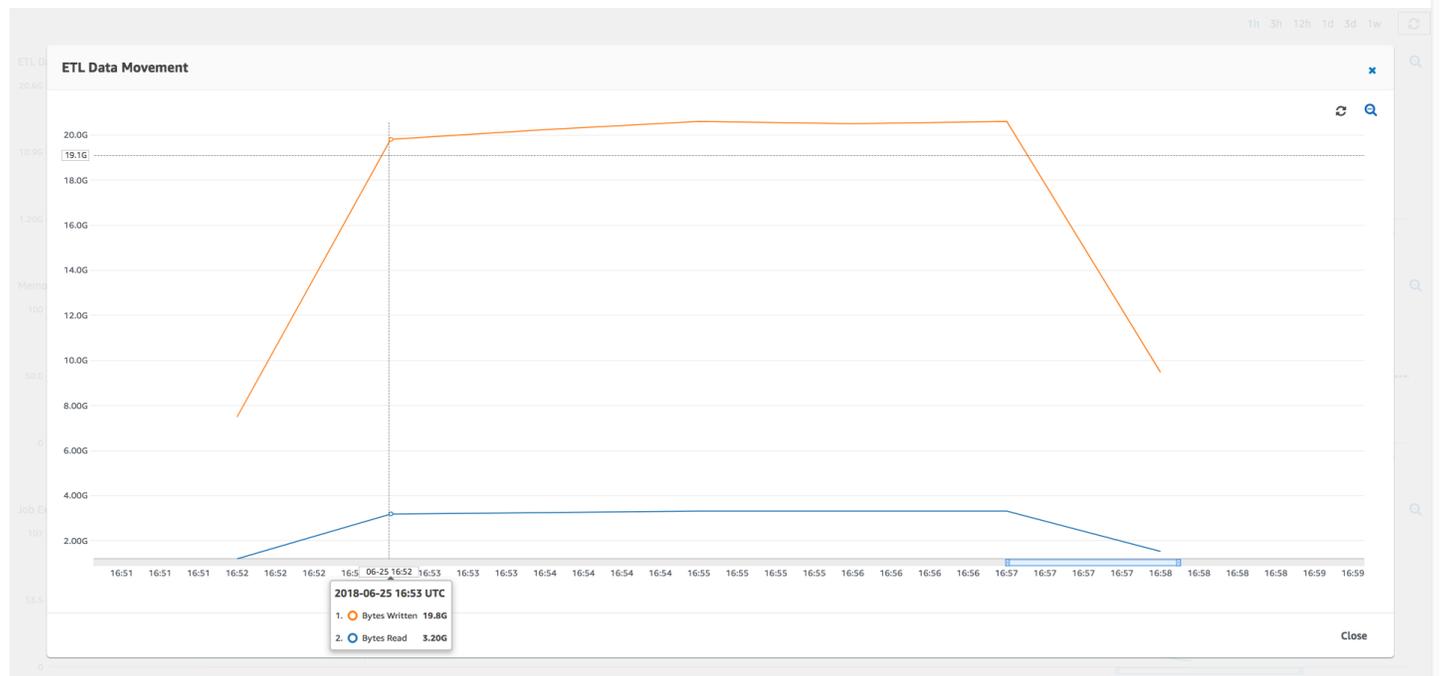

As the graph shows, the number of maximum needed executors starts at 107 at the beginning of the job, whereas the number of active executors remains 17. This is the same as the number of maximum allocated executors with 10 DPUs. The ratio between the maximum needed executors and maximum allocated executors (adding 1 to both for the Spark driver) gives you the under-provisioning factor: $108/18 = 6x$. You can provision 6 (under provisioning ratio) * 9 (current DPU capacity - 1) + 1 DPUs = 55 DPUs to scale out the job to run it with maximum parallelism and finish faster.

The Amazon Glue console displays the detailed job metrics as a static line representing the original number of maximum allocated executors. The console computes the maximum allocated executors from the job definition for the metrics. By contrast, for detailed job run metrics, the console computes the maximum allocated executors from the job run configuration, specifically the DPUs allocated for the job run. To view metrics for an individual job run, select the job run and choose **View run metrics**.

Jobs > e2e-dpus

Detailed job metrics

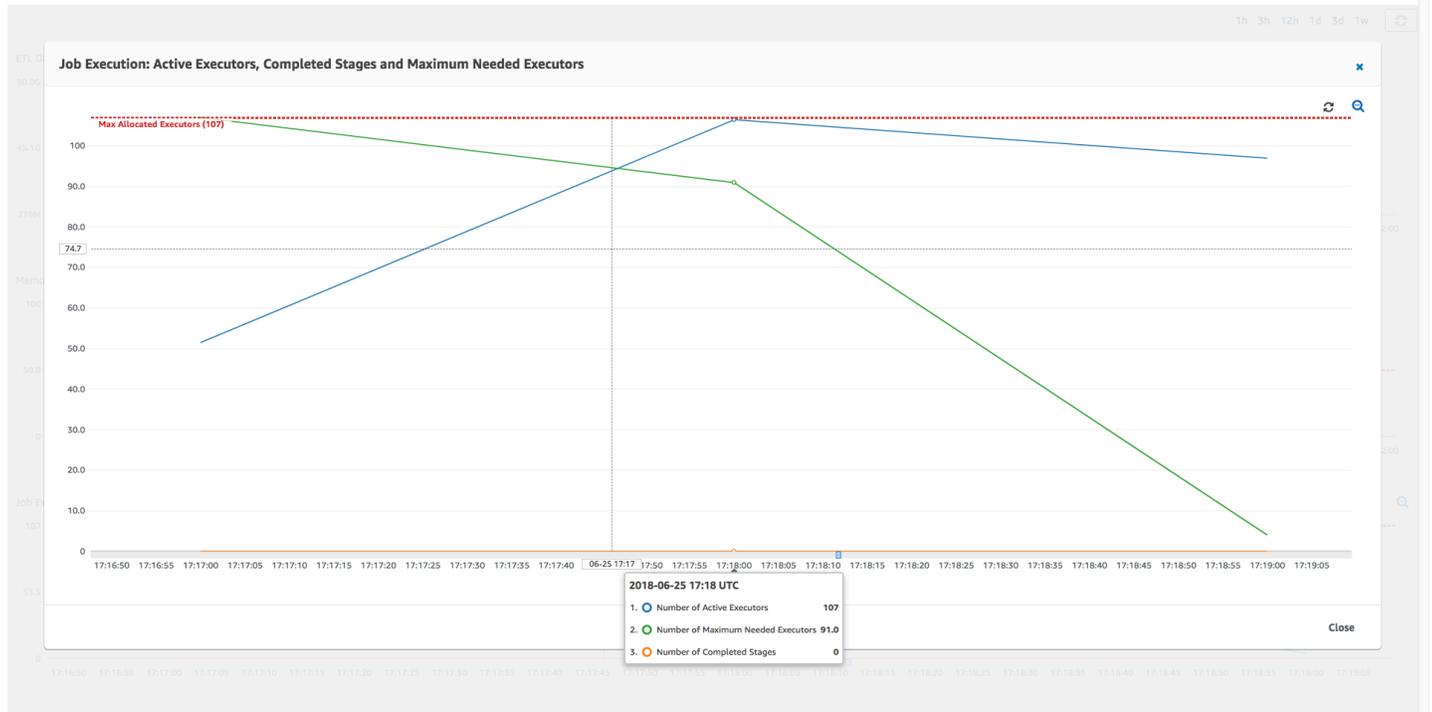

Looking at the Amazon S3 bytes [read](#) and [written](#), notice that the job spends all six minutes streaming in data from Amazon S3 and writing it out in parallel. All the cores on the allocated DPUs are reading and writing to Amazon S3. The maximum number of needed executors being 107 also matches the number of files in the input Amazon S3 path—428. Each executor can launch four Spark tasks to process four input files (JSON gzipped).

Determine the optimal DPU capacity

Based on the results of the previous job run, you can increase the total number of allocated DPUs to 55, and see how the job performs. The job finishes in less than three minutes—half the time it required previously. The job scale-out is not linear in this case because it is a short running job. Jobs with long-lived tasks or a large number of tasks (a large number of max needed executors) benefit from a close-to-linear DPU scale-out performance speedup.

Jobs > e2e-dpua

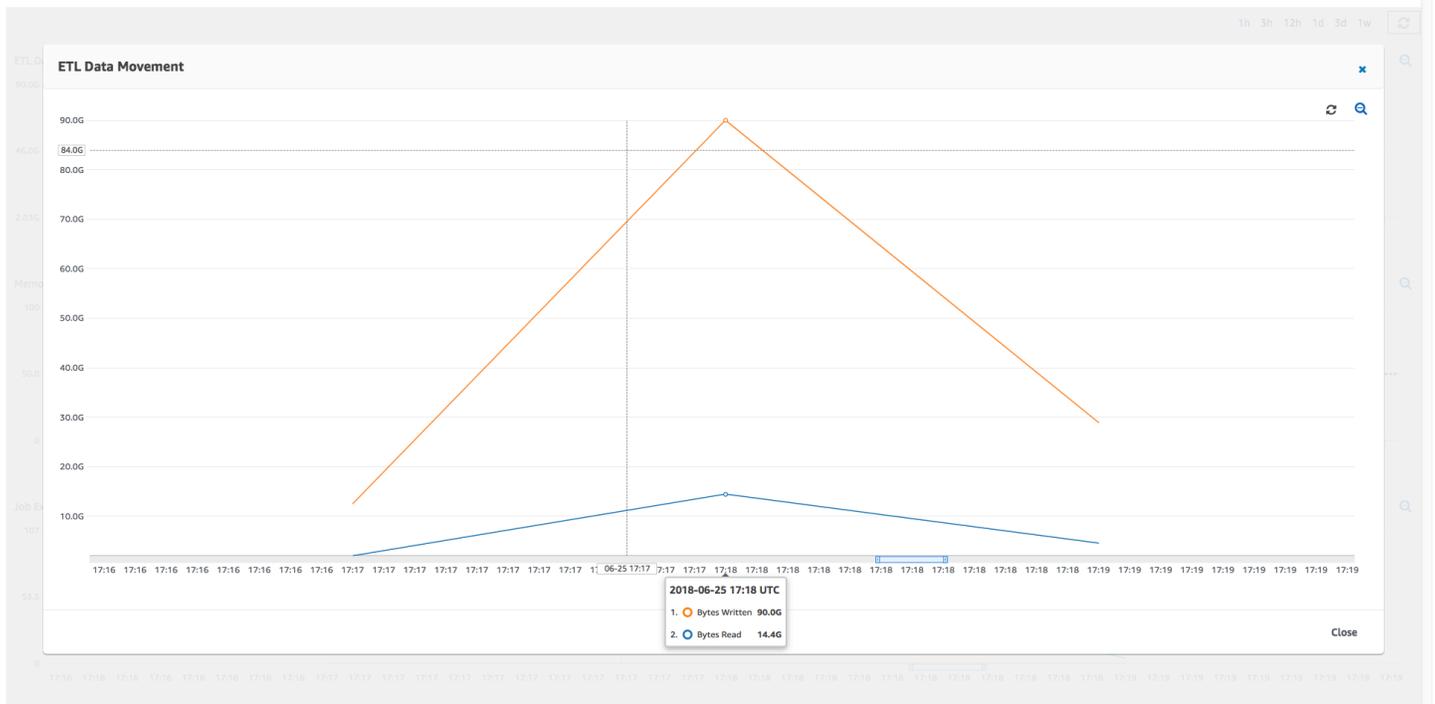

Detailed job metrics

As the above image shows, the total number of active executors reaches the maximum allocated —107 executors. Similarly, the maximum needed executors is never above the maximum allocated executors. The maximum needed executors number is computed from the actively running and pending task counts, so it might be smaller than the number of active executors. This is because there can be executors that are partially or completely idle for a short period of time and are not yet decommissioned.

Jobs > e2e-dpus

Detailed job metrics

This job run uses 6x more executors to read and write from Amazon S3 in parallel. As a result, this job run uses more Amazon S3 bandwidth for both reads and writes, and finishes faster.

Identify overprovisioned DPUs

Next, you can determine whether scaling out the job with 100 DPUs ($99 * 2 = 198$ executors) helps to scale out any further. As the following graph shows, the job still takes three minutes to finish. Similarly, the job does not scale out beyond 107 executors (55 DPUs configuration), and the remaining 91 executors are overprovisioned and not used at all. This shows that increasing the number of DPUs might not always improve performance, as evident from the maximum needed executors.

Jobs > e2e-dpus

Detailed job metrics

Compare time differences

The three job runs shown in the following table summarize the job execution times for 10 DPUs, 55 DPUs, and 100 DPUs. You can find the DPU capacity to improve the job execution time using the estimates you established by monitoring the first job run.

Job ID	Number of DPUs	Execution time
jr_c894524c8ef5048a4d9...	10	6 min.
jr_1a466cf2575e7ffe6856...	55	3 min.
jr_34fa1ed4c6aa9ff0a814...	100	3 min.

Generative AI troubleshooting for Apache Spark in Amazon Glue

Generative AI Troubleshooting for Apache Spark jobs in Amazon Glue is a new capability that helps data engineers and scientists diagnose and fix issues in their Spark applications with ease. Utilizing machine learning and generative AI technologies, this feature analyzes issues in Spark jobs and provides detailed root cause analysis along with actionable recommendations to resolve those

issues. The generative AI troubleshooting for Apache Spark is available for jobs running on Amazon Glue version 4.0 and above.

Transform your Apache Spark troubleshooting with our AI-powered Troubleshooting Agent, now supporting all major deployment modes including Amazon Glue, Amazon EMR-EC2, Amazon EMR-Serverless and Amazon SageMaker AI Notebooks. This powerful agent eliminates complex debugging processes by combining natural language interactions, real-time workload analysis, and smart code recommendations into a seamless experience. For implementation details, refer to [What is Apache Spark Troubleshooting Agent for Amazon EMR](#). View the second demonstration in [Using the Troubleshooting Agent](#) for Amazon Glue troubleshooting examples.

How does Generative AI Troubleshooting for Apache Spark work?

For your failed Spark jobs, Generative AI Troubleshooting analyzes the job metadata and the precise metrics and logs associated with the error signature of your job to generate a root cause analysis, and recommends specific solutions and best practices to help address job failures.

Setting up Generative AI Troubleshooting for Apache Spark for your jobs

Configuring IAM permissions

Granting permissions to the APIs used by Spark Troubleshooting for your jobs in Amazon Glue requires appropriate IAM permissions. You can obtain permissions by attaching the following custom Amazon policy to your IAM identity (such as a user, role, or group).

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartCompletion",
        "glue:GetCompletion"
      ],
      "Resource": [
        "arn:aws:glue:*:*:completion/*",
        "arn:aws:glue:*:*:job/*"
      ]
    }
  ]
}
```

```
    ]
  }
]
}
```

Note

The following two APIs are used in the IAM policy for enabling this experience through the Amazon Glue Studio Console: `StartCompletion` and `GetCompletion`.

Assigning permissions

To provide access, add permissions to your users, groups, or roles:

- For users and groups in IAM Identity Center: Create a permission set. Follow the instructions in [Create a permission set](#) in the IAM Identity Center User Guide.
- For users managed in IAM through an identity provider: Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the IAM User Guide.
- For IAM users: Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the IAM User Guide.

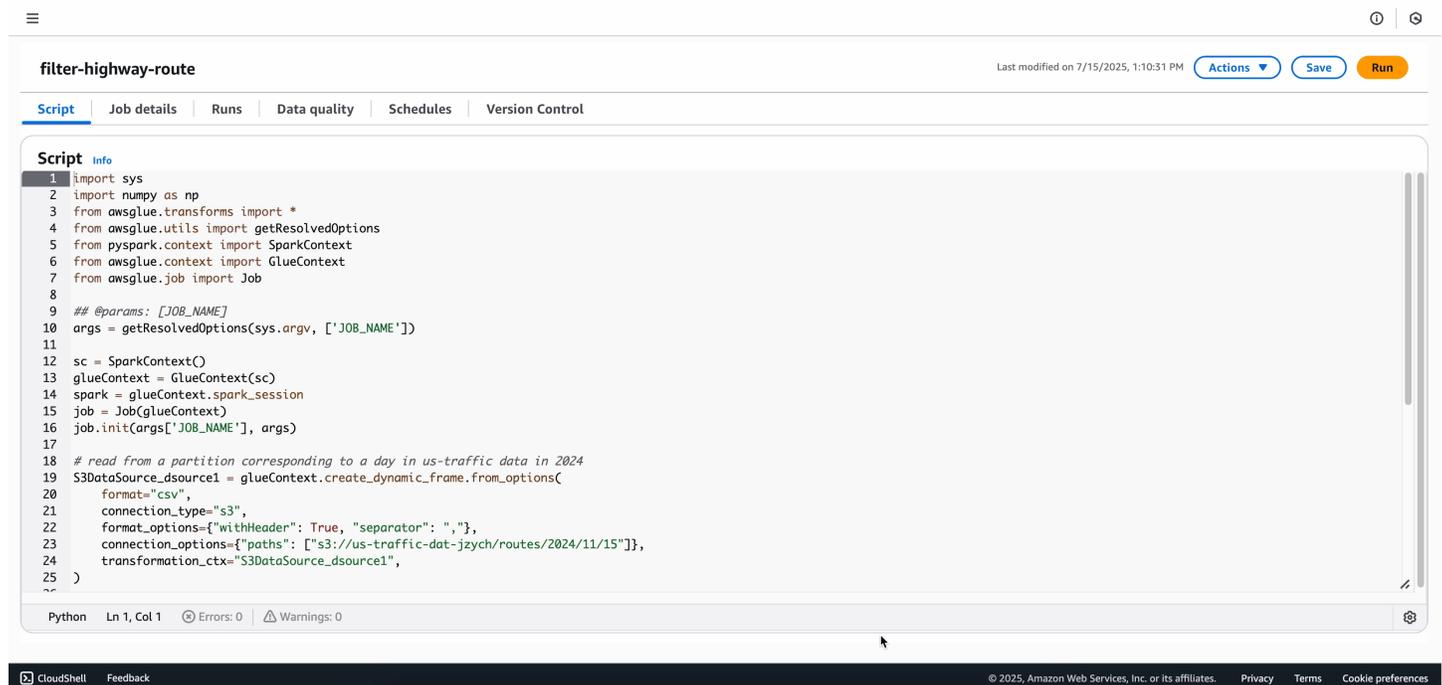

Running troubleshooting analysis from a failed job run

You can access the troubleshooting feature through multiple paths in the Amazon Glue console. Here's how to get started:

Option 1: From the Jobs List page

1. Open the Amazon Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **ETL Jobs**.
3. Locate your failed job in the jobs list.
4. Select the **Runs** tab in the job details section.
5. Click on the failed job run you want to analyze.
6. Choose **Troubleshoot with AI** to start the analysis.

7. When the troubleshooting analysis is complete, you can view the root-cause analysis and recommendations in the **Troubleshooting analysis** tab at the bottom of the screen.

The screenshot displays the Amazon Glue console interface for a job named "filter-highway-route". The top navigation bar includes a menu icon, the job name, and a timestamp "Last modified on 7/15/2025, 1:10:31 PM". Action buttons for "Actions", "Save", and "Run" are visible. Below the navigation bar, tabs for "Script", "Job details", "Runs", "Data quality", "Schedules", and "Version Control" are shown. The "Script" tab is active, displaying a Python script with the following content:

```
1 import sys
2 import numpy as np
3 from awsglue.transforms import *
4 from awsglue.utils import getResolvedOptions
5 from pyspark.context import SparkContext
6 from awsglue.context import GlueContext
7 from awsglue.job import Job
8
9 ## @params: [JOB_NAME]
10 args = getResolvedOptions(sys.argv, ['JOB_NAME'])
11
12 sc = SparkContext()
13 glueContext = GlueContext(sc)
14 spark = glueContext.spark_session
15 job = Job(glueContext)
16 job.init(args['JOB_NAME'], args)
17
18 # read from a partition corresponding to a day in us-traffic data in 2024
19 S3DataSource_dsource1 = glueContext.create_dynamic_frame.from_options(
20     format="csv",
21     connection_type="s3",
22     format_options={"withHeader": True, "separator": ","},
23     connection_options={"paths": ["s3://us-traffic-dat-jzych/routes/2024/11/15"]},
24     transformation_ctx="S3DataSource_dsource1",
25 )
```

The status bar at the bottom of the script editor shows "Python Ln 1, Col 1" and "Errors: 0 Warnings: 0". The footer of the console includes "CloudShell", "Feedback", and copyright information: "© 2025, Amazon Web Services, Inc. or its affiliates. Privacy Terms Cookie preferences".

Option 2: Using the Job Run Monitoring page

1. Navigate to the **Job run monitoring** page.
2. Locate your failed job run.
3. Choose the **Actions** drop-down menu.
4. Choose **Troubleshoot with AI**.

The screenshot displays the AWS Glue Studio interface. On the left is a navigation sidebar. The main area is titled 'AWS Glue Studio' and features a 'Create job' section with three options: 'Visual ETL', 'Notebook', and 'Script editor'. Below this is an 'Example jobs' section with a 'Create example job' button. The 'Your jobs (22)' section contains a table of job runs with columns for Job name, Type, Created by, Last modified, AWS Glue version, and Action.

Job name	Type	Created by	Last modified	AWS Glue version	Action
filter-highway-route	Glue ETL	Script	7/15/2025, 1:10:31 PM	5.0	-
test-lyra-overflow	Glue ETL	Script	7/14/2025, 2:23:14 PM	5.0	-
eycho-hackathon	Glue ETL	Script	7/11/2025, 12:59:44 PM	4.0	-
test-lyra-streaming	Glue Streaming	Script	7/2/2025, 1:10:46 PM	5.0	-
test-lyra-ray	Ray	Script	7/2/2025, 1:06:39 PM	4.0	-
python-shell-lyra	Python shell	Script	7/2/2025, 1:03:27 PM	-	-
llm-jailbreak	Glue ETL	Script	6/25/2025, 12:14:33 PM	4.0	Upgrade with AI
eycho-hack	Glue ETL	Visual	5/16/2025, 1:30:01 PM	5.0	-
glue-hackathon-25-test-job	Glue ETL	Script	5/16/2025, 10:37:33 AM	5.0	-
big compute	Glue ETL	Script	5/15/2025, 2:59:49 PM	5.0	-

Option 3: From the Job Run Details page

1. Navigate to your failed job run's details page by either clicking **View details** on a failed run from the **Runs** tab or selecting the job run from the **Job run monitoring** page.
2. In the job run details page, find the **Troubleshooting analysis** tab.

Supported troubleshooting categories

This service focuses on three primary categories of issues that data engineers and developers frequently encounter in their Spark applications:

- **Resource setup and access errors:** When running Spark applications in Amazon Glue, resource setup and access errors are among the most common yet challenging issues to diagnose. These errors often occur when your Spark application attempts to interact with Amazon resources but encounters permission issues, missing resources, or configuration problems.
- **Spark driver and executor memory issues:** Memory-related errors in Apache Spark jobs can be complex to diagnose and resolve. These errors often manifest when your data processing requirements exceed the available memory resources, either on the driver node or executor nodes.
- **Spark disk capacity issues:** Storage-related errors in Amazon Glue Spark jobs often emerge during shuffle operations, data spilling, or when dealing with large-scale data transformations.

These errors can be particularly tricky because they might not manifest until your job has been running for a while, potentially wasting valuable compute time and resources.

- **Query execution errors:** Query failures in Spark SQL and DataFrame operations can be difficult to troubleshoot because error messages may not clearly point to the root cause, and queries that work fine with small datasets can suddenly fail at scale. These errors become even more challenging when they occur deep within complex transformation pipelines, where the actual issue may stem from data quality problems in earlier stages rather than the query logic itself.

Note

Before implementing any suggested changes in your production environment, review the suggested changes thoroughly. The service provides recommendations based on patterns and best practices, but your specific use case might require additional considerations.

Supported regions

Generative AI troubleshooting for Apache Spark is available in the following regions:

- **Africa:** Cape Town (af-south-1)
- **Asia Pacific:** Hong Kong (ap-east-1), Tokyo (ap-northeast-1), Seoul (ap-northeast-2), Osaka (ap-northeast-3), Mumbai (ap-south-1), Singapore (ap-southeast-1), Sydney (ap-southeast-2), and Jakarta (ap-southeast-3)
- **Europe:** Frankfurt (eu-central-1), Stockholm (eu-north-1), Milan (eu-south-1), Ireland (eu-west-1), London (eu-west-2), and Paris (eu-west-3)
- **Middle East:** Bahrain (me-south-1) and UAE (me-central-1)
- **North America:** Canada (ca-central-1)
- **South America:** São Paulo (sa-east-1)
- **United States:** North Virginia (us-east-1), Ohio (us-east-2), North California (us-west-1), and Oregon (us-west-2)

Using materialized views with Amazon Glue

Amazon Glue version 5.1 and later supports creating and managing Apache Iceberg materialized views in the Amazon Glue Data Catalog. A materialized view is a managed table that stores the

precomputed result of a SQL query in Apache Iceberg format and incrementally updates as the underlying source tables change. You can use materialized views to simplify data transformation pipelines and accelerate query performance for complex analytical workloads.

When you create a materialized view using Spark in Amazon Glue, the view definition and metadata are stored in the Amazon Glue Data Catalog. The precomputed results are stored as Apache Iceberg tables in Amazon S3 Tables buckets or Amazon S3 general purpose buckets within your account. The Amazon Glue Data Catalog automatically monitors source tables and refreshes materialized views using managed compute infrastructure.

Topics

- [How materialized views work with Amazon Glue](#)
- [Prerequisites](#)
- [Configuring Spark to use materialized views](#)
- [Creating materialized views](#)

- [Refreshing materialized views](#)
- [Managing materialized views](#)
- [Permissions for materialized views](#)
- [Monitoring materialized view operations](#)
- [Example: Complete workflow](#)
- [Considerations and limitations](#)

How materialized views work with Amazon Glue

Materialized views integrate with Amazon Glue through Apache Spark's Iceberg support in Amazon Glue jobs and Amazon Glue Studio notebooks. When you configure your Spark session to use the Amazon Glue Data Catalog, you can create materialized views using standard SQL syntax. The Spark optimizer can automatically rewrite queries to use materialized views when they provide better performance, eliminating the need to manually modify application code.

The Amazon Glue Data Catalog handles all operational aspects of materialized view maintenance, including:

- Detecting changes in source tables using Apache Iceberg's metadata layer
- Scheduling and executing refresh operations using managed Spark compute

- Determining whether to perform full or incremental refresh based on the data changes
- Storing precomputed results in Apache Iceberg format for multi-engine access

You can query materialized views from Amazon Glue using the same Spark SQL interfaces you use for regular tables. The precomputed data is also accessible from other services including Amazon Athena and Amazon Redshift.

Prerequisites

To use materialized views with Amazon Glue, you need:

- An account
- Amazon Glue version 5.1 or later
- Source tables in Apache Iceberg format registered in the Amazon Glue Data Catalog
- Amazon Lake Formation permissions configured for source tables and target databases
- An S3 Tables bucket or S3 general purpose bucket registered with Amazon Lake Formation for storing materialized view data
- An IAM role with permissions to access Amazon Glue Data Catalog and Amazon S3

Configuring Spark to use materialized views

To create and manage materialized views in Amazon Glue, configure your Spark session with the required Iceberg extensions and catalog settings. The configuration method varies depending on whether you're using Amazon Glue jobs or Amazon Glue Studio notebooks.

Configuring Amazon Glue jobs

When creating or updating an Amazon Glue job, add the following configuration parameters as job parameters:

For S3 Tables buckets

```
job = glue.create_job(  
    Name='materialized-view-job',  
    Role='arn:aws:iam::111122223333:role/GlueServiceRole',  
    Command={  
        'Name': 'glueetl',
```

```

        'ScriptLocation': 's3://amzn-s3-demo-bucket/scripts/mv-script.py',
        'PythonVersion': '3'
    },
    DefaultArguments={
        '--enable-glue-datacatalog': 'true',
        '--conf':
'spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
',
        '--conf spark.sql.catalog.glue_catalog=org.apache.iceberg.spark.SparkCatalog '
        '--conf spark.sql.catalog.glue_catalog.type=glue '
        '--conf spark.sql.catalog.glue_catalog.warehouse=s3://amzn-s3-demo-
bucket/warehouse '
        '--conf spark.sql.catalog.glue_catalog.glue.region=us-east-1 '
        '--conf spark.sql.catalog.glue_catalog.glue.id=111122223333 '
        '--conf spark.sql.catalog.glue_catalog.glue.account-id=111122223333
',
        '--conf spark.sql.catalog.glue_catalog.glue.lakeformation-
enabled=true ',
        '--conf
spark.sql.catalog.s3t_catalog=org.apache.iceberg.spark.SparkCatalog '
        '--conf spark.sql.catalog.s3t_catalog.type=glue '
        '--conf
spark.sql.catalog.s3t_catalog.glue.id=111122223333:s3tablescatalog/my-table-bucket ',
        '--conf spark.sql.catalog.s3t_catalog.glue.account-id=111122223333 ',
        '--conf spark.sql.catalog.s3t_catalog.glue.lakeformation-enabled=true
',
        '--conf spark.sql.catalog.s3t_catalog.warehouse=s3://amzn-s3-demo-
bucket/mv-warehouse '
        '--conf spark.sql.catalog.s3t_catalog.glue.region=us-east-1 '
        '--conf spark.sql.defaultCatalog=s3t_catalog '
        '--conf spark.sql.optimizer.answerQueriesWithMVs.enabled=true '
        '--conf spark.sql.materializedViews.metadataCache.enabled=true '
    },
    GlueVersion='5.1'
)

```

For S3 general purpose buckets

```

job = glue.create_job(
    Name='materialized-view-job',
    Role='arn:aws:iam::111122223333:role/GlueServiceRole',
    Command={

```

```

    'Name': 'glueetl',
    'ScriptLocation': 's3://amzn-s3-demo-bucket/scripts/mv-script.py',
    'PythonVersion': '3'
  },
  DefaultArguments={
    '--enable-glue-datacatalog': 'true',
    '--conf':
'spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
',
        '--conf
spark.sql.catalog.glue_catalog=org.apache.iceberg.spark.SparkCatalog '
        '--conf spark.sql.catalog.glue_catalog.type=glue '
        '--conf spark.sql.catalog.glue_catalog.warehouse=s3://amzn-s3-demo-
bucket/warehouse '
        '--conf spark.sql.catalog.glue_catalog.glue.region=us-east-1 '
        '--conf spark.sql.catalog.glue_catalog.glue.id=111122223333 ',
        '--conf spark.sql.catalog.glue_catalog.glue.account-id=111122223333
',
        '--conf spark.sql.catalog.glue_catalog.glue.lakeformation-
enabled=true ',
        '--conf spark.sql.defaultCatalog=glue_catalog '
        '--conf spark.sql.optimizer.answerQueriesWithMVs.enabled=true '
        '--conf spark.sql.materializedViews.metadataCache.enabled=true'
    },
  GlueVersion='5.1'
)

```

Configuring Amazon Glue Studio notebooks

In Amazon Glue Studio notebooks, configure your Spark session using the %%configure magic command at the beginning of your notebook:

```

%%configure
{
  "conf": {
    "spark.sql.extensions":
"org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions",
    "spark.sql.catalog.glue_catalog": "org.apache.iceberg.spark.SparkCatalog",
    "spark.sql.catalog.glue_catalog.type": "glue",
    "spark.sql.catalog.glue_catalog.warehouse": "s3://amzn-s3-demo-bucket/
warehouse",
    "spark.sql.catalog.glue_catalog.glue.region": "us-east-1",
    "spark.sql.catalog.glue_catalog.glue.id": "111122223333",

```

```
"spark.sql.catalog.glue_catalog.glue.account-id": "111122223333",
"spark.sql.catalog.glue_catalog.glue.lakeformation-enabled": "true",
"spark.sql.defaultCatalog": "glue_catalog",
"spark.sql.optimizer.answerQueriesWithMVs.enabled": "true",
"spark.sql.materializedViews.metadataCache.enabled": "true"
}
}
```

Enabling incremental refresh

To enable incremental refresh optimization, add the following configuration properties to your job parameters or notebook configuration:

```
--conf spark.sql.optimizer.incrementalMVRefresh.enabled=true
--conf spark.sql.optimizer.incrementalMVRefresh.deltaThresholdCheckEnabled=false
```

Configuration parameters

The following configuration parameters control materialized view behavior:

- `spark.sql.extensions` – Enables Iceberg Spark session extensions required for materialized view support.
- `spark.sql.optimizer.answerQueriesWithMVs.enabled` – Enables automatic query rewrite to use materialized views. Set to true to activate this optimization.
- `spark.sql.materializedViews.metadataCache.enabled` – Enables caching of materialized view metadata for query optimization. Set to true to improve query rewrite performance.
- `spark.sql.optimizer.incrementalMVRefresh.enabled` – Enables incremental refresh optimization. Set to true to process only changed data during refresh operations.
- `spark.sql.optimizer.answerQueriesWithMVs.decimalAggregateCheckEnabled` – Controls validation of decimal aggregate operations in query rewrite. Set to false to disable certain decimal overflow checks.

Creating materialized views

You create materialized views using the CREATE MATERIALIZED VIEW SQL statement in Amazon Glue jobs or notebooks. The view definition specifies the transformation logic as a SQL query that references one or more source tables.

Creating a basic materialized view in Amazon Glue jobs

The following example demonstrates creating a materialized view in a Amazon Glue job script, use fully qualified table names with three part naming convention in view definition:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

# Create materialized view
spark.sql("""
    CREATE MATERIALIZED VIEW customer_orders
    AS
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM glue_catalog.sales.orders
    GROUP BY customer_name
""")
```

Creating a materialized view with automatic refresh

To configure automatic refresh, specify a refresh schedule when creating the view, using fully qualified table names with three part naming convention in view definition:

```
spark.sql("""
    CREATE MATERIALIZED VIEW customer_orders
    SCHEDULE REFRESH EVERY 1 HOUR
    AS
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM glue_catalog.sales.orders
    GROUP BY customer_name
""")
```

Creating a materialized view with cross-catalog references

When your source tables are in a different catalog than your materialized view, use fully qualified table names with three-part naming convention in both view name and view definition:

```
spark.sql("""
    CREATE MATERIALIZED VIEW s3t_catalog.analytics.customer_summary
    AS
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM glue_catalog.sales.orders
    GROUP BY customer_name
    """)
```

Creating materialized views in Amazon Glue Studio notebooks

In Amazon Glue Studio notebooks, you can use the `%%sql` magic command to create materialized views, using fully qualified table names with three part naming convention in view definition:

```
%%sql
CREATE MATERIALIZED VIEW customer_orders
AS
SELECT
    customer_name,
    COUNT(*) as order_count,
    SUM(amount) as total_amount
FROM glue_catalog.sales.orders
GROUP BY customer_name
```

Querying materialized views

After creating a materialized view, you can query it like any other table using standard SQL `SELECT` statements in your Amazon Glue jobs or notebooks.

Querying in Amazon Glue jobs

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext
```

```
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

# Query materialized view
result = spark.sql("SELECT * FROM customer_orders")
result.show()
```

Querying in Amazon Glue Studio notebooks

```
%%sql
SELECT * FROM customer_orders
```

Automatic query rewrite

When automatic query rewrite is enabled, the Spark optimizer analyzes your queries and automatically uses materialized views when they can improve performance. For example, if you execute the following query:

```
result = spark.sql("""
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM orders
    GROUP BY customer_name
    """)
```

The Spark optimizer automatically rewrites this query to use the `customer_orders` materialized view instead of processing the base `orders` table, provided the materialized view is current.

Verifying automatic query rewrite

To verify whether a query uses automatic query rewrite, use the `EXPLAIN EXTENDED` command:

```
spark.sql("""
    EXPLAIN EXTENDED
    SELECT customer_name, COUNT(*) as order_count, SUM(amount) as total_amount
    FROM orders
    GROUP BY customer_name
    """).show(truncate=False)
```

In the execution plan, look for the materialized view name in the BatchScan operation. If the plan shows BatchScan glue_catalog.analytics.customer_orders instead of BatchScan glue_catalog.sales.orders, the query has been automatically rewritten to use the materialized view.

Note that automatic query rewrite requires time for the Spark metadata cache to populate after creating a materialized view. This process typically completes within 30 seconds.

Refreshing materialized views

You can refresh materialized views using two methods: full refresh or incremental refresh. Full refresh recomputes the entire materialized view from all base table data, while incremental refresh processes only the data that has changed since the last refresh.

Manual full refresh in Amazon Glue jobs

To perform a full refresh of a materialized view:

```
spark.sql("REFRESH MATERIALIZED VIEW customer_orders FULL")

# Verify updated results
result = spark.sql("SELECT * FROM customer_orders")
result.show()
```

Manual incremental refresh in Amazon Glue jobs

To perform an incremental refresh, ensure incremental refresh is enabled in your Spark session configuration, then execute:

```
spark.sql("REFRESH MATERIALIZED VIEW customer_orders")

# Verify updated results
result = spark.sql("SELECT * FROM customer_orders")
result.show()
```

The Amazon Glue Data Catalog automatically determines whether incremental refresh is applicable based on the view definition and the amount of changed data. If incremental refresh is not possible, the operation falls back to full refresh.

Refreshing in Amazon Glue Studio notebooks

In notebooks, use the %%sql magic command:

```
%%sql
REFRESH MATERIALIZED VIEW customer_orders FULL
```

Verifying incremental refresh execution

To confirm that incremental refresh executed successfully, enable debug logging in your Amazon Glue job:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext
import logging

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

# Enable debug logging
logger = logging.getLogger('org.apache.spark.sql')
logger.setLevel(logging.DEBUG)

# Execute refresh
spark.sql("REFRESH MATERIALIZED VIEW customer_orders")
```

Search for the following message in the Amazon Glue job logs:

```
DEBUG RefreshMaterializedViewExec: Executed Incremental Refresh
```

Managing materialized views

Amazon Glue provides SQL commands for managing the lifecycle of materialized views in your jobs and notebooks.

Describing a materialized view

To view metadata about a materialized view, including its definition, refresh status, and last refresh timestamp:

```
spark.sql("DESCRIBE EXTENDED customer_orders").show(truncate=False)
```

Altering a materialized view

To modify the refresh schedule of an existing materialized view:

```
spark.sql("""
    ALTER MATERIALIZED VIEW customer_orders
    ADD SCHEDULE REFRESH EVERY 2 HOURS
""")
```

To remove automatic refresh:

```
spark.sql("""
    ALTER MATERIALIZED VIEW customer_orders
    DROP SCHEDULE
""")
```

Dropping a materialized view

To delete a materialized view:

```
spark.sql("DROP MATERIALIZED VIEW customer_orders")
```

This command removes the materialized view definition from the Amazon Glue Data Catalog and deletes the underlying Iceberg table data from your S3 bucket.

Listing materialized views

To list all materialized views in a database:

```
spark.sql("SHOW VIEWS FROM analytics").show()
```

Permissions for materialized views

To create and manage materialized views, you must configure Amazon Lake Formation permissions. The IAM role creating the materialized view (the definer role) requires specific permissions on source tables and target databases.

Required permissions for the definer role

The definer role must have the following Lake Formation permissions:

- On source tables – SELECT or ALL permissions without row, column, or cell filters
- On the target database – CREATE_TABLE permission
- On the Amazon Glue Data Catalog – GetTable and CreateTable API permissions

When you create a materialized view, the definer role's ARN is stored in the view definition. The Amazon Glue Data Catalog assumes this role when executing automatic refresh operations. If the definer role loses access to source tables, refresh operations will fail until permissions are restored.

IAM permissions for Amazon Glue jobs

Your Amazon Glue job's IAM role requires the following permissions:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:GetCatalog",
        "glue:GetCatalogs",
        "glue:GetTable",
        "glue:GetTables",
        "glue:CreateTable",
        "glue:UpdateTable",
        "glue>DeleteTable",
        "glue:GetDatabase",
        "glue:GetDatabases",
        "cloudwatch:PutMetricData"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3>DeleteObject"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
    }
  ]
}
```

```

        "Resource": [
            "arn:aws:s3:::amzn-s3-demo-bucket"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "logs:CreateLogGroup",
            "logs:CreateLogStream",
            "logs:PutLogEvents"
        ],
        "Resource": [
            "arn:aws:logs:*:*:*:/aws-glue/*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "lakeformation:GetDataAccess"
        ],
        "Resource": "*"
    }
]
}

```

The role you use for Materialized View auto-refresh must have the `iam:PassRole` permission on the role.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam::111122223333:role/materialized-view-role-name"
      ]
    }
  ]
}

```

To let Glue automatically refresh the materialized view for you, the role must also have the following trust policy that enables the service to assume the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam::111122223333:role/materialized-view-role-name"
      ]
    }
  ]
}
```

If the Materialized View is stored in S3 Tables Buckets, you also need to add the following permission to the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3tables:PutTableMaintenanceConfiguration"
      ],
      "Resource": "arn:aws:s3tables:*:123456789012:*"
    }
  ]
}
```

Granting access to materialized views

To grant other users access to query a materialized view, use Amazon Lake Formation to grant SELECT permission on the materialized view table. Users can query the materialized view without requiring direct access to the underlying source tables.

For detailed information about configuring Lake Formation permissions, see [Granting and revoking permissions on Data Catalog resources in the Amazon Lake Formation Developer Guide](#).

Monitoring materialized view operations

The Amazon Glue Data Catalog publishes metrics and logs for materialized view refresh operations to Amazon CloudWatch. You can monitor refresh status, duration, and data volume processed through CloudWatch metrics.

Viewing job logs

To view logs for Amazon Glue jobs that create or refresh materialized views:

1. Open the Amazon Glue console.
2. Choose Jobs from the navigation pane.
3. Select your job and choose Runs.
4. Select a specific run and choose Logs to view CloudWatch logs.

Setting up alarms

To receive notifications when refresh operations fail or exceed expected duration, create CloudWatch alarms on materialized view metrics. You can also configure Amazon EventBridge rules to trigger automated responses to refresh events.

Example: Complete workflow

The following example demonstrates a complete workflow for creating and using a materialized view in Amazon Glue.

Example Amazon Glue job script

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
```

```
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ['JOB_NAME'])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

# Create database and base table
spark.sql("CREATE DATABASE IF NOT EXISTS sales")
spark.sql("USE sales")

spark.sql("""
    CREATE TABLE IF NOT EXISTS orders (
        id INT,
        customer_name STRING,
        amount DECIMAL(10,2),
        order_date DATE
    )
""")

# Insert sample data
spark.sql("""
    INSERT INTO orders VALUES
        (1, 'John Doe', 150.00, DATE('2024-01-15')),
        (2, 'Jane Smith', 200.50, DATE('2024-01-16')),
        (3, 'Bob Johnson', 75.25, DATE('2024-01-17'))
""")

# Create materialized view
spark.sql("""
    CREATE MATERIALIZED VIEW customer_summary
    AS
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM glue_catalog.sales.orders
    GROUP BY customer_name
""")

# Query the materialized view
```

```
print("Initial materialized view data:")
spark.sql("SELECT * FROM customer_summary").show()

# Insert additional data
spark.sql("""
    INSERT INTO orders VALUES
        (4, 'Jane Smith', 350.00, DATE('2024-01-18')),
        (5, 'Bob Johnson', 100.25, DATE('2024-01-19'))
""")

# Refresh the materialized view
spark.sql("REFRESH MATERIALIZED VIEW customer_summary FULL")

# Query updated results
print("Updated materialized view data:")
spark.sql("SELECT * FROM customer_summary").show()

job.commit()
```

Example Amazon Glue Studio notebook

```
%%configure
{
  "conf": {
    "spark.sql.extensions":
"org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions",
    "spark.sql.catalog.glue_catalog": "org.apache.iceberg.spark.SparkCatalog",
    "spark.sql.catalog.glue_catalog.type": "glue",
    "spark.sql.catalog.glue_catalog.warehouse": "s3://amzn-s3-demo-bucket/
warehouse",
    "spark.sql.catalog.glue_catalog.glue.region": "us-east-1",
    "spark.sql.catalog.glue_catalog.glue.id": "111122223333",
    "spark.sql.catalog.glue_catalog.glue.account-id": "111122223333",
    "spark.sql.catalog.glue_catalog.glue.lakeformation-enabled": "true",
    "spark.sql.defaultCatalog": "glue_catalog",
    "spark.sql.optimizer.answerQueriesWithMVs.enabled": "true",
    "spark.sql.materializedViews.metadataCache.enabled": "true"
  }
}
```

```
%%sql
CREATE DATABASE IF NOT EXISTS sales
```

```
%%sql
USE sales
```

```
%%sql
CREATE TABLE IF NOT EXISTS orders (
  id INT,
  customer_name STRING,
  amount DECIMAL(10,2),
  order_date DATE
)
```

```
%%sql
INSERT INTO orders VALUES
  (1, 'John Doe', 150.00, DATE('2024-01-15')),
  (2, 'Jane Smith', 200.50, DATE('2024-01-16')),
  (3, 'Bob Johnson', 75.25, DATE('2024-01-17'))
```

```
%%sql
CREATE MATERIALIZED VIEW customer_summary
AS
SELECT
  customer_name,
  COUNT(*) as order_count,
  SUM(amount) as total_amount
FROM glue_catalog.sales.orders
GROUP BY customer_name
```

```
%%sql
SELECT * FROM customer_summary
```

```
%%sql
INSERT INTO orders VALUES
  (4, 'Jane Smith', 350.00, DATE('2024-01-18')),
  (5, 'Bob Johnson', 100.25, DATE('2024-01-19'))
```

```
%%sql
REFRESH MATERIALIZED VIEW customer_summary FULL
```

```
%%sql
```

```
SELECT * FROM customer_summary
```

Considerations and limitations

Consider the following when using materialized views with Amazon Glue:

- Materialized views require Amazon Glue version 5.1 or later.
- Source tables must be Apache Iceberg tables registered in the Amazon Glue Data Catalog. Apache Hive, Apache Hudi, and Linux Foundation Delta Lake tables are not supported at launch.
- Source tables must reside in the same Region and account as the materialized view.
- All source tables must be governed by Amazon Lake Formation. IAM-only permissions and hybrid access are not supported.
- Materialized views cannot reference Amazon Glue Data Catalog views, multi-dialect views, or other materialized views as source tables.
- The view definer role must have full read access (SELECT or ALL permission) on all source tables without row, column, or cell filters applied.
- Materialized views are eventually consistent with source tables. During the refresh window, queries may return stale data. Execute manual refresh for immediate consistency.
- The minimum automatic refresh interval is one hour.
- Incremental refresh supports a restricted subset of SQL operations. The view definition must be a single SELECT-FROM-WHERE-GROUP BY-HAVING block and cannot contain set operations, subqueries, the DISTINCT keyword in SELECT or aggregate functions, window functions, or joins other than INNER JOIN.
- Incremental refresh does not support user-defined functions or certain built-in functions. Only a subset of Spark SQL built-in functions are supported.
- Query automatic rewrite only considers materialized views whose definitions belong to a restricted SQL subset similar to incremental refresh restrictions.
- Identifiers containing special characters other than alphanumeric characters and underscores are not supported in CREATE MATERIALIZED VIEW queries. This applies to all identifier types including catalog/namespace/table names, column and struct field names, CTEs, and aliases.
- Materialized view columns starting with the `__ivm` prefix are reserved for system use. Amazon reserves the right to modify or remove these columns in future releases.
- The SORT BY, LIMIT, OFFSET, CLUSTER BY, and ORDER BY clauses are not supported in materialized view definitions.
- Cross-Region and cross-account source tables are not supported.

- Tables referenced in the view query must use three-part naming convention (e.g., glue_catalog.my_db.my_table) because automatic refresh does not use default catalog and database settings.
- Full refresh operations override the entire table and make previous snapshots unavailable.
- Non-deterministic functions such as rand() or current_timestamp() are not supported in materialized view definitions.

Amazon Glue worker types

Overview

Amazon Glue provides multiple worker types to accommodate different workload requirements, from small streaming jobs to large-scale, memory-intensive data processing tasks. This section provides comprehensive information about all available worker types, their specifications, and usage recommendations.

Worker type categories

Amazon Glue offers two main categories of worker types:

- **G Worker Types:** General-purpose compute workers optimized for standard ETL workloads
- **R Worker Types:** Memory-optimized workers designed for memory-intensive Spark applications

Data Processing Units (DPUs)

The resources available on Amazon Glue workers are measured in DPUs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory.

Memory-Optimized DPUs (M-DPUs): R type workers use M-DPUs, which provide double the memory allocation for a given size compared to standard DPUs. This means that while a standard DPU provides 16 GB of memory, an M-DPU in R type workers provides 32GB of memory optimized for memory-intensive Spark applications.

Available worker types

G.1X

- **DPU:** 1 DPU (4 vCPUs, 16 GB memory)

- **Storage:** 94GB disk (approximately 44GB free)
- **Use Case:** Data transforms, joins, and queries - scalable and cost-effective for most jobs

G.2X

- **DPU:** 2 DPU (8 vCPUs, 32 GB memory)
- **Storage:** 138GB disk (approximately 78GB free)
- **Use Case:** Data transforms, joins, and queries - scalable and cost-effective for most jobs

G.4X

- **DPU:** 4 DPU (16 vCPUs, 64 GB memory)
- **Storage:** 256GB disk (approximately 230GB free)
- **Use Case:** Demanding transforms, aggregations, joins, and queries

G.8X

- **DPU:** 8 DPU (32 vCPUs, 128 GB memory)
- **Storage:** 512GB disk (approximately 485GB free)
- **Use Case:** Demanding transforms, aggregations, joins, and queries

G.12X

- **DPU:** 12 DPU (48 vCPUs, 192 GB memory)
- **Storage:** 768GB disk (approximately 741GB free)
- **Use Case:** Very large and resource-intensive workloads requiring significant compute capacity

G.16X

- **DPU:** 16 DPU (64 vCPUs, 256 GB memory)
- **Storage:** 1024GB disk (approximately 996GB free)
- **Use Case:** Largest and most resource-intensive workloads requiring maximum compute capacity

R.1X - Memory-Optimized*

- **DPU:** 1 M-DPU (4 vCPUs, 32 GB memory)
- **Use Case:** Memory-intensive workloads with frequent out-of-memory errors or high memory-to-CPU ratio requirements

R.2X - Memory-Optimized*

- **DPU:** 2 M-DPU (8 vCPUs, 64 GB memory)
- **Use Case:** Memory-intensive workloads with frequent out-of-memory errors or high memory-to-CPU ratio requirements

R.4X - Memory-Optimized*

- **DPU:** 4 M-DPU (16 vCPUs, 128 GB memory)
- **Use Case:** Large memory-intensive workloads with frequent out-of-memory errors or high memory-to-CPU ratio requirements

R.8X - Memory-Optimized*

- **DPU:** 8 M-DPU (32 vCPUs, 256 GB memory)
- **Use Case:** Very large memory-intensive workloads with frequent out-of-memory errors or high memory-to-CPU ratio requirements

* You may encounter higher startup latency with these workers. To resolve the issue, try the following:

- Wait a few minutes and then submit your job again.
- Submit a new job with a reduced number of workers.
- Submit a new job using a different worker type or size.

Worker type specifications table

Worker Type Specifications

Worker Type	DPU per Node	vCPU	Memory (GB)	Disk (GB)	Approximate Free Disk Space (GB)	Spark Executors per Node
G.1X	1	4	16	94	44	1
G.2X	2	8	32	138	78	1
G.4X	4	16	64	256	230	1
G.8X	8	32	128	512	485	1
G.12X	12	48	192	768	741	1
G.16X	16	64	256	1024	996	1
R.1X	1	4	32	94	44	1
R.2X	2	8	64	138	78	1
R.4X	4	16	128	256	230	1
R.8X	8	32	256	512	485	1

Note: R worker types have memory-optimized configurations with specifications optimized for memory-intensive workloads.

Important considerations

Startup latency

Important

G.12X and G.16X worker types, as well as all R worker types (R.1X through R.8X), may encounter higher startup latency. To resolve the issue, try the following:

- Wait a few minutes and then submit your job again.
- Submit a new job with a reduced number of workers.
- Submit a new job using a different worker type and size.

Choosing the right worker type

For standard ETL workloads

- **G.1X or G.2X:** Most cost-effective for typical data transforms, joins, and queries
- **G.4X or G.8X:** For more demanding workloads with larger datasets

For large-scale workloads

- **G.12X:** Very large datasets requiring significant compute resources
- **G.16X:** Maximum compute capacity for the most demanding workloads

For memory-intensive workloads

- **R.1X or R.2X:** Small to medium memory-intensive jobs
- **R.4X or R.8X:** Large memory-intensive workloads with frequent OOM errors

Cost Optimization Considerations

- **Standard G workers:** Provide a balance of compute, memory and networking resources, and can be used for a variety of diverse workloads at lower cost
- **R workers:** Specialized for memory-intensive tasks with fast performance for workloads that process large data sets in memory

Best practices

Worker selection guidelines

1. **Start with standard workers (G.1X, G.2X)** for most workloads

2. **Use R workers** when experiencing frequent out-of-memory errors or workloads with memory-intensive operations like caching, shuffling, and aggregating
3. **Consider G.12X/G.16X** for compute-intensive workloads requiring maximum resources
4. **Account for capacity constraints** when using new worker types in time-sensitive workflows

Performance optimization

- Monitor CloudWatch metrics to understand resource utilization
- Use appropriate worker counts based on data size and complexity
- Consider data partitioning strategies to optimize worker efficiency

Streaming ETL jobs in Amazon Glue

You can create streaming extract, transform, and load (ETL) jobs that run continuously, consume data from streaming sources like Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK). The jobs cleanse and transform the data, and then load the results into Amazon S3 data lakes or JDBC data stores.

Additionally, you can produce data for Amazon Kinesis Data Streams streams. This feature is only available when writing Amazon Glue scripts. For more information, see [the section called “Kinesis connections”](#).

By default, Amazon Glue processes and writes out data in 100-second windows. This allows data to be processed efficiently and permits aggregations to be performed on data arriving later than expected. You can modify this window size to increase timeliness or aggregation accuracy. Amazon Glue streaming jobs use checkpoints rather than job bookmarks to track the data that has been read.

Note

Amazon Glue bills hourly for streaming ETL jobs while they are running.

This video discusses streaming ETL cost challenges, and cost-saving features in Amazon Glue.

Creating a streaming ETL job involves the following steps:

1. For an Apache Kafka streaming source, create an Amazon Glue connection to the Kafka source or the Amazon MSK cluster.
2. Manually create a Data Catalog table for the streaming source.
3. Create an ETL job for the streaming data source. Define streaming-specific job properties, and supply your own script or optionally modify the generated script.

For more information, see [Streaming ETL in Amazon Glue](#).

When creating a streaming ETL job for Amazon Kinesis Data Streams, you don't have to create an Amazon Glue connection. However, if there is a connection attached to the Amazon Glue streaming ETL job that has Kinesis Data Streams as a source, then a virtual private cloud (VPC) endpoint to Kinesis is required. For more information, see [Creating an interface endpoint](#) in the *Amazon VPC User Guide*. When specifying a Amazon Kinesis Data Streams stream in another account, you must setup the roles and policies to allow cross-account access. For more information, see [Example: Read From a Kinesis Stream in a Different Account](#).

Amazon Glue streaming ETL jobs can auto-detect compressed data, transparently decompress the streaming data, perform the usual transformations on the input source, and load to the output store.

Amazon Glue supports auto-decompression for the following compression types given the input format:

Compression type	Avro file	Avro datum	JSON	CSV	Grok
BZIP2	Yes	Yes	Yes	Yes	Yes
GZIP	No	Yes	Yes	Yes	Yes
SNAPPY	Yes (raw Snappy)	Yes (framed Snappy)	Yes (framed Snappy)	Yes (framed Snappy)	Yes (framed Snappy)
XZ	Yes	Yes	Yes	Yes	Yes
ZSTD	Yes	No	No	No	No
DEFLATE	Yes	Yes	Yes	Yes	Yes

Creating an Amazon Glue connection for an Apache Kafka data stream

To read from an Apache Kafka stream, you must create an Amazon Glue connection.

To create an Amazon Glue connection for a Kafka source (Console)

1. Open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Connections**.
3. Choose **Add connection**, and on the **Set up your connection's properties** page, enter a connection name.

Note

For more information about specifying connection properties, see [Amazon Glue connection properties](#).

4. For **Connection type**, choose **Kafka**.
5. For **Kafka bootstrap servers URLs**, enter the host and port number for the bootstrap brokers for your Amazon MSK cluster or Apache Kafka cluster. Use only Transport Layer Security (TLS) endpoints for establishing the initial connection to the Kafka cluster. Plaintext endpoints are not supported.

The following is an example list of hostname and port number pairs for an Amazon MSK cluster.

```
myserver1.kafka.us-east-1.amazonaws.com:9094,myserver2.kafka.us-  
east-1.amazonaws.com:9094,  
myserver3.kafka.us-east-1.amazonaws.com:9094
```

For more information about getting the bootstrap broker information, see [Getting the Bootstrap Brokers for an Amazon MSK Cluster](#) in the *Amazon Managed Streaming for Apache Kafka Developer Guide*.

6. If you want a secure connection to the Kafka data source, select **Require SSL connection**, and for **Kafka private CA certificate location**, enter a valid Amazon S3 path to a custom SSL certificate.

For an SSL connection to self-managed Kafka, the custom certificate is mandatory. It's optional for Amazon MSK.

For more information about specifying a custom certificate for Kafka, see [the section called "SSL connection properties"](#).

7. Use Amazon Glue Studio or the Amazon CLI to specify a Kafka client authentication method. To access Amazon Glue Studio select **Amazon Glue** from the **ETL** menu in the left navigation pane.

For more information about Kafka client authentication methods, see [Amazon Glue Kafka connection properties for client authentication](#).

8. Optionally enter a description, and then choose **Next**.
9. For an Amazon MSK cluster, specify its virtual private cloud (VPC), subnet, and security group. The VPC information is optional for self-managed Kafka.
10. Choose **Next** to review all connection properties, and then choose **Finish**.

For more information about Amazon Glue connections, see [Connecting to data](#).

Amazon Glue Kafka connection properties for client authentication

SASL/GSSAPI (Kerberos) authentication

Choosing this authentication method will allow you to specify Kerberos properties.

Kerberos Keytab

Choose the location of the keytab file. A keytab stores long-term keys for one or more principals. For more information, see [MIT Kerberos Documentation: Keytab](#).

Kerberos krb5.conf file

Choose the krb5.conf file. This contains the default realm (a logical network, similar to a domain, that defines a group of systems under the same KDC) and the location of the KDC server. For more information, see [MIT Kerberos Documentation: krb5.conf](#).

Kerberos principal and Kerberos service name

Enter the Kerberos principal and service name. For more information, see [MIT Kerberos Documentation: Kerberos principal](#).

SASL/SCRAM-SHA-512 authentication

Choosing this authentication method will allow you to specify authentication credentials.

Amazon Secrets Manager

Search for your token in the Search box by typing the name or ARN.

Provider username and password directly

Search for your token in the Search box by typing the name or ARN.

SSL client authentication

Choosing this authentication method allows you to select the location of the Kafka client keystore by browsing Amazon S3. Optionally, you can enter the Kafka client keystore password and Kafka client key password.

IAM authentication

This authentication method does not require any additional specifications and is only applicable when the Streaming source is MSK Kafka.

SASL/PLAIN authentication

Choosing this authentication method allows you to specify authentication credentials.

Creating a Data Catalog table for a streaming source

A Data Catalog table that specifies source data stream properties, including the data schema can be manually created for a streaming source. This table is used as the data source for the streaming ETL job.

If you don't know the schema of the data in the source data stream, you can create the table without a schema. Then when you create the streaming ETL job, you can turn on the Amazon Glue schema detection function. Amazon Glue determines the schema from the streaming data.

Use the [Amazon Glue console](#), the Amazon Command Line Interface (Amazon CLI), or the Amazon Glue API to create the table. For information about creating a table manually with the Amazon Glue console, see [the section called "Creating tables"](#).

Note

You can't use the Amazon Lake Formation console to create the table; you must use the Amazon Glue console.

Also consider the following information for streaming sources in Avro format or for log data that you can apply Grok patterns to.

- [the section called "Notes and restrictions for Avro streaming sources"](#)
- [the section called "Applying grok patterns to streaming sources"](#)

Topics

- [Kinesis data source](#)
- [Kafka data source](#)
- [Amazon Glue Schema Registry table source](#)

Kinesis data source

When creating the table, set the following streaming ETL properties (console).

Type of Source

Kinesis

For a Kinesis source in the same account:

Region

The Amazon Region where the Amazon Kinesis Data Streams service resides. The Region and Kinesis stream name are together translated to a Stream ARN.

Example: <https://kinesis.us-east-1.amazonaws.com>

Kinesis stream name

Stream name as described in [Creating a Stream](#) in the *Amazon Kinesis Data Streams Developer Guide*.

For a Kinesis source in another account, refer to [this example](#) to set up the roles and policies to allow cross-account access. Configure these settings:

Stream ARN

The ARN of the Kinesis data stream that the consumer is registered with. For more information, see [Amazon Resource Names \(ARNs\) and Amazon Service Namespaces](#) in the *Amazon Web Services General Reference*.

Assumed Role ARN

The Amazon Resource Name (ARN) of the role to assume.

Session name (optional)

An identifier for the assumed role session.

Use the role session name to uniquely identify a session when the same role is assumed by different principals or for different reasons. In cross-account scenarios, the role session name is visible to, and can be logged by the account that owns the role. The role session name is also used in the ARN of the assumed role principal. This means that subsequent cross-account API requests that use the temporary security credentials will expose the role session name to the external account in their Amazon CloudTrail logs.

To set streaming ETL properties for Amazon Kinesis Data Streams (Amazon Glue API or Amazon CLI)

- To set up streaming ETL properties for a Kinesis source in the same account, specify the `streamName` and `endpointUrl` parameters in the `StorageDescriptor` structure of the `CreateTable` API operation or the `create_table` CLI command.

```
"StorageDescriptor": {  
  "Parameters": {  
    "typeOfData": "kinesis",  
    "streamName": "sample-stream",
```

```

    "endpointUrl": "https://kinesis.us-east-1.amazonaws.com"
  }
  ...
}

```

Or, specify the streamARN.

Example

```

"StorageDescriptor": {
  "Parameters": {
    "typeOfData": "kinesis",
    "streamARN": "arn:aws:kinesis:us-east-1:123456789:stream/sample-stream"
  }
  ...
}

```

- To set up streaming ETL properties for a Kinesis source in another account, specify the streamARN, awsSTSRoleARN and awsSTSSessionName (optional) parameters in the StorageDescriptor structure in the CreateTable API operation or the create_table CLI command.

```

"StorageDescriptor": {
  "Parameters": {
    "typeOfData": "kinesis",
    "streamARN": "arn:aws:kinesis:us-east-1:123456789:stream/sample-stream",
    "awsSTSRoleARN": "arn:aws:iam::123456789:role/sample-assume-role-arn",
    "awsSTSSessionName": "optional-session"
  }
  ...
}

```

Kafka data source

When creating the table, set the following streaming ETL properties (console).

Type of Source

Kafka

For a Kafka source:

Topic name

Topic name as specified in Kafka.

Connection

An Amazon Glue connection that references a Kafka source, as described in [the section called "Creating a connection for a Kafka data stream"](#).

Amazon Glue Schema Registry table source

To use Amazon Glue Schema Registry for streaming jobs, follow the instructions at [Use case: Amazon Glue Data Catalog](#) to create or update a Schema Registry table.

Currently, Amazon Glue Streaming supports only Glue Schema Registry Avro format with schema inference set to `false`.

Notes and restrictions for Avro streaming sources

The following notes and restrictions apply for streaming sources in the Avro format:

- When schema detection is turned on, the Avro schema must be included in the payload. When turned off, the payload should contain only data.
- Some Avro data types are not supported in dynamic frames. You can't specify these data types when defining the schema with the **Define a schema** page in the create table wizard in the Amazon Glue console. During schema detection, unsupported types in the Avro schema are converted to supported types as follows:
 - `EnumType` => `StringType`
 - `FixedType` => `BinaryType`
 - `UnionType` => `StructType`
- If you define the table schema using the **Define a schema** page in the console, the implied root element type for the schema is `record`. If you want a root element type other than `record`, for example `array` or `map`, you can't specify the schema using the **Define a schema** page. Instead you must skip that page and specify the schema either as a table property or within the ETL script.

- To specify the schema in the table properties, complete the create table wizard, edit the table details, and add a new key-value pair under **Table properties**. Use the key `avroSchema`, and enter a schema JSON object for the value, as shown in the following screenshot.

Edit table details

Key

Value

Description

Type description...

Table properties

Key	Value	
classification	avro	✕
avroSchema	{"type": "array", "items": "strin	✕

- To specify the schema in the ETL script, modify the `datasource0` assignment statement and add the `avroSchema` key to the `additional_options` argument, as shown in the following Python and Scala examples.

Python

```

SCHEMA_STRING = '{"type": "array", "items": "string"}'
datasource0 = glueContext.create_data_frame.from_catalog(database =
    "database", table_name = "table_name", transformation_ctx = "datasource0",
    additional_options = {"startingPosition": "TRIM_HORIZON", "inferSchema":
    "false", "avroSchema": SCHEMA_STRING})
  
```

Scala

```
val SCHEMA_STRING = """"{"type":"array","items":"string"}""""
val datasource0 = glueContext.getCatalogSource(database = "database", tableName
= "table_name", redshiftTmpDir = "", transformationContext = "datasource0",
additionalOptions = JsonOptions(s""""{"startingPosition": "TRIM_HORIZON",
"inferSchema": "false", "avroSchema": "$SCHEMA_STRING"}"""")).getDataFrame()
```

Applying grok patterns to streaming sources

You can create a streaming ETL job for a log data source and use Grok patterns to convert the logs to structured data. The ETL job then processes the data as a structured data source. You specify the Grok patterns to apply when you create the Data Catalog table for the streaming source.

For information about Grok patterns and custom pattern string values, see [Writing grok custom classifiers](#).

To add grok patterns to the Data Catalog table (console)

- Use the create table wizard, and create the table with the parameters specified in [the section called “Creating a Data Catalog table for a streaming source”](#). Specify the data format as Grok, fill in the **Grok pattern** field, and optionally add custom patterns under **Custom patterns (optional)**.

Choose a data format

Classification

CSV
 JSON
 ORC
 Parquet
 Avro
 Grok

Choose the format of the data in your table.

Grok pattern

Built-in and custom named patterns used to parse your data into a structured schema. For more information, see the [list of built-in patterns](#).

Custom patterns

1

Optional custom building blocks for the grok pattern.

Press **Enter** after each custom pattern.

To add grok patterns to the Data Catalog table (Amazon Glue API or Amazon CLI)

- Add the GrokPattern parameter and optionally the CustomPatterns parameter to the CreateTable API operation or the create_table CLI command.

```
"Parameters": {
...
  "grokPattern": "string",
  "grokCustomPatterns": "string",
...
},
```

Express grokCustomPatterns as a string and use "\n" as the separator between patterns.

The following is an example of specifying these parameters.

Example

```
"parameters": {  
  ...  
  "grokPattern": "%{USERNAME:username} %{DIGIT:digit:int}",  
  "grokCustomPatterns": "digit \\d",  
  ...  
}
```

Defining job properties for a streaming ETL job

When you define a streaming ETL job in the Amazon Glue console, provide the following streams-specific properties. For descriptions of additional job properties, see [Defining job properties for Spark jobs](#).

IAM role

Specify the Amazon Identity and Access Management (IAM) role that is used for authorization to resources that are used to run the job, access streaming sources, and access target data stores.

For access to Amazon Kinesis Data Streams, attach the `AmazonKinesisFullAccess` Amazon managed policy to the role, or attach a similar IAM policy that permits more fine-grained access. For sample policies, see [Controlling Access to Amazon Kinesis Data Streams Resources Using IAM](#).

For more information about permissions for running jobs in Amazon Glue, see [Identity and access management for Amazon Glue](#).

Type

Choose **Spark streaming**.

Amazon Glue version

The Amazon Glue version determines the versions of Apache Spark, and Python or Scala, that are available to the job. Choose a selection that specifies the version of Python or Scala available to the job. Amazon Glue Version 2.0 with Python 3 support is the default for streaming ETL jobs.

Maintenance window

Specifies a window where a streaming job can be restarted. See [the section called “Maintenance windows”](#).

Job timeout

Optionally enter a duration in minutes. The default value is blank.

- Streaming jobs must have a timeout value less than 7 days or 10080 minutes.
- When the value is left blank, the job will be restarted after 7 days, if you have not set up a maintenance window. If you have set up a maintenance window, the job will be restarted during the maintenance window after 7 days.

Data source

Specify the table that you created in [the section called “Creating a Data Catalog table for a streaming source”](#).

Data target

Do one of the following:

- Choose **Create tables in your data target** and specify the following data target properties.

Data store

Choose Amazon S3 or JDBC.

Format

Choose any format. All are supported for streaming.

- Choose **Use tables in the data catalog and update your data target**, and choose a table for a JDBC data store.

Output schema definition

Do one of the following:

- Choose **Automatically detect schema of each record** to turn on schema detection. Amazon Glue determines the schema from the streaming data.
- Choose **Specify output schema for all records** to use the Apply Mapping transform to define the output schema.

Script

Optionally supply your own script or modify the generated script to perform operations that the Apache Spark Structured Streaming engine supports. For information on the available operations, see [Operations on streaming DataFrames/Datasets](#).

Streaming ETL notes and restrictions

Keep in mind the following notes and restrictions:

- Auto-decompression for Amazon Glue streaming ETL jobs is only available for the supported compression types. Also note the following:
 - Framed Snappy refers to the official [framing format](#) for Snappy.
 - Deflate is supported in Glue version 3.0, not Glue version 2.0.
- When using schema detection, you cannot perform joins of streaming data.
- Amazon Glue streaming ETL jobs do not support the Union data type for Amazon Glue Schema Registry with Avro format.
- Your ETL script can use Amazon Glue's built-in transforms and the transforms native to Apache Spark Structured Streaming. For more information, see [Operations on streaming DataFrames/Datasets](#) on the Apache Spark website or [Amazon Glue PySpark transforms reference](#).
- Amazon Glue streaming ETL jobs use checkpoints to keep track of the data that has been read. Therefore, a stopped and restarted job picks up where it left off in the stream. If you want to reprocess data, you can delete the checkpoint folder referenced in the script.
- Job bookmarks aren't supported.
- To use enhanced fan-out feature of Kinesis Data Streams in your job, consult [the section called "Using enhanced fan-out in Kinesis streaming jobs"](#).
- If you use a Data Catalog table created from Amazon Glue Schema Registry, when a new schema version becomes available, to reflect the new schema, you need to do the following:
 1. Stop the jobs associated with the table.
 2. Update the schema for the Data Catalog table.
 3. Restart the jobs associated with the table.

Record matching with Amazon Lake Formation FindMatches

Note

Record matching is currently unavailable in the following Regions in the Amazon Glue console: Middle East (UAE), Europe (Spain), Asia Pacific (Jakarta), and Europe (Zurich).

Amazon Lake Formation provides machine learning capabilities to create custom transforms to cleanse your data. There is currently one available transform named FindMatches. The FindMatches transform enables you to identify duplicate or matching records in your dataset, even when the records do not have a common unique identifier and no fields match exactly. This will not require writing any code or knowing how machine learning works. FindMatches can be useful in many different problems, such as:

- **Matching customers:** Linking customer records across different customer databases, even when many customer fields do not match exactly across the databases (e.g. different name spelling, address differences, missing or inaccurate data, etc).
- **Matching products:** Matching products in your catalog against other product sources, such as product catalog against a competitor's catalog, where entries are structured differently.
- **Improving fraud detection:** Identifying duplicate customer accounts, determining when a newly created account is (or might be) a match for a previously known fraudulent user.
- **Other matching problems:** Match addresses, movies, parts lists, etc etc. In general, if a human being could look at your database rows and determine that they were a match, there is a really good chance that the FindMatches transform can help you.

You can create these transforms when you create a job. The transform that you create is based on a source data store schema and example data from the source data set that you label (we call this process "teaching" a transform). The records that you label must be present in the source dataset. In this process we generate a file which you label and then upload back which the transform would in a manner learn from. After you teach your transform, you can call it from your Spark-based Amazon Glue job (PySpark or Scala Spark) and use it in other scripts with a compatible source data store.

After the transform is created, it is stored in Amazon Glue. On the Amazon Glue console, you can manage the transforms that you create. In the navigation pane under **Data Integration and ETL, Data classification tools > Record Matching**, you can edit and continue to teach your machine

learning transform. For more information about managing transforms on the console, see [Working with machine learning transforms](#).

Note

Amazon Glue version 2.0 FindMatches jobs use the Amazon S3 bucket `aws-glue-temp-<accountID>-<region>` to store temporary files while the transform is processing data. You can delete this data after the run has completed, either manually or by setting an Amazon S3 Lifecycle rule.

Types of machine learning transforms

You can create machine learning transforms to cleanse your data. You can call these transforms from your ETL script. Your data passes from transform to transform in a data structure called a *DynamicFrame*, which is an extension to an Apache Spark SQL DataFrame. The *DynamicFrame* contains your data, and you reference its schema to process your data.

The following types of machine learning transforms are available:

Find matches

Finds duplicate records in the source data. You teach this machine learning transform by labeling example datasets to indicate which rows match. The machine learning transform learns which rows should be matches the more you teach it with example labeled data. Depending on how you configure the transform, the output is one of the following:

- A copy of the input table plus a `match_id` column filled in with values that indicate matching sets of records. The `match_id` column is an arbitrary identifier. Any records which have the same `match_id` have been identified as matching to each other. Records with different `match_id`'s do not match.
- A copy of the input table with duplicate rows removed. If multiple duplicates are found, then the record with the lowest primary key is kept.

Find incremental matches

The Find matches transform can also be configured to find matches across the existing and incremental frames and return as output a column containing a unique ID per match group.

For more information, see: [Finding incremental matches](#)

Using the FindMatches transform

You can use the FindMatches transform to find duplicate records in the source data. A labeling file is generated or provided to help teach the transform.

Note

Currently, FindMatches transforms that use a custom encryption key aren't supported in the following Regions:

- Asia Pacific (Osaka) - ap-northeast-3

To get started with the FindMatches transform, you can follow the steps below. For a more advanced and detailed example, see the **Amazon Big Data Blog**: [Harmonize data using Amazon Glue and Amazon Lake Formation FindMatches ML to build a customer 360 view](#).

Getting started using the Find Matches transform

Follow these steps to get started with the FindMatches transform:

1. Create a table in the Amazon Glue Data Catalog for the source data that is to be cleaned. For information about how to create a crawler, see [Working with Crawlers on the Amazon Glue Console](#).

If your source data is a text-based file such as a comma-separated values (CSV) file, consider the following:

- Keep your input record CSV file and labeling file in separate folders. Otherwise, the Amazon Glue crawler might consider them as multiple parts of the same table and create tables in the Data Catalog incorrectly.
 - Unless your CSV file includes ASCII characters only, ensure that UTF-8 without BOM (byte order mark) encoding is used for the CSV files. Microsoft Excel often adds a BOM in the beginning of UTF-8 CSV files. To remove it, open the CSV file in a text editor, and resave the file as **UTF-8 without BOM**.
2. On the Amazon Glue console, create a job, and choose the **Find matches** transform type.

⚠ Important

The data source table that you choose for the job can't have more than 100 columns.

3. Tell Amazon Glue to generate a labeling file by choosing **Generate labeling file**. Amazon Glue takes the first pass at grouping similar records for each `labeling_set_id` so that you can review those groupings. You label matches in the `label` column.
 - If you already have a labeling file, that is, an example of records that indicate matching rows, upload the file to Amazon Simple Storage Service (Amazon S3). For information about the format of the labeling file, see [Labeling file format](#). Proceed to step 4.
4. Download the labeling file and label the file as described in the [Labeling](#) section.
5. Upload the corrected labelled file. Amazon Glue runs tasks to teach the transform how to find matches.

On the **Machine learning transforms** list page, choose the **History** tab. This page indicates when Amazon Glue performs the following tasks:

- **Import labels**
 - **Export labels**
 - **Generate labels**
 - **Estimate quality**
6. To create a better transform, you can iteratively download, label, and upload the labelled file. In the initial runs, a lot more records might be mismatched. But Amazon Glue learns as you continue to teach it by verifying the labeling file.
 7. Evaluate and tune your transform by evaluating performance and results of finding matches. For more information, see [Tuning machine learning transforms in Amazon Glue](#).

Labeling

When `FindMatches` generates a labeling file, records are selected from your source table. Based on previous training, `FindMatches` identifies the most valuable records to learn from.

The act of *labeling* is editing a labeling file (we suggest using a spreadsheet such as Microsoft Excel) and adding identifiers, or labels, into the `label` column that identifies matching and nonmatching records. It is important to have a clear and consistent definition of a match in your source data.

FindMatches learns from which records you designate as matches (or not) and uses your decisions to learn how to find duplicate records.

When a labeling file is generated by FindMatches, approximately 100 records are generated. These 100 records are typically divided into 10 *labeling sets*, where each labeling set is identified by a unique `labeling_set_id` generated by FindMatches. Each labeling set should be viewed as a separate labeling task independent of the other labeling sets. Your task is to identify matching and non-matching records within each labeling set.

Tips for editing labeling files in a spreadsheet

When editing the labeling file in a spreadsheet application, consider the following:

- The file might not open with column fields fully expanded. You might need to expand the `labeling_set_id` and `label` columns to see content in those cells.
- If the primary key column is a number, such as a `long` data type, the spreadsheet might interpret it as a number and change the value. This key value must be treated as text. To correct this problem, format all the cells in the primary key column as **Text data**.

Labeling file format

The labeling file that is generated by Amazon Glue to teach your FindMatches transform uses the following format. If you generate your own file for Amazon Glue, it must follow this format as well:

- It is a comma-separated values (CSV) file.
- It must be encoded in UTF-8. If you edit the file using Microsoft Windows, it might be encoded with cp1252.
- It must be in an Amazon S3 location to pass it to Amazon Glue.
- Use a moderate number of rows for each labeling task. 10–20 rows per task are recommended, although 2–30 rows per task are acceptable. Tasks larger than 50 rows are not recommended and may cause poor results or system failure.
- If you have already-labeled data consisting of pairs of records labeled as "match" or a "no-match", this is fine. These labeled pairs can be represented as labeling sets of size 2. In this case label both records with, for instance, a letter "A" if they match, but label one as "A" and one as "B" if they do not match.

Note

Because it has additional columns, the labeling file has a different schema from a file that contains your source data. Place the labeling file in a different folder from any transform input CSV file so that the Amazon Glue crawler does not consider it when it creates tables in the Data Catalog. Otherwise, the tables created by the Amazon Glue crawler might not correctly represent your data.

- The first two columns (`labeling_set_id`, `label`) are required by Amazon Glue. The remaining columns must match the schema of the data that is to be processed.
- For each `labeling_set_id`, you identify all matching records by using the same label. A label is a unique string placed in the `label` column. We recommend using labels that contain simple characters, such as A, B, C, and so on. Labels are case sensitive and are entered in the `label` column.
- Rows that contain the same `labeling_set_id` and the same label are understood to be labeled as a match.
- Rows that contain the same `labeling_set_id` and a different label are understood to be labeled as *not* a match
- Rows that contain a different `labeling_set_id` are understood to be conveying no information for or against matching.

The following is an example of labeling the data:

<code>labeling_set_id</code>	<code>label</code>	<code>first_name</code>	<code>last_name</code>	<code>Birthday</code>
ABC123	A	John	Doe	04/01/1980
ABC123	B	Jane	Smith	04/03/1980
ABC123	A	Johnny	Doe	04/01/1980
ABC123	A	Jon	Doe	04/01/1980
DEF345	A	Richard	Jones	12/11/1992
DEF345	A	Rich	Jones	11/12/1992

labeling_set_id	label	first_name	last_name	Birthday
DEF345	B	Sarah	Jones	12/11/1992
DEF345	C	Richie	Jones Jr.	05/06/2017
DEF345	B	Sarah	Jones-Walker	12/11/1992
GHI678	A	Robert	Miller	1/3/1999
GHI678	A	Bob	Miller	1/3/1999
XYZABC	A	William	Robinson	2/5/2001
XYZABC	B	Andrew	Robinson	2/5/1971

- In the above example we identify John/Johnny/Jon Doe as being a match and we teach the system that these records do not match Jane Smith. Separately, we teach the system that Richard and Rich Jones are the same person, but that these records are not a match to Sarah Jones/Jones-Walker and Richie Jones Jr.
- As you can see, the scope of the labels is limited to the `labeling_set_id`. So labels do not cross `labeling_set_id` boundaries. For example, a label "A" in `labeling_set_id` 1 does not have any relation to label "A" in `labeling_set_id` 2.
- If a record does not have any matches within a labeling set, then assign it a unique label. For instance, Jane Smith does not match any record in labeling set ABC123, so it is the only record in that labeling set with the label of B.
- The labeling set "GHI678" shows that a labeling set can consist of just two records which are given the same label to show that they match. Similarly, "XYZABC" shows two records given different labels to show that they do not match.
- Note that sometimes a labeling set may contain no matches (that is, you give every record in the labeling set a different label) or a labeling set might all be "the same" (you gave them all the same label). This is okay as long as your labeling sets collectively contain examples of records that are and are not "the same" by your criteria.

Important

Confirm that the IAM role that you pass to Amazon Glue has access to the Amazon S3 bucket that contains the labeling file. By convention, Amazon Glue policies grant

permission to Amazon S3 buckets or folders whose names are prefixed with **aws-glue-**. If your labeling files are in a different location, add permission to that location in the IAM role.

Tuning machine learning transforms in Amazon Glue

You can tune your machine learning transforms in Amazon Glue to improve the results of your data-cleansing jobs to meet your objectives. To improve your transform, you can teach it by generating a labeling set, adding labels, and then repeating these steps several times until you get your desired results. You can also tune by changing some machine learning parameters.

For more information about machine learning transforms, see [Record matching with Amazon Lake Formation FindMatches](#).

Topics

- [Machine learning measurements](#)
- [Deciding between precision and recall](#)
- [Deciding Between accuracy and cost](#)
- [Estimating the quality of matches using match confidence scores](#)
- [Teaching the Find Matches transform](#)

Machine learning measurements

To understand the measurements that are used to tune your machine learning transform, you should be familiar with the following terminology:

True positive (TP)

A match in the data that the transform correctly found, sometimes called a *hit*.

True negative (TN)

A nonmatch in the data that the transform correctly rejected.

False positive (FP)

A nonmatch in the data that the transform incorrectly classified as a match, sometimes called a *false alarm*.

False negative (FN)

A match in the data that the transform didn't find, sometimes called a *miss*.

For more information about the terminology that is used in machine learning, see [Confusion matrix](#) in Wikipedia.

To tune your machine learning transforms, you can change the value of the following measurements in the **Advanced properties** of the transform.

- **Precision** measures how well the transform finds true positives among the total number of records that it identifies as positive (true positives and false positives). For more information, see [Precision and recall](#) in Wikipedia.
- **Recall** measures how well the transform finds true positives from the total records in the source data. For more information, see [Precision and recall](#) in Wikipedia.
- **Accuracy** measures how well the transform finds true positives and true negatives. Increasing accuracy requires more machine resources and cost. But it also results in increased recall. For more information, see [Accuracy and precision](#) in Wikipedia.
- **Cost** measures how many compute resources (and thus money) are consumed to run the transform.

Deciding between precision and recall

Each FindMatches transform contains a `precision-recall` parameter. You use this parameter to specify one of the following:

- If you are more concerned about the transform falsely reporting that two records match when they actually don't match, then you should emphasize *precision*.
- If you are more concerned about the transform failing to detect records that really do match, then you should emphasize *recall*.

You can make this trade-off on the Amazon Glue console or by using the Amazon Glue machine learning API operations.

When to favor precision

Favor precision if you are more concerned about the risk that FindMatches results in a pair of records matching when they don't actually match. To favor precision, choose a *higher* precision-

recall trade-off value. With a higher value, the `FindMatches` transform requires more evidence to decide that a pair of records should be matched. The transform is tuned to bias toward saying that records do not match.

For example, suppose that you're using `FindMatches` to detect duplicate items in a video catalog, and you provide a higher precision-recall value to the transform. If your transform incorrectly detects that *Star Wars: A New Hope* is the same as *Star Wars: The Empire Strikes Back*, a customer who wants *A New Hope* might be shown *The Empire Strikes Back*. This would be a poor customer experience.

However, if the transform fails to detect that *Star Wars: A New Hope* and *Star Wars: Episode IV —A New Hope* are the same item, the customer might be confused at first but might eventually recognize them as the same. It would be a mistake, but not as bad as the previous scenario.

When to favor recall

Favor recall if you are more concerned about the risk that the `FindMatches` transform results might fail to detect a pair of records that actually do match. To favor recall, choose a *lower* precision-recall trade-off value. With a lower value, the `FindMatches` transform requires less evidence to decide that a pair of records should be matched. The transform is tuned to bias toward saying that records do match.

For example, this might be a priority for a security organization. Suppose that you are matching customers against a list of known defrauders, and it is important to determine whether a customer is a defrauder. You are using `FindMatches` to match the defrauder list against the customer list. Every time `FindMatches` detects a match between the two lists, a human auditor is assigned to verify that the person is, in fact, a defrauder. Your organization might prefer to choose recall over precision. In other words, you would rather have the auditors manually review and reject some cases when the customer is not a defrauder than fail to identify that a customer is, in fact, on the defrauder list.

How to favor both precision and recall

The best way to improve both precision and recall is to label more data. As you label more data, the overall accuracy of the `FindMatches` transform improves, thus improving both precision and recall. Nevertheless, even with the most accurate transform, there is always a gray area where you need to experiment with favoring precision or recall, or choose a value in the middle.

Deciding Between accuracy and cost

Each FindMatches transform contains an accuracy-cost parameter. You can use this parameter to specify one of the following:

- If you are more concerned with the transform accurately reporting that two records match, then you should emphasize *accuracy*.
- If you are more concerned about the cost or speed of running the transform, then you should emphasize *lower cost*.

You can make this trade-off on the Amazon Glue console or by using the Amazon Glue machine learning API operations.

When to favor accuracy

Favor accuracy if you are more concerned about the risk that the `find matches` results won't contain matches. To favor accuracy, choose a *higher* accuracy-cost trade-off value. With a higher value, the FindMatches transform requires more time to do a more thorough search for correctly matching records. Note that this parameter doesn't make it less likely to falsely call a nonmatching record pair a match. The transform is tuned to bias towards spending more time finding matches.

When to favor cost

Favor cost if you are more concerned about the cost of running the `find matches` transform and less about how many matches are found. To favor cost, choose a *lower* accuracy-cost trade-off value. With a lower value, the FindMatches transform requires fewer resources to run. The transform is tuned to bias towards finding fewer matches. If the results are acceptable when favoring lower cost, use this setting.

How to favor both accuracy and lower cost

It takes more machine time to examine more pairs of records to determine whether they might be matches. If you want to reduce cost without reducing quality, here are some steps you can take:

- Eliminate records in your data source that you aren't concerned about matching.
- Eliminate columns from your data source that you are sure aren't useful for making a match/no-match decision. A good way of deciding this is to eliminate columns that you don't think affect your own decision about whether a set of records is "the same."

Estimating the quality of matches using match confidence scores

Match confidence scores provide an estimate of the quality of matches found by FindMatches to distinguish between matched records in which the machine learning model is highly confident, uncertain, or unlikely. A match confidence score will be between 0 and 1, where a higher score means higher similarity. Examining match confidence scores lets you distinguish between clusters of matches in which the system is highly confident (which you may decide to merge), clusters about which the system is uncertain (which you may decide to have reviewed by a human), and clusters that the system deems to be unlikely (which you may decide to reject).

You may want to adjust your training data in situations where you see a high match confidence score, but determine there are not matches, or where you see a low score but determine there are, in fact, matches.

Confidence scores are particularly useful when there are large sized industrial datasets, where it is infeasible to review every FindMatches decision.

Match confidence scores are available in Amazon Glue version 2.0 or later.

Generating match confidence scores

You can generate match confidence scores by setting the Boolean value of `computeMatchConfidenceScores` to `True` when calling the `FindMatches` or `FindIncrementalMatches` API.

Amazon Glue adds a new column `match_confidence_score` to the output.

Match scoring examples

For example, consider the following matched records:

Score \geq 0.9

Summary of matched records:

<code>primary_id</code>	<code>match_id</code>	<code>match_confidence_score</code>
3281355037663	85899345947	0.9823658302132061
1546188247619	85899345947	0.9823658302132061

Details:

From this example, we can see that these records share only the same `primary_name`.

For more information, see:

- [Step 5: Add and run a job with your machine learning transform](#)
- PySpark: [FindMatches class](#)
- PySpark: [FindIncrementalMatches class](#)
- Scala: [FindMatches class](#)
- Scala: [FindIncrementalMatches class](#)

Teaching the Find Matches transform

Each `FindMatches` transform must be taught what should be considered a match and what should not be considered a match. You teach your transform by adding labels to a file and uploading your choices to Amazon Glue.

You can orchestrate this labeling on the Amazon Glue console or by using the Amazon Glue machine learning API operations.

How many times should I add labels? How many labels do I need?

The answers to these questions are mostly up to you. You must evaluate whether `FindMatches` is delivering the level of accuracy that you need and whether you think the extra labeling effort is worth it for you. The best way to decide this is to look at the “Precision,” “Recall,” and “Area under the precision recall curve” metrics that you can generate when you choose **Estimate quality** on the Amazon Glue console. After you label more sets of tasks, rerun these metrics and verify whether they have improved. If, after labeling a few sets of tasks, you don't see improvement on the metric that you are focusing on, the transform quality might have reached a plateau.

Why are both true positive and true negative labels needed?

The FindMatches transform needs both positive and negative examples to learn what you think is a match. If you are labeling FindMatches-generated training data (for example, using the **I do not have labels** option), FindMatches tries to generate a set of “label set ids” for you. Within each task, you give the same “label” to some records and different “labels” to other records. In other words, the tasks generally are not either all the same or all different (but it's okay if a particular task is all “the same” or all “not the same”).

If you are teaching your FindMatches transform using the **Upload labels from S3** option, try to include both examples of matching and nonmatching records. It's acceptable to have only one type. These labels help you build a more accurate FindMatches transform, but you still need to label some records that you generate using the **Generate labeling file** option.

How can I enforce that the transform matches exactly as I taught it?

The FindMatches transform learns from the labels that you provide, so it might generate records pairs that don't respect the provided labels. To enforce that the FindMatches transform respects your labels, select **EnforceProvidedLabels** in **FindMatchesParameter**.

What techniques can you use when an ML transform identifies items as matches that are not true matches?

You can use the following techniques:

- Increase the `precisionRecallTradeoff` to a higher value. This eventually results in finding fewer matches, but it should also break up your big cluster when it reaches a high enough value.
- Take the output rows corresponding to the incorrect results and reformat them as a labeling set (removing the `match_id` column and adding a `labeling_set_id` and `label` column). If necessary, break up (subdivide) into multiple labeling sets to ensure that the labeler can keep each labeling set in mind while assigning labels. Then, correctly label the matching sets and upload the label file and append it to your existing labels. This might teach your transformer enough about what it is looking for to understand the pattern.
- (Advanced) Finally, look at that data to see if there is a pattern that you can detect that the system is not noticing. Preprocess that data using standard Amazon Glue functions to *normalize* the data. Highlight what you want the algorithm to learn from by separating data that you know to be differently important into their own columns. Or construct combined columns from columns whose data you know to be related.

Working with machine learning transforms

You can use Amazon Glue to create custom machine learning transforms that can be used to cleanse your data. You can use these transforms when you create a job on the Amazon Glue console.

For information about how to create a machine learning transform, see [Record matching with Amazon Lake Formation FindMatches](#).

Topics

- [Transform properties](#)
- [Adding and editing machine learning transforms](#)
- [Viewing transform details](#)
- [Teach transforms using labels](#)

Transform properties

To view an existing machine learning transform, sign in to the Amazon Web Services Management Console, and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>. In the navigation pane under **Data Integration and ETL**, choose **Data classification tools > Record Matching**.

The properties for each transform:

Transform name

The unique name you gave the transform when you created it.

ID

A unique identifier of the transform.

Label count

The number of labels in the labeling file that was provided to help teach the transform.

Status

Indicates whether the transform is **Ready** or **Needs training**. To run a machine learning transform successfully in a job, it must be **Ready**.

Created

The date the transform was created.

Modified

The date the transform was last updated.

Description

The description supplied for the transform, if one was provided.

Amazon Glue version

The version of Amazon Glue used.

Run ID

The unique name you gave the transform when you created it.

Task type

The type of machine learning transform; for example, **Find matching records**.

Status

Indicates the status of the task run. Possible statuses include:

- Starting
- Running
- Stopping
- Stopped
- Succeeded
- Failed
- Timeout

Error

If the status is Failed, an error message is displayed describing the reason for the failure.

Adding and editing machine learning transforms

You can view, delete, set up and teach, or tune a transform on the Amazon Glue console. Select the check box next to the transform in the list, choose **Action**, and then choose the action that you want to take.

Creating a new ML transform

To add a new machine learning transform, choose **Create transform**. Follow the instructions in the **Add job** wizard. For more information, see [Record matching with Amazon Lake Formation FindMatches](#).

Step 1. Set transform properties.

1. Enter the name and description (optional).
2. Optionally, set security configuration. See [Using data encryption with machine learning transforms](#).
3. Optionally, set Task execution settings. Task execution settings allow you to customize how the task is run. Select the Worker type, number of workers, task timeout (in minutes), the number of retries, and the Amazon Glue version.
4. Optionally, set Tags. Tags are labels that you can assign to an Amazon resource. Each tag consists of a key and an optional value. Tags can be used to search and filter your resource or track your Amazon costs.

Step 2. Choose table and primary key.

1. Choose the Amazon Glue Catalog database and table.
2. Choose a primary key from the selected table. The primary key column typically contains a unique identifier for every record in the data source.

Step 3. Select tuning options.

1. For **Recall vs. precision**, choose the tuning value to tune the transform to favor recall or precision. By default, **Balanced** is selected, but you can choose to favor recall or favor precision, or choose **Custom** and enter a value between 0.0 and 1.0 (inclusive).
2. For **Lower cost vs. accuracy**, choose the tuning value to favor lower cost or accuracy, or choose **Custom** and enter a value between 0.0 and 1.0 (inclusive).
3. For **Match enforcement**, choose **Force output to match labels** if you want to teach the ML transform by forcing the output to match the labels used.

Step 4. Review and create.

1. Review the options for steps 1 – 3.

2. Choose **Edit** for any step that needs to be modified. Choose **Create transform** to complete the create transform wizard.

Using data encryption with machine learning transforms

When adding a machine learning transform to Amazon Glue, you can optionally specify a security configuration that is associated with the data source or data target. If the Amazon S3 bucket used to store the data is encrypted with a security configuration, specify the same security configuration when creating the transform.

You can also choose to use server-side encryption with Amazon KMS (SSE-KMS) to encrypt the model and labels to prevent unauthorized persons from inspecting it. If you choose this option, you're prompted to choose the Amazon KMS key by name, or you can choose **Enter a key ARN**. If you choose to enter the ARN for the KMS key, a second field appears where you can enter the KMS key ARN.

Note

Currently, ML transforms that use a custom encryption key aren't supported in the following Regions:

- Asia Pacific (Osaka) - `ap-northeast-3`

Viewing transform details

Viewing transform properties

The **Transform properties** page includes attributes of your transform. It shows you the details about the transform definition, including the following:

- **Transform name** shows the name of the transform.
- **Type** lists the type of the transform.
- **Status** displays whether the transform is ready to be used in a script or job.
- **Force output to match labels** displays whether the transform forces the output to match the labels provided by the user.

- **Spark version** is related to the Amazon Glue version you chose in the **Task run properties** when adding the transform. Amazon Glue 1.0 and Spark 2.4 is recommended for most customers. For more information, see [Amazon Glue Versions](#).

History, Estimate quality and Tags tabs

Transform details include the information that you defined when you created the transform. To view the details of a transform, select the transform in the **Machine learning transforms** list, and review the information on the following tabs:

- History
- Estimate quality
- Tags

History

The **History** tab shows your transform task run history. Several types of tasks are run to teach a transform. For each task, the run metrics include the following:

- **Run ID** is an identifier created by Amazon Glue for each run of this task.
- **Task type** shows the type of task run.
- **Status** shows the success of each task listed with the most recent run at the top.
- **Error** shows the details of an error message if the run was not successful.
- **Start time** shows the date and time (local time) that the task started.
- **End time** shows the date and time (local time) that the task ended.
- **Logs** links to the logs written to stdout for this job run.

The **Logs** link takes you to Amazon CloudWatch Logs. There you can view the details about the tables that were created in the Amazon Glue Data Catalog and any errors that were encountered. You can manage your log retention period on the CloudWatch console. The default log retention is `Never Expire`. For more information about how to change the retention period, see [Change Log Data Retention in CloudWatch Logs](#) in the *Amazon CloudWatch Logs User Guide*.

- **Label file** shows a link to Amazon S3 for a generated labeling file.

Estimate quality

The **Estimate quality** tab shows the metrics that you use to measure the quality of the transform. Estimates are calculated by comparing the transform match predictions using a subset of your labeled data against the labels you have provided. These estimates are approximate. You can invoke an **Estimate quality** task run from this tab.

The **Estimate quality** tab shows the metrics from the last **Estimate quality** run including the following properties:

- **Area under the Precision-Recall curve** is a single number estimating the upper bound of the overall quality of the transform. It is independent of the choice made for the precision-recall parameter. Higher values indicate that you have a more attractive precision-recall tradeoff.
- **Precision** estimates how often the transform is correct when it predicts a match.
- **Recall upper limit** estimates that for an actual match, how often the transform predicts the match.
- **F1** estimates the transform's accuracy between 0 and 1, where 1 is the best accuracy. For more information, see [F1 score](#) in Wikipedia.
- The **Column importance** table show the column names and importance score for each column. Column importance helps you understand how columns contribute to your model, by identifying which columns in your records are being used the most to do the matching. This data may prompt you to add to or change your labelset to raise or lower the importance of columns.

The Importance column provides a numerical score for each column, as a decimal not greater than 1.0.

For information about understanding quality estimates versus true quality, see [Quality estimates versus end-to-end \(true\) quality](#).

For more information about tuning your transform, see [Tuning machine learning transforms in Amazon Glue](#).

Quality estimates versus end-to-end (true) quality

Amazon Glue estimates the quality of your transform by presenting the internal machine-learned model with a number of pairs of records that you provided matching labels for but that the model has not seen before. These quality estimates are a function of the quality of the machine-learned model (which is influenced by the number of records that you label to “teach” the transform). The

end-to-end, or *true* recall (which is not automatically calculated by the ML transform) is also influenced by the ML transform filtering mechanism that proposes a wide variety of possible matches to the machine-learned model.

You can tune this filtering method primarily by specifying the **Lower Cost-Accuracy** tuning value. As the tuning value gets closer to favor **Accuracy**, the system does a more thorough and expensive search for pairs of records that might be matches. More pairs of records are fed to your machine-learned model, and your ML transform's end-to-end or true recall gets closer to the estimated recall metric. As a result, changes in the end-to-end quality of your matches as a result of changes in the cost/accuracy tradeoff for your matches will typically not be reflected in the quality estimate.

Tags

Tags are labels that you can assign to an Amazon resource. Each tag consists of a key and an optional value. Tags can be used to search and filter your resource or track your Amazon costs.

Teach transforms using labels

You can teach your ML transform using labels (examples) by choosing **Teach transform** from the ML transform details page. When you teach your machine learning algorithm by providing examples (called labels), you can choose existing labels to use, or create a labeling file.

Teach the transform using labels

Labeling

Teach your machine learning algorithms by providing examples, called labels. For your transform, provide examples of matching and nonmatching records.

I do not have labels

I have labels

► [How to label](#)

Generate labeling file

AWS Glue extracts records from your source data and suggests potential matching records. The file will contain approximately 100 data samples for you to work with. You can download the file once it has been generated.

Existing labels

Append to my existing labels

Overwrite my existing labels

Upload labeling file from S3

- **Labeling** – If you have labels, choose **I have labels**. If you do not have labels, you can still continue with the next step in generating a labeling file.
- **Generate labeling file** – Amazon Glue extracts records from your source data and suggest potential matching records. You choose the Amazon S3 bucket to store the generated label file. Choose **Generate labeling file** to start the process. When done, choose **Download labeling file**. The downloaded file will have a column for labels where you can fill in the labels.
- **Upload labels from Amazon S3** – Choose the completed labeling file from the Amazon S3 bucket where the label file is stored. Then, choose to either append the labels to your existing labels or to overwrite your existing labels. Choose **Upload labeling file from Amazon S3**.

Tutorial: Creating a machine learning transform with Amazon Glue

This tutorial guides you through the actions to create and manage a machine learning (ML) transform using Amazon Glue. Before using this tutorial, you should be familiar with using the

Amazon Glue console to add crawlers and jobs and edit scripts. You should also be familiar with finding and downloading files on the Amazon Simple Storage Service (Amazon S3) console.

In this example, you create a `FindMatches` transform to find matching records, teach it how to identify matching and nonmatching records, and use it in an Amazon Glue job. The Amazon Glue job writes a new Amazon S3 file with an additional column named `match_id`.

The source data used by this tutorial is a file named `dblp_acm_records.csv`. This file is a modified version of academic publications (DBLP and ACM) available from the original [DBLP ACM dataset](#). The `dblp_acm_records.csv` file is a comma-separated values (CSV) file in UTF-8 format with no byte-order mark (BOM).

A second file, `dblp_acm_labels.csv`, is an example labeling file that contains both matching and nonmatching records used to teach the transform as part of the tutorial.

Topics

- [Step 1: Crawl the source data](#)
- [Step 2: Add a machine learning transform](#)
- [Step 3: Teach your machine learning transform](#)
- [Step 4: Estimate the quality of your machine learning transform](#)
- [Step 5: Add and run a job with your machine learning transform](#)
- [Step 6: Verify output data from Amazon S3](#)

Step 1: Crawl the source data

First, crawl the source Amazon S3 CSV file to create a corresponding metadata table in the Data Catalog.

Important

To direct the crawler to create a table for only the CSV file, store the CSV source data in a different Amazon S3 folder from other files.

1. Sign in to the Amazon Web Services Management Console and open the Amazon Glue console at <https://console.amazonaws.cn/glue/>.
2. In the navigation pane, choose **Crawlers, Add crawler**.

3. Follow the wizard to create and run a crawler named `demo-crawl-dblp-acm` with output to database `demo-db-dblp-acm`. When running the wizard, create the database `demo-db-dblp-acm` if it doesn't already exist. Choose an Amazon S3 include path to sample data in the current Amazon Region. For example, for `us-east-1`, the Amazon S3 include path to the source file is `s3://ml-transforms-public-datasets-us-east-1/dblp-acm/records/dblp_acm_records.csv`.

If successful, the crawler creates the table `dbl_p_acm_records_csv` with the following columns: `id`, `title`, `authors`, `venue`, `year`, and `source`.

Step 2: Add a machine learning transform

Next, add a machine learning transform that is based on the schema of your data source table created by the crawler named `demo-crawl-dblp-acm`.

1. On the Amazon Glue console, in the navigation pane under **Data Integration and ETL**, choose **Data classification tools > Record Matching**, then **Add transform**. Follow the wizard to create a `Find matches` transform with the following properties.
 - a. For **Transform name**, enter `demo-xform-dblp-acm`. This is the name of the transform that is used to find matches in the source data.
 - b. For **IAM role**, choose an IAM role that has permission to the Amazon S3 source data, labeling file, and Amazon Glue API operations. For more information, see [Create an IAM Role for Amazon Glue](#) in the *Amazon Glue Developer Guide*.
 - c. For **Data source**, choose the table named `dbl_p_acm_records_csv` in database `demo-db-dblp-acm`.
 - d. For **Primary key**, choose the primary key column for the table, `id`.
2. In the wizard, choose **Finish** and return to the **ML transforms** list.

Step 3: Teach your machine learning transform

Next, you teach your machine learning transform using the tutorial sample labeling file.

You can't use a machine language transform in an extract, transform, and load (ETL) job until its status is **Ready for use**. To get your transform ready, you must teach it how to identify matching and nonmatching records by providing examples of matching and nonmatching records. To teach your transform, you can **Generate a label file**, add labels, and then **Upload label file**. In

this tutorial, you can use the example labeling file named `dblp_acm_labels.csv`. For more information about the labeling process, see [Labeling](#).

1. On the Amazon Glue console, in the navigation pane, choose **Record Matching**.
2. Choose the `demo-xform-dblp-acm` transform, and then choose **Action, Teach**. Follow the wizard to teach your `Find matches` transform.
3. On the transform properties page, choose **I have labels**. Choose an Amazon S3 path to the sample labeling file in the current Amazon Region. For example, for `us-east-1`, upload the provided labeling file from the Amazon S3 path `s3://ml-transforms-public-datasets-us-east-1/dblp-acm/labels/dblp_acm_labels.csv` with the option to **overwrite** existing labels. The labeling file must be located in Amazon S3 in the same Region as the Amazon Glue console.

When you upload a labeling file, a task is started in Amazon Glue to add or overwrite the labels used to teach the transform how to process the data source.

4. On the final page of the wizard, choose **Finish**, and return to the **ML transforms** list.

Step 4: Estimate the quality of your machine learning transform

Next, you can estimate the quality of your machine learning transform. The quality depends on how much labeling you have done. For more information about estimating quality, see [Estimate quality](#).

1. On the Amazon Glue console, in the navigation pane under **Data Integration and ETL**, choose **Data classification tools > Record Matching**.
2. Choose the `demo-xform-dblp-acm` transform, and choose the **Estimate quality** tab. This tab displays the current quality estimates, if available, for the transform.
3. Choose **Estimate quality** to start a task to estimate the quality of the transform. The accuracy of the quality estimate is based on the labeling of the source data.
4. Navigate to the **History** tab. In this pane, task runs are listed for the transform, including the **Estimating quality** task. For more details about the run, choose **Logs**. Check that the run status is **Succeeded** when it finishes.

Step 5: Add and run a job with your machine learning transform

In this step, you use your machine learning transform to add and run a job in Amazon Glue. When the transform `demo-xform-dblp-acm` is **Ready for use**, you can use it in an ETL job.

1. On the Amazon Glue console, in the navigation pane, choose **Jobs**.
2. Choose **Add job**, and follow the steps in the wizard to create an ETL Spark job with a generated script. Choose the following property values for your transform:
 - a. For **Name**, choose the example job in this tutorial, **demo-etl-dblp-acm**.
 - b. For **IAM role**, choose an IAM role with permission to the Amazon S3 source data, labeling file, and Amazon Glue API operations. For more information, see [Create an IAM Role for Amazon Glue](#) in the *Amazon Glue Developer Guide*.
 - c. For **ETL language**, choose **Scala**. This is the programming language in the ETL script.
 - d. For **Script file name**, choose **demo-etl-dblp-acm**. This is the file name of the Scala script (same as the job name).
 - e. For **Data source**, choose **dbl_acm_records_csv**. The data source you choose must match the machine learning transform data source schema.
 - f. For **Transform type**, choose **Find matching records** to create a job using a machine learning transform.
 - g. Clear **Remove duplicate records**. You don't want to remove duplicate records because the output records written have an additional `match_id` field added.
 - h. For **Transform**, choose **demo-xform-dblp-acm**, the machine learning transform used by the job.
 - i. For **Create tables in your data target**, choose to create tables with the following properties:
 - **Data store type** — **Amazon S3**
 - **Format** — **CSV**
 - **Compression type** — **None**
 - **Target path** — The Amazon S3 path where the output of the job is written (in the current console Amazon Region)
3. Choose **Save job and edit script** to display the script editor page.

4. Edit the script to add a statement to cause the job output to the **Target path** to be written to a single partition file. Add this statement immediately following the statement that runs the FindMatches transform. The statement is similar to the following.

```
val single_partition = findmatches1.repartition(1)
```

You must modify the `.writeDynamicFrame(findmatches1)` statement to write the output as `.writeDynamicFrame(single_partition)`.

5. After you edit the script, choose **Save**. The modified script looks similar to the following code, but customized for your environment.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.ml.FindMatches
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    // @params: [JOB_NAME]
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    // @type: DataSource
    // @args: [database = "demo-db-dblp-acm", table_name = "dblp_acm_records_csv",
transformation_ctx = "datasource0"]
    // @return: datasource0
    // @inputs: []
    val datasource0 = glueContext.getCatalogSource(database = "demo-db-dblp-acm",
tableName = "dblp_acm_records_csv", redshiftTmpDir = "", transformationContext =
"datasource0").getDynamicFrame()
    // @type: FindMatches
    // @args: [transformId = "tfm-123456789012", emitFusion = false,
survivorComparisonField = "<primary_id>", transformation_ctx = "findmatches1"]
    // @return: findmatches1
    // @inputs: [frame = datasource0]
```

```

val findmatches1 = FindMatches.apply(frame = datasource0, transformId
= "tfm-123456789012", transformationContext = "findmatches1",
computeMatchConfidenceScores = true)

// Repartition the previous DynamicFrame into a single partition.
val single_partition = findmatches1.repartition(1)

// @type: DataSink
// @args: [connection_type = "s3", connection_options = {"path": "s3://aws-
glue-ml-transforms-data/sal"}, format = "csv", transformation_ctx = "datasink2"]
// @return: datasink2
// @inputs: [frame = findmatches1]
val datasink2 = glueContext.getSinkWithFormat(connectionType =
"s3", options = JsonOptions("""{"path": "s3://aws-glue-ml-transforms-
data/sal"}"""), transformationContext = "datasink2", format =
"csv").writeDynamicFrame(single_partition)
  Job.commit()
}
}

```

6. Choose **Run job** to start the job run. Check the status of the job in the jobs list. When the job finishes, in the **ML transform, History** tab, there is a new **Run ID** row added of type **ETL job**.
7. Navigate to the **Jobs, History** tab. In this pane, job runs are listed. For more details about the run, choose **Logs**. Check that the run status is **Succeeded** when it finishes.

Step 6: Verify output data from Amazon S3

In this step, you check the output of the job run in the Amazon S3 bucket that you chose when you added the job. You can download the output file to your local machine and verify that matching records were identified.

1. Open the Amazon S3 console at <https://console.amazonaws.cn/s3/>.
2. Download the target output file of the job demo-etl-db1p-acm. Open the file in a spreadsheet application (you might need to add a file extension `.csv` for the file to properly open).

The following image shows an excerpt of the output in Microsoft Excel.

	B	C	D	E	F	G	H	I

The data source and target file both have 4,911 records. However, the Find matches transform adds another column named `match_id` to identify matching records in the output. Rows with the same `match_id` are considered matching records. The `match_confidence_score` is a number between 0 and 1 that provides an estimate of the quality of matches found by Find matches.

- Sort the output file by `match_id` to easily see which records are matches. Compare the values in the other columns to see if you agree with the results of the Find matches transform. If you don't, you can continue to teach the transform by adding more labels.

You can also sort the file by another field, such as `title`, to see if records with similar titles have the same `match_id`.

Finding incremental matches

The Find matches feature allows you to identify duplicate or matching records in your dataset, even when the records don't have a common unique identifier and no fields match exactly. The initial release of the Find matches transform identified matching records within a single dataset. When you add new data to the dataset, you had to merge it with the existing clean dataset and rerun matching against the complete merged dataset.

The incremental matching feature makes it simpler to match to incremental records against existing matched datasets. Suppose that you want to match prospects data with existing customer datasets. The incremental match capability provides you the flexibility to match hundreds of thousands of new prospects with an existing database of prospects and customers by merging the results into a single database or table. By matching only between the new and existing datasets, the find incremental matches optimization reduces computation time, which also reduces cost.

The usage of incremental matching is similar to Find matches as described in [Tutorial: Creating a machine learning transform with Amazon Glue](#). This topic identifies only the differences with incremental matching.

For more information, see the blog post on [Incremental data matching](#).

Running an incremental matching job

For the following procedure, suppose the following:

- You have crawled the existing dataset into the table *first_records*. The *first_records* dataset must be a matched dataset, or the output of the matched job.
 - You have created and trained a Find matches transform with Amazon Glue version 2.0. This is the only version of Amazon Glue that supports incremental matches.
 - The ETL language is Scala. Note that Python is also supported.
 - The model already generated is called `demo-xform`.
1. Crawl the incremental dataset to the table *second_records*.
 2. On the Amazon Glue console, in the navigation pane, choose **Jobs**.
 3. Choose **Add job**, and follow the steps in the wizard to create an ETL Spark job with a generated script. Choose the following property values for your transform:
 - a. For **Name**, choose **demo-etl**.
 - b. For **IAM role**, choose an IAM role with permission to the Amazon S3 source data, labeling file, and [Amazon Glue API operations](#).
 - c. For **ETL language**, choose **Scala**.
 - d. For **Script file name**, choose **demo-etl**. This is the file name of the Scala script.
 - e. For **Data source**, choose **first_records**. The data source you choose must match the machine learning transform data source schema.
 - f. For **Transform type**, choose **Find matching records** to create a job using a machine learning transform.
 - g. Select the incremental matching option, and for **Data Source** select the table named **second_records**.
 - h. For **Transform**, choose **demo-xform**, the machine learning transform used by the job.
 - i. Choose **Create tables in your data target** or **Use tables in the data catalog and update your data target**.

4. Choose **Save job and edit script** to display the script editor page.
5. Choose **Run job** to start the job run.

Using FindMatches in a visual job

To use the **FindMatches** transform in Amazon Glue Studio, you can use the **Custom Transform** node that invokes the FindMatches API. For more information on how to use a custom transform, see [Creating a custom transformation](#)

Note

Currently, the FindMatches API only works with Glue 2.0. In order to run a job with the Custom transform that invokes the FindMatches API, ensure the Amazon Glue version is Glue 2.0 in the **Job details** tab. If the version of Amazon Glue is not Glue 2.0, the job will fail at runtime with the following error message: "cannot import name 'FindMatches' from 'awsglueml.transforms'".

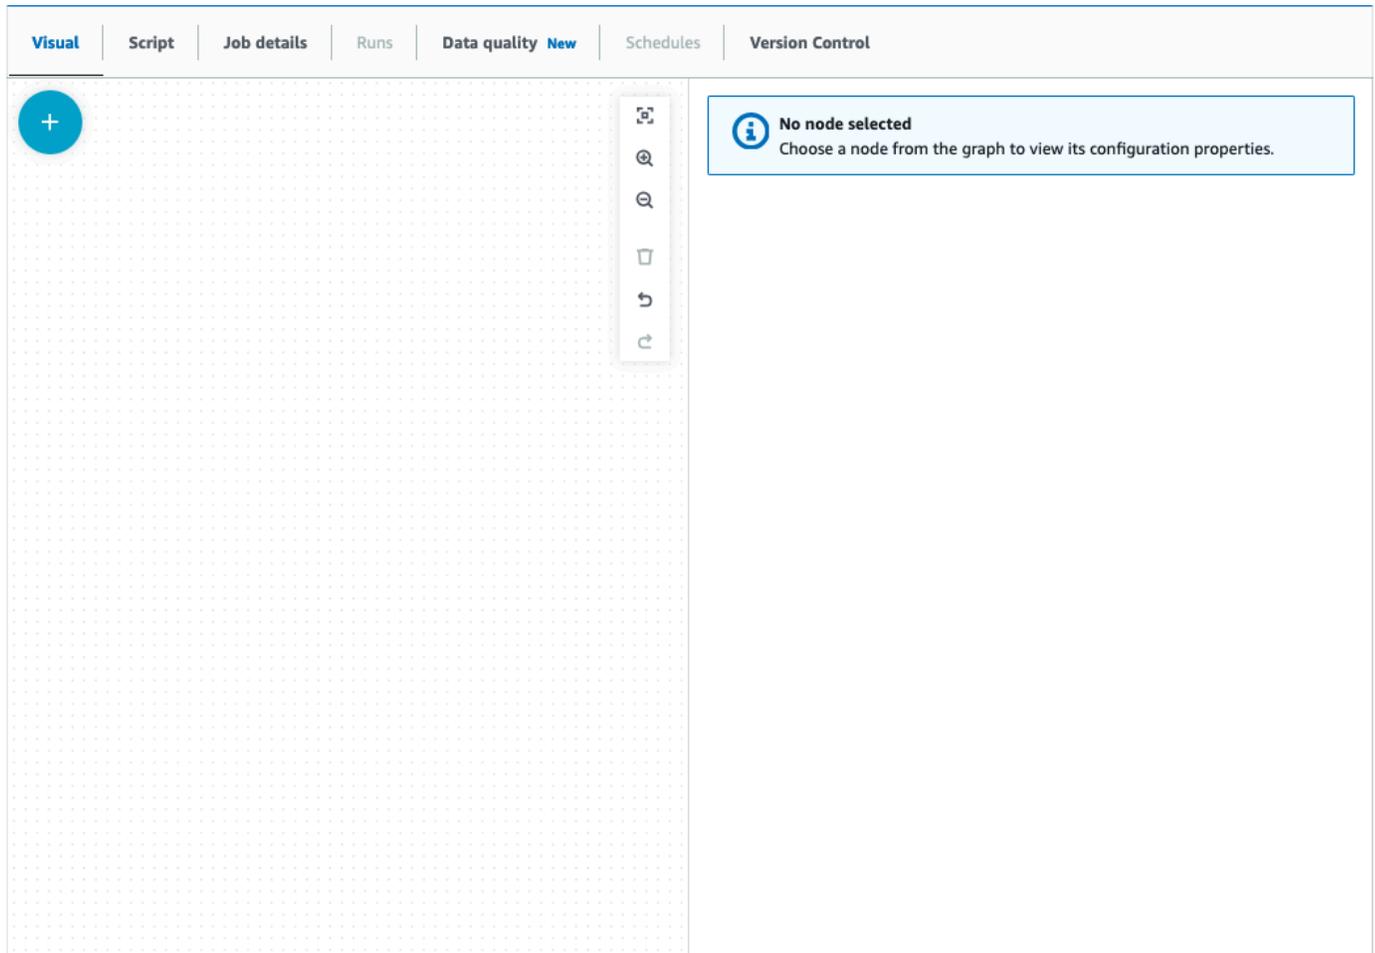

Prerequisites

- In order to use the **Find Matches** transform, open the Amazon Glue Studio console at <https://console.aws.amazon.com/gluestudio/>.
- Create a machine learning transform. When created, a transformId is generated. You will need this ID for the steps below. For more information on how to create a machine learning transform, see [Adding and editing machine learning transforms](#).

Adding a FindMatches transform

To add a FindMatches transform:

1. In the Amazon Glue Studio job editor, open the Resource panel by clicking on the cross symbol in the upper left-hand corner of the visual job graph and choose a Data source by choosing the **Data tab**. This is the data source you want to check for matches.

2. Choose the data source node, then open the Resource panel by clicking on the cross symbol in the upper left-hand corner of the visual job graph and search for 'custom transform'. Choose the **Custom Transform** node to add it to the graph. The **Custom Transform** is linked to the data source node. If it is not, you can click on the **Custom Transform** node and choose the **Node properties** tab, then under **Node parents**, choose the data source.
3. Click the **Custom Transform** node in the visual graph, then choose the **Node properties** tab and name the custom transform. It is recommended that you rename the transform so that the transform name is easily identifiable in the visual graph.
4. Choose the **Transform** tab, where you can edit the code block. This is where the code to invoke the FindMatches API can be added.

The screenshot displays the Amazon Glue console interface. At the top, there are navigation tabs: Visual, Script, Job details, Runs, Data quality New, Schedules, and Version Control. The 'Visual' tab is active, showing a job graph with two nodes: 'Data source - S3 bucket Amazon S3' and 'Transform - Custom code ml transform'. A blue arrow points from the data source to the transform node. To the right of the graph is a 'Code block' editor with the following content:

```

Node properties | Transform | Output schema | Data preview

Code block Info
Enter a custom script to add to your job.

1 - def MyTransform (glueContext, dfc) -> DynamicFrameCollection:
2

```

The code block contains pre-populated code to get you started. Overwrite the pre-populated code with the template below. The template has a placeholder for the **transformId**, which you can provide.

```

def MyTransform (glueContext, dfc) -> DynamicFrameCollection:
    dynf = dfc.select(list(dfc.keys())[0])
    from awsglueml.transforms import FindMatches
    findmatches = FindMatches.apply(frame = dynf, transformId = "<your id>")
    return(DynamicFrameCollection({"FindMatches": findmatches}, glueContext))

```

5. Click the **Custom Transform** node in the visual graph, then open the Resource panel by clicking on the cross symbol in the upper left-hand corner of the visual job graph and search for 'Select From Collection'. There is no need to change the default selection since there is only one DynamicFrame in the collection.

6. You can continue adding transformations or store the result, which is now enriched with the find matches additional columns. If you want to reference those new columns in downstream transforms, you need to add them to the transform output schema. the easiest way to do that is to choose the **Data preview** tab and then in the schema tab choose "Use datapreview schema".
7. To customize FindMatches, you can add additional parameters to pass to the 'apply' method. See [FindMatches class](#).

Adding a FindMatches incrementally transformation

In the case of incremental matches, the process is the same as **Adding a FindMatches transformation** with the following differences:

- Instead of a parent node for the custom transform, you need two parent nodes.
- The first parent node should be the dataset.
- The second parent node should be the incremental dataset.

Replace the `transformId` with your `transformId` in the template code block:

```
def MyTransform (glueContext, dfc) -> DynamicFrameCollection:
    dfs = list(dfc.values())
    dynf = dfs[0]
    inc_dynf = dfs[1]
    from awsglueml.transforms import FindIncrementalMatches
    findmatches = FindIncrementalMatches.apply(existingFrame = dynf, incrementalFrame
    = inc_dynf,
                                             transformId = "<your id>")
    return(DynamicFrameCollection({"FindMatches": findmatches}, glueContext))
```

- For optional parameters, see [FindIncrementalMatches class](#).

Migrate Apache Spark programs to Amazon Glue

Apache Spark is an open-source platform for distributed computing workloads performed on large datasets. Amazon Glue leverages Spark's capabilities to provide an optimized experience for ETL. You can migrate Spark programs to Amazon Glue to take advantage of our features. Amazon Glue

provides the same performance enhancements you would expect from Apache Spark on Amazon EMR.

Run Spark code

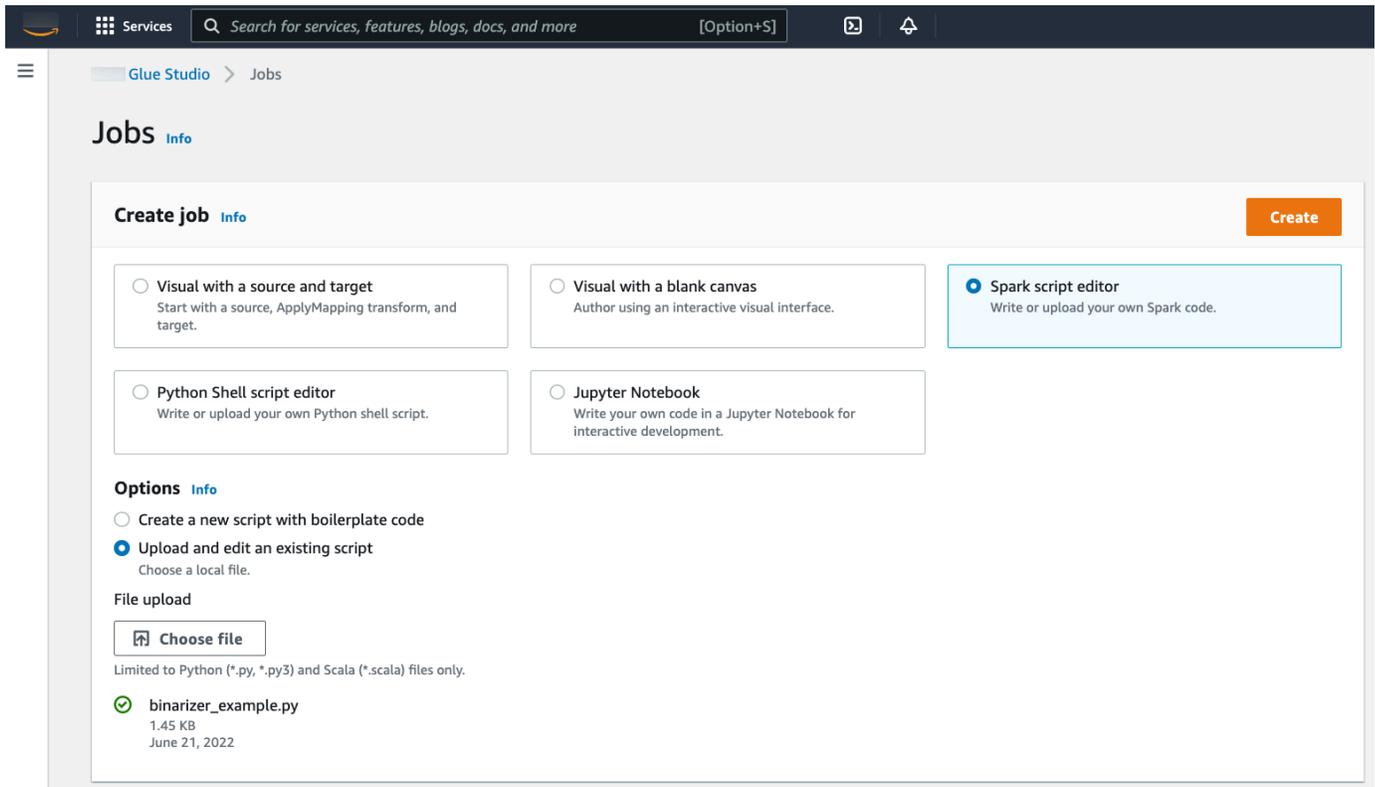

Native Spark code can be run in a Amazon Glue environment out of the box. Scripts are often developed by iteratively changing a piece of code, a workflow suited for an Interactive Session. However, existing code is more suited to run in a Amazon Glue job, which allows you to schedule and consistently get logs and metrics for each script run. You can upload and edit an existing script through the console.

1. Acquire the source to your script. For this example, you will use an example script from the Apache Spark repository. [Binarizer Example](#)
2. In the Amazon Glue Console, expand the left-side navigation pane and select **ETL > Jobs**

In the **Create job** panel, select **Spark script editor**. An **Options** section will appear. Under **Options**, select **Upload and edit an existing script**.

A **File upload** section will appear. Under **File upload**, click **Choose file**. Your system file chooser will appear. Navigate to the location where you saved `binarizer_example.py`, select it and confirm your selection.

A **Create** button will appear on the header for the **Create job** panel. Click it.

The screenshot shows the Amazon Glue Studio interface. At the top, there is a navigation bar with the Amazon logo, a 'Services' menu, a search bar containing 'Search for services, features, blogs, docs, and more', and a keyboard shortcut '[Option+S]'. Below the navigation bar, the breadcrumb 'Glue Studio > Jobs' is visible. The main content area is titled 'Jobs Info' and features a 'Create job Info' section with an orange 'Create' button. There are five radio button options for creating a job:

- Visual with a source and target: Start with a source, ApplyMapping transform, and target.
- Visual with a blank canvas: Author using an interactive visual interface.
- Spark script editor: Write or upload your own Spark code.
- Python Shell script editor: Write or upload your own Python shell script.
- Jupyter Notebook: Write your own code in a Jupyter Notebook for interactive development.

Below these options is an 'Options Info' section with two radio button options:

- Create a new script with boilerplate code
- Upload and edit an existing script: Choose a local file.

Under the 'Upload and edit an existing script' option, there is a 'File upload' section with a 'Choose file' button. Below the button, it states 'Limited to Python (*.py, *.py3) and Scala (*.scala) files only.' A file named 'binarizer_example.py' is listed with a green checkmark, a size of 1.45 KB, and a date of June 21, 2022.

3. Your browser will navigate to the script editor. On the header, click the **Job details** tab. Set the **Name** and **IAM Role**. For guidance around Amazon Glue IAM roles, consult [the section called “Setting up IAM permissions”](#).

Optionally - set **Requested number of workers** to 2 and **Number of retries** to 1. These options are valuable when running production jobs, but turning them down will streamline your experience while testing out a feature.

In the title bar, click **Save**, then **Run**

The screenshot shows the Amazon Glue console interface. At the top, there is a navigation bar with the Amazon logo, a 'Services' menu, a search bar with the placeholder text 'Search for services, features, blogs, docs, and more', and a keyboard shortcut '[Option+S]'. Below the navigation bar, the main content area is titled 'Binarizer Example' and includes a 'Save' button, a 'Delete' button, an 'Actions' dropdown menu, and a 'Run' button. The 'Job details' tab is selected, showing a 'Basic properties' section with the following fields:

- Name:** Binarizer Example
- Description - optional:** (Empty text area with a note: 'Descriptions can be up to 2048 characters long.')
- IAM Role:** AWSGlueServiceRole (with a refresh button)
- Type:** Spark (with a note: 'The type of ETL job. This is set automatically based on the types of data sources you have selected.')
- Glue version:** Glue 3.0 - Supports spark 3.1, Scala 2, Python 3

4. Navigate to the **Runs** tab. You will see a panel corresponding to your job run. Wait a few minutes and the page should automatically refresh to show **Succeeded** under **Run status**.

Binarizer Example Last modified on 7/13/2022, 12:24:55 PM Save Delete Actions Run

Script | Job details | **Runs** | Schedules

Recent job runs (1) [Info](#) Refresh

< 1 >

July 13, 2022 12:24:58 PM Rewind job bookmark

Job name	Id	Run status	Glue version

Retry attempt number	Start time	End time	Start-up time
Initial run	July 13, 2022 12:24:58 PM	July 13, 2022 12:25:36 PM	7 seconds
Execution time	Last modified on	Trigger name	Security configuration
30 seconds	July 13, 2022 12:25:36 PM	-	-
Timeout	Max capacity	Number of workers	Worker type
2880 minutes	2 DPUs	2	G.1X
Execution class	Log group name	Cloudwatch logs	Performance and debugging recommendations
-	/aws-glue/jobs	<ul style="list-style-type: none"> All logs ↗ Output logs ↗ Error logs ↗ 	<ul style="list-style-type: none"> View in CloudWatch ↗

▶ **Input arguments (10)**
Arguments used when this job run was executed.

- You will want to examine your output to confirm that the Spark script ran as intended. This Apache Spark sample script should write a string to the output stream. You can find that by navigating to **Output logs** under **Cloudwatch logs** in the panel for the successful job run. Note the job run id, a generated id under the **Id** label beginning with jr_.

This will open the CloudWatch console, set to visualize the contents of the default Amazon Glue log group `/aws-glue/jobs/output`, filtered to the contents of the log streams for the job run id. Each worker will have generated a log stream, shown as rows under the **Log streams**. One worker should have run the requested code. You will need to open all the log streams to identify the correct worker. Once you find the right worker, you should see the output of the script, as seen in the following image:

The screenshot shows the Amazon CloudWatch console interface. The breadcrumb navigation indicates the path: CloudWatch > Log groups > /aws-glue/jobs/output > jr_EXAMPLEID. The main content area displays 'Log events' for this log group. It includes a search bar with the placeholder 'Filter events', a 'View as text' checkbox, and a 'Create Metric Filter' button. Below the search bar is a table with two columns: 'Timestamp' and 'Message'. The table contains three log entries:

Timestamp	Message
2022-07-13T13:27:33.060-07:00	2022-07-13 20:27:33,058 main WARN JNDI lookup class is not available because...
2022-07-13T13:27:33.062-07:00	2022-07-13 20:27:33,062 main INFO Log4j appears to be running in a Servlet e...
2022-07-13T13:27:54.066-07:00	Binarizer output with Threshold = 0.500000 Binarizer output with Threshold = 0.500000

The third log entry is expanded to show a table of binarized features:

```

+-----+-----+-----+-----+-----+
| id|feature|binarized_feature|
+-----+-----+-----+-----+
| 0| 0.1| 0.0|
| 1| 0.8| 1.0|
| 2| 0.2| 0.0|
+-----+-----+-----+-----+

```

At the bottom of the log events list, it states: 'No newer events at this moment. Auto retry paused. Resume'.

Common procedures needed for migrating Spark programs

Assess Spark version support

Amazon Glue release versions define the version of Apache Spark and Python available to the Amazon Glue job. You can find our Amazon Glue versions and what they support at [the section called "Amazon Glue versions"](#). You may need to update your Spark program to be compatible with a newer version of Spark in order to access certain Amazon Glue features.

Include third-party libraries

Many existing Spark programs will have dependencies, both on private and public artifacts. Amazon Glue supports JAR style dependencies for Scala Jobs as well as Wheel and source pure-Python dependencies for Python jobs.

Python - For information about Python dependencies, see [the section called "Python libraries"](#)

Common Python dependencies are provided in the Amazon Glue environment, including the commonly requested [Pandas](#) library. Dependencies are included in Amazon Glue Version 2.0+. For more information about provided modules, see [the section called "Python modules already"](#)

[provided in Amazon Glue](#)". If you need to supply a Job with a different version of a dependency included by default, you can use `--additional-python-modules`. For information about job arguments, see [the section called "Job parameters"](#).

You can supply additional Python dependencies with the `--extra-py-files` job argument. If you are migrating a job from a Spark program, this parameter is a good option because it is functionally equivalent to the `--py-files` flag in PySpark, and is subject to the same limitations. For more information about the `--extra-py-files` parameter, see [the section called "Including Python files with PySpark native features"](#)

For new jobs, you can manage Python dependencies with the `--additional-python-modules` job argument. Using this argument allows for a more thorough dependency management experience. This parameter supports Wheel style dependencies, including those with native code bindings compatible with Amazon Linux 2.

Scala

You can supply additional Scala dependencies with the `--extra-jars` Job Argument. Dependencies must be hosted in Amazon S3 and the argument value should be a comma delimited list of Amazon S3 paths with no spaces. You may find it easier to manage your configuration by rebundling your dependencies before hosting and configuring them. Amazon Glue JAR dependencies contain Java bytecode, which can be generated from any JVM language. You can use other JVM languages, such as Java, to write custom dependencies.

Manage data source credentials

Existing Spark programs may come with complex or custom configuration to pull data from their datasources. Common datasource auth flows are supported by Amazon Glue connections. For more information about Amazon Glue connections, see [Connecting to data](#).

Amazon Glue connections facilitate connecting your Job to a variety of types of data stores in two primary ways: through method calls to our libraries and setting the **Additional network connection** in the Amazon Web Services console. You may also call the Amazon SDK from within your job to retrieve information from a connection.

Method calls – Amazon Glue Connections are tightly integrated with the Amazon Glue Data Catalog, a service that allows you to curate information about your datasets, and the methods available to interact with Amazon Glue connections reflect that. If you have an existing auth configuration you would like to reuse, for JDBC connections, you can access your Amazon Glue

connection configuration through the `extract_jdbc_conf` method on the `GlueContext`. For more information, see [the section called “extract_jdbc_conf”](#)

Console configuration – Amazon Glue Jobs use associated Amazon Glue connections to configure connections to Amazon VPC subnets. If you directly manage your security materials, you may need to provide a NETWORK type **Additional network connection** in the Amazon Web Services console to configure routing. For more information about the Amazon Glue connection API, see [the section called “Connections”](#)

If your Spark programs has a custom or uncommon auth flow, you may need to manage your security materials in a hands-on fashion. If Amazon Glue connections do not seem like a good fit, you can securely host security materials in Secrets Manager and access them through the boto3 or Amazon SDK, which are provided in the job.

Configure Apache Spark

Complex migrations often alter Spark configuration to accommodate their workloads. Modern versions of Apache Spark allow runtime configuration to be set with the `SparkSession`. Amazon Glue 3.0+ Jobs are provided a `SparkSession`, which can be modified to set runtime configuration. [Apache Spark Configuration](#). Tuning Spark is complex, and Amazon Glue does not guarantee support for setting all Spark configuration. If your migration requires substantial Spark-level configuration, contact support.

Set custom configuration

Migrated Spark programs may be designed to take custom configuration. Amazon Glue allows configuration to be set on the job and job run level, through the job arguments. For information about job arguments, see [the section called “Job parameters”](#). You can access job arguments within the context of a job through our libraries. Amazon Glue provides a utility function to provide a consistent view between arguments set on the job and arguments set on the job run. See [the section called “getResolvedOptions”](#) in Python and [the section called “GlueArgParser”](#) in Scala.

Migrate Java code

As explained in [the section called “Third-party libraries”](#), your dependencies can contain classes generated by JVM languages, such as Java or Scala. Your dependencies can include a `main` method. You can use a `main` method in a dependency as the entrypoint for a Amazon Glue Scala job. This allows you to write your `main` method in Java, or reuse a `main` method packaged to your own library standards.

To use a main method from a dependency, perform the following: Clear the contents of the editing pane providing the default GlueApp object. Provide the fully qualified name of a class in a dependency as a job argument with the key `--class`. You should then be able to trigger a Job run.

You cannot configure the order or structure of the arguments Amazon Glue passes to the main method. If your existing code needs to read configuration set in Amazon Glue, this will likely cause incompatibility with prior code. If you use `getResolvedOptions`, you will also not have a good place to call this method. Consider invoking your dependency directly from a main method generated by Amazon Glue. The following Amazon Glue ETL script shows an example of this.

```
import com.amazonaws.services.glue.util.GlueArgParser

object GlueApp {
  def main(sysArgs: Array[String]) {
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)

    // Invoke static method from JAR. Pass some sample arguments as a String[], one
    // defined inline and one taken from the job arguments, using getResolvedOptions
    com.mycompany.myproject.MyClass.myStaticPublicMethod(Array("string parameter1",
    args("JOB_NAME")))

    // Alternatively, invoke a non-static public method.
    (new com.mycompany.myproject.MyClass).someMethod()
  }
}
```

Working with Ray jobs in Amazon Glue

This section provides information about using Amazon Glue for Ray jobs. For more information about writing Amazon Glue for Ray scripts, consult the [the section called “Amazon Glue for Ray”](#) section.

Topics

- [Getting started with Amazon Glue for Ray](#)
- [Supported Ray runtime environments](#)
- [Accounting for workers in Ray jobs](#)
- [Using job parameters in Ray jobs](#)
- [Monitoring Ray jobs with metrics](#)

Getting started with Amazon Glue for Ray

To work with Amazon Glue for Ray, you use the same Amazon Glue jobs and interactive sessions that you use with Amazon Glue for Spark. Amazon Glue jobs are designed for running the same script on a recurring cadence, while interactive sessions are designed to let you run snippets of code sequentially against the same provisioned resources.

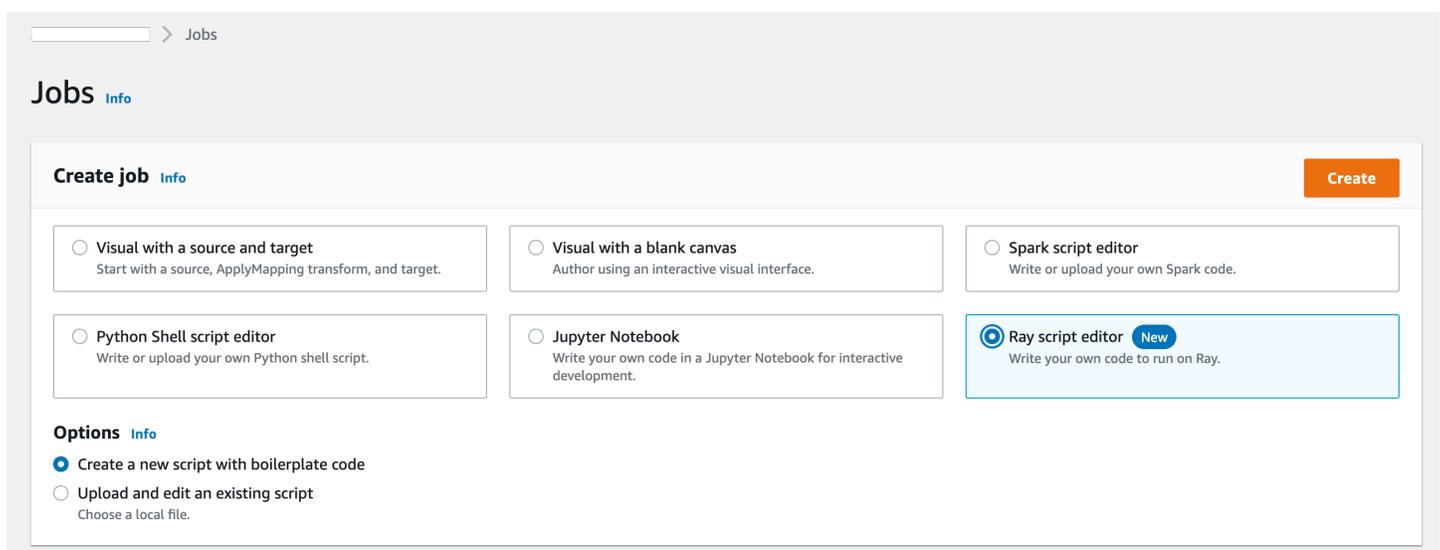

Amazon Glue ETL and Ray are different underneath, so in your script, you have access to different tools, features, and configuration. As a new computation framework managed by Amazon Glue, Ray has a different architecture and uses different vocabulary to describe what it does. For more information, see [Architecture Whitepapers](#) in the Ray documentation.

Note

Amazon Glue for Ray is available in US East (N. Virginia), US East (Ohio), US West (Oregon), Asia Pacific (Tokyo), and Europe (Ireland).

Ray jobs in the Amazon Glue Studio console

On the **Jobs** page in the Amazon Glue Studio console, you can select a new option when you're creating a job in Amazon Glue Studio—**Ray script editor**. Choose this option to create a Ray job in the console. For more information about jobs and how they're used, see [Building visual ETL jobs](#).

The screenshot shows the 'Jobs' page in the Amazon Glue Studio console. At the top, there is a breadcrumb 'Jobs' and a 'Create job' button. Below this, there are six options for creating a job, each with a radio button and a description:

- Visual with a source and target
Start with a source, ApplyMapping transform, and target.
- Visual with a blank canvas
Author using an interactive visual interface.
- Spark script editor
Write or upload your own Spark code.
- Python Shell script editor
Write or upload your own Python shell script.
- Jupyter Notebook
Write your own code in a Jupyter Notebook for interactive development.
- Ray script editor **New**
Write your own code to run on Ray.

Below the job creation options, there is an 'Options' section with two radio buttons:

- Create a new script with boilerplate code
- Upload and edit an existing script
Choose a local file.

Ray jobs in the Amazon CLI and SDK

Ray jobs in the Amazon CLI use the same SDK actions and parameters as other jobs. Amazon Glue for Ray introduces new values for certain parameters. For more information in the Jobs API, see [the section called “Jobs”](#).

Supported Ray runtime environments

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python available in an Amazon Glue for Spark job. The Python version indicates the version that is supported for jobs of type Spark. This is not how Ray runtime environments are configured.

For Ray jobs, you should set `GlueVersion` to `4.0` or greater. However, the versions of Ray, Python, and additional libraries that are available in your Ray job are determined by the `Runtime` field in the job definition.

The `Ray2.4` runtime environment will be available for a minimum of 6 months after release. As Ray rapidly evolves, you will be able to incorporate Ray updates and improvements through future runtime environment releases.

Valid values: `Ray2.4`

Runtime value	Ray and Python versions
<code>Ray2.4</code> (for Amazon Glue 4.0+)	Ray 2.4.0 Python 3.9

Additional information

- For release notes that accompany Amazon Glue on Ray releases, see [the section called “Amazon Glue versions”](#).
- For Python libraries that are provided in a runtime environment, see [the section called “Modules provided with Ray jobs”](#).

Accounting for workers in Ray jobs

Amazon Glue runs Ray jobs on new Graviton-based EC2 worker types, which are only available for Ray jobs. To appropriately provision these workers for the workloads Ray is designed for, we provide a different ratio of compute resources to memory resources from most workers. In order to account for these resources, we use the memory-optimized data processing unit (M-DPU) rather than the standard data processing unit (DPU).

- One M-DPU corresponds to 4 vCPUs and 32 GB of memory.
- One DPU corresponds to 4 vCPUs and 16 GB of memory. DPUs are used to account for resources in Amazon Glue with Spark jobs and corresponding workers.

Ray jobs currently have access to one worker type, Z.2X. The Z.2X worker maps to 2 M-DPUs (8 vCPUs, 64 GB of memory) and has 128 GB of disk space. A Z.2X machine provides 8 Ray workers (one per vCPU).

The number of M-DPUs that you can use concurrently in an account is subject to a service quota. For more information about your Amazon Glue account limits, see [Amazon Glue endpoints and quotas](#).

You specify the number of worker nodes that are available to a Ray job with `--number-of-workers` (`NumberOfWorkers`) in the job definition. For more information about Ray values in the Jobs API, see [the section called "Jobs"](#).

You can further specify a minimum number of workers that a Ray job must allocate with the `--min-workers` job parameter. For more information about job parameters, see [the section called "Reference"](#).

Using job parameters in Ray jobs

You set arguments for Amazon Glue Ray jobs the same way you set arguments for Amazon Glue for Spark jobs. For more information about the Amazon Glue API, see [the section called "Jobs"](#). You can configure Amazon Glue Ray jobs with different arguments, which are listed in this reference. You can also provide your own arguments.

You can configure a job through the console, on the **Job details** tab, under the **Job Parameters** heading. You can also configure a job through the Amazon CLI by setting `DefaultArguments` on a job, or setting `Arguments` on a job run. Default arguments and job parameters stay with the job through multiple runs.

For example, the following is the syntax for running a job using `--arguments` to set a special parameter.

```
$ aws glue start-job-run --job-name "CSV to CSV" --arguments='--scriptLocation="s3://my_glue/libraries/test_lib.py",--test-environment="true"'
```

After you set the arguments, you can access job parameters from within your Ray job through environment variables. This gives you a way to configure your job for each run. The name of the environment variable will be the job argument name without the `--` prefix.

For instance, in the previous example, the variable names would be `scriptLocation` and `test-environment`. You would then retrieve the argument through methods available in the standard library: `test_environment = os.environ.get('test-environment')`. For more information about accessing environment variables with Python, see [os module](#) in the Python documentation.

Configure how Ray jobs generate logs

By default, Ray jobs generate logs and metrics that are sent to CloudWatch and Amazon S3. You can use the `--logging_configuration` parameter to alter how logs are generated, currently you can use it to stop Ray jobs from generating various types of logs. This parameter takes a JSON object, whose keys correspond to the logs/behaviors you would like to alter. It supports the following keys:

- `CLOUDWATCH_METRICS` – Configures CloudWatch metrics series that can be used to visualize job health. For more information about metrics, see [the section called “Ray job metrics”](#).
- `CLOUDWATCH_LOGS` – Configures CloudWatch logs that provide Ray application level details about the status the job run. For more information about logs, see [the section called “Troubleshooting Ray errors”](#).
- `S3` – Configures what Amazon Glue writes to Amazon S3, primarily similar information to CloudWatch logs but as files rather than log streams.

To disable a Ray logging behavior, provide the value `{"IS_ENABLED": "False"}`. For example, to disable CloudWatch metrics and CloudWatch logs, provide the following configuration:

```
"--logging_configuration": "{\"CLOUDWATCH_METRICS\": {\"IS_ENABLED\": \"False\"},  
  \"CLOUDWATCH_LOGS\": {\"IS_ENABLED\": \"False\"}}"
```

Reference

Ray jobs recognize the following argument names that you can use to set up the script environment for your Ray jobs and job runs:

- `--logging_configuration` – Used to stop the generation of various logs created by Ray jobs. These logs are generated by default on all Ray jobs. Format: String-escaped JSON object. For more information, see [the section called “Configure how Ray jobs generate logs”](#).
- `--min-workers` – The minimum number of worker nodes that are allocated to a Ray job. A worker node can run multiple replicas, one per virtual CPU. Format: integer. Minimum: 0. Maximum: value specified in `--number-of-workers` (`NumberOfWorkers`) on the job definition. For more information about accounting for worker nodes, see [the section called “Accounting for workers in Ray jobs”](#).
- `--object_spilling_config` – Amazon Glue for Ray supports using Amazon S3 as a way of extending the space available to Ray's object store. To enable this behavior, you can provide Ray an *object_spilling* JSON config object with this parameter. For more information about Ray object spilling configuration, see [Object Spilling](#) in the Ray documentation. Format: JSON object.

Amazon Glue for Ray only supports spilling to disk or spilling to Amazon S3 at once. You can provide multiple locations for spilling, as long as they respect this limitation. When spilling to Amazon S3, you will also need to add IAM permissions to your job for this bucket.

When providing a JSON object as configuration with the CLI, you must provide it as a string, with the JSON object string-escaped. For example, a string value for spilling to one Amazon S3 path would look like: `"{"type": "smart_open", "params": {"uri": "s3path"}}`". In Amazon Glue Studio, provide this parameter as a JSON object with no extra formatting.

- `--object_store_memory_head` – The memory allocated to the Plasma object store on the Ray head node. This instance runs cluster management services, as well as worker replicas. The value represents a percentage of free memory on the instance after a warm start. You use this parameter to tune memory intensive workloads—defaults are acceptable for most use cases. Format: positive integer. Minimum: 1. Maximum: 100.

For more information about Plasma, see [The Plasma In-Memory Object Store](#) in the Ray documentation.

- `--object_store_memory_worker` – The memory allocated to the Plasma object store on the Ray worker nodes. These instances only run worker replicas. The value represents a percentage

of free memory on the instance after a warm start. This parameter is used to tune memory intensive workloads—defaults are acceptable for most use cases. Format: positive integer. Minimum: 1. Maximum: 100.

For more information about Plasma, see [The Plasma In-Memory Object Store](#) in the Ray documentation.

- `--pip-install` – A set of Python packages to be installed. You can install packages from PyPI using this argument. Format: comma-delimited list.

A PyPI package entry is in the format `package==version`, with the PyPI name and version of your target package. Entries use Python version matching to match the package and version, such as `==`, not the single equals `=`. There are other version-matching operators. For more information, see [PEP 440](#) on the Python website. You can also provide custom modules with `--s3-py-modules`.

- `--s3-py-modules` – A set of Amazon S3 paths that host Python module distributions. Format: comma-delimited list.

You can use this to distribute your own modules to your Ray job. You can also provide modules from PyPI with `--pip-install`. Unlike with Amazon Glue ETL, custom modules are not set up through pip, but are passed to Ray for distribution. For more information, see [the section called “Additional Python modules for Ray jobs”](#).

- `--working-dir` – A path to a .zip file hosted in Amazon S3 that contains files to be distributed to all nodes running your Ray job. Format: string. For more information, see [the section called “Providing files to your Ray job”](#).

Monitoring Ray jobs with metrics

You can monitor Ray jobs using Amazon Glue Studio and Amazon CloudWatch. CloudWatch collects and processes raw metrics from Amazon Glue with Ray, which makes them available for analysis. These metrics are visualized in the Amazon Glue Studio console, so you can monitor your job as it runs.

For a general overview of how to monitor Amazon Glue, see [the section called “Using CloudWatch metrics”](#). For a general overview of how to use CloudWatch metrics that are published by Amazon Glue, see [the section called “Monitoring with CloudWatch”](#).

Monitoring Ray jobs in the Amazon Glue console

On the details page for a job run, below the **Run details** section, you can view pre-built aggregated graphs that visualize your available job metrics. Amazon Glue Studio sends job metrics to CloudWatch for every job run. With these, you can build a profile of your cluster and tasks, as well as access detailed information about each node.

For more information about available metrics graphs, see [the section called "Viewing Amazon CloudWatch metrics for a Ray job run"](#).

Overview of Ray jobs metrics in CloudWatch

We publish Ray metrics when detailed monitoring is enabled in CloudWatch. Metrics are published to the Glue/Ray CloudWatch namespace.

- **Instance metrics**

We publish metrics about the CPU, memory and disk utilization of instances assigned to a job. These metrics are identified by features such as `ExecutorId`, `ExecutorType` and `host`. These metrics are a subset of the standard Linux CloudWatch agent metrics. You can find information about metric names and features in the CloudWatch documentation. For more information, see [Metrics collected by the CloudWatch agent](#).

- **Ray cluster metrics**

We forward metrics from the Ray processes that run your script to this namespace, then provide those most critical for you. The metrics that are available might differ by Ray version. For more information about which Ray version your job is running, see [the section called "Amazon Glue versions"](#).

Ray collects metrics at the instance level. It also provides metrics for tasks and the cluster. For more information about Ray's underlying metric strategy, see [Metrics](#) in the Ray documentation.

Note

We don't publish Ray metrics to the `Glue/Job Metrics/` namespace, which is only used for Amazon Glue ETL jobs.

Configuring job properties for Python shell jobs in Amazon Glue

You can use a Python shell job to run Python scripts as a shell in Amazon Glue. With a Python shell job, you can run scripts that are compatible with Python 3.6 or Python 3.9.

Note

Support for Pyshell v3.6 will end on March 1, 2026. To migrate your workloads, see [Migrate from Amazon Glue Python shell jobs](#). If you wish to continue with Python shell v3.9 see [Migrating from Python shell 3.6 to Python shell 3.9](#).

Topics

- [Limitations](#)
- [Execution environment](#)
- [Defining job properties for Python shell jobs](#)
- [Supported libraries for Python shell jobs](#)
- [Providing your own Python library](#)
- [Use Amazon CloudFormation with Python shell jobs in Amazon Glue](#)
- [Migrating from Python shell 3.6 to Python shell 3.9](#)
- [Migrate from Amazon Glue Python shell jobs](#)

Limitations

Note the following limitations of Python Shell jobs:

- You can't use job bookmarks with Python shell jobs.
- You can't package any Python libraries as .egg files in Python 3.9+. Instead, use .whl.
- The `--extra-files` option cannot be used, because of a limitation on temporary copies of S3 data.

Execution environment

Python shell jobs run in a managed execution environment that provides access to local storage for temporary data processing:

Local temporary storage

The `/tmp` directory is available for temporary storage during job execution. This directory provides approximately 14 GiB of free space that you can use for:

- Temporary file processing
- Intermediate data storage
- Caching small datasets

Note

The `/tmp` directory is ephemeral and is cleaned up after job completion. Do not use it for persistent storage of important data.

Defining job properties for Python shell jobs

These sections describe defining job properties in Amazon Glue Studio, or using the Amazon CLI.

Amazon Glue Studio

When you define your Python shell job in Amazon Glue Studio, you provide some of the following properties:

IAM role

Specify the Amazon Identity and Access Management (IAM) role that is used for authorization to resources that are used to run the job and access data stores. For more information about permissions for running jobs in Amazon Glue, see [Identity and access management for Amazon Glue](#).

Type

Choose **Python shell** to run a Python script with the job command named `pythonshell`.

Python version

Choose the Python version. The default is Python 3.9. Valid versions are Python 3.6 and Python 3.9.

Load common analytics libraries (Recommended)

Choose this option to include common libraries for Python 3.9 in the Python shell.

If your libraries are either custom or they conflict with the pre-installed ones, you can choose not to install common libraries. However, you can install additional libraries besides the common libraries.

When you select this option, the `library-set` option is set to `analytics`. When you de-select this option, the `library-set` option is set to `none`.

Script filename and Script path

The code in the script defines your job's procedural logic. You provide the script name and location in Amazon Simple Storage Service (Amazon S3). Confirm that there isn't a file with the same name as the script directory in the path. To learn more about using scripts, see [Amazon Glue programming guide](#).

Script

The code in the script defines your job's procedural logic. You can code the script in Python 3.6 or Python 3.9. You can edit a script in Amazon Glue Studio.

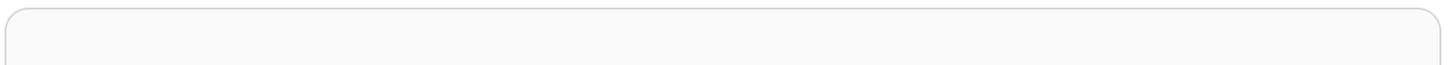

Data processing units

The maximum number of Amazon Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see [Amazon Glue pricing](#).

You can set the value to 0.0625 or 1. The default is 0.0625. In either case, the local disk for the instance will be 20GB.

CLI

You can also create a **Python shell** job using the Amazon CLI, as in the following example.

```
aws glue create-job --name python-job-cli --role Glue_DefaultRole
  --command '{"Name" : "pythonshell", "PythonVersion": "3.9", "ScriptLocation" :
"s3://amzn-s3-demo-bucket/scriptname.py}'
  --max-capacity 0.0625
```

Note

You don't need to specify the version of Amazon Glue since the parameter `--glue-version` doesn't apply for Amazon Glue shell jobs. Any version specified will be ignored.

Jobs that you create with the Amazon CLI default to Python 3. Valid Python versions are 3 (corresponding to 3.6), and 3.9. To specify Python 3.6, add this tuple to the `--command` parameter: `"PythonVersion": "3"`

To specify Python 3.9, add this tuple to the `--command` parameter: `"PythonVersion": "3.9"`

To set the maximum capacity used by a Python shell job, provide the `--max-capacity` parameter. For Python shell jobs, the `--allocated-capacity` parameter can't be used.

Supported libraries for Python shell jobs

In Python shell using Python 3.9, you can choose the library set to use pre-packaged library sets for your needs. You can use the `library-set` option to choose the library set. Valid values are `analytics`, and `none`.

The environment for running a Python shell job supports the following libraries:

Python version	Python 3.6	Python 3.9	
Library set	N/A	analytics	none
avro		1.11.0	
awscli	116.242	1.23.5	1.23.5
awswrangler		2.15.1	
botocore	1.12.232	1.24.21	1.23.5

Python version	Python 3.6	Python 3.9	
boto3	1.9.203	1.21.21	
elasticsearch		8.2.0	
numpy	1.16.2	1.22.3	
pandas	0.24.2	1.4.2	
psycopg2		2.9.3	
pyathena		2.5.3	
PyGreSQL	5.0.6		
PyMySQL		1.0.2	
pyodbc		4.0.32	
pyorc		0.6.0	
redshift-connector		2.0.907	
requests	2.22.0	2.27.1	
scikit-learn	0.20.3	1.0.2	
scipy	1.2.1	1.8.0	
SQLAlchemy		1.4.36	
s3fs		2022.3.0	

You can use the NumPy library in a Python shell job for scientific computing. For more information, see [NumPy](#). The following example shows a NumPy script that can be used in a Python shell job. The script prints "Hello world" and the results of several mathematical calculations.

```
import numpy as np
print("Hello world")
```

```
a = np.array([20,30,40,50])
print(a)

b = np.arange( 4 )

print(b)

c = a-b

print(c)

d = b**2

print(d)
```

Providing your own Python library

Using PIP

Python shell using Python 3.9 lets you provide additional Python modules or different versions at the job level. You can use the `--additional-python-modules` option with a list of comma-separated Python modules to add a new module or change the version of an existing module. You cannot provide custom Python modules hosted on Amazon S3 with this parameter when using Python shell jobs.

For example to update or to add a new `scikit-learn` module use the following key and value: `--additional-python-modules", "scikit-learn==0.21.3"`.

Amazon Glue uses the Python Package Installer (`pip3`) to install the additional modules. You can pass additional `pip3` options inside the `--additional-python-modules` value. For example, `"scikit-learn==0.21.3 -i https://pypi.python.org/simple/"`. Any incompatibilities or limitations from `pip3` apply.

Note

To avoid incompatibilities in the future, we recommend that you use libraries built for Python 3.9.

Using an Egg or Whl file

You might already have one or more Python libraries packaged as an `.egg` or a `.whl` file. If so, you can specify them to your job using the Amazon Command Line Interface (Amazon CLI) under the `--extra-py-files` flag, as in the following example.

```
aws glue create-job --name python-redshift-test-cli --role role --command '{"Name" :
"pythonshell", "ScriptLocation" : "s3://MyBucket/python/library/redshift_test.py"}'
--connections Connections=connection-name --default-arguments '{"--extra-py-
files" : ["s3://amzn-s3-demo-bucket/EGG-FILE", "s3://amzn-s3-demo-bucket/WHEEL-FILE"]}'
```

If you aren't sure how to create an `.egg` or a `.whl` file from a Python library, use the following steps. This example is applicable on macOS, Linux, and Windows Subsystem for Linux (WSL).

To create a Python `.egg` or `.whl` file

1. Create an Amazon Redshift cluster in a virtual private cloud (VPC), and add some data to a table.
2. Create an Amazon Glue connection for the VPC-SecurityGroup-Subnet combination that you used to create the cluster. Test that the connection is successful.
3. Create a directory named `redshift_example`, and create a file named `setup.py`. Paste the following code into `setup.py`.

```
from setuptools import setup

setup(
    name="redshift_module",
    version="0.1",
    packages=['redshift_module']
)
```

4. In the `redshift_example` directory, create a `redshift_module` directory. In the `redshift_module` directory, create the files `__init__.py` and `pygresql_redshift_common.py`.
5. Leave the `__init__.py` file empty. In `pygresql_redshift_common.py`, paste the following code. Replace `port`, `db_name`, `user`, and `password_for_user` with details specific to your Amazon Redshift cluster. Replace `table_name` with the name of the table in Amazon Redshift.

```
import pg

def get_connection(host):
    rs_conn_string = "host=%s port=%s dbname=%s user=%s password=%s" % (
        host, port, db_name, user, password_for_user)

    rs_conn = pg.connect(dbname=rs_conn_string)
    rs_conn.query("set statement_timeout = 1200000")
    return rs_conn

def query(con):
    statement = "Select * from table_name;"
    res = con.query(statement)
    return res
```

6. If you're not already there, change to the `redshift_example` directory.
7. Do one of the following:
 - To create an `.egg` file, run the following command.

```
python setup.py bdist_egg
```

- To create a `.whl` file, run the following command.

```
python setup.py bdist_wheel
```

8. Install the dependencies that are required for the preceding command.
9. The command creates a file in the `dist` directory:
 - If you created an egg file, it's named `redshift_module-0.1-py2.7.egg`.
 - If you created a wheel file, it's named `redshift_module-0.1-py2.7-none-any.whl`.

Upload this file to Amazon S3.

In this example, the uploaded file path is either `s3://amzn-s3-demo-bucket/EGG-FILE` or `s3://amzn-s3-demo-bucket/WHEEL-FILE`.

10. Create a Python file to be used as a script for the Amazon Glue job, and add the following code to the file.

```
from redshift_module import pygresql_redshift_common as rs_common

con1 = rs_common.get_connection(redshift_endpoint)
res = rs_common.query(con1)

print "Rows in the table cities are: "

print res
```

11. Upload the preceding file to Amazon S3. In this example, the uploaded file path is *s3://amzn-s3-demo-bucket/scriptname.py*.
12. Create a Python shell job using this script. On the Amazon Glue console, on the **Job properties** page, specify the path to the .egg/.whl file in the **Python library path** box. If you have multiple .egg/.whl files and Python files, provide a comma-separated list in this box.

When modifying or renaming .egg files, the file names must use the default names generated by the "python setup.py bdist_egg" command or must adhere to the Python module naming conventions. For more information, see the [Style Guide for Python Code](#).

Using the Amazon CLI, create a job with a command, as in the following example.

```
aws glue create-job --name python-redshift-test-cli --role Role --command
'{"Name" : "pythonshell", "ScriptLocation" : "s3://amzn-s3-demo-bucket/
scriptname.py"}'
  --connections Connections="connection-name" --default-arguments '{"--extra-
py-files" : ["s3://amzn-s3-demo-bucket/EGG-FILE", "s3://amzn-s3-demo-bucket/WHEEL-
FILE"]}'
```

When the job runs, the script prints the rows created in the *table_name* table in the Amazon Redshift cluster.

Use Amazon CloudFormation with Python shell jobs in Amazon Glue

You can use Amazon CloudFormation with Python shell jobs in Amazon Glue. The following is an example:

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  Python39Job:
    Type: 'AWS::Glue::Job'
    Properties:
      Command:
        Name: pythonshell
        PythonVersion: '3.9'
        ScriptLocation: 's3://bucket/location'
      MaxRetries: 0
      Name: python-39-job
      Role: RoleName
```

The Amazon CloudWatch Logs group for Python shell jobs output is `/aws-glue/python-jobs/output`. For errors, see the log group `/aws-glue/python-jobs/error`.

Migrating from Python shell 3.6 to Python shell 3.9

To migrate your Python shell jobs to the latest Amazon Glue version:

1. In the Amazon Glue console (<https://console.amazonaws.cn/glue/>), choose your existing Python shell job.
2. In the **Job** details tab, set the Python version to Python 3.9 and choose **Save**.
3. Ensure that your job script is compatible with Python 3.9 and that it runs successfully.

Migrate from Amazon Glue Python shell jobs

Amazon launched the Amazon Glue Python shell jobs in 2018 in order to give customers an easy way to run Python scripts for small-to-medium sized ETL jobs, and to trigger SQL queries. However, there are now more modern and flexible options to address the workloads currently running on PythonShell. This topic explains how to migrate your workloads from Amazon Glue Python shell jobs to one of these alternative options in order to take advantage of the newer capabilities that are available.

This topic explains how to migrate from Amazon Glue Python shell jobs to alternative options.

Migrating workload to Amazon Glue Spark jobs

[Amazon Glue Spark and PySpark jobs](#) allow you to run your workloads in a distributed fashion. Since both Amazon Glue Python Shell jobs and Amazon Glue Spark jobs run on the same platform, it's easy to migrate, and you can continue using existing Amazon Glue features that you're using with Python Shell jobs, such as Amazon Glue Workflows, Amazon Glue Triggers, Amazon Glue's Amazon EventBridge integration, \ PIP-based package installation, and so on.

However, Amazon Glue Spark jobs are designed to run Spark workloads, and the minimum number of workers is 2. If you migrate from Python Shell jobs without modifying your scripts, only one worker will be actually used, and the other workers will remain idle. This will increase your costs.

To make it efficient, rewrite your Python job script to utilize Spark's capabilities and distribute the workload across multiple workers. If your Python script is Pandas-based, it's easy to migrate using the New Pandas API on Spark. Learn more about this in [the Amazon Big Data Blog: Dive deep into Amazon Glue 4.0 for Apache Spark](#).

Migrating workload to Amazon Lambda

Amazon Lambda is a serverless computing service that lets you run code without provisioning or managing servers. Because Amazon Lambda has lower startup times and more flexible options for compute capacity, you can benefit from these advantages. For managing extra Python libraries, Amazon Glue Python Shell jobs use PIP-based installation. However, for Amazon Lambda, you need to choose one of the following options: a zip archive, a container image, or Lambda Layers.

On the other hand, Amazon Lambda's maximum timeout is 900 seconds (15 minutes). If the job duration of your existing Amazon Glue Python Shell job workload is more than that, or if your workload has a spiky pattern that may cause longer job durations, then we recommend exploring other options instead of Amazon Lambda.

Migrating workload to Amazon ECS/Fargate

Amazon Elastic Container Service (Amazon ECS) is a fully managed service that simplifies the deployment, management, and scaling of containerized applications. Amazon Fargate is a serverless compute engine for containerized workloads running on Amazon ECS and Amazon Elastic Kubernetes Service (Amazon EKS). There's no maximum timeout on Amazon ECS and Fargate, so this is a good option for long-running jobs. Since you have full control over your container image, you can bring your Python script and extra Python libraries into the container and use them. However, you need to containerize your Python script to use this approach.

Migrating workload to Amazon Managed Workflows for Apache Airflow Python Operator

Amazon Managed Workflows for Apache Airflow (Managed Workflows for Apache Airflow) is a managed orchestration service for Apache Airflow that makes it easier to set up and operate end-to-end data pipelines in the cloud at scale. If you already have an MWAA environment, it will be straightforward to use the Python operator instead of Amazon Glue Python Shell jobs. The Python operator is an operator that runs Python code inside an Airflow workflow. However, if you don't have an existing MWAA environment, we recommend exploring other options.

Migrating workload to Amazon SageMaker AI AI training jobs

Amazon SageMaker AI Training is a fully managed machine learning (ML) service offered by Amazon SageMaker AI that helps you efficiently train a wide range of ML models at scale. The core of Amazon SageMaker AI AI jobs is the containerization of ML workloads and the capability of managing Amazon compute resources. If you prefer a serverless environment where there is no maximum timeout, Amazon SageMaker AI AI training jobs could be a good fit for you. However, the startup latency tends to be longer than Amazon Glue Python Shell jobs. For jobs that are latency-sensitive, we recommend exploring other options.

Monitoring Amazon Glue

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Glue and your other Amazon solutions. Amazon provides monitoring tools that you can use to watch Amazon Glue, report when something is wrong, and take action automatically when appropriate:

You can use the following automated monitoring tools to watch Amazon Glue and report when something is wrong:

- **Amazon CloudWatch Events** delivers a near real-time stream of system events that describe changes in Amazon resources. CloudWatch Events enables automated event-driven computing. You can write rules that watch for certain events and trigger automated actions in other Amazon services when these events occur. For more information, see the [Amazon CloudWatch Events User Guide](#).
- **Amazon CloudWatch Logs** enables you to monitor, store, and access your log files from Amazon EC2 instances, Amazon CloudTrail, and other sources. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log

data in highly durable storage. For more information, see the [Amazon CloudWatch Logs User Guide](#).

- **Amazon CloudTrail** captures API calls and related events made by or on behalf of your Amazon account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts call Amazon, the source IP address from which the calls are made, and when the calls occur. For more information, see the [Amazon CloudTrail User Guide](#).

Additionally, you have access to the following insights in the Amazon Glue console to help you debug and profile jobs:

- Spark jobs – you can see a visualization of selected CloudWatch metrics series, and newer jobs have access to the Spark UI. For more information, see [the section called “Monitoring Spark jobs”](#).
- Ray jobs – you can see a visualization of selected CloudWatch metrics series. For more information, see [the section called “Ray job metrics”](#).

Topics

- [Amazon tags in Amazon Glue](#)
- [Automating Amazon Glue with EventBridge](#)
- [Monitoring Amazon Glue resources](#)
- [Logging Amazon Glue API calls with Amazon CloudTrail](#)

Amazon tags in Amazon Glue

To help you manage your Amazon Glue resources, you can optionally assign your own tags to some Amazon Glue resource types. A tag is a label that you assign to an Amazon resource. Each tag consists of a key and an optional value, both of which you define. You can use tags in Amazon Glue to organize and identify your resources. Tags can be used to create cost accounting reports and restrict access to resources. If you're using Amazon Identity and Access Management, you can control which users in your Amazon account have permission to create, edit, or delete tags. In addition to the permissions to call the tag-related APIs, you also need the `glue:GetConnection` permission to call tagging APIs on connections, and the `glue:GetDatabase` permission to call tagging APIs on databases. For more information, see [ABAC with Amazon Glue](#).

In Amazon Glue, you can tag the following resources:

- Connection
- Database
- Crawler
- Interactive session
- Development endpoint
- Job
- Trigger
- Workflow
- Blueprint
- Machine learning transform
- Data quality ruleset
- Stream schemas
- Stream schema registries

 **Note**

As a best practice, to allow tagging of these Amazon Glue resources, always include the `glue:TagResource` action in your policies.

Consider the following when using tags with Amazon Glue.

- A maximum of 50 tags are supported per entity.
- In Amazon Glue, you specify tags as a list of key-value pairs in the format `{"string": "string" ...}`
- When you create a tag on an object, the tag key is required, and the tag value is optional.
- The tag key and tag value are case sensitive.
- The tag key and the tag value must not contain the prefix `aws`. No operations are allowed on such tags.
- The maximum tag key length is 128 Unicode characters in UTF-8. The tag key must not be empty or null.
- The maximum tag value length is 256 Unicode characters in UTF-8. The tag value may be empty or null.

Tagging support for Amazon Glue connections

You can restrict `CreateConnection`, `UpdateConnection`, `GetConnection` and, `DeleteConnection` action permission based on the resource tag. This enables you to implement the least privilege access control on Amazon Glue jobs with JDBC data sources which need to fetch JDBC connection information from the Data Catalog.

Example usage

Create an Amazon Glue connection with the tag ["connection-category", "dev-test"].

Specify the tag condition for the `GetConnection` action in the IAM policy.

```
{
  "Effect": "Allow",
  "Action": [
    "glue:GetConnection"
  ],
  "Resource": "*",
  "Condition": {
    "ForAnyValue:StringEquals": {
      "aws:ResourceTag/tagKey": "dev-test"
    }
  }
}
```

Examples

The following examples create a job with assigned tags.

Amazon CLI

```
aws glue create-job --name job-test-tags --role MyJobRole --command
  Name=glueetl,ScriptLocation=S3://aws-glue-scripts//prod-job1
  --tags key1=value1,key2=value2
```

Amazon CloudFormation JSON

```
{
  "Description": "AWS Glue Job Test Tags",
  "Resources": {
    "MyJobRole": {
      "Type": "AWS::IAM::Role",
```

```

"Properties": {
  "AssumeRolePolicyDocument": {
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": [
            "glue.amazonaws.com"
          ]
        },
        "Action": [
          "sts:AssumeRole"
        ]
      }
    ]
  },
  "Path": "/",
  "Policies": [

        "Statement": [
          {
            "Effect": "Allow",
            "Action": "*",
            "Resource": "*"
          }
        ]
      }
    }
  ]
},
"MyJob": {
  "Type": "AWS::Glue::Job",
  "Properties": {
    "Command": {
      "Name": "glueetl",
      "ScriptLocation": "s3://aws-glue-scripts//prod-job1"
    },
    "DefaultArguments": {
      "--job-bookmark-option": "job-bookmark-enable"
    }
  }
}

```

```
MyJob:
  Type: AWS::Glue::Job
  Properties:
    Command:
      Name: glueetl
      ScriptLocation: s3://aws-glue-scripts//prod-job1
    DefaultArguments:
      "--job-bookmark-option": job-bookmark-enable
    ExecutionProperty:
      MaxConcurrentRuns: 2
    MaxRetries: 0
    Name: cf-job1
    Role:
      Ref: MyJobRole
    Tags:
      key1: value1
      key2: value2
```

For more information, see [Amazon Tagging Strategies](#).

For information about how to control access using tags, see [ABAC with Amazon Glue](#).

Automating Amazon Glue with EventBridge

You can use Amazon EventBridge to automate your Amazon services and respond automatically to system events such as application availability issues or resource changes. Events from Amazon services are delivered to EventBridge in near real time. You can write simple rules to indicate which events are of interest to you, and what automated actions to take when an event matches a rule.

The actions that can be automatically triggered include the following:

- Invoking an Amazon Lambda function
- Invoking Amazon EC2 Run Command
- Relaying the event to Amazon Kinesis Data Streams
- Activating an Amazon Step Functions state machine
- Notifying an Amazon SNS topic or an Amazon SQS queue

Some examples of using EventBridge with Amazon Glue include the following:

- Activating a Lambda function when an ETL job succeeds
- Notifying an Amazon SNS topic when an ETL job fails

The following EventBridge are generated by Amazon Glue.

- Events for "detail-type": "Glue Job State Change" are generated for SUCCEEDED, FAILED, TIMEOUT, and STOPPED.
- Events for "detail-type": "Glue Job Run Status" are generated for RUNNING, STARTING, and STOPPING job runs when they exceed the job delay notification threshold. You must set the job delay notification threshold property to receive these events.

Only one event is generated per job run status when the job delay notification threshold is exceeded.

- Events for "detail-type": "Glue Crawler State Change" are generated for Started, Succeeded, and Failed.
- Events for "detail-type": "Glue Scheduled Crawler Invocation Failure" are generated when the scheduled crawler fails to start. In the details of the notification:
 - `customerId` contains the account ID of the customer.
 - `crawlerName` contains the name of the crawler that failed to start.
 - `errorMessage` contains the exception message of the invocation failure.
- Events for "detail-type": "Glue Auto Statistics Invocation Failure" are generated when the auto-managed column statistics task run fails to start. In the details of the notification:
 - `catalogId` contains the ID associated with a catalog.
 - `databaseName` contains the name of the affected database.
 - `tableName` contains the name of the affected table.
 - `errorMessage` contains the exception message of the invocation failure.
- Events for "detail-type": "Glue Scheduled Statistics Invocation Failure" are generated when the (cron) scheduled column statistics task run fails to start. In the details of the notification:
 - `catalogId` contains the ID associated with a catalog.
 - `databaseName` contains the name of the affected database.
 - `tableName` contains the name of the affected table.
 - `errorMessage` contains the exception message of the invocation failure.
- Events for "detail-type": "Glue Statistics Task Started" are generated when the column statistics task run starts.

- Events for "detail_type": "Glue Statistics Task Succeeded" are generated when the column statistics task run succeeds.
- Events for "detail_type": "Glue Statistics Task Failed" are generated when the column statistics task run fails.
- Events for "detail-type": "Glue Data Catalog Database State Change" are generated for CreateDatabase, DeleteDatabase, CreateTable, DeleteTable and BatchDeleteTable. For example, if a table is created or deleted, a notification is sent to EventBridge. Note that you cannot write a program that depends on the order or existence of notification events, as they might be out of sequence or missing. Events are emitted on a best effort basis. In the details of the notification:
 - The typeOfChange contains the name of the API operation.
 - The databaseName contains the name of the affected database.
 - The changedTables contains up to 100 names of affected tables per notification. When table names are long, multiple notifications might be created.
- Events for "detail-type": "Glue Data Catalog Table State Change" are generated for UpdateTable, CreatePartition, BatchCreatePartition, UpdatePartition, DeletePartition, BatchUpdatePartition and BatchDeletePartition. For example, if a table or partition is updated, a notification is sent to EventBridge. Note that you cannot write a program that depends on the order or existence of notification events, as they might be out of sequence or missing. Events are emitted on a best effort basis. In the details of the notification:
 - The typeOfChange contains the name of the API operation.
 - The databaseName contains the name of the database that contains the affected resources.
 - The tableName contains the name of the affected table.
 - The changedPartitions specifies up to 100 affected partitions in one notification. When partition names are long, multiple notifications might be created.

For example if there are two partition keys, Year and Month, then "2018,01", "2018,02" modifies the partition where "Year=2018" and "Month=01" and the partition where "Year=2018" and "Month=02".

```
{
  "version": "0",
  "id": "abcdef00-1234-5678-9abc-def012345678",
  "detail-type": "Glue Data Catalog Table State Change",
  "source": "aws.glue",
  "account": "123456789012",
```

```
"time": "2017-09-07T18:57:21Z",
"region": "us-west-2",
"resources": ["arn:aws:glue:us-west-2:123456789012:database/default/foo"],
"detail": {
  "changedPartitions": [
    "2018,01",
    "2018,02"
  ],
  "databaseName": "default",
  "tableName": "foo",
  "typeOfChange": "BatchCreatePartition"
}
}
```

For more information, see the [Amazon CloudWatch Events User Guide](#). For events specific to Amazon Glue, see [Amazon Glue Events](#).

Monitoring Amazon Glue resources

Amazon Glue has service limits to protect customers from unexpected excessive provisioning and from malicious actions intended to increase your bill. The limits also protect the service. Logging into the Amazon Service Quota console, customers can view their current resource limits and request an increase (where appropriate).

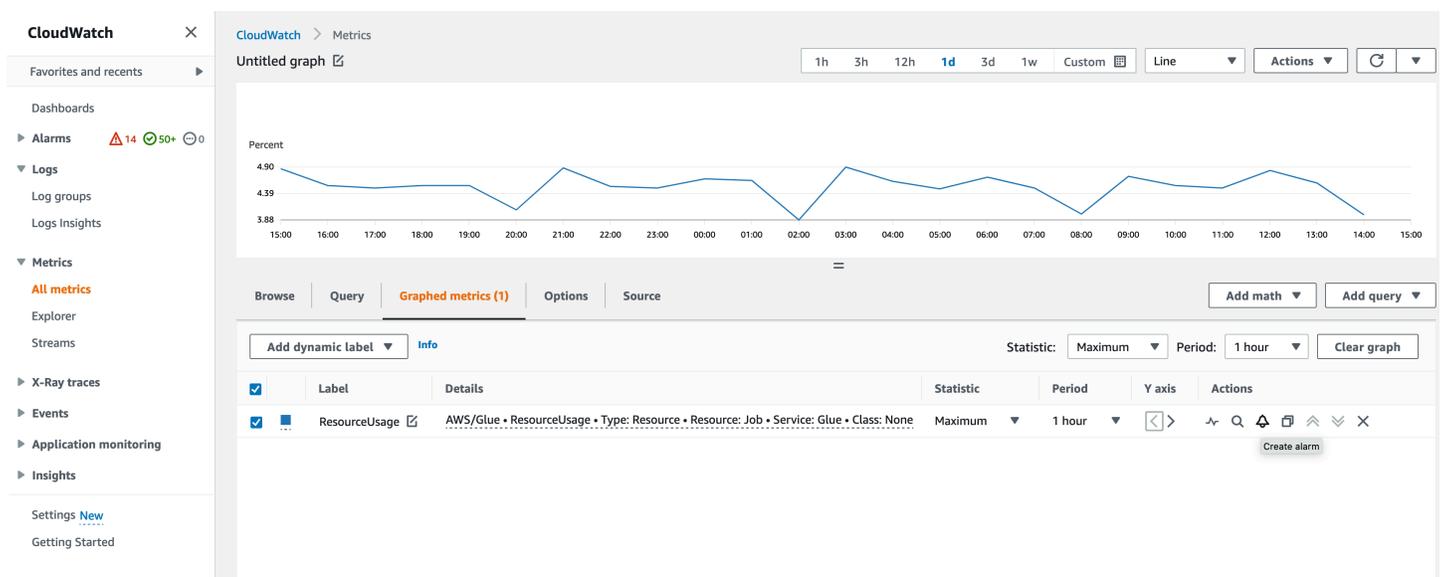

Amazon Glue allows you to view the service's resource usage as a percentage in Amazon CloudWatch and to configure CloudWatch alarms on it to monitor usage. Amazon CloudWatch provides monitoring for Amazon resources and the customer applications running on the Amazon infrastructure. The metrics are free of charge to you. The following metrics are supported:

- Number of workflows per account
- Number of triggers per account
- Number of jobs per account
- Number of concurrent job runs per account
- Number of blueprints per account
- Number of interactive sessions per account

Configuring and using resource metrics

To use this feature, you can go to the Amazon CloudWatch console to view the metrics and configure alarms. The metrics are under the Amazon/Glue namespace and are a percentage of the actual resource usage count divided by the resource quota. The CloudWatch metrics are delivered to your accounts, which will be no cost for you. For example, if you have 10 workflows created, and your service quota allows you to have 200 workflows in maximum, then your usage is $10/200 = 5\%$, and in graph, you will see a datapoint of 5 as a percentage. To be more specific:

```
Namespace: AWS/Glue
Metric name: ResourceUsage
Type: Resource
Resource: Workflow (or Trigger, Job, JobRun, Blueprint, InteractiveSession)
Service: Glue
Class: None
```

To create an alarm on a metric in the CloudWatch console:

1. Once you locate the metric, go to **Graphed metrics**.
2. Click **Create alarm** under **Actions**.
3. Configure the alarm as needed.

We emit metrics whenever your resource usage has a change (such as an increase or decrease). But if your resource usage doesn't change, we emit metrics hourly, so that you have a continuous

CloudWatch graph. To avoid having missing data points, we do not recommend you to configure a period less than 1 hour.

You can also configure alarms using Amazon CloudFormation as in the following example. In this example, once the workflow resource usage reaches 80%, it triggers an alarm to send a message to the existing SNS topic, where you can subscribe to it to get notifications.

```
{
  "Type": "AWS::CloudWatch::Alarm",
  "Properties": {
    "AlarmName": "WorkflowUsageAlarm",
    "ActionsEnabled": true,
    "OKActions": [],
    "AlarmActions": [
      "arn:aws:sns:af-south-1:085425700061:Default_CloudWatch_Alarms_Topic"
    ],
    "InsufficientDataActions": [],
    "MetricName": "ResourceUsage",
    "Namespace": "AWS/Glue",
    "Statistic": "Maximum",
    "Dimensions": [{
      "Name": "Type",
      "Value": "Resource"
    },
    {
      "Name": "Resource",
      "Value": "Workflow"
    },
    {
      "Name": "Service",
      "Value": "Glue"
    },
    {
      "Name": "Class",
      "Value": "None"
    }
  ],
  "Period": 3600,
  "EvaluationPeriods": 1,
  "DatapointsToAlarm": 1,
  "Threshold": 80,
  "ComparisonOperator": "GreaterThanThreshold",
  "TreatMissingData": "notBreaching"
}
```

```
}  
}
```

Logging Amazon Glue API calls with Amazon CloudTrail

Amazon Glue is integrated with Amazon CloudTrail, a service that provides a record of actions taken by a user, role, or an Amazon service in Amazon Glue. CloudTrail captures all API calls for Amazon Glue as events. The calls captured include calls from the Amazon Glue console and code calls to the Amazon Glue API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon Glue. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to Amazon Glue, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [Amazon CloudTrail User Guide](#).

Amazon Glue information in CloudTrail

CloudTrail is enabled on your Amazon account when you create the account. When activity occurs in Amazon Glue, that activity is recorded in a CloudTrail event along with other Amazon service events in **Event history**. You can view, search, and download recent events in your Amazon account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your Amazon account, including events for Amazon Glue, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all Amazon Regions. The trail logs events from all Regions in the Amazon partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other Amazon services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Creating a trail for your Amazon account](#)
- [CloudTrail supported services and integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

All Amazon Glue actions are logged by CloudTrail and are documented in the [Amazon Glue API](#) . For example, calls to the `CreateDatabase`, `CreateTable` and `CreateScript` actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another Amazon service.

For more information, see the [CloudTrail userIdentity Element](#).

However, CloudTrail doesn't log all information regarding calls. For example, it doesn't log certain sensitive information, such as the `ConnectionProperties` used in connection requests, and it logs a `null` instead of the responses returned by the following APIs:

<code>BatchGetPartition</code>	<code>GetCrawlers</code>	<code>GetJobs</code>	<code>GetTable</code>
<code>CreateScript</code>	<code>GetCrawlerMetrics</code>	<code>GetJobRun</code>	<code>GetTables</code>
<code>GetCatalogImportStatus</code>	<code>GetDatabase</code>	<code>GetJobRuns</code>	<code>GetTableVersions</code>
<code>GetClassifier</code>	<code>GetDatabases</code>	<code>GetMapping</code>	<code>GetTrigger</code>
<code>GetClassifiers</code>	<code>GetDataflowGraph</code>	<code>GetObjects</code>	<code>GetTriggers</code>
<code>GetConnection</code>	<code>GetDevEndpoint</code>	<code>GetPartition</code>	<code>GetUserDefinedFunction</code>
<code>GetConnections</code>	<code>GetDevEndpoints</code>	<code>GetPartitions</code>	<code>GetUserDefinedFunctions</code>
<code>GetCrawler</code>	<code>GetJob</code>	<code>GetPlan</code>	

Understanding Amazon Glue log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `DeleteCrawler` action.

```
{
  "eventVersion": "1.05",
```

```

"userIdentity": {
  "type": "IAMUser",
  "principalId": "AKIAIOSFODNN7EXAMPLE",
  "arn": "arn:aws-cn:iam::123456789012:user/johndoe",
  "accountId": "123456789012",
  "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
  "userName": "johndoe"
},
"eventTime": "2017-10-11T22:29:49Z",
"eventSource": "glue.amazonaws.com",
"eventName": "DeleteCrawler",

}
```

Amazon Glue Streaming

Amazon Glue Streaming, a component of Amazon Glue, enables you to efficiently handle streaming data in near real-time, empowering you to carry out crucial tasks such as data ingestion, processing, and machine learning. Using the Apache Spark Streaming framework, Amazon Glue Streaming provides a serverless service that can handle streaming data at scale. Amazon Glue provides various optimizations on top of Apache Spark such as serverless infrastructure, auto-scaling, visual job development, instant-on notebooks for streaming jobs and other performance improvements.

Use cases for streaming

Some common use cases for Amazon Glue Streaming include:

Near-real-time data processing: Amazon Glue Streaming allows organizations to process streaming data in near real-time, enabling them to derive insights and make timely decisions based on the latest information.

Fraud detection: You can utilize Amazon Glue Streaming for real-time analysis of streaming data, making it valuable for detecting fraudulent activities, such as credit card fraud, network intrusion, or online scams. By continuously processing and analyzing incoming data, you can swiftly identify suspicious patterns or anomalies.

Social media analytics: Amazon Glue Streaming can process real-time social media data, such as tweets, posts, or comments, enabling organizations to monitor trends, sentiment analysis, and manage brand reputation in real-time.

Internet of Things (IoT) analytics: Amazon Glue Streaming is suitable for handling and analyzing high-velocity streams of data generated by IoT devices, sensors, and connected machinery. It allows for real-time monitoring, anomaly detection, predictive maintenance, and other IoT analytics use cases.

Clickstream analysis: Amazon Glue Streaming can process and analyze real-time clickstream data from websites or mobile applications. This enables businesses to gain insights into user behavior, personalize user experiences, and optimize marketing campaigns based on real-time clickstream data.

Log monitoring and analysis: Amazon Glue Streaming can continuously process and analyze log data from servers, applications, or network devices in real-time. This helps in detecting anomalies, troubleshooting issues, and monitoring system health and performance.

Recommendation systems: Amazon Glue Streaming can process user activity data in real-time and update recommendation models dynamically. This allows for personalized and real-time recommendations based on user behavior and preferences.

These are some examples of the diverse range of use cases where Amazon Glue Streaming can be applied. Its integration with the Amazon ecosystem and managed services make it a convenient choice for real-time stream processing and analytics in the cloud.

What are the benefits of using Amazon Glue Streaming?

The benefits of using Amazon Glue Streaming are as follows:

- **Serverless:** Amazon Glue Streaming is serverless, eliminating the need to manage infrastructure. This reduces the operational overhead and allows users to focus on data processing and analytics tasks rather than infrastructure management.
- **Autoscaling:** Amazon Glue Streaming provides autoscaling capabilities, dynamically adjusting the processing capacity based on the workload. It automatically scales out or in to handle fluctuations in data volume, ensuring optimal performance and resource utilization.
- **Visual development:** Streaming job development can be complex. Amazon Glue Streaming addresses this challenge by offering Amazon Glue Studio, a visual authoring tool. Amazon Glue Studio simplifies the process of creating streaming workflows and enables developers to design and manage streaming applications visually, reducing the learning curve and increasing productivity.
- **Cost-effective:** As a serverless service, Amazon Glue Streaming offers cost efficiency by eliminating the need for provisioning and maintaining infrastructure. Users are billed based on the resources consumed during the execution of streaming jobs, allowing for cost optimization and scaling based on actual usage.
- **Handles complex workloads:** Amazon Glue Streaming is designed to handle complex streaming workloads. It can process and analyze large volumes of real-time data, support advanced transformations, and integrate with other Amazon services, enabling sophisticated streaming data pipelines and analytics workflows.
- **No lock-in:** Amazon Glue Streaming provides flexibility and avoids vendor lock-in. Users can leverage Amazon Glue Streaming as part of the broader Amazon ecosystem, integrating it with

other Amazon services seamlessly. This allows for easy integration with existing data sources, applications, and services without being tied to a specific technology or platform.

When to use Amazon Glue Streaming?

There are many options when it comes to streaming use cases. We recommend Amazon Glue streaming in the following scenarios.

- 1. If you are already using Amazon Glue or Spark for batch processing**, Amazon Glue Streaming is the ideal choice for you. It provides a seamless transition to building streaming jobs without the need to learn a new language or framework. Leveraging your existing knowledge and infrastructure, Amazon Glue Streaming simplifies the job development process and allows you to easily extend your data processing capabilities to real-time streaming scenarios.
- 2. If you require a unified service or product to handle batch, streaming, and event-driven workloads**, Amazon Glue Streaming is the solution for you. With Amazon Glue Streaming, you can consolidate your data processing needs into a single framework, eliminating the complexity of managing multiple systems. This enables efficient development and maintenance of diverse data workflows while ensuring consistency and compatibility across different workload types.
- 3. Amazon Glue Streaming is well-suited for scenarios involving extremely large streaming data volumes and complex transformations**, such as joins between streams or relational databases. It can efficiently process and analyze massive streams of data, enabling you to tackle demanding workloads with ease. Whether it is high-velocity data ingestion or intricate data manipulations, Amazon Glue Streaming's scalability and advanced processing capabilities ensure optimal performance and accurate results.
- 4. If you prefer a visual approach to building streaming jobs**, Amazon Glue offers Amazon Glue Studio, with which you can visually design and manage your streaming applications, simplifying the development process. This intuitive interface enables developers to create, configure, and monitor streaming workflows using a visual interface, reducing the learning curve and increasing productivity.
- 5. Amazon Glue Streaming is an excellent choice for near-real-time use cases where there are stringent SLAs (Service Level Agreements) greater than 10 seconds.**
- 6. If you are building a transactional data lake using Apache Iceberg, Apache Hudi, or Delta Lake**, Amazon Glue Streaming provides native support for these open table formats. This seamless integration enables you to process streaming data directly from these transactional data lakes, ensuring data consistency, integrity, and compatibility.

7. **When needing to ingest streaming data for a variety of data targets:** Amazon Glue Streaming provides native targets to a variety of data targets such as Amazon Redshift, Amazon RDS, Amazon Aurora, Oracle, SQL Server and other targets.

Supported data sources

Amazon Glue Streaming supports the following data sources:

- Amazon Kinesis
- Amazon MSK (Managed Streaming for Apache Kafka)
- Self-managed Apache Kafka

Supported data targets

Amazon Glue Streaming supports a variety of data targets such as:

- Data targets supported by Amazon Glue Data Catalog
- Amazon S3
- Amazon Redshift
- MySQL
- PostgreSQL
- Oracle
- Microsoft SQL Server
- Snowflake
- Any database that can be connected using JDBC
- Apache Iceberg, Delta and Apache Hudi
- Amazon Glue Marketplace connectors

Tutorial: Build your first streaming workload using Amazon Glue Studio

In this tutorial, you are going to learn how to create a streaming job using Amazon Glue Studio. Amazon Glue Studio is a visual interface to create Amazon Glue jobs.

You can create streaming extract, transform, and load (ETL) jobs that run continuously and consume data from streaming sources in Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK).

Prerequisites

To follow this tutorial you'll need a user with Amazon console permissions to use Amazon Glue, Amazon Kinesis, Amazon S3, Amazon Athena, Amazon CloudFormation, Amazon Lambda and Amazon Cognito.

Consume streaming data from Amazon Kinesis

Topics

- [Generating mock data with Kinesis Data Generator](#)
- [Creating an Amazon Glue streaming job with Amazon Glue Studio](#)
- [Performing a transformation and storing the transformed result in Amazon S3](#)

Generating mock data with Kinesis Data Generator

You can synthetically generate sample data in JSON format using the Kinesis Data Generator (KDG). You can find full instructions and details in the [tool documentation](#).

1. To get started, click

to run an Amazon CloudFormation template on your Amazon environment.

Note

You may encounter a CloudFormation template failure because some resources, such as the Amazon Cognito user for Kinesis Data Generator already exist in your Amazon account. This could be because you already set that up from another tutorial or blog. To address this, you can either try the template in a new Amazon account for a fresh start, or explore a different Amazon Region. These options let you run the tutorial without conflicting with existing resources.

The template provisions a Kinesis data stream and a Kinesis Data Generator account for you. It also creates an Amazon S3 bucket to hold the data and a Glue Service Role with the required permission for this tutorial.

2. Enter a **Username** and **Password** that the KDG will use to authenticate. Note the username and password for further usage.
3. Select **Next** all the way to the last step. Acknowledge the creation of IAM resources. Check for any errors at the top of the screen, such as the password not meeting the minimum requirements, and deploy the template.
4. Navigate to the **Outputs** tab of the stack. Once the template is deployed, it will display the generated property **KinesisDataGeneratorUrl**. Click that URL.
5. Enter the **Username** and **Password** you noted down.
6. Select the Region you are using and select the Kinesis Stream `GlueStreamTest-
{AWS::AccountId}`
7. Enter the following template:

```
{
  "ventilatorid": {{random.number(100)}},
  "eventtime": "{{date.now("YYYY-MM-DD HH:mm:ss")}}",
  "serialnumber": "{{random.uuid}}",
  "pressurecontrol": {{random.number(
    {
      "min":5,
      "max":30
    }
  )}},
  "o2stats": {{random.number(
    {
      "min":92,
      "max":98
    }
  )}},
  "minutevolume": {{random.number(
    {
      "min":5,
      "max":8
    }
  )}},
  "manufacturer": "{{random.arrayElement(
```

```

    ["3M", "GE", "Vyaire", "Getinge"]
  )}]"
}

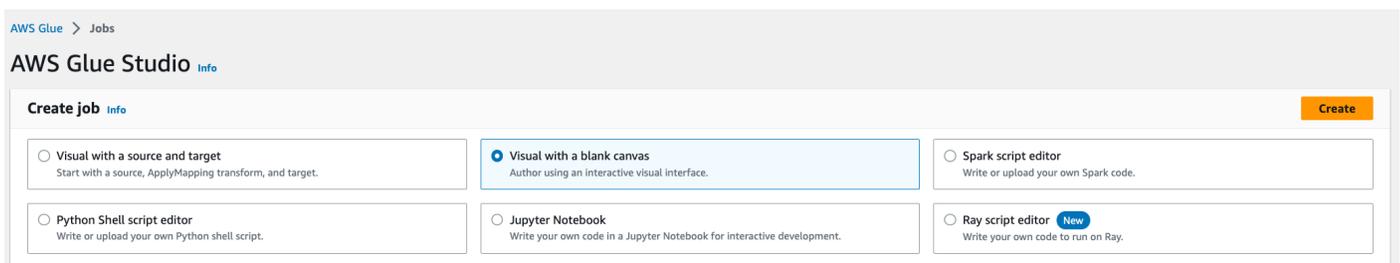

```

You can now view mock data with **Test template** and ingest the mock data to Kinesis with **Send data**.

8. Click **Send data** and generate 5-10K records to Kinesis.

Creating an Amazon Glue streaming job with Amazon Glue Studio

1. Navigate to Amazon Glue in the console on the same Region.
2. Select **ETL jobs** under the left side navigation bar under **Data Integration and ETL**.
3. Create an Amazon Glue Job via **Visual with a blank canvas**.

4. Navigate to the **Job Details** tab.
5. For the Amazon Glue job name, enter DemoStreamingJob.
6. For **IAM Role**, select the role provisioned by the CloudFormation template, glue-tutorial-role-\${Amazon::AccountId}.
7. For **Glue version**, select **Glue 3.0**. Leave all other options as default.

Basic properties [Info](#)

Name

DemoStreamingJob

Description - *optional*

Descriptions can be up to 2048 characters long.

IAM Role

Role assumed by the job with permission to access your data stores. Ensure that this role has permission to your Amazon S3 sources, targets, temporary directory, scripts, and any libraries used by the job.

glue-tutorial-role-

Type

The type of ETL job. This is set automatically based on the types of data sources you have selected.

Spark Streaming

Glue version [Info](#)

Glue 3.0 - Supports spark 3.1, Scala 2, Python 3

Language

Python 3

Worker type

Set the type of predefined worker that is allowed when a job runs.

G 1X

(4vCPU and 16GB RAM)

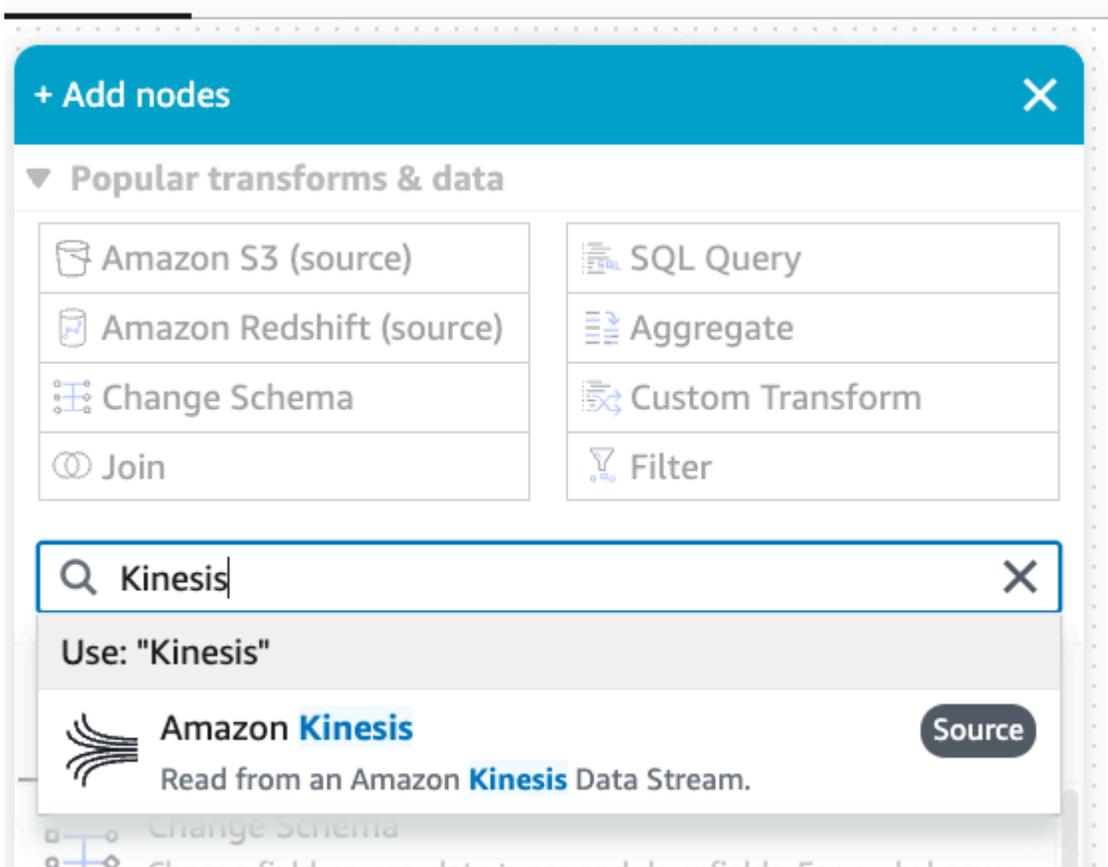

Automatically scale the number of workers

- AWS Glue will optimize costs and resource usage by dynamically scaling the number of workers up and down throughout the job run. Requires Glue 3.0 or later.

8. Navigate to the **Visual tab**.

9. Click on the plus icon. Enter **Kinesis** in the search bar. Select the **Amazon Kinesis** data source.

10 Select **Stream details** for **Amazon Kinesis Source** under the tab **Data source properties - Kinesis Stream**.

11 Select **Stream is located in my account** for **Location of data stream**.

12 Select the Region you are using.

13 Select the `GlueStreamTest- $\{AWS::AccountId\}$` stream.

14 Keep all other settings as default.

Tutorial: Build your first streaming workload using Amazon Glue Studio notebooks

In this tutorial, you will explore how to leverage Amazon Glue Studio notebooks to interactively build and refine your ETL jobs for near real-time data processing. Whether you're new to Amazon Glue or looking to enhance your skill set, this guide will walk you through the process, empowering you to harness the full potential of Amazon Glue interactive session notebooks.

With Amazon Glue Streaming, you can create streaming extract, transform, and load (ETL) jobs that run continuously and consume data from streaming sources such as Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK).

Prerequisites

To follow this tutorial you'll need a user with Amazon console permissions to use Amazon Glue, Amazon Kinesis, Amazon S3, Amazon Athena, Amazon CloudFormation, Amazon Lambda and Amazon Cognito.

Consume streaming data from Amazon Kinesis

- [Conclusion](#)

Generating mock data with Kinesis Data Generator

Note

If you have already completed our previous [Tutorial: Build your first streaming workload using Amazon Glue Studio](#), you already have the Kinesis Data Generator installed on your account and you can skip steps 1-8 below and move on to the section [Creating an Amazon Glue streaming job with Amazon Glue Studio](#).

You can synthetically generate sample data in JSON format using the Kinesis Data Generator (KDG). You can find full instructions and details in the [tool documentation](#).

1. To get started, click

to run an Amazon CloudFormation template on your Amazon environment.

Note

You may encounter a CloudFormation template failure because some resources, such as the Amazon Cognito user for Kinesis Data Generator already exist in your Amazon account. This could be because you already set that up from another tutorial or blog. To address this, you can either try the template in a new Amazon account for a fresh start, or explore a different Amazon Region. These options let you run the tutorial without conflicting with existing resources.

The template provisions a Kinesis data stream and a Kinesis Data Generator account for you.

2. Enter a **Username** and **Password** that the KDG will use to authenticate. Note the username and password for further usage.
3. Select **Next** all the way to the last step. Acknowledge the creation of IAM resources. Check for any errors at the top of the screen, such as the password not meeting the minimum requirements, and deploy the template.
4. Navigate to the **Outputs** tab of the stack. Once the template is deployed, it will display the generated property **KinesisDataGeneratorUrl**. Click that URL.
5. Enter the **Username** and **Password** you noted down.
6. Select the Region you are using and select the Kinesis Stream `GlueStreamTest-
{AWS::AccountId}`
7. Enter the following template:

```
{
  "ventilatorid": {{random.number(100)}},
  "eventtime": "{{date.now("YYYY-MM-DD HH:mm:ss")}}",
  "serialnumber": "{{random.uuid}}",
  "pressurecontrol": {{random.number(
    {
      "min":5,
      "max":30
    }
  )}},
  "o2stats": {{random.number(
    {
      "min":92,
      "max":98
    }
  )}}
```

```
    }
  )}},
  "minutevolume": {{random.number(
    {
      "min":5,
      "max":8
    }
  )}},
  "manufacturer": "{{random.arrayElement(
    ["3M", "GE","Vyair", "Getinge"]
  )}}"
```

You can now view mock data with **Test template** and ingest the mock data to Kinesis with **Send data**.

8. Click **Send data** and generate 5-10K records to Kinesis.

Creating an Amazon Glue streaming job with Amazon Glue Studio

Amazon Glue Studio is a visual interface that simplifies the process of designing, orchestrating, and monitoring data integration pipelines. It enables users to build data transformation pipelines without writing extensive code. Apart from the visual job authoring experience, Amazon Glue Studio also includes a Jupyter notebook backed by Amazon Glue Interactive sessions, which you will be using in the remainder of this tutorial.

Set up the Amazon Glue Streaming interactive sessions job

1. Download the provided [notebook file](#) and save it to a local directory
2. Open the Amazon Glue Console and on the left pane click **Notebooks > Jupyter Notebook > Upload and edit an existing notebook**. Upload the notebook from the previous step and click **Create**.

The screenshot shows the AWS Glue Studio 'Create job' page. On the left is a navigation sidebar with 'Notebooks' highlighted (1). The main area has three columns of options: 'Visual with a source and target', 'Visual with a blank canvas', and 'Spark script editor'. The 'Jupyter Notebook' option is selected (2). Below these are 'Options' for creating a notebook: 'Create a new notebook from scratch' and 'Upload and edit an existing notebook' (3). The 'Upload and edit an existing notebook' option is selected, and a 'Choose file' button is highlighted (4). A file named 'glue_tutorial_notebook.ipynb' is listed below (5). A 'Create' button is in the top right corner (6).

3. Provide the job a name, role and select the default Spark kernel. Next click **Start notebook**. For the **IAM Role**, select the role provisioned by the CloudFormation template. You can see this in the **Outputs** tab of CloudFormation.

The screenshot shows the 'Notebook setup' configuration page in AWS Glue. The page title is 'Notebook setup'. Under 'Initial configuration', there are three sections: 'Job name' with a text input field containing 'glue_tutorial_notebook'; 'IAM Role' with a dropdown menu showing 'glue-tutorial-role-62' and a refresh button; and 'Kernel' with a dropdown menu showing 'Spark'. At the bottom right, there are 'Cancel' and 'Start notebook' buttons.

The notebook has all necessary instructions to continue the tutorial. You can either run the instructions on the notebook or follow along with this tutorial to continue with the job development.

6. In the following cell, you explore the incoming stream by taking a sample set and print its schema and the actual data. For example:

Sample and print the incoming records

the sampling is for debugging purpose. You may comment off the entire code cell below, before deploying the actual code

```
[4]: options = {
  -- "pollingTimeInMs": "20000",
  -- "windowSize": "5 seconds"
}
sampled_dynamic_frame = glueContext.getSampleStreamingDynamicFrame(data_frame, options, None)

count_of_sampled_records = sampled_dynamic_frame.count()

print(count_of_sampled_records)

sampled_dynamic_frame.printSchema()

sampled_dynamic_frame.toDF().show(10, False)
```

```
100
root
```

```
|-- eventtime: string
|-- manufacturer: string
|-- minutevolume: long
|-- o2stats: long
|-- pressurecontrol: long
|-- serialnumber: string
|-- ventilatorid: long
```

eventtime	manufacturer	minutevolume	o2stats	pressurecontrol	serialnumber	ventilatorid
2023-07-18 10:20:11	3M	6	92	24	a3e860ba-24b9-41c4-bc10-91c6b35e1406	6
2023-07-18 10:20:11	Vyair	6	95	6	96101dca-3e88-457f-b390-e3291df48a81	26
2023-07-18 10:20:12	Getinge	8	96	24	18f3d448-1dee-4c80-835b-1a0daa818915	22
2023-07-18 10:20:12	Getinge	7	98	30	25f425cd-b978-4953-9a03-4d607a639364	91
2023-07-18 10:20:12	GE	5	93	25	2cd7cdc2-f5f5-4ff2-ae32-45e5a8922d53	93

7. Next, define the actual data transformation logic. The cell consists of the `processBatch` method that is triggered during every micro-batch. Run the cell. At a high level, we do the following to the incoming stream:
- Select a subset of the input columns.
 - Rename a column (`o2stats` to `oxygen_stats`).
 - Derive new columns (`serial_identifier`, `ingest_year`, `ingest_month` and `ingest_day`).
 - Store the results into an Amazon S3 bucket and also create a partitioned Amazon Glue catalog table
8. In the last cell, you trigger the process batch every 10 seconds. Run the cell and wait for about 30 seconds for it to populate the Amazon S3 bucket and the Amazon Glue catalog table.
9. Finally, browse the stored data using the Amazon Athena query editor. You can see the renamed column and also the new partitions.

1 `select * from test_stream_001 limit 10`

The notebook has all necessary instructions to continue the tutorial. You can either run the instructions on the notebook or follow along with this tutorial to continue with the job development.

Save and run the Amazon Glue job

With the development and testing of your application complete using the interactive sessions notebook, click **Save** at the top of the notebook interface. Once saved you can also run the application as a job.

AWS Glue Streaming Tutorials - Working with Studio Notebook

Clean up

To avoid incurring additional charges to your account, stop the streaming job that you started as part of the instructions. You can do this by stopping the notebook, which will end the session. Empty the Amazon S3 bucket and delete the Amazon CloudFormation stack that you provisioned earlier.

Conclusion

In this tutorial, we demonstrated how to do the following using the Amazon Glue Studio notebook

- Author a streaming ETL job using notebooks
- Preview incoming data streams
- Code and fix issues without having to publish Amazon Glue jobs
- Review the end-to-end working code, remove any debugging, and print statements or cells from the notebook
- Publish the code as an Amazon Glue job

The goal of this tutorial is to give you hands-on experience working with Amazon Glue Streaming and interactive sessions. We encourage you to use this as a reference for your individual Amazon Glue Streaming use cases. For more information, see [Getting started with Amazon Glue interactive sessions](#).

Amazon Glue Streaming concepts

The following sections provide information on concepts of Amazon Glue Streaming.

Topics

- [Anatomy of a Amazon Glue streaming job](#)

Anatomy of a Amazon Glue streaming job

Amazon Glue streaming jobs operate on the Spark streaming paradigm and leverage structured streaming from the Spark framework. Streaming jobs constantly poll on the streaming data source, at a specific interval of time, to fetch records as micro batches. The following sections examine the different parts of a Amazon Glue streaming job.

```

def processBatch(data_frame, batchId):
    if data_frame.count() > 0:
        AmazonKinesis_node1696872487972 = DynamicFrame.fromDF(
            glueContext.add_ingestion_time_columns(data_frame, "hour"),
            glueContext,
            "from_data_frame",
        )
        # Script generated for node Change Schema
        ChangeSchema_node1696872679326 = ApplyMapping.apply(
            frame=AmazonKinesis_node1696872487972,
            mappings=[
                ("eventtime", "string", "eventtime", "string"),
                ("manufacturer", "string", "manufacturer", "string"),
                ("minutevolume", "long", "minutevolume", "int"),
                ("o2stats", "long", "OxygenSaturation", "int"),
                ("pressurecontrol", "long", "pressurecontrol", "int"),
                ("serialnumber", "string", "serialnumber", "string"),
                ("ventilatorid", "long", "ventilatorid", "long"),
                ("ingest_year", "string", "ingest_year", "string"),
                ("ingest_month", "string", "ingest_month", "string"),
                ("ingest_day", "string", "ingest_day", "string"),
                ("ingest_hour", "string", "ingest_hour", "string"),
            ],
            transformation_ctx="ChangeSchema_node1696872679326",
        )
        # Script generated for node Amazon S3
        AmazonS3_node1696872743449_path = (
            "s3://streaming-tutorial-s3-target-
        )
        AmazonS3_node1696872743449 = glueContext.getSink(
            path=AmazonS3_node1696872743449_path,
            connection_type="s3",
            update_behavior="UPDATE_IN_DATABASE",
            partition_keys=["ingest_year", "ingest_month", "ingest_day", "ingest_hour"],
            compression="snappy",
            enable_update_catalog=True,
            transformation_ctx="AmazonS3_node1696872743449",
        )
        AmazonS3_node1696872743449.setCatalogInfo(
            catalog_database="demo", catalog_table_name="demo_stream_transform_result"
        )
        AmazonS3_node1696872743449.setFormat("glueparquet")
        AmazonS3_node1696872743449.writeFrame(ChangeSchema_node1696872679326)

    glueContext.forEachBatch(
        frame=dataFrame_AmazonKinesis_node1696872487972,
        batch_function=processBatch,
        options={
            "windowSize": "100 seconds",
            "checkpointLocation": args["TempDir"] + "/" + args["JOB_NAME"] + "/checkpoint/",
        },
    ),
}
job.commit()

```

2

3

4

5

6

1 ← Entry Point

forEachBatch

The `forEachBatch` method is the entry point of a Amazon Glue streaming job run. Amazon Glue streaming jobs uses the `forEachBatch` method to poll data functioning like an iterator that remains active during the lifecycle of the streaming job and regularly polls the streaming source for new data and processes the latest data in micro batches.

```

glueContext.forEachBatch(
    frame=dataFrame_AmazonKinesis_node1696872487972,
    batch_function=processBatch,
    options={
        "windowSize": "100 seconds",
        "checkpointLocation": args["TempDir"] + "/" + args["JOB_NAME"] + "/
checkpoint/",
    },
)

```

Configure the `frame` property of `forEachBatch` to specify a streaming source. In this example, the source node that you created in the blank canvas during job creation is populated with the default `DataFrame` of the job. Set the `batch_function` property as the function that you decide to invoke for each micro batch operation. You must define a function to handle the batch transformation on the incoming data.

Source

In the first step of the `processBatch` function, the program verifies the record count of the `DataFrame` that you defined as `frame` property of `forEachBatch`. The program appends an ingestion time stamp to a non-empty `DataFrame`. The `data_frame.count()>0` clause determines whether the latest micro batch is not empty and is ready for further processing.

```
def processBatch(data_frame, batchId):
    if data_frame.count() > 0:
        AmazonKinesis_node1696872487972 = DynamicFrame.fromDF(
            glueContext.add_ingestion_time_columns(data_frame, "hour"),
            glueContext,
            "from_data_frame",
        )
```

Mapping

The next section of the program is to apply mapping. The `Mapping.apply` method on a spark `DataFrame` allows you to define transformation rule around data elements. Typically you can rename, change the data type, or apply a custom function on the source data column and map those to the target columns.

```
#Script generated for node ChangeSchema
ChangeSchema_node16986872679326 = ApplyMapping.apply(
    frame = AmazonKinesis_node1696872487972,
    mappings = [
        ("eventtime", "string", "eventtime", "string"),
        ("manufacturer", "string", "manufacturer", "string"),
        ("minutevolume", "long", "minutevolume", "int"),
        ("o2stats", "long", "OxygenSaturation", "int"),
        ("pressurecontrol", "long", "pressurecontrol", "int"),
        ("serialnumber", "string", "serialnumber", "string"),
```

```

        ("ventilatorid", "long", "ventilatorid", "long"),
        ("ingest_year", "string", "ingest_year", "string"),
        ("ingest_month", "string", "ingest_month", "string"),
        ("ingest_day", "string", "ingest_day", "string"),
        ("ingest_hour", "string", "ingest_hour", "string"),
    ],
    transformation_ctx="ChangeSchema_node16986872679326",
)
)

```

Sink

In this section, the incoming data set from the streaming source are stored at a target location. In this example we will write the data to an Amazon S3 location. The `AmazonS3_node_path` property details is pre-populated as determined by the settings you used during job creation from the canvas. You can set the `updateBehavior` based on your use case and decide to either Not update the data catalog table, or Create data catalog and update data catalog schema on subsequent runs, or create a catalog table and not update the schema definition on subsequent runs.

The `partitionKeys` property defines the storage partition option. The default behavior is to partition the data per the `ingestion_time_columns` that was made available in the source section. The `compression` property allows you to set the compression algorithm to be applied during target write. You have options to set Snappy, LZO, or GZIP as the compression technique. The `enableUpdateCatalog` property controls whether the Amazon Glue catalog table needs to be updated. Available options for this property are `True` or `False`.

```

#Script generated for node Amazon S3
AmazonS3_node1696872743449 = glueContext.getSink(
    path = AmazonS3_node1696872743449_path,
    connection_type = "s3",
    updateBehavior = "UPDATE_IN_DATABASE",
    partitionKeys = ["ingest_year", "ingest_month", "ingest_day", "ingest_hour"],
    compression = "snappy",
    enableUpdateCatalog = True,
    transformation_ctx = "AmazonS3_node1696872743449",
)

```

Amazon Glue Catalog sink

This section of the job controls the Amazon Glue catalog table update behavior. Set `catalogDatabase` and `catalogTableName` property per your Amazon Glue Catalog database name and the table name associated with the Amazon Glue job that you are designing. You can define the file format of the target data via the `setFormat` property. For this example we will store the data in parquet format.

Once you set up and run the Amazon Glue streaming job referring this tutorial, the streaming data produced at Amazon Kinesis Data Streams will be stored at the Amazon S3 location in a parquet format with snappy compression. On successful runs of the streaming job you will be able to query the data through Amazon Athena.

```
AmazonS3_node1696872743449 = setCatalogInfo(  
    catalogDatabase = "demo", catalogTableName = "demo_stream_transform_result"  
)  
AmazonS3_node1696872743449.setFormat("glueparquet")  
AmazonS3_node1696872743449.writeFormat("ChangeSchema_node16986872679326")  
)
```

Amazon Glue Streaming connections

The following sections provide information on how to use connections in Amazon Glue Streaming.

Topics

- [Working with Kafka connections](#)
- [Working with Kinesis connections](#)

Working with Kafka connections

You can use a Kafka connection to read and write to Kafka data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. The connection supports a Kafka cluster or an Amazon Managed Streaming for Apache Kafka cluster. You can read information from Kafka into a Spark DataFrame, then convert it to a Amazon Glue

DynamicFrame. You can write DynamicFrames to Kafka in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kafka streaming source, or `getCatalogSink` or `write_dynamic_frame_from_catalog` to write records to Kafka, and the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kafka streaming source. If you use `getSource`, `getCatalogSink`, `getSourceWithFormat`, `getSinkWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, or `write_dynamic_frame_from_catalog`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kafka using the following arguments for the specified methods in the `GlueContext` class.

- Scala
 - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
 - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
 - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
 - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
 - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
 - `options`: Use with `getSource`, `getSink`

For notes and restrictions about streaming ETL jobs, consult [the section called "Streaming ETL notes and restrictions"](#).

Topics

- [Configure Kafka](#)
- [Example: Reading from Kafka streams](#)
- [Example: Writing to Kafka streams](#)
- [Kafka connection option reference](#)

Configure Kafka

There are no Amazon prerequisites to connecting to Kafka streams available through the internet.

You can create a Amazon Glue Kafka connection to manage your connection credentials. For more information, see [the section called "Creating a connection for a Kafka data stream"](#). In your Amazon Glue job configuration, provide *connectionName* as an **Additional network connection**, then, in your method call, provide *connectionName* to the `connectionName` parameter.

In certain cases, you will need to configure additional prerequisites:

- If using Amazon Managed Streaming for Apache Kafka with IAM authentication, you will need appropriate IAM configuration.
- If using Amazon Managed Streaming for Apache Kafka within an Amazon VPC, you will need appropriate Amazon VPC configuration. You will need to create a Amazon Glue connection that provides Amazon VPC connection information. You will need your job configuration to include the Amazon Glue connection as an **Additional network connection**.

For more information about Streaming ETL job prerequisites, consult [the section called "Streaming ETL jobs"](#).

Example: Reading from Kafka streams

Used in conjunction with [the section called "forEachBatch"](#).

Example for Kafka streaming source:

```
kafka_options =
  { "connectionName": "ConfluentKafka",
    "topicName": "kafka-auth-topic",
    "startingOffsets": "earliest",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kafka",
  connection_options=kafka_options)
```

Example: Writing to Kafka streams

Examples for writing to Kafka:

Example with the `getSink` method:

```
data_frame_datasource0 =
glueContext.getSink(
  connectionType="kafka",
  connectionOptions={
    JsonOptions("""{
      "connectionName": "ConfluentKafka",
      "classification": "json",
      "topic": "kafka-auth-topic",
      "typeOfData": "kafka"}
    """)),
transformationContext="dataframe_ApacheKafka_node1711729173428")
.getDataFrame()
```

Example with the `write_dynamic_frame.from_options` method:

```
kafka_options =
  { "connectionName": "ConfluentKafka",
    "topicName": "kafka-auth-topic",
    "classification": "json"
  }
data_frame_datasource0 =
glueContext.write_dynamic_frame.from_options(connection_type="kafka",
connection_options=kafka_options)
```

Kafka connection option reference

When reading, use the following connection options with `"connectionType": "kafka"`:

- `"bootstrap.servers"` (Required) A list of bootstrap server URLs, for example, as `b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094`. This option must be specified in the API call or defined in the table metadata in the Data Catalog.
- `"security.protocol"` (Required) The protocol used to communicate with brokers. The possible values are `"SSL"` or `"PLAINTEXT"`.
- `"topicName"` (Required) A comma-separated list of topics to subscribe to. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.
- `"assign"`: (Required) A JSON string specifying the specific `TopicPartitions` to consume. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.

Example: '{"topicA":[0,1],"topicB":[2,4]}'

- "subscribePattern": (Required) A Java regex string that identifies the topic list to subscribe to. You must specify one and only one of "topicName", "assign" or "subscribePattern".

Example: 'topic.*'

- "classification" (Required) The file format used by the data in the record. Required unless provided through the Data Catalog.
- "delimiter" (Optional) The value separator used when classification is CSV. Default is ",",.
- "startingOffsets": (Optional) The starting position in the Kafka topic to read data from. The possible values are "earliest" or "latest". The default value is "latest".
- "startingTimestamp": (Optional, supported only for Amazon Glue version 4.0 or later) The Timestamp of the record in the Kafka topic to read data from. The possible value is a Timestamp string in UTC format in the pattern yyyy-mm-ddTHH:MM:SSZ (where Z represents a UTC timezone offset with a +/-). For example: "2023-04-04T08:00:00-04:00".

Note: Only one of 'startingOffsets' or 'startingTimestamp' can be present in the Connection Options list of the Amazon Glue streaming script, including both these properties will result in job failure.

- "endingOffsets": (Optional) The end point when a batch query is ended. Possible values are either "latest" or a JSON string that specifies an ending offset for each TopicPartition.

For the JSON string, the format is {"topicA":{"0":23,"1":-1},"topicB":{"0":-1}}. The value -1 as an offset represents "latest".

- "pollTimeoutMs": (Optional) The timeout in milliseconds to poll data from Kafka in Spark job executors. The default value is 600000.
- "numRetries": (Optional) The number of times to retry before failing to fetch Kafka offsets. The default value is 3.
- "retryIntervalMs": (Optional) The time in milliseconds to wait before retrying to fetch Kafka offsets. The default value is 10.
- "maxOffsetsPerTrigger": (Optional) The rate limit on the maximum number of offsets that are processed per trigger interval. The specified total number of offsets is proportionally split across topicPartitions of different volumes. The default value is null, which means that the consumer reads all offsets until the known latest offset.

- **"minPartitions"**: (Optional) The desired minimum number of partitions to read from Kafka. The default value is null, which means that the number of spark partitions is equal to the number of Kafka partitions.
- **"includeHeaders"**: (Optional) Whether to include the Kafka headers. When the option is set to "true", the data output will contain an additional column named "glue_streaming_kafka_headers" with type `Array[Struct(key: String, value: String)]`. The default value is "false". This option is available in Amazon Glue version 3.0 or later.
- **"schema"**: (Required when `inferSchema` set to false) The schema to use to process the payload. If classification is `avro` the provided schema must be in the Avro schema format. If the classification is not `avro` the provided schema must be in the DDL schema format.

The following are schema examples.

Example in DDL schema format

```
'column1' INT, 'column2' STRING , 'column3' FLOAT
```

Example in Avro schema format

```
{
  "type": "array",
  "items":
  {
    "type": "record",
    "name": "test",
    "fields":
    [
      {
        "name": "_id",
        "type": "string"
      },
      {
        "name": "index",
        "type":
        [
          "int",
          "string",
          "float"
        ]
      }
    ]
  }
}
```

```
]
}
}
```

- `"inferSchema"`: (Optional) The default value is `'false'`. If set to `'true'`, the schema will be detected at runtime from the payload within `foreachbatch`.
- `"avroSchema"`: (Deprecated) Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the `schema` parameter.
- `"addRecordTimestamp"`: (Optional) When this option is set to `'true'`, the data output will contain an additional column named `"__src_timestamp"` that indicates the time when the corresponding record received by the topic. The default value is `'false'`. This option is supported in Amazon Glue version 4.0 or later.
- `"emitConsumerLagMetrics"`: (Optional) When the option is set to `'true'`, for each batch, it will emit the metrics for the duration between the oldest record received by the topic and the time it arrives in Amazon Glue to CloudWatch. The metric's name is `"glue.driver.streaming.maxConsumerLagInMs"`. The default value is `'false'`. This option is supported in Amazon Glue version 4.0 or later.

When writing, use the following connection options with `"connectionType": "kafka"`:

- `"connectionName"` (Required) Name of the Amazon Glue connection used to connect to the Kafka cluster (similar to Kafka source).
- `"topic"` (Required) If a `topic` column exists then its value is used as the topic when writing the given row to Kafka, unless the `topic` configuration option is set. That is, the `topic` configuration option overrides the `topic` column.
- `"partition"` (Optional) If a valid partition number is specified, that `partition` will be used when sending the record.

If no `partition` is specified but a `key` is present, a `partition` will be chosen using a hash of the `key`.

If neither `key` nor `partition` is present, a `partition` will be chosen based on sticky partitioning those changes when at least `batch.size` bytes are produced to the `partition`.

- `"key"` (Optional) Used for partitioning if `partition` is null.
- `"classification"` (Optional) The file format used by the data in the record. We only support JSON, CSV and Avro.

With Avro format, we can provide a custom avroSchema to serialize with, but note that this needs to be provided on the source for deserializing as well. Else, by default it uses the Apache AvroSchema for serializing.

Additionally, you can fine-tune the Kafka sink as required by updating the [Kafka producer configuration parameters](#). Note that there is no allow listing on connection options, all the key-value pairs are persisted on the sink as is.

However, there is a small deny list of options that will not take effect. For more information, see [Kafka specific configurations](#).

Working with Kinesis connections

You can use a Kinesis connection to read and write to Amazon Kinesis data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. You can read information from Kinesis into a Spark DataFrame, then convert it to a Amazon Glue DynamicFrame. You can write DynamicFrames to Kinesis in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kinesis streaming source, the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kinesis streaming source. If you use `getSource`, `getSourceWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kinesis using the following arguments for the specified methods in the `GlueContext` class.

- Scala
 - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
 - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
 - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
 - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`

- `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
- `options`: Use with `getSource`, `getSink`

For notes and restrictions about Streaming ETL jobs, consult [the section called “Streaming ETL notes and restrictions”](#).

Configure Kinesis

To connect to a Kinesis data stream in an Amazon Glue Spark job, you will need some prerequisites:

- If reading, the Amazon Glue job must have Read access level IAM permissions to the Kinesis data stream.
- If writing, the Amazon Glue job must have Write access level IAM permissions to the Kinesis data stream.

In certain cases, you will need to configure additional prerequisites:

- If your Amazon Glue job is configured with **Additional network connections** (typically to connect to other datasets) and one of those connections provides Amazon VPC **Network options**, this will direct your job to communicate over Amazon VPC. In this case you will also need to configure your Kinesis data stream to communicate over Amazon VPC. You can do this by creating an interface VPC endpoint between your Amazon VPC and Kinesis data stream. For more information, see [Using Kinesis Data Streams with Interface VPC Endpoints](#).
- When specifying Amazon Kinesis Data Streams in another account, you must setup the roles and policies to allow cross-account access. For more information, see [Example: Read From a Kinesis Stream in a Different Account](#).

For more information about Streaming ETL job prerequisites, consult [the section called “Streaming ETL jobs”](#).

Read from Kinesis

Example: Reading from Kinesis streams

Used in conjunction with [the section called “forEachBatch”](#).

Example for Amazon Kinesis streaming source:

```
kinesis_options =
  { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
    "startingPosition": "TRIM_HORIZON",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kinesis",
  connection_options=kinesis_options)
```

Write to Kinesis

Example: Writing to Kinesis streams

Used in conjunction with [the section called “forEachBatch”](#). Your DynamicFrame will be written to the stream in a JSON format. If the job cannot write after several retries, it will fail. By default, each DynamicFrame record will be sent to the Kinesis stream individually. You can configure this behavior using aggregationEnabled and associated parameters.

Example writing to Amazon Kinesis from a streaming job:

Python

```
glueContext.write_dynamic_frame.from_options(
  frame=frameToWrite
  connection_type="kinesis",
  connection_options={
    "partitionKey": "part1",
    "streamARN": "arn:aws:kinesis:us-east-1:111122223333:stream/streamName",
  }
)
```

Scala

```
glueContext.getSinkWithFormat(

  options=JsonOptions("""{
    "streamARN": "arn:aws:kinesis:us-
east-1:111122223333:stream/streamName",
    "partitionKey": "part1"
  }"""),
```

```
)  
    .writeDynamicFrame(frameToWrite)
```

Kinesis connection parameters

Designates connection options for Amazon Kinesis Data Streams.

Use the following connection options for Kinesis streaming data sources:

- "streamARN" (Required) Used for Read/Write. The ARN of the Kinesis data stream.
- "classification" (Required for read) Used for Read. The file format used by the data in the record. Required unless provided through the Data Catalog.
- "streamName" – (Optional) Used for Read. The name of a Kinesis data stream to read from. Used with `endpointUrl`.
- "endpointUrl" – (Optional) Used for Read. Default: "https://kinesis.us-east-1.amazonaws.com". The Amazon endpoint of the Kinesis stream. You do not need to change this unless you are connecting to a special region.
- "partitionKey" – (Optional) Used for Write. The Kinesis partition key used when producing records.
- "delimiter" (Optional) Used for Read. The value separator used when `classification` is CSV. Default is ",".
- "startingPosition": (Optional) Used for Read. The starting position in the Kinesis data stream to read data from. The possible values are "latest", "trim_horizon", "earliest", or a Timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where Z represents a UTC timezone offset with a +/-). For example "2023-04-04T08:00:00-04:00". The default value is "latest". Note: the Timestamp string in UTC Format for "startingPosition" is supported only for Amazon Glue version 4.0 or later.
- "failOnDataLoss": (Optional) Fail the job if any active shard is missing or expired. The default value is "false".
- "awsSTSRoleARN": (Optional) Used for Read/Write. The Amazon Resource Name (ARN) of the role to assume using Amazon Security Token Service (Amazon STS). This role must have permissions for describe or read record operations for the Kinesis data stream. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSSessionName".

- "awsSTSSessionName": (Optional) Used for Read/Write. An identifier for the session assuming the role using Amazon STS. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSRoleARN".
- "awsSTSEndpoint": (Optional) The Amazon STS endpoint to use when connecting to Kinesis with an assumed role. This allows using the regional Amazon STS endpoint in a VPC, which is not possible with the default global endpoint.
- "maxFetchTimeInMs": (Optional) Used for Read. The maximum time spent for the job executor to read records for the current batch from the Kinesis data stream, specified in milliseconds (ms). Multiple GetRecords API calls may be made within this time. The default value is 1000.
- "maxFetchRecordsPerShard": (Optional) Used for Read. The maximum number of records to fetch per shard in the Kinesis data stream per microbatch. Note: The client can exceed this limit if the streaming job has already read extra records from Kinesis (in the same get-records call). If maxFetchRecordsPerShard needs to be strict then it needs to be a multiple of maxRecordPerRead. The default value is 100000.
- "maxRecordPerRead": (Optional) Used for Read. The maximum number of records to fetch from the Kinesis data stream in each getRecords operation. The default value is 10000.
- "addIdleTimeBetweenReads": (Optional) Used for Read. Adds a time delay between two consecutive getRecords operations. The default value is "False". This option is only configurable for Glue version 2.0 and above.
- "idleTimeBetweenReadsInMs": (Optional) Used for Read. The minimum time delay between two consecutive getRecords operations, specified in ms. The default value is 1000. This option is only configurable for Glue version 2.0 and above.
- "describeShardInterval": (Optional) Used for Read. The minimum time interval between two ListShards API calls for your script to consider resharding. For more information, see [Strategies for Resharding](#) in *Amazon Kinesis Data Streams Developer Guide*. The default value is 1s.
- "numRetries": (Optional) Used for Read. The maximum number of retries for Kinesis Data Streams API requests. The default value is 3.
- "retryIntervalMs": (Optional) Used for Read. The cool-off time period (specified in ms) before retrying the Kinesis Data Streams API call. The default value is 1000.
- "maxRetryIntervalMs": (Optional) Used for Read. The maximum cool-off time period (specified in ms) between two retries of a Kinesis Data Streams API call. The default value is 10000.

- **"avoidEmptyBatches"**: (Optional) Used for Read. Avoids creating an empty microbatch job by checking for unread data in the Kinesis data stream before the batch is started. The default value is "False".
- **"schema"**: (Required when inferSchema set to false) Used for Read. The schema to use to process the payload. If classification is avro the provided schema must be in the Avro schema format. If the classification is not avro the provided schema must be in the DDL schema format.

The following are schema examples.

Example in DDL schema format

```
`column1` INT, `column2` STRING , `column3` FLOAT
```

Example in Avro schema format

```
{
  "type": "array",
  "items":
  {
    "type": "record",
    "name": "test",
    "fields":
    [
      {
        "name": "_id",
        "type": "string"
      },
      {
        "name": "index",
        "type":
        [
          "int",
          "string",
          "float"
        ]
      }
    ]
  }
}
```

- **"inferSchema"**: (Optional) Used for Read. The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within foreachbatch.

- "avroSchema": (Deprecated) Used for Read. Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the schema parameter.
- "addRecordTimestamp": (Optional) Used for Read. When this option is set to 'true', the data output will contain an additional column named "__src_timestamp" that indicates the time when the corresponding record received by the stream. The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.
- "emitConsumerLagMetrics": (Optional) Used for Read. When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the stream and the time it arrives in Amazon Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in Amazon Glue version 4.0 or later.
- "fanoutConsumerARN": (Optional) Used for Read. The ARN of a Kinesis stream consumer for the stream specified in streamARN. Used to enable enhanced fan-out mode for your Kinesis connection. For more information on consuming a Kinesis stream with enhanced fan-out, see [the section called "Using enhanced fan-out in Kinesis streaming jobs"](#).
- "recordMaxBufferedTime" – (Optional) Used for Write. Default: 1000 (ms). Maximum time a record is buffered while waiting to be written.
- "aggregationEnabled" – (Optional) Used for Write. Default: true. Specifies if records should be aggregated before sending them to Kinesis.
- "aggregationMaxSize" – (Optional) Used for Write. Default: 51200 (bytes). If a record is larger than this limit, it will bypass the aggregator. Note Kinesis enforces a limit of 50KB on record size. If you set this beyond 50KB, oversize records will be rejected by Kinesis.
- "aggregationMaxCount" – (Optional) Used for Write. Default: 4294967295. Maximum number of items to pack into an aggregated record.
- "producerRateLimit" – (Optional) Used for Write. Default: 150 (%). Limits per-shard throughput sent from a single producer (such as your job), as a percentage of the backend limit.
- "collectionMaxCount" – (Optional) Used for Write. Default: 500. Maximum number of items to pack into an PutRecords request.
- "collectionMaxSize" – (Optional) Used for Write. Default: 5242880 (bytes). Maximum amount of data to send with a PutRecords request.

Amazon Glue streaming autoscaling

Amazon Glue streaming ETL jobs continuously consume data from streaming sources, clean and transform the data in-flight, and make it available for analysis. By monitoring each stage of the job run, Amazon Glue autoscaling can turn off workers when they are idle or add workers if additional parallel processing is possible.

The following sections provide information on Amazon Glue streaming autoscaling

Enabling Auto Scaling in Amazon Glue Studio

On the **Job details** tab in Amazon Glue Studio, choose the type as **Spark** or **Spark Streaming**, and **Glue version** as **Glue 3.0** or **Glue 4.0**. Then a check box will show up below **Worker type**.

- Select the **Automatically scale the number of workers** option.
- Set the **Maximum number of workers** to define the maximum number of workers that can be vended to the job run.

Visual | Script | **Job details** | Runs | Schedules

Type
The type of ETL job. This is set automatically based on the types of data sources you have selected.

Spark

Glue version [Info](#)

Glue 3.0 - Supports spark 3.1, Scala 2, Python 3 ▼

Language

Python 3 ▼

Worker type
Set the type of predefined worker that is allowed when a job runs.

G.1X ▼

Automatically scale the number of workers
Glue will optimize costs and resource usage by dynamically scaling the number of workers up and down throughout the job run.
Requires Glue 3.0 or later.

Maximum number of workers
The number of workers you want Glue to allocate to this job.

10

The maximums are 299 for G.1X and 149 for G.2X, and the minimum is 2.

Enabling Auto Scaling with the Amazon CLI or SDK

To enable Auto Scaling From the Amazon CLI for your job run, run `start-job-run` with the following configuration:

```
{
  "JobName": "<your job name>",
  "Arguments": {
    "--enable-auto-scaling": "true"
  },
  "WorkerType": "G.2X", // G.1X, G.2X, G.4X, G.8X, G.12X, G.16X, R.1X, R.2X, R.4X,
and R.8X are supported for Auto Scaling Jobs
  "NumberOfWorkers": 20, // represents Maximum number of workers
  ...other job run configurations...
}
```

Once an ETL job run is finished, you can also call `get-job-run` to check the actual resource usage of the job run in DPU-seconds. Note: the new field **DPUSecods** will only show up for your batch jobs on Amazon Glue 3.0 or later enabled with Auto Scaling. This field is not supported for streaming jobs.

```
$ aws glue get-job-run --job-name your-job-name --run-id jr_xx --endpoint https://
glue.us-east-1.amazonaws.com --region us-east-1
{
  "JobRun": {
    ...
    "GlueVersion": "3.0",
    "DPUSecods": 386.0
  }
}
```

You can also configure job runs with Auto Scaling using the [Amazon Glue SDK](#) with the same configuration.

How it works

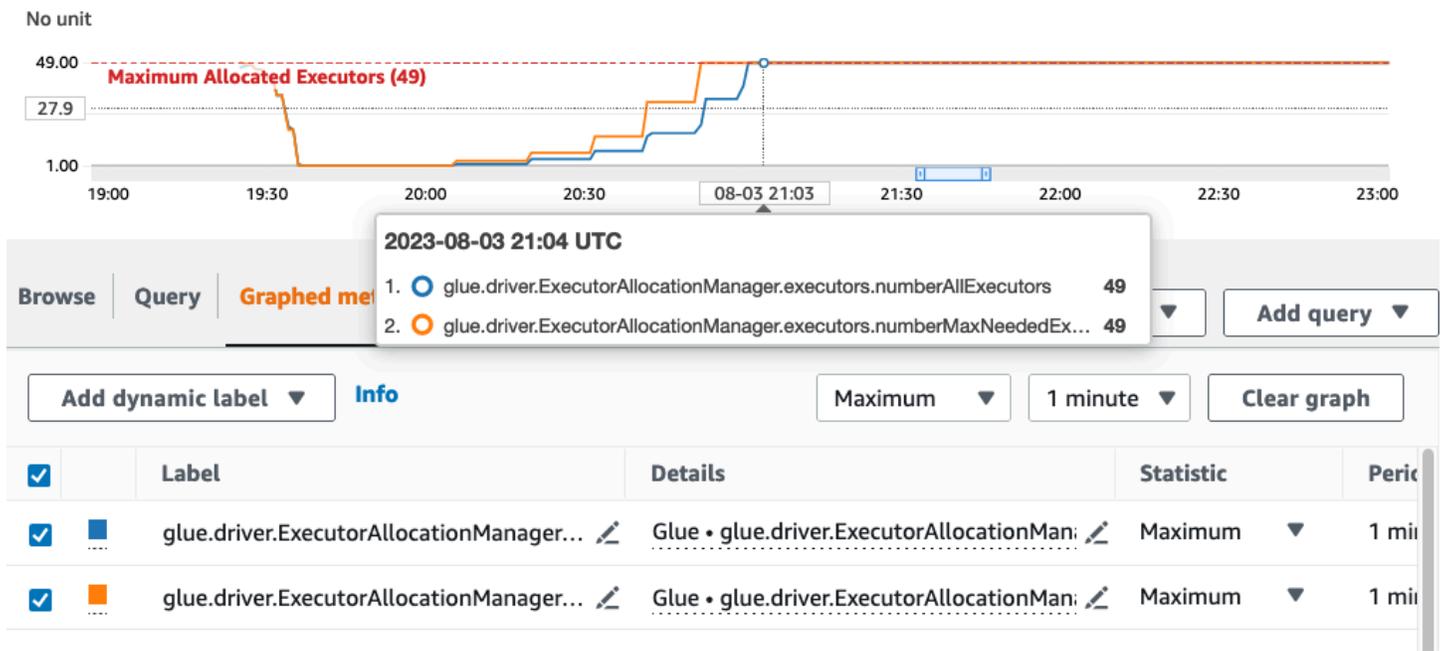

Scaling across microbatch

The following example is used to describe how autoscaling works.

- You have an Amazon Glue job that starts with 50 DPUs.
- Autoscaling is enabled.

In this example, Amazon Glue looks at the `batchProcessingTimeInMs` metric for a few micro batches and determines if your jobs are completing within the window size that you have established. If your jobs are completing sooner and depending on how soon they complete, Amazon Glue may scale down. This metric, plotted with `numberAllExecutors` can be monitored in Amazon CloudWatch to see how autoscaling works.

The number of executors exponentially scales up or down only after each micro batch completes. As you can see from the Amazon CloudWatch Monitoring log, Amazon Glue looks at the number of needed executors (Orange Line) and scales the executors (blue line) to match that automatically.

Once Amazon Glue scales down the number of executors and observes that data volumes increase, consequently increasing the micro batch processing time, Amazon Glue will scale up to 50 DPUs, which is the specified upper limit.

Scaling within microbatch

In the above example, the system monitors a few completed micro-batches to make a decision on whether to scale up or down. Longer windows require autoscaling to respond more quickly within the microbatch, rather than waiting for a few micro batches. For these cases, you can use an additional configuration `--auto-scale-within-microbatch` to `true`. You can add this to the Amazon Glue job properties in Amazon Glue Studio as shown below.

Job parameters [Info](#)

Key Value - optional

Q --auto-scale-within-microbatch X

Remove

Add new parameter

You can add 49 more parameters.

Maintenance windows for Amazon Glue Streaming

Amazon Glue periodically performs maintenance activities. During these maintenance windows, Amazon Glue will need to restart your streaming jobs. You can control when the jobs are restarted by specifying maintenance windows. In this section, we outline where you can setup the maintenance window and specific behaviors you should consider.

Topics

- [Setting up a maintenance window](#)
- [Maintenance window behavior](#)
- [Job monitoring](#)
- [Data loss handling](#)

Setting up a maintenance window

You can set up a maintenance window using Amazon Glue Studio or APIs.

Setting up a maintenance windows in Amazon Glue Studio

You can specify a maintenance window in the **Job Details** page of your Amazon Glue Streaming job. You can specify the day and time in GMT. Amazon Glue will restart your job within the specified time window.

Maintenance window

Restart on

at hours (GMT)

For maintenance reasons, AWS Glue will restart streaming jobs within 3 hours of the specified maintenance window. You have the option to designate the start time in GMT for this maintenance. For more information, refer to documentation.

Setting up a maintenance windows in the API

You can alternatively set up the maintenance window in the Create Job API. Here is an example of configuring a maintenance windows via the API.

```
aws glue create-job --name jobName --role roleArnForTheJob --command
Name=gluestreaming,ScriptLocation=s3-path-to-the-script --maintenance-window="Sun:10"
```

An example command is as follows:

```
aws glue create-job --name testMaintenance --role arn:aws:iam::012345678901:role/
Glue_DefaultRole --command Name=gluestreaming,ScriptLocation=s3://glue-example-test/
example.py --maintenance-window="Sun:10"
```

Maintenance window behavior

Amazon Glue goes through a series of steps to decide when to restart a job:

1. When a new streaming job is initiated, Amazon Glue first checks if there is a timeout associated with the job run. A timeout allows you to configure the end time of the job. If the timeout is less than 7 days, then the job will not be restarted.
2. If the timeout is greater than 7 days, then Amazon Glue checks if the maintenance window is configured for the job. If it is then that window is picked up and the window gets assigned to the job run. Amazon Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.
3. If the maintenance window is not configured, Amazon Glue automatically sets the restart time to 7 days past job run initiation time. For instance, if you initiated your job on 7/1/2024 12:00AM GMT and you did not specify maintenance windows, your job will be set to restart on 7/8/2024 at 12:00 AM GMT.

Note

If you are already running streaming jobs, this change will impact you starting July 1, 2024. You will have time until June 30th to configure your maintenance windows. After July 1st, any streaming jobs that you start will be restarted per this documentation. If you require any additional support, you can reach out to Amazon Support.

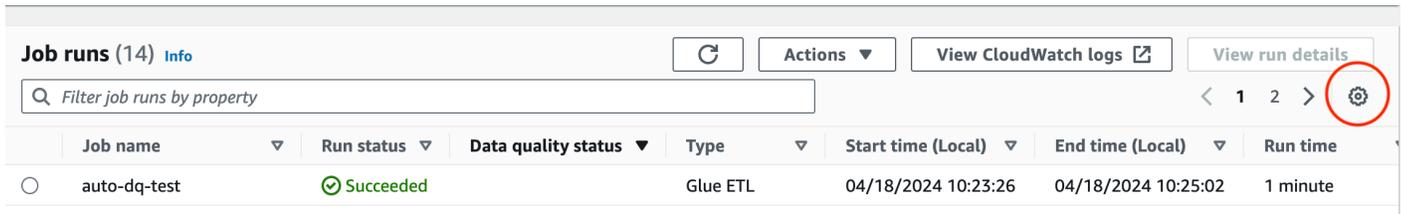

4. Sometimes, Amazon Glue may not be able to restart the job, especially when the ongoing micro-batch is not processed. In these instances, the job will not be interrupted. In these instances, Amazon Glue will restart the job after 14 days, and in this case, the maintenance window is not honored.

Job monitoring

You can monitor the jobs in the Amazon Glue Studio **Monitoring** page.

To see the expected next restart time of streaming jobs, show the column on the Job runs table on the **Monitoring** page.

1. Click the Gear icon in the top right of the table.

The screenshot shows the 'Job runs' table in Amazon Glue Studio. The table header includes 'Job runs (14) Info', a refresh button, an 'Actions' dropdown, a 'View CloudWatch logs' button, and a 'View run details' button. Below the header is a search bar with the placeholder text 'Filter job runs by property'. The table has the following columns: Job name, Run status, Data quality status, Type, Start time (Local), End time (Local), and Run time. The first row shows a job named 'auto-dq-test' with a status of 'Succeeded', type 'Glue ETL', start time '04/18/2024 10:23:26', end time '04/18/2024 10:25:02', and a run time of '1 minute'. A gear icon in the top right corner of the table is circled in red.

Job name	Run status	Data quality status	Type	Start time (Local)	End time (Local)	Run time
auto-dq-test	Succeeded		Glue ETL	04/18/2024 10:23:26	04/18/2024 10:25:02	1 minute

2. Scroll down, and turn on the **Expected restart time** column. Both UTC and Local time options are available.

worker type

DPU hours

Last modified (Local)

Worker utilization

Start time (UTC)

End time (UTC)

Last modified (UTC)

Data quality

Expected restart time (UTC)

Expected restart time (Local)

Cancel
Confirm

3. You can then view the columns in the table.

Job runs (14) [Info](#) ↻ Actions ▾ View CloudWatch logs ↗ View run details

	Job name ▾	Run status ▾	Type ▾	Start time (Local) ▾	End time (Local) ▾	Expected restart time (Local) ▾
<input type="radio"/>	auto-dq-test	✔ Succeeded	Glue ETL	04/18/2024 10:23:26	04/18/2024 10:25:02	-
<input type="radio"/>	StreamingTest	🔄 Running	Glue Streaming	04/16/2024 16:32:49	-	04/23/2024 02:00:00
<input type="radio"/>	StreamingProd	🔄 Running	Glue Streaming	04/16/2024 13:45:10	-	04/25/2024 05:00:00

The original job will have an "EXPIRED" status and the new job instance will have a "RUNNING" status. The new job run that was restarted will have a job run ID as a concatenation of initial job run ID plus the prefix "restart_" representing the restart count. For example, if the initial job run ID is `jr_1234`, then the restarted job run will have the ID `jr1234_restart_1` for the first restart. The second restart will be `jr1234_restart_2` for the second restart and so on.

Your retry attempt will not be impacted because of the restarts. If a run fails and a new run is started due to an automatic retry, the counter of restart will start from 1 again. For example, if a run fails at `jr_1234_attempt_3_restart_5`, then an automatic retry will start new run with ID: `jr_id1_attempt_4` and when this attempt is restarted after 7 days, the new run ID will be `jr_id1_attempt_4_restart_1`.

Data loss handling

During maintenance restarts, Amazon Glue Streaming follows a process that ensures data integrity and consistency between the previous job run and the restarted job run. Note that Amazon Glue does not guarantee data integrity and consistency between job restarts and we recommend architecture considerations to handle duplicated data within streaming jobs.

1. Detecting maintenance restart conditions: Amazon Glue Streaming monitors conditions that indicate when a maintenance restart should be triggered, such as when a maintenance window is reached after 7 days or a hard restart is necessary after 14 days.
2. Invoking a graceful termination: When the maintenance restart conditions are met, Amazon Glue Streaming initiates a graceful termination process for the currently running job. This process involves the following steps:
 - a. Stopping the ingestion of new data: The streaming job stops consuming new data from the input sources (for example, Kafka topics, Kinesis streams, or files).
 - b. Processing pending data: The job continues to process any data that is already present in its internal buffers or queues.
 - c. Committing offsets and checkpoints: The job commits the latest offsets or checkpoints to external systems (for example, Kafka, Kinesis, or Amazon S3) to ensure that the restarted job can pick up from where the previous job left off.
3. Restarting the job: After the graceful termination process is complete, Amazon Glue Streaming restarts the job using the preserved state and checkpoints. The restarted job picks up processing from the last committed offset or checkpoint, ensuring that no data is lost or duplicated.

4. Resuming data processing: The restarted job resumes data processing from the point where the previous job left off. It continues ingesting new data from the input sources, starting from the last committed offset or checkpoint, and processes the data according to the defined ETL logic.

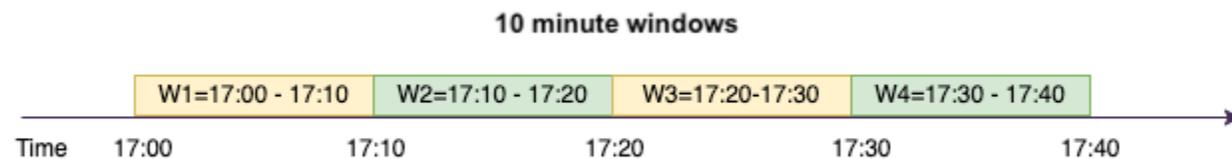

Advanced Amazon Glue streaming concepts

In contemporary data-driven applications, the significance of data diminishes over time and its value transitions from being predictive to reactive. As a result, customers want to process data in real-time for making faster decisions. When dealing with real-time data feeds, such as from IoT sensors, the data may arrive unordered or experience delays in processing due to network latency and other source-related failures during ingestion. As part of the Amazon Glue platform, Amazon Glue Streaming builds on these capabilities to provide scalable, serverless streaming ETL, powered by Apache Spark structured streaming, empowering users with real-time data processing.

In this topic, we will explore advanced streaming concepts and capabilities of Amazon Glue Streaming.

Time considerations when processing streams

There are four notions of time when processing streams:

- **Event-time** – The time at which the event occurred. In most cases, this field is embedded into the event-data itself, at the source.
- **Event-time-window** – The time frame between two event-times. As shown in the above diagram, **W1** is an event-time-window from 17:00 to 17:10. Each event-time-window is a grouping of multiple events.
- **Trigger-time** – The trigger time controls how often the processing of data and updating of results occurs. This is the time when the micro-batch processing started.
- **Ingestion-time** – The time when the stream-data was ingested into the streaming service. If event-time is not embedded into the event itself, this time can be used for windowing in some cases.

Windowing

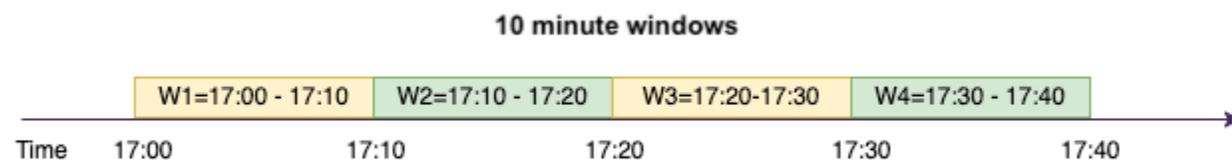

Windowing is a technique where you group and aggregate multiple events by event-time-window. We will explore the benefits of windowing and when you would use it in the following examples.

Depending on the business use case, there are three types of time windows supported by spark.

- **Tumbling window** – a series of non-overlapping fixed size event-time-windows over which you aggregate.
- **Sliding window** – similar to the tumbling windows from the point of being “fixed-sized”, but windows can overlap or slide as long as the duration of slide is smaller than the duration of window itself.
- **Session window** – starts with an input data event and continues to expands itself as long as it receives input within a gap or duration of inactivity. A session window can have a static or dynamic size of the window length, depending on the inputs.

Tumbling window

Tumbling window is a series of non-overlapping fixed size event-time-windows over which you aggregate. Lets understand this with a real world example.

Company ABC Auto wants to do a marketing campaign for a new brand of sports car. They want to pick a city where they have biggest sports car fans. To achieve this goal, they showcase a short 15 second advertisement introducing the car on their website. All the “clicks” and the corresponding “city” are recorded and streamed to Amazon Kinesis Data Streams. We want to count the number of clicks in a 10 minute window and group it by city to see which city has the highest demand. The following is the output of the aggregation.

window_start_time	window_end_time	city	total_clicks
2023-07-10 17:00:00	2023-07-10 17:10:00	Dallas	75

window_start_time	window_end_time	city	total_clicks
2023-07-10 17:00:00	2023-07-10 17:10:00	Chicago	10
2023-07-10 17:20:00	2023-07-10 17:30:00	Dallas	20
2023-07-10 17:20:00	2023-07-10 17:30:00	Chicago	50

As explained above, these event-time-windows are different from trigger-time intervals. For example, even if your trigger time is every minute, the output results will only show 10 minute non-overlapping aggregation windows. For optimization, its better to have the trigger interval aligned with the event-time-window.

In the table above, Dallas saw 75 clicks in the 17:00-17:10 window, while Chicago had 10 clicks. Also, there is no data for the 17:10 - 17:20 window for any city, so this window is omitted.

Now you can run further analysis on this data in the downstream analytics application to determine the most exclusive city to run the marketing campaign.

Using tumbling windows in Amazon Glue

1. Create a Amazon Kinesis Data Streams DataFrame and read from it. Example:

```
parsed_df = kinesis_raw_df \
    .selectExpr('CAST(data AS STRING)') \
    .select(from_json("data", ticker_schema).alias("data")) \
    .select('data.event_time', 'data.ticker', 'data.trade', 'data.volume',
'data.price')
```

2. Process data in a tumbling window. In the example below, data is grouped based on the input field "event_time" in 10 minute tumbling windows and writing the output to an Amazon S3 data lake.

```
grouped_df = parsed_df \
    .groupBy(window("event_time", "10 minutes"), "city") \
    .agg(sum("clicks").alias("total_clicks"))

summary_df = grouped_df \
    .withColumn("window_start_time", col("window.start")) \
```

```

        .withColumn("window_end_time", col("window.end")) \
        .withColumn("year", year("window_start_time")) \
        .withColumn("month", month("window_start_time")) \
        .withColumn("day", dayofmonth("window_start_time")) \
        .withColumn("hour", hour("window_start_time")) \
        .withColumn("minute", minute("window_start_time")) \
        .drop("window")

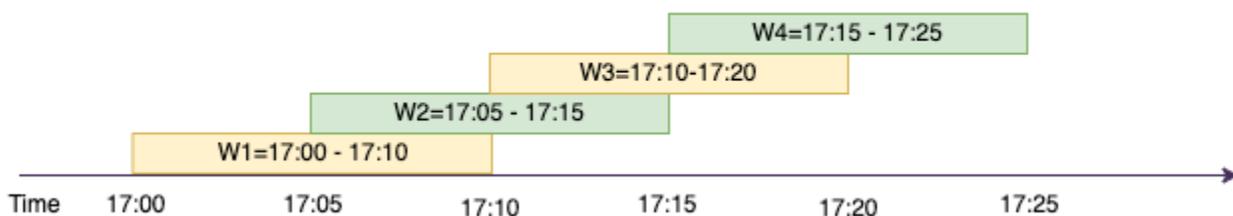

write_result = summary_df \
    .writeStream \
    .format("parquet") \
    .trigger(processingTime="10 seconds") \
    .option("checkpointLocation", "s3a://bucket-stock-stream/stock-
stream-catalog-job/checkpoint/") \
    .option("path", "s3a://bucket-stock-stream/stock-stream-catalog-
job/summary_output/") \
    .partitionBy("year", "month", "day") \
    .start()

```

Sliding window

Sliding windows are similar to the tumbling windows from the point of being “fixed-sized”, but windows can overlap or slide as long as the duration of slide is smaller than the duration of window itself. Due to the nature of sliding, an input can be bound to the multiple windows.

Sliding Window (10 min window, sliding by 5 min)

To better understand, let's consider the example of a bank that wants to detect potential credit card fraud. A streaming application could monitor a continuous stream of credit card transactions. These transactions could be aggregated into windows of 10 minutes duration and every 5 minutes, the window would slide forward, eliminating the oldest 5 minutes of data and adding the latest 5 minutes of new data. Within each window, the transactions could be grouped by country checking for suspicious patterns, such as a transaction in the US immediately followed by another in

Australia. For simplicity, let's categorize such transactions as fraud when the total transactions amount is greater than \$100. If such a pattern is detected, it signals potential fraud and the card could be frozen.

The credit card processing system is sending a stream of transaction events to Kinesis for each card-id along with the country. An Amazon Glue job runs the analysis and produces the following aggregated output.

window_start_time	window_end_time	card_last_four	country	total_amount
2023-07-10 17:00:00	2023-07-10 17:10:00	6544	US	85
2023-07-10 17:00:00	2023-07-10 17:10:00	6544	Australia	10
2023-07-10 17:05:45	2023-07-10 17:15:45	6544	US	50
2023-07-10 17:10:45	2023-07-10 17:20:45	6544	US	50
2023-07-10 17:10:45	2023-07-10 17:20:45	6544	Australia	150

Based on the above aggregation, you can see the 10 minute window sliding every 5 minutes, summed by transaction amount. The anomaly is detected in the 17:10 - 17:20 window where there is an outlier, which is a transaction for \$150 in Australia. Amazon Glue can detect this anomaly and push an alarm-event with the offending key to an SNS topic using boto3. Further a Lambda function can subscribe to this topic and take action.

Process data in a sliding window

The `group-by` clause and the window function is used to implement the sliding window as shown below.

```
grouped_df = parsed_df \
```

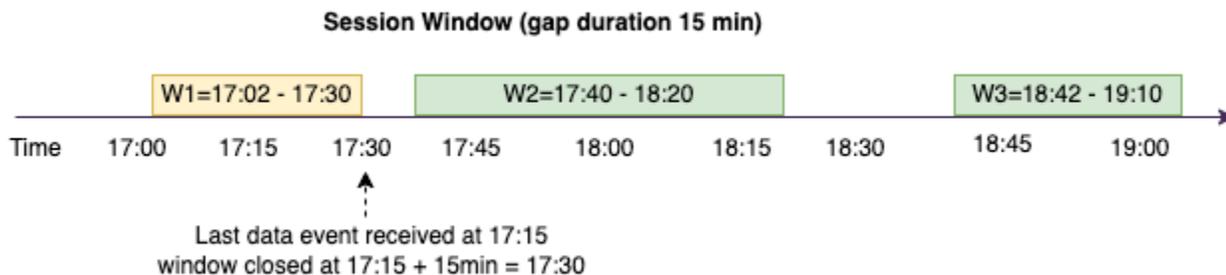

```

.groupBy(window(col("event_time"), "10 minute", "5 min"), "country",
"card_last_four") \
.agg(sum("tx_amount").alias("total_amount"))

```

Session window

Unlike the above two windows that have a fixed-size, session window can have a static or dynamic size of the window length, depending on the inputs. A session window starts with an input data event and continues to expand itself as long as it receives input within a gap or duration of inactivity.

Lets take an example. Company ABC hotel wants to find out when is the busiest time in a week and provide better deals for their guests. As soon as a guest checks-in, a session window is started and spark maintains a state with aggregation for that event-time-window. Every time a guests checks in, an event is generated and sent to Amazon Kinesis Data Streams. The hotel makes a decision that if there is no check-ins for a period of 15 minutes, the event-time-window can be closed. The next event-time-window will start again when there is a new check-in. The output looks as follows.

window_start_time	window_end_time	city	total_checkins
2023-07-10 17:02:00	2023-07-10 17:30:00	Dallas	50
2023-07-10 17:02:00	2023-07-10 17:30:00	Chicago	25
2023-07-10 17:40:00	2023-07-10 18:20:00	Dallas	75
2023-07-10 18:50:45	2023-07-10 19:15:45	Dallas	20

The first check-in occurred at event_time=17:02. The aggregation event-time-window will start at 17:02. This aggregation will continue as long as we receive events within 15 minute duration. In

the above example, the last event we received was at 17:15 and then for the next 15 minutes there were no events. As a result, Spark closed that event-time-window at 17:15+15min = 17:30 and set it as 17:02 - 17:30. It started a new event-time-window at 17:47 when it received a new check-in data event.

Process data in a session window

The group-by clause and the window function is used to implement the sliding window.

```
grouped_df = parsed_df \
    .groupBy(session_window(col("event_time"), "10 minute"), "city") \
    .agg(count("check_in").alias("total_checkins"))
```

Output modes

Output mode is the mode in which the results from the unbounded table are written to the external sink. There are three modes available. In the following example you are counting occurrences of a word as lines of data are being streamed and processed in each micro batch.

- **Complete mode** – The whole result table will be written to the sink after every micro batch processing even though the word count was not updated in the current event-time-window.
- **Append mode** – This is the default mode, where only the new words and or rows added to the result table since the last trigger will be written to the sink. This mode is good for stateless streaming for queries like map, flatMap, filter, etc.
- **Update mode** – Only the words and or rows in the Result Table that were updated or added since the last trigger will be written to the sink.

Note

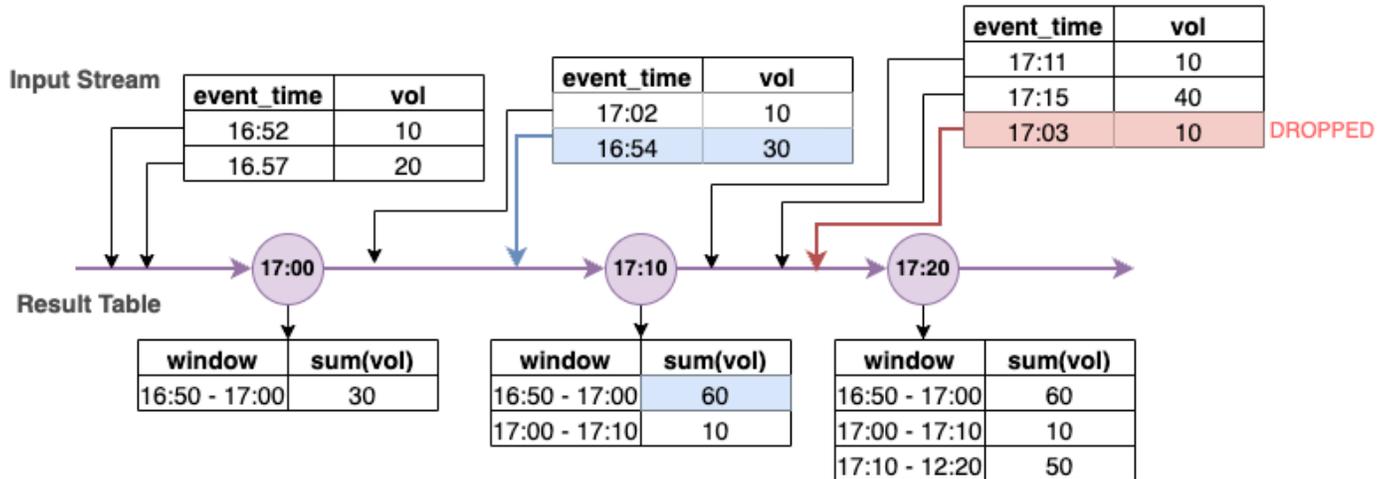

Output mode = "update" is not supported for session windows.

Handling late data and watermarks

When working with real-time data there could be delays in the arrival of data due to network latency and upstream failures and we need a mechanism to perform the aggregation again on the missed event-time-window. However, to do this, state needs to be maintained. At the same

time, the older data needs to be cleaned up to limit the size of the state. Spark version 2.1 added support for a feature called watermarking which maintains state and allows the user to specify the threshold for late data.

With reference to our stock ticker example above, let's consider the allowed threshold for the late data as no more than 10 minutes. To keep it simple we will assume tumbling window, ticker as AMZ, trade as BUY.

In the above diagram, we are calculating the total volume over a tumbling 10 minute window. We have the trigger at 17:00, 17:10 and 17:20. Above the timeline arrow, we have the input data stream and below is the unbounded results table.

In the first 10 minute tumbling window we aggregated based on event_time and the total_volume was calculated as 30. In the second event-time-window, spark got the first data event with event_time=17:02. Since this is the max event_time seen thus far by spark, the watermark threshold is set 10 minutes back (that is, watermark_event_time=16:52). Any data event with an event_time after 16:52 will be considered for time bound aggregation and any data event before that will be dropped. This allows spark to maintain an intermediate state for additional 10 minutes to accommodate late data. Around wall clock time 17:08 Spark received an event with an event_time=16:54 which was within threshold. Hence spark recalculated the "16:50 - 17:00" event-time-window and the total volume was updated from 30 to 60.

However, at the trigger time 17:20, when spark received event with event_time=17:15 it set the watermark_event_time=17:05. Hence the late data event with event_time=17:03 was considered "too late" and ignored.

$$\text{Watermark Boundary} = \text{Max(Event Time)} - \text{Watermark Threshold}$$

Using watermarks in Amazon Glue

Spark will not emit or write the data to the external sink until the watermark boundary is passed. To implement a watermark in Amazon Glue, see the example below.

```
grouped_df = parsed_df \  
    .withWatermark("event_time", "10 minutes") \  
    .groupBy(window("event_time", "5 minutes"), "ticker") \  
    .agg(sum("volume").alias("total_volume"))
```

About monitoring Amazon Glue streaming jobs

Monitoring your streaming job is a critical part of building your ETL pipeline. Apart from using the Spark UI, you can also use Amazon CloudWatch to monitor the metrics. Below is a list of streaming metrics emitted by the Amazon Glue framework. For a complete list of all the Amazon Glue metrics, see [Monitoring Amazon Glue using Amazon CloudWatch metrics](#).

Amazon Glue uses a structured streaming framework to process the input events. You can either use the Spark API directly in your code or leverage the `ForEachBatch` provided by `GlueContext`, which publishes these metrics. To understand these metrics, we need to first understand `windowSize`.

windowSize: `windowSize` is the micro-batch interval that you provide. If you specify a window size of 60 seconds, the Amazon Glue streaming job will wait for 60 seconds (or more if the previous batch hasn't completed by then) before it will read data in a batch from the streaming source and apply the transformations provided in `ForEachBatch`. This is also referred to as the trigger interval.

Lets review the metrics in greater detail to understand the health and performance characteristics.

Note

The metrics are emitted every 30 seconds. If your `windowSize` is less than 30 seconds then the reported metrics are an aggregation. For example say your `windowSize` is 10 seconds and you are steadily processing 20 records per micro-batch. In this scenario, the emitted metric value for `numRecords` would be 60.

A metric is not emitted if there is no data available for it. Also, in case of the consumer lag metric, you have to enable the feature to get metrics for it.

Visualizing Amazon Glue streaming metrics

To plot visual metrics:

1. Go to **Metrics** in the Amazon CloudWatch console and then choose the **Browse** tab. Then choose **Glue** under "Custom namespaces".

2. Choose **Job Metrics** to show you the metrics for all your jobs.
3. Filter the metrics based on your JobName=glue-feb-monitoring and then JobRunId=ALL. You can click on the "+" sign as shown in the figure below to add it to the search filter.
4. Select the checkbox for the metrics that you are interested in. In the below figure we have selected numberAllExecutors and numberMaxNeededExecutors.

5. Once you have selected these metrics, you can go to the **Graphed metrics** tab and apply your statistics.
6. Since the metrics are emitted every min, you can apply the "average" over a minute for batchProcessingTimeInMs and maxConsumerLagInMs. For the numRecords you can apply the "sum" over every minute.
7. You can add a horizontal windowSize annotation to your graph using the **Options** tab.

8. Once you have your metrics selected, create a dashboard and add it. Here is a sample dashboard.

Using Amazon Glue streaming metrics

This section describes each of the metrics and how they co-relate with each other.

Number of records (metric: streaming.numRecords)

This metric indicates how many records are being processed.

This streaming metric provides visibility into the number of records you are processing in a window. Along with the number of records being processed, it will also help you understand the behavior of the input traffic.

- Indicator #1 shows an example of stable traffic without any bursts. Typically this will be applications like IoT sensors that are collecting data at regular intervals and sending it to the streaming source.
- Indicator #2 shows an example of a sudden burst in traffic on an otherwise stable load. This could happen in a clickstream application when there is a marketing event like Black Friday and there is a burst in the number of clicks
- Indicator #3 shows an example of unpredictable traffic. Unpredictable traffic doesn't mean there is a problem. It is just the nature of the input data. Going back to the IoT sensor example, you can think of hundreds of sensors that are sending weather change events to the streaming source. As the weather change is not predictable, neither is the data. Understanding the traffic pattern is key to sizing your executors. If the input is very spiky, you may consider using autoscaling (more on that later).

You can combine this metric with the Kinesis PutRecords metric to make sure the number of events being ingested and the number of records being read are nearly the same. This is especially useful when you are trying to understand lag. As the ingestion rate increases, so do the numRecords read by Amazon Glue.

Batch processing time (metric: streaming.batchProcessingTimeInMs)

The batch processing time metric helps you determine if the cluster is underprovisioned or overprovisioned.

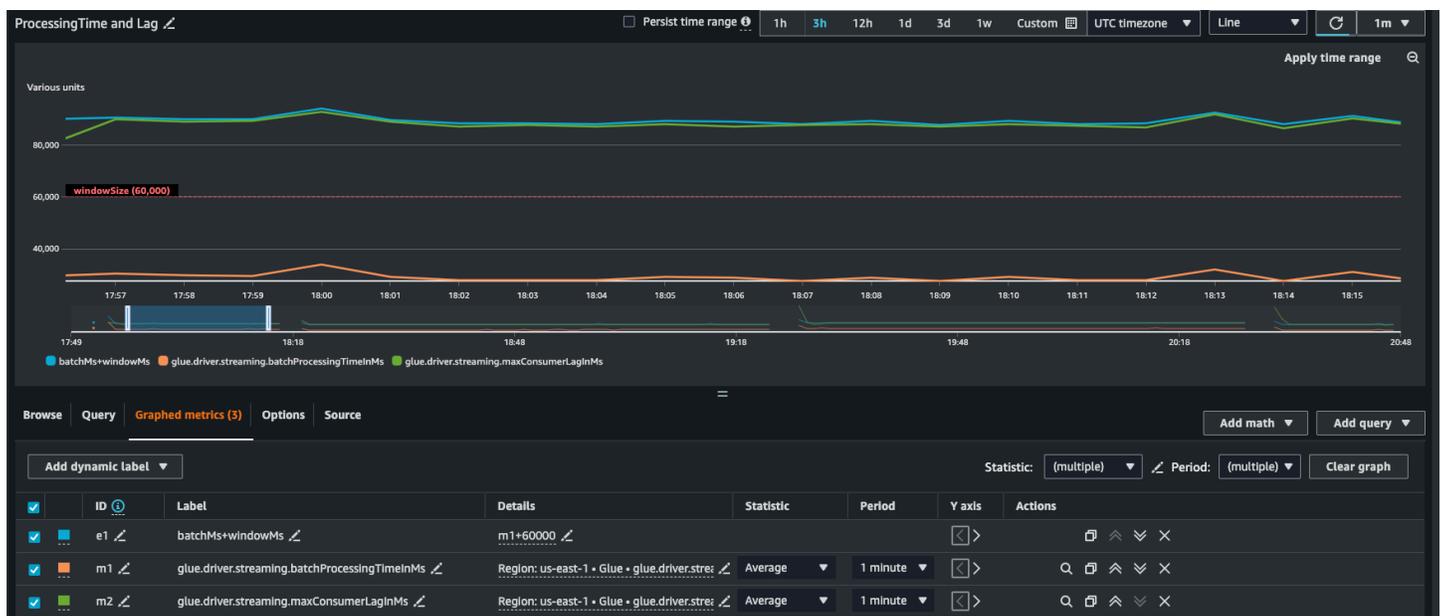

This metric indicates the number of milliseconds that it took to process each micro-batch of records. The main goal here is to monitor this time to make sure it less than the `windowSize` interval. It is okay if the `batchProcessingTimeInMs` goes over temporarily as long as it recovers in the following window interval. Indicator #1 shows a more or less stable time taken to process the job. However if the number of input records are increasing, the time it takes to process the job will increase as well as shown by indicator #2. If the `numRecords` is not going

up, but the processing time is going up, then you would need to take a deeper look into the job processing on the executors. It is a good practice to set a threshold and alarm to make sure the `batchProcessingTimeInMs` doesn't stay over 120% for more than 10 minutes. For more information on setting alarms, see [Using Amazon CloudWatch alarms](#).

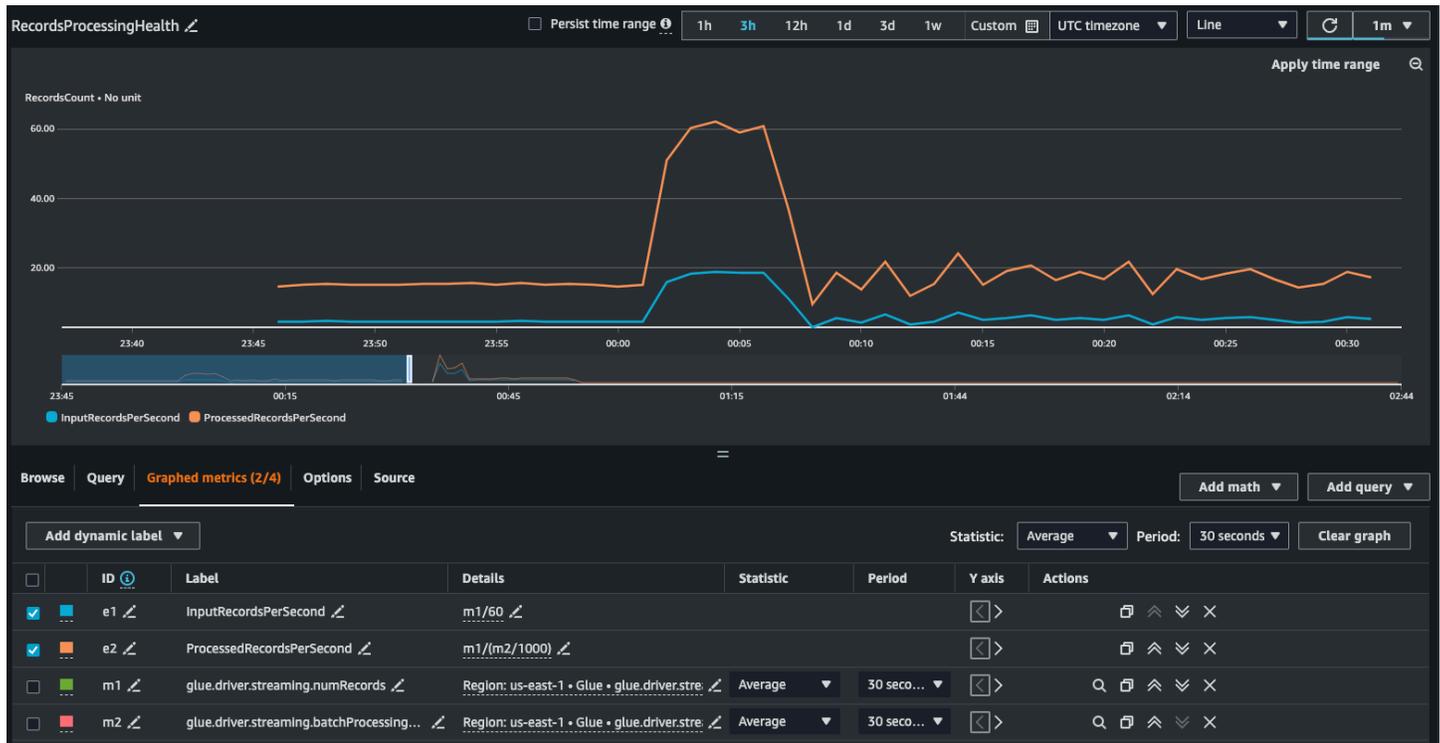

Consumer lag (metric: `streaming.maxConsumerLagInMs`)

The consumer lag metric helps you understand if there is a lag in processing events. If your lag is too high, then you could miss the processing SLA that your business depends on, even though you have a correct `windowSize`. You have to explicitly enable this metrics using the `emitConsumerLagMetrics` connection option. For more information, see [KinesisStreamingSourceOptions](#).

Derived metrics

To gain deeper insights, you can create derived metrics to understand more about your streaming jobs in Amazon CloudWatch.

You can build a graph with derived metrics to decide if you need to use more DPUs. While autoscaling helps you do this automatically, you can use derived metrics to determine if autoscaling is working effectively.

- **InputRecordsPerSecond** indicates the rate at which you are getting input records. It is derived as follows: number of input records (`glue.driver.streaming.numRecords`)/ `WindowSize`.
- **ProcessingRecordsPerSecond** indicates the rate at which your records are being processed. It is derived as follows: number of input records (`glue.driver.streaming.numRecords`)/ `batchProcessingTimeInMs`.

If the input rate is higher than the processing rate, then you may need to add more capacity to process your job or increase the parallelism.

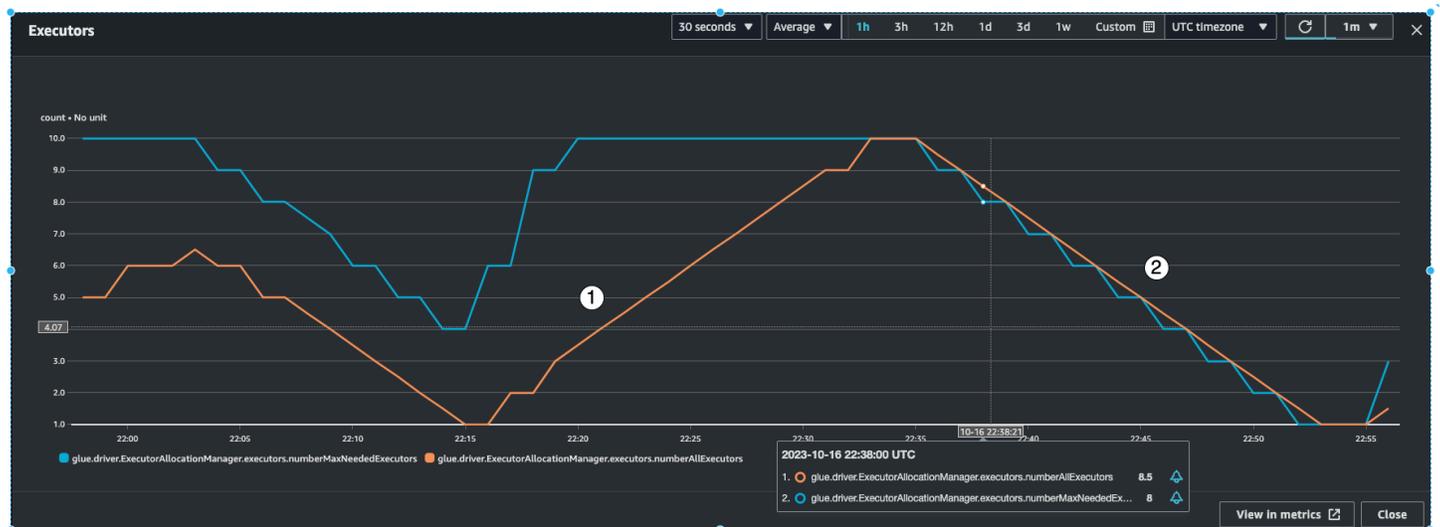

Autoscaling metrics

When your input traffic is spiky, then you should consider enabling autoscaling and specify the max workers. With that you get two additional metrics, `numberAllExecutors` and `numberMaxNeededExecutors`.

- **numberAllExecutors** is the number of actively running job executors

- **numberMaxNeededExecutors** is the number of maximum (actively running and pending) job executors needed to satisfy the current load.

These two metrics will help you understand if your autoscaling is working correctly.

Amazon Glue will monitor the `batchProcessingTimeInMs` metric over a few micro-batches and do one of two things. It will scale-out the executors, if `batchProcessingTimeInMs` is closer to the `windowSize`, or scale-in the executors, if `batchProcessingTimeInMs` is comparatively lower than `windowSize`. Also, it will use an algorithm for step-scaling the executors.

- indicator #1 shows you how the active executors scaled up to catch up with the max needed executors so as to process the load.
- indicator #2 shows you how the active executors scaled in since the `batchProcessingTimeInMs` was low.

You can use these metrics to monitor current executor-level parallelism and adjust the number of max workers in your auto-scaling configuration accordingly.

How to get the best performance

Spark will try to create one task per shard, to read from, in the Amazon Kinesis stream. The data in each shard becomes a partition. It will then distribute these tasks across the executors/workers, depending of the number of cores on each worker (the number of cores per worker depends on the worker type you select G.025X, G.1X, etc). However it is non-deterministic how the tasks are

distributed. All tasks are executed in parallel on their respective cores. If there are more shards than the number of available executor cores, the tasks are queued up.

You can use a combination of the above metrics and the number of shards, to provision your executors for a stable load with some room for bursts. It is recommend that you run a few iterations of your job in order to determine the approximate number of workers. For an unstable/spiky workload you can do the same by setting up autoscaling and max workers.

Set the `windowSize` as per the SLA requirement of your business. For example, if your business requires that the processed data cannot be more than 120 seconds stale, then set your `windowSize` to at least 60 seconds such that your average consumer lag is less than 120 seconds (refer to the section on consumer lag above). From there depending on the `numRecords` and number of shards, plan for the capacity in DPUs making sure your `batchProcessingTimeInMs` is less than 70% of your `windowSize` most of the time.

 **Note**

Hot shards can cause data skew which means that some shards/partitions are much bigger than the others. This may cause some tasks that are running in parallel to take longer time causing straggler tasks. As a result, the next batch can't start until all tasks from the previous one complete, this will impact the `batchProcessingTimeInMillis` and the max lag.

Zero-ETL integrations

[Zero-ETL](#) is a set of fully managed integrations by Amazon that minimizes the need to build ETL data pipelines for common ingestion and replication use cases. It makes data available in Amazon SageMaker Lakehouse and Amazon Redshift from multiple operational, transactional, and application sources. With zero-ETL integration, you have fresher data for analytics, AI/ML, and reporting. You get more accurate and timely insights for use cases like business dashboards, optimized gaming experience, data quality monitoring, and customer behavior analysis. You can make data-driven predictions with more confidence, improve customer experiences, and promote data-driven insights across the business.

Amazon Redshift is a fast, fully managed, petabyte-scale data warehouse service that makes it simple and cost-effective to efficiently analyze all your data using your existing business intelligence tools.

Amazon SageMaker Lakehouse unifies all your data across Amazon Simple Storage Service (S3) data lakes and Amazon Redshift data warehouses, helping you build powerful analytics and AI/ML applications on a single copy of data. SageMaker Lakehouse gives you the flexibility to access and query your data in-place with all Apache Iceberg compatible tools and engines. With SageMaker Lakehouse, you also have the flexibility to access and query your data in-place with Apache Iceberg compatible tools and engines. Additionally, you can secure your data with integrated, fine-grained access controls, that are enforced across all your data in all analytic tools and engines. Define permissions once and confidently share data across your organization.

Zero-ETL capabilities in Amazon Glue

Zero-ETL integrations in Amazon Glue simplify data ingestion and replication from Amazon data service, third-party applications, and self-managed databases to Amazon destinations.

Amazon services supported as zero-ETL sources in Amazon Glue include:

- Amazon DynamoDB

Third-party applications supported as zero-ETL sources in Amazon Glue include:

- Facebook Ads
- Instagram Ads

- Salesforce
- Salesforce Marketing Cloud Account Engagement
- SAP OData
- ServiceNow
- Zendesk
- Zoho CRM

Self-managed databases supported as zero-ETL sources in Amazon Glue include:

- Oracle
- SQL Server
- MySQL
- PostgreSQL

For more information about zero-ETL integrations from self-managed sources, see [Amazon zero-ETL integration for self-managed database sources](#).

Amazon services supported as zero-ETL targets in Amazon Glue include:

- Amazon Redshift
- Amazon SageMaker Lakehouse

 **Note**

When creating a zero-ETL integration with an Amazon DynamoDB source in Amazon Glue, the target is supported by Amazon SageMaker Lakehouse.

Prerequisites for setting up a zero-ETL integration

Setting up an integration between the source and target require some prerequisites such as configuring IAM roles which Amazon Glue uses to access data from the source and write to the target, and the use of KMS keys to encrypt the data in intermediate or the target location.

Topics

- [Setting up source resources](#)
- [Setting up target resources](#)
- [Creating an Amazon Redshift data warehouse](#)
- [Setting up a VPC for your zero-ETL integration](#)
- [Setting up a zero-ETL cross-account integration](#)

Setting up source resources

Perform the following set up tasks as required for your source.

Setting up the source role

This section describe how you pass a source role to allow the zero-ETL integration to access your connection. This is also applicable only for SaaS sources.

Note

To restrict access to only a few connections, you can first create the connection to obtain the connection ARN. See [Configuring a source for a zero-ETL integration](#).

Create a role which has permissions for the integration to access the connection:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GlueConnections",
      "Effect": "Allow",
      "Action": [
        "glue:GetConnections",
        "glue:GetConnection"
      ],
      "Resource": [
        "arn:aws:glue:*:111122223333:catalog",
        "arn:aws:glue:us-east-1:111122223333:connection/*"
      ]
    }
  ]
}
```

```

    },
    {
      "Sid": "GlueActionBasedPermissions",
      "Effect": "Allow",
      "Action": [
        "glue:ListEntities",
        "glue:RefreshOAuth2Tokens"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}

```

Trust policy:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}

```

Setting up target resources

Perform the following set up tasks as required for Amazon Glue Data Catalog or Amazon Redshift data warehouse integration target.

For integrations with an Amazon Glue database target:

- [Setting up an Amazon Glue database](#)
- [Providing a catalog Resource Based Access \(RBAC\) policy](#)
- [Creating a target IAM role](#)

For integrations with an Amazon Redshift datawarehouse target:

- <https://docs.amazonaws.cn/glue/latest/dg/zero-etl-prerequisites.html#zero-etl-setup-target-redshift-data-warehouse>

Setting up an Amazon Glue database

For integrations that use an Amazon Glue database:

To set up a target database in the Amazon Glue Data Catalog with an Amazon S3 location:

1. In the Amazon Glue console home page, select **Database** under Data Catalog.
2. Choose **Add database** in the top right corner. If you have already created a database, make sure that the location with Amazon S3 URI is set for the database.
3. Enter a name and **Location** (Amazon S3 URI). Note that the location is required for the zero-ETL integration. Click **Create database** when done.

Note

The Amazon S3 bucket must be in the same region as the Amazon Glue database.

For information on creating a new database in Amazon Glue, see [Getting started with the Amazon Glue Data Catalog](#).

You can also use the [create-database](#) CLI to create the database in Amazon Glue. Note that the `LocationUri` in `--database-input` is required.

Optimizing Iceberg tables

Once a table is created by Amazon Glue in the target database, you can enable the compaction to speed up queries in Amazon Athena. For information on setting up the resources (IAM Role) for compaction, see [Table optimization prerequisites](#).

For more information on setting up compaction on the Amazon Glue table created by the integration, see [Optimizing Iceberg tables](#).

Providing a catalog Resource Based Access (RBAC) policy

For integrations that use an Amazon Glue database, add the following permissions to the catalog RBAC Policy to allow for integrations between source and target.

Note

For cross-account integrations, both Alice (user creating the integration) role policy and catalog resource policy need to allow `glue:CreateInboundIntegration` on the resource. For same-account, either a resource policy or role policy allowing `glue:CreateInboundIntegration` on the resource is sufficient. Both scenarios do still need to allow `glue.amazonaws.com` to `glue:AuthorizeInboundIntegration`.

You can access the **Catalog settings** under **Data Catalog**. Then provide the following permissions and fill in the missing information.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": {
        "AWS": [
          "arn:aws:iam::123456789012:user/Alice"
        ]
      },
      "Effect": "Allow",
      "Action": [
        "glue:CreateInboundIntegration"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:catalog",
        "arn:aws:glue:us-east-1:111122223333:database/DatabaseName"
      ],
      "Condition": {
        "StringLike": {
```

```

    "aws:SourceArn": "arn:aws:dynamodb:us-east-1:444455556666:table/<table-
name>"
  }
}
},
{
  "Principal": {
    "Service": [
      "glue.amazonaws.com"
    ]
  },
  "Effect": "Allow",
  "Action": [
    "glue:AuthorizeInboundIntegration"
  ],
  "Resource": [
    "arn:aws:glue:us-east-1:111122223333:catalog",
    "arn:aws:glue:us-east-1:111122223333:database/DatabaseName"
  ],
  "Condition": {
    "StringEquals": {
      "aws:SourceArn": "arn:aws:dynamodb:us-east-1:444455556666:table/<table-
name>"
    }
  }
}
]
}
}

```

Creating a target IAM role

Create a target IAM role with the following permissions and trust relationships:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket",
      "Effect": "Allow"
    }
  ]
}

```

```

    },
    {
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/*",
      "Effect": "Allow"
    },
    {
      "Action": [
        "glue:GetDatabase"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:catalog",
        "arn:aws:glue:us-east-1:111122223333:database/DatabaseName"
      ],
      "Effect": "Allow"
    },
    {
      "Action": [
        "glue:CreateTable",
        "glue:GetTable",
        "glue:GetTables",
        "glue>DeleteTable",
        "glue:UpdateTable",
        "glue:GetTableVersion",
        "glue:GetTableVersions",
        "glue:GetResourcePolicy"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:catalog",
        "arn:aws:glue:us-east-1:111122223333:database/DatabaseName",
        "arn:aws:glue:us-east-1:111122223333:table/DatabaseName/*"
      ],
      "Effect": "Allow"
    },
    {
      "Action": [
        "cloudwatch:PutMetricData"
      ],
      "Resource": "*",
      "Condition": {

```

```
        "StringEquals": {
            "cloudwatch:namespace": "AWS/Glue/ZeroETL"
        }
    },
    "Effect": "Allow"
},
{
    "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents"
    ],
    "Resource": "*",
    "Effect": "Allow"
}
]
```

Add the following trust policy to allow the Amazon Glue service to assume the role:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Creating an Amazon Redshift data warehouse

When your zero-ETL integration target is an Amazon Redshift data warehouse, create the data warehouse if you don't already have one. To create an Amazon Redshift Serverless workgroup,

see [Creating a workgroup with a namespace](#). To create an Amazon Redshift cluster, see [Creating a cluster](#).

The target Amazon Redshift workgroup or cluster must have the `enable_case_sensitive_identifier` parameter turned on for the integration to be successful. For more information on enabling case sensitivity, see [Turn on case sensitivity for your data warehouse](#) in the Amazon Redshift management guide.

After the Amazon Redshift workgroup or cluster setup is complete, you need to configure your data warehouse. See [Getting started with zero-ETL integrations](#) in the Amazon Redshift Management Guide for more information.

Setting up a VPC for your zero-ETL integration

To set up a VPC for your zero-ETL integration:

1. Go to **VPC** > Your VPCs and choose **Create VPC**.
 - a. Select **VPC and more**.
 - b. Set your VPC name.
 - c. Set the IPv4 CIDR: 10.0.0.0/16.
 - d. Set the number of AZ to 1.
 - e. Set the number of public and private subnets to 1.
 - f. Set **NAT gateways** to None.
 - g. Set **VPC endpoints** to S3 Gateway.
 - h. Enable DNS hostnames and DNS resolution.
2. Go to **Endpoints** and choose **Create Endpoint**.
3. Create endpoints for these services in the private subnet of your VPC (use the default security group):
 - a. com.amazonaws.us-east-1.lambda
 - b. com.amazonaws.us-east-1.glue
 - c. com.amazonaws.us-east-1.sts

Create the Amazon Glue connection:

1. Go to **Amazon Glue** > **Data connections** and choose **Create connection**.
2. Select **Network**.

3. Select the VPC, Subnet (private), and default Security Group that you created.

Setting up the target role for the VPC

The target role must have these permissions (in addition to the other permissions required by Zero-ETL integrations):

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CustomerVpc",
      "Effect": "Allow",
      "Action": [
        "ec2:CreateTags",
        "ec2>DeleteTags",
        "ec2:DescribeRouteTables",
        "ec2:DescribeVpcEndpoints",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:CreateNetworkInterface",
        "ec2>DeleteNetworkInterface",
        "glue:GetConnection"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

Setting up the target leg resource properties

If you are using the CLI, set the target leg resource properties to the target Amazon Glue database you created. Pass the target role ARN, as well as the Amazon Glue connection name.

```
aws glue create-integration-resource-property \
```

```
--resource-arn arn:aws:glue:us-east-1:<account-id>:database/exampltarget \  
--target-processing-properties '{"RoleArn" : "arn:aws:iam::<account-id>:role/example-  
role", "ConnectionName":"example-vpc-3"}' \  
--endpoint-url https://example.amazonaws.com --region us-east-1
```

Possible client errors

The following are possible client errors for an integration configured with a VPC.

Error message	Action required
Provided role is not authorized to perform glue:GetConnection on connection. Add this permission to role policy, and then wait for the integration to recover.	Update role policy
Provided role is not authorized to perform ec2:DescribeSubnets. Add this permission to role policy, and then wait for the integration to recover.	Update role policy
Provided role is not authorized to perform ec2:DescribeSecurityGroups. Add this permission to role policy, and then wait for the integration to recover.	Update role policy
Provided role is not authorized to perform ec2:DescribeVpcEndpoints. Add this permission to role policy, and then wait for the integration to recover.	Update role policy
Provided role is not authorized to perform ec2:DescribeRouteTables. Add this permission to role policy, and then wait for the integration to recover.	Update role policy
Provided role is not authorized to perform ec2:CreateTags. Add this permission to role	Update role policy

Error message	Action required
policy, and then wait for the integration to recover.	
Provided role is not authorized to perform <code>ec2:CreateNetworkInterface</code> . Add this permission to role policy, and then wait for the integration to recover.	Update role policy
Provided connection subnet does not contain a valid S3 endpoint or NAT gateway. Update subnet, and then wait for the integration to recover.	Update VPC subnet endpoints
Connection subnet not found. Update connection subnet, and then wait for the integration to recover.	Update Amazon Glue connection
Connection security group not found. Update connection security group, and then wait for the integration to recover.	Update Amazon Glue connection
Can't connect to S3 through provided VPC connection. Update subnet configurations, and then wait for the integration to recover.	Update VPC subnet endpoints
Can't connect to Lambda through provided VPC connection. Update subnet configurations, and then wait for the integration to recover.	Update VPC subnet endpoints

Setting up a zero-ETL cross-account integration

To set up a zero-ETL cross-account integration:

1. Configure a target Resource Policy as described in [Providing a catalog Resource Based Access \(RBAC\) policy](#). Ensure that the source account role is explicitly allowed on the target resource.

2. Check that the source account role (the role used to create the integration) has the following:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Stmt123456789012",
      "Action": [
        "glue:CreateInboundIntegration"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:catalog",
        "arn:aws:glue:us-east-1:111122223333:database/DatabaseName"
      ]
    }
  ]
}
```

3. Create the integration as described in [Creating an integration](#).

Configuring a source for a zero-ETL integration

Support for Special SAP Entities

Amazon Glue zero-ETL supports SAP OData entities that use SAP's Operational Data Provisioning (ODP) framework as well as those that do not use the ODP framework (non-ODP entities). The list of supported entities includes: ODP_SAP (Business Warehouse or BW extractors), ODP_CDS (Core Data Services or CDS Views) and non-ODP based OData services for SAP APIs. Amazon Glue zero-ETL supports full snapshot and incremental change data capture for ODP and non-ODP SAP entities. For ODP entities, incremental changes are captured using delta links. For non-ODP entities, if a queryable field that can be used for timestamp based ingestion is selected, then zero-ETL will use that field for incremental ingestion.

While ingesting data from SAP entities using Amazon Glue zero-ETL, the following things should be noted:

- Zero-ETL can only ingest SAP entities which have been configured for GET_ENTITYSET method in SAP.
- For non-ODP SAP entities, if a timestamp field is not selected for incremental updates, Amazon Glue zero-ETL supports a full data extraction and replication with upserts only (no deletions).
- For ODP extractor entities, we determine the valid primary key sets during data processing. Other SAP entities require an extra step of providing the valid primary key set as input, specifically SAP entities that start with EntityOf. When an EntityOf entity is selected, you will be directed to provide the set of primary keys.

Settings (1)

Configure settings for the selected source data. You can add or delete source data in the source details section above.

Find objects < 1 >		
Selected source data	Primary keys ✎	Partition keys
/sap/opu/odata/sap/ZCUSTOMER_ATTR_1_SRV/EntityOf0CUSTOMER_ATTR	No primary keys selected	Default partition key

Configuring an Amazon DynamoDB source

To access data from your source Amazon DynamoDB table, Amazon Glue requires access to describe the table and export data from it. Amazon DynamoDB recently introduced a feature which allows configuring a Resource Based Access (RBAC) policy.

The following example Resource Based Access (RBAC) Policy uses a wild card (*) for integration:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "1111",
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Resource": "*",
      "Action": [
        "dynamodb:ExportTableToPointInTime",

```

```

    "dynamodb:DescribeTable",
    "dynamodb:DescribeExport"
  ],
  "Condition": {
    "StringEquals": {
      "aws:SourceAccount": "111122223333"
    },
    "ArnLike": {
      "aws:SourceArn": "arn:aws:glue:us-east-1:111122223333:integration:*"
    }
  }
}
]
}

```

1. For the DynamoDB that you want to replicate, paste the above RBAC policy template into **Resource-based policy for table** and fill in the fields.
2. If you want to make the policy restrictive, you must update the policy after creating the integration and specify the full `integrationArn` and use the `StringEquals` condition instead of `StringLike`.
3. Make sure that Point-in-time recovery (PITR) is enabled for the DynamoDB table.
4. Make sure that you add `Describe Export` to the Resource Based Access (RBAC) policy.

You can also add the RBAC policy to the table using the following command:

```

aws dynamodb put-resource-policy \
--resource-arn arn:aws:dynamodb:<region>:<account-id>:table/<ddb-table-name> \
--policy file://resource-policy-with-condition.json \
--region <region>

```

To verify that policy is applied correctly, use the following command to get the resource policy for a table:

```

aws dynamodb get-resource-policy \
--resource-arn arn:aws:dynamodb:<region>:<account-id>:table/<ddb-table-name> \
--region <region>

```

Configuring a Salesforce source

To create a connection for an Salesforce source, see [Connecting to Salesforce](#).

Once you've created the connection, you can specify the source data to replicate.

AWS Glue > Data pipeline integrations > Create integration

- Step 1
Select source type
- Step 2
Configure source and target
- Step 3
Configure integration
- Step 4
Review and create

Configure source and target

Source details

Configure the details for your destination in your AWS Glue zero-ETL integration.

Source type

 Salesforce

Salesforce connection

Choose the AWS Glue connection for Salesforce, or [create a new connection](#).

SalesforceConnection0731

Source IAM role

Choose an IAM role to associate with your source data, or [create a new one](#).

admin_iad_role

Select source data

Select source data to add to this data pipeline.

Salesforce objects (36)

Q contact X

<input type="checkbox"/>	Object name	Number of fields	Action
<input type="checkbox"/>	AccountContactRole	11	Preview
<input type="checkbox"/>	AccountContactRoleChangeEvent	11	Preview
<input type="checkbox"/>	CaseContactRole	10	Preview
<input checked="" type="checkbox"/>	Contact	63	Preview
<input type="checkbox"/>	ContactCenterChannel	11	Preview

Select all objects

Select all objects across all pages in this table. This action cannot be undone after creating this integration.

Selected source data (3)

Account X Contact X Lead X

Using your zero-ETL integration you can perform DDL operations for supported entities. For a list of entities which are not supported, see [Unsupported entities and fields for Salesforce](#).

Configuring a Salesforce Marketing Cloud Account Engagement source

To create a connection for an Salesforce Marketing Cloud Account Engagement source, see [???](#).

Using your zero-ETL integration you can perform DDL operations for the following supported entities:

Entity label	Entity name
Campaign	campaign

Entity label	Entity name
List	list
Dynamic Content	dynamic-content
List Membership	list-membership
Prospect	prospect
User	user
EmailTemplate	email-template
EngagementStudioProgram	engagement-studio-program
Landing Page	landing-page
List Email	list-email

Additional Salesforce Configuration

Salesforce Zero-ETL needs Lake Formation permission on Glue database, otherwise it will get `IngestionFailed` from the Log with the following error:

```
"errorMessage": "Insufficient lake formation permissions on Target Glue database."
```

Configuring an SAP OData source

To create a connection for an SAP OData source, see [Connecting to SAP OData](#).

Zero-ETL integrations with an SAP OData source now supports entities starting with `EntityOf`. The ability to override the primary key is currently supported only for `SAPData EntityOf` objects. Once this property has been set, it cannot be modified.

Configuring a ServiceNow source

To create a connection for a ServiceNow source, see [???](#).

Configuring a Zendesk source

To create a connection for a Zendesk source, see [???](#).

Using your zero-ETL integration you can perform the following DDL operations for supported entities:

Entity label	Entity name	Create supported	Update supported	Delete supported
Tickets	tickets	Y	Y	Y
User	users	Y	Y	Y
Satisfaction Rating	satisfaction-rating	Y	Y	N
Articles	articles	Y	Y	N
Organization	organizations	Y	Y	Y
Calls	calls	Y	Y	N
Call Legs	legs	Y	Y	N

Configuring a Zoho CRM source

To create a connection for a Zoho CRM source, see [???](#).

Using your zero-ETL integration you can perform the following DDL operations for supported entities:

Entity label	Entity name	DML-Insert supported	DML-Modify supported	DML-Delete supported	DDL-Insert supported	DDL-Modify supported	DDL-Delete supported
Leads	lead	Y	Y	Y	Y	Y	Y
Accounts	account	Y	Y	Y	Y	Y	Y

Entity label	Entity name	DML-Insert supported	DML-Modify supported	DML-Delete supported	DDL-Insert supported	DDL-Modify supported	DDL-Delete supported
Contacts	contact	Y	Y	Y	Y	Y	Y
Campaigns	campaign	Y	Y	Y	Y	Y	Y
Tasks	task	Y	Y	Y	Y	Y	Y
Events	event	Y	Y	Y	Y	Y	Y
Calls	call	Y	Y	Y	Y	Y	Y
Solutions	solution	Y	Y	Y	Y	Y	Y
Products	product	Y	Y	Y	Y	Y	Y
Vendors	vendor	Y	Y	Y	Y	Y	Y
Quotes	quote	Y	Y	Y	Y	Y	Y
Sales Orders	sales-order	Y	Y	Y	Y	Y	Y
Purchase Orders	purchase-order	Y	Y	Y	Y	Y	Y
Invoices	invoice	Y	Y	Y	Y	Y	Y
Cases	case	Y	Y	Y	Y	Y	Y
Price Books	price-book	Y	Y	Y	Y	Y	Y

Configuring a Facebook Ads source

To create a connection for a Facebook Ads source, see [???](#).

Using your zero-ETL integration you can perform the following DDL operations for supported entities:

Entity label	Entity name	Create supported	Update supported	Delete supported
Adset	*/adsets	Y	Y	Y
Campaign	*/campaigns	Y	Y	Y
Ads	*/ads	Y	Y	Y

Configuring an Instagram Ads source

To create a connection for an Instagram Ads source, see [???](#).

Using your zero-ETL integration you can perform the following DDL operations for supported entities:

Entity name	Create supported	Update supported	Delete supported
*/adsets	Y	Y	Y
*/campaigns	Y	Y	Y
*/ads	Y	Y	Y

Unsupported entities and fields for Salesforce

The following Salesforce entities or fields are unsupported for use in a zero-ETL integration with a Salesforce source.

```
AccountChangeEvent, AccountContactRoleChangeEvent, AccountHistory, AccountShare,
ActiveFeatureLicenseMetric, ActivePermSetLicenseMetric, ActiveProfileMetric,
ActivityFieldHistory, amzsec__asi_Telemetry_Data_Store__ChangeEvent,
amzsec__asi_Telemetry_Data_Store__History, amzsec__asi_Telemetry_Data_Store__Share,
amzsec__asi_Telemetry_Job_Log__ChangeEvent, amzsec__asi_Telemetry_Job_Log__History,
amzsec__asi_Telemetry_Job_Log__Share, amzsec__asi_Telemetry_Requirement__ChangeEvent,
amzsec__asi_Telemetry_Requirement__History, amzsec__asi_Telemetry_Requirement__Share,
```

ApexClass, ApexComponent, ApexLog, ApexPage, ApexTestQueueItem, ApexTestResult, ApexTrigger, AssetChangeEvent, AssetHistory, AssetRelationshipHistory, AssetShare, AssignmentRule, AssociatedLocationHistory, AsyncApexJob, AuditTrailFileExportShare, AuthorizationFormConsentChangeEvent, AuthorizationFormConsentHistory, AuthorizationFormConsentShare, AuthorizationFormDataUseHistory, AuthorizationFormDataUseShare, AuthorizationFormHistory, AuthorizationFormShare, AuthorizationFormTextHistory, AuthProvider, AuthSession, BatchJobHistory, BatchJobPartFailedRecordHistory, BatchJobPartHistory, BatchJobShare, BrandTemplate, BriefcaseAssignmentChangeEvent, BriefcaseDefinitionChangeEvent, BusinessBrandShare, BusinessHours, BusinessProcess, CalcMatrixColumnRangeHistory, CalcProcStepRelationshipHistory, CalculationMatrixColumnHistory, CalculationMatrixHistory, CalculationMatrixRowHistory, CalculationMatrixShare, CalculationMatrixVersionHistory, CalculationProcedureHistory, CalculationProcedureShare, CalculationProcedureStepHistory, CalculationProcedureVariableHistory, CalculationProcedureVersionHistory, Calendar, CalendarViewShare, CallCenter, CallCoachConfigModifyEvent, CampaignChangeEvent, CampaignHistory, CampaignMemberChangeEvent, CampaignMemberStatusChangeEvent, CampaignShare, CaseChangeEvent, CaseHistory, CaseHistory2, CaseHistory2ChangeEvent, CaseRelatedIssueChangeEvent, CaseRelatedIssueHistory, CaseShare, CaseStatus, CaseTeamMember, CaseTeamRole, CaseTeamTemplate, CaseTeamTemplateMember, CaseTeamTemplateRecord, CategoryNode, ChangeRequestChangeEvent, ChangeRequestHistory, ChangeRequestRelatedIssueChangeEvent, ChangeRequestRelatedIssueHistory, ChangeRequestRelatedItemChangeEvent, ChangeRequestRelatedItemHistory, ChangeRequestShare, ChatRetirementRdyMetrics, ChatterActivity, ClientBrowser, CollaborationGroup, CollaborationGroupMember, CollaborationGroupMemberRequest, CollaborationInvitation, CommSubscriptionChannelTypeHistory, CommSubscriptionChannelTypeShare, CommSubscriptionConsentChangeEvent, CommSubscriptionConsentHistory, CommSubscriptionConsentShare, CommSubscriptionHistory, CommSubscriptionShare, CommSubscriptionTimingHistory, Community, ConnectedApplication, ContactChangeEvent, ContactHistory, ContactPointAddressChangeEvent, ContactPointAddressHistory, ContactPointAddressShare, ContactPointConsentChangeEvent, ContactPointConsentHistory, ContactPointConsentShare, ContactPointEmailChangeEvent, ContactPointEmailHistory, ContactPointEmailShare, ContactPointPhoneChangeEvent, ContactPointPhoneHistory, ContactPointPhoneShare, ContactPointTypeConsentChangeEvent, ContactPointTypeConsentHistory, ContactPointTypeConsentShare, ContactRequestShare, ContactShare, ContentDocumentChangeEvent, ContentDocumentHistory, ContentDocumentLink, ContentDocumentLinkChangeEvent, ContentDocumentSubscription, ContentFolderItem, ContentFolderLink, ContentFolderMember, ContentNote, ContentNotification, ContentTagSubscription, ContentUserSubscription, ContentVersionChangeEvent, ContentVersionComment, ContentVersionHistory, ContentVersionRating, ContentWorkspace, ContentWorkspaceMember, ContentWorkspacePermission, ContentWorkspaceSubscription, ContractChangeEvent, ContractHistory, ContractLineItemChangeEvent, ContractLineItemHistory, ContractStatus, Conversation, ConversationParticipant, CronJobDetail,

Configuring a zero-ETL integration target

There are several options offered by Amazon when configuring a target for a zero-ETL integration. The target may be an encrypted Amazon Redshift data warehouse or an Amazon SageMaker Lakehouse catalog.

Before selecting the target for the zero-ETL integration, you need to configure one of the following target resources.

The configuration options for a target in a zero-ETL integration include:

- An Amazon SageMaker Lakehouse catalog and database configured with regular Amazon S3 storage. See [Configuring an Amazon SageMaker Lakehouse catalog with regular S3 storage](#).
- An Amazon SageMaker Lakehouse catalog configured with Amazon S3 Tables bucket. See [Configuring Amazon S3 tables as a target](#).
- An Amazon SageMaker Lakehouse catalog configured with Amazon Redshift managed storage. See [Configuring an Amazon SageMaker Lakehouse catalog with Amazon Redshift managed storage](#).
- An Amazon Redshift data warehouse identified by a Redshift namespace. See [Configuring an Amazon Redshift data warehouse target](#).

Note

You cannot modify the target of a zero-ETL integration after creation.

Configuring an Amazon SageMaker Lakehouse catalog with regular S3 storage

This section describes the prerequisites and setup steps for configuring a regular Amazon S3 bucket as storage for your Amazon SageMaker Lakehouse catalog target in a zero-ETL integration.

Prerequisites for setting up an integration

Before creating a zero-ETL integration with an Amazon SageMaker Lakehouse catalog using regular S3 storage, you need to complete the following setup tasks:

1. Set up an Amazon Glue database
2. Provide Catalog RBAC policy
3. Create target IAM role

After configuring the Amazon SageMaker Lakehouse catalog with regular Amazon S3 storage, you can proceed to [Configuring the integration with your target](#) to complete the integration setup.

Configuring Amazon S3 tables as a target

This section describes the prerequisites and setup steps for configuring Amazon S3 Tables as a target for your zero-ETL integration.

Prerequisites for setting up an integration

Before creating a zero-ETL integration with Amazon S3 Tables as a target, you need to complete the following setup tasks:

1. Setup Amazon S3 tables bucket
2. Provide Catalog RBAC policy
3. Create target IAM role

Setup Amazon S3 tables bucket

1. Create an S3 table bucket in your account by following the instructions at [Getting started with Amazon S3 Tables](#).
2. Enable Analytics integrations with your S3-Table bucket by following these instructions: [Integrating Amazon services with Amazon S3 Tables](#).

Provide Catalog RBAC Policy

The following permissions must be added to the Catalog RBAC Policy to allow for integrations between source and Amazon S3 tables catalog target.

Target Amazon Glue Catalog resource policy needs to include Glue Service permissions to `AuthorizeInboundIntegration`. Additionally, `CreateInboundIntegration` permission is required either on the source principal creating the Integration or in the target Amazon Glue resource policy.

Note

For cross-account scenario, both source principal as well as target Amazon Glue Catalog resource policy need to include `glue:CreateInboundIntegration` permissions on the resource.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": {
        "AWS": [
          "arn:aws:iam::123456789012:user/Alice"
        ]
      },
      "Effect": "Allow",
      "Action": [
        "glue:CreateInboundIntegration"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:catalog/<s3tablescatalog>/*"
      ],
      "Condition": {
        "StringLike": {
          "aws:SourceArn": "arn:aws:dynamodb:us-east-1:444455556666:table/<table-
name>"
        }
      }
    },
    {
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
      "Effect": "Allow",
      "Action": [
        "glue:AuthorizeInboundIntegration"
      ],
      "Resource": [
```

```

    "arn:aws:glue:us-east-1:111122223333:catalog/<s3tablescatalog>/*"
  ],
  "Condition": {
    "StringEquals": {
      "aws:SourceArn": "arn:aws:dynamodb:us-east-1:444455556666:table/<table-
name>"
    }
  }
}
]
}

```

Note

Replace <s3tablescatalog> with the catalog name of your S3 tables.

Create target IAM Role

Create a target IAM role with the following permissions and trust relationships:

Example IAM policy:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "s3tables:ListTableBuckets",
        "s3tables:GetTableBucket",
        "s3tables:GetTableBucketEncryption",
        "s3tables:GetNamespace",
        "s3tables>CreateNamespace",
        "s3tables:ListNamespaces",
        "s3tables:CreateTable",
        "s3tables:GetTable",
        "s3tables:GetTableEncryption",
        "s3tables:ListTables",
        "s3tables:GetTableMetadataLocation",

```

```

    "s3tables:UpdateTableMetadataLocation",
    "s3tables:GetTableData",
    "s3tables:PutTableData"
  ],
  "Resource": "arn:aws:s3tables:us-east-1:111122223333:bucket/*",
  "Effect": "Allow"
},
{
  "Action": [
    "cloudwatch:PutMetricData"
  ],
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "cloudwatch:namespace": "AWS/Glue/ZeroETL"
    }
  },
  "Effect": "Allow"
},
{
  "Action": [
    "logs:CreateLogGroup",
    "logs:CreateLogStream",
    "logs:PutLogEvents"
  ],
  "Resource": "*",
  "Effect": "Allow"
}
]
}

```

Add the following trust policy in the Target IAM role to allow Amazon Glue Service to assume it:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      }
    }
  ]
}

```

```
    },  
    "Action": "sts:AssumeRole"  
  }  
]  
}
```

Note

Make sure there is no explicit DENY statement for this target IAM role in the S3-Tables bucket resource policy. An explicit DENY would override any ALLOW permissions and prevent the integration from working properly.

Configuring an Amazon SageMaker Lakehouse catalog with Amazon Redshift managed storage

This section describes the prerequisites and setup steps for configuring an Amazon SageMaker Lakehouse catalog with Amazon Redshift managed storage (RMS) as a target for your zero-ETL integration.

Prerequisites for setting up an integration

Before creating a zero-ETL integration with an Amazon SageMaker Lakehouse catalog using Redshift managed storage, you need to complete the following setup tasks:

1. Set up an Amazon Redshift cluster or Serverless workgroup
2. Register the Amazon Redshift integration with Lake Formation
3. Create a managed catalog in Lake Formation
4. Configure IAM permissions

Setting up Amazon Redshift managed storage

To set up Amazon Redshift managed storage for your zero-ETL integration:

1. Create or use an existing Amazon Redshift cluster or Serverless workgroup. Make sure the target Amazon Redshift workgroup or cluster has the `enable_case_sensitive_identifier` parameter turned on for the integration to be successful. For more information on enabling

- case sensitivity, see [Turn on case sensitivity for your data warehouse](#) in the Amazon Redshift management guide.
2. Register an integration from Redshift into the catalog in Amazon Lake Formation. See [Registering Amazon Redshift clusters and namespaces to the Amazon Glue Data Catalog](#).
 3. Create a federated or managed catalog in Amazon Lake Formation. For more information, see:
 - [Bringing Amazon Redshift data into the Amazon Glue Data Catalog](#)
 - [Creating an Amazon Redshift managed catalog in the Amazon Glue Data Catalog](#)
 4. Configure IAM permissions for the target role. The role needs permissions to access both Redshift and Lake Formation resources. At minimum, the role should have:
 - Permissions to access the Redshift cluster or workgroup
 - Permissions to access the Lake Formation catalog
 - Permissions to create and manage tables in the catalog
 - CloudWatch and CloudWatch Logs permissions for monitoring

After configuring the Amazon SageMaker Lakehouse catalog with Amazon Redshift managed storage, you can proceed to [Configuring the integration with your target](#) to complete the integration setup.

Configuring an Amazon Redshift data warehouse target

This section describes the prerequisites and setup steps for configuring an Amazon Redshift data warehouse as a target for your zero-ETL integration.

Prerequisites for setting up an integration

Before creating a zero-ETL integration with an Amazon Redshift data warehouse target, you need to complete the following setup tasks:

1. Set up an Amazon Redshift cluster or Serverless workgroup
2. Configure case sensitivity
3. Configure IAM permissions

Setting up the Amazon Redshift data warehouse

To set up an Amazon Redshift data warehouse for your zero-ETL integration:

1. Navigate to the [Amazon Redshift console](#) and click **Create cluster** or use an existing cluster. For Amazon Redshift Serverless, click **Create workgroup**.
2. If creating a new cluster, choose an appropriate cluster size and ensure your cluster is encrypted. For Serverless, configure the workgroup settings according to your requirements.
3. Make sure the target Amazon Redshift workgroup or cluster has the `enable_case_sensitive_identifier` parameter turned on for the integration to be successful. For more information on enabling case sensitivity, see [Turn on case sensitivity for your data warehouse](#) in the Amazon Redshift management guide.
4. Configure IAM permissions to allow the zero-ETL integration to access your Amazon Redshift data warehouse. You'll need to create an IAM role with the following permissions:
 - Permissions to access the Amazon Redshift cluster or workgroup
 - Permissions to create and manage databases and tables in Amazon Redshift
 - CloudWatch and Amazon CloudWatch Logs permissions for monitoring
5. After the Amazon Redshift workgroup or cluster setup is complete, you need to configure your data warehouse for zero-ETL integrations. See [Getting started with zero-ETL integrations](#) in the Amazon Redshift Management Guide for more information.

Note

When using a Amazon Redshift data warehouse as a target, the integration creates a schema in the specified database to store the replicated data. The schema name is derived from the integration name.

After configuring the Amazon Redshift data warehouse, you can proceed to [Configuring the integration with your target](#) to complete the integration setup.

Configuring the integration with your target

After you have configured your target resources and selected your connection and specified a source IAM role, follow these steps to complete the integration setup:

1. Specify the target you've configured in the previous steps.
2. Select the Amazon Glue **Fix it for me** option. For the Amazon Redshift target, this will:
 - Apply an authorized service principal on the Amazon Redshift cluster or Serverless workgroup.

- Apply an authorized Amazon Glue source ARN to the Amazon Redshift cluster or Serverless workgroup.
- Associate a new parameter group with `enable_case_sensitive_identifier = true`.

Target details

Target type

 Transactional Data Lake

Namespace or Catalog
Choose an Amazon Redshift namespace or AWS Glue Catalog

redshift-cluster-1008  [View](#)  | [Create new namespace](#) 

Note: the target of a zero-ETL integration cannot be modified after creation

 **Fix resource policy and case sensitivity parameter**

The selected target does not have the correct resource policy and case sensitivity parameter to support a zero-ETL integration. You can have AWS Glue fix this for you, or you can manually update them in the Redshift console.

Fix it for me
AWS Glue will fix this by adding the current account and the selected source in the resource policy and enabling case sensitivity. A reboot may be required.

3. Provide the integration name and choose **Create and launch Integration**.
4. Once your integration is in the active state, navigate to the integration details page and choose **Create a database from integration**.
5. Finally, you can navigate to the Redshift query editor, and connect to your database to validate the snapshot and incremental data.

Note

You can only use lowercase alphanumeric characters and underscores in the namespace or catalog name. This is different from what the Amazon Glue Data Catalog allows to create a database with any name (including special characters).

Partition specification and schema unnesting guide

When working with NoSQL data sources like DynamoDB and SaaS applications, data often presents unique challenges for analytics:

1. Records within the same table may have different schema
2. Nested records within the same table can be represented differently
3. Complex nested structures like maps and arrays require transformation for efficient querying
4. Optimal data organization is needed to ensure query performance at scale

Amazon Glue Zero-ETL integrations address these challenges through two powerful capabilities:

- **Schema Unnesting:** Automatically flattens complex nested data structures into analytics-friendly formats, with configurable levels of unnesting to balance between preserving data structure and optimizing for query simplicity.
- **Data Partitioning:** Organizes data into logical partitions based on specified columns or time-based dimensions, improving query performance and reducing costs by enabling partition pruning during query execution.

In order to query such data sources effectively, Amazon Glue Zero-ETL provides out-of-the-box schema handling and partitioning schemes for source data being replicated in the target Amazon Glue Database. You can configure schema unnesting and partitioning settings for each table through the `CreateIntegrationTableProperty` API, allowing for fine-tuned control over how data is structured and organized for analytics workloads.

Default unnesting & partitioning behavior

1. Amazon Glue Zero-ETL defaults to FULL Unnest when no Unnesting options are provided for target table
2. Amazon Glue Zero-ETL defaults to Bucket partitioning when no PartitionSpec are provided for target table

Schema unnesting

When integrating with analytics services through Zero-ETL, you can choose how nested structures are represented in the target tables. Amazon Glue Zero-ETL provides schema unnesting options to flatten complex data structures into more analytics-friendly formats.

Unnesting options

When creating a Zero-ETL integration with a source, you can choose from the following unnesting options. These options correspond to specific enumeration values that you'll use when calling the `CreateIntegrationTableProperty` API.

No unnesting (default)

API value: NO_UNNEST

Preserves the original nested structure of DynamoDB items. Maps and lists are stored as structured columns in the target.

Best for: Preserving the exact structure of your DynamoDB data when your analytics tools can work with nested data.

Unnest one level

API value: TOP_LEVEL

Flattens the top level of nested maps into individual columns. List structures remain nested.

Best for: Balancing between data structure preservation and query simplicity when your DynamoDB items have a consistent schema.

Unnest all levels

API value: FULL

Recursively flattens all nested structures (maps and lists) into individual columns with dot notation for naming.

Best for: Maximizing query simplicity when working with deeply nested structures and analytics tools that prefer flat schemas.

Note

Full unnesting can lead to very wide tables with many columns if your DynamoDB data has variable or deeply nested structures.

Example Using unnesting options in the API

When configuring schema unnesting through the `CreateIntegrationTableProperty` API, specify the unnesting option in the `UnnestSpec` parameter:

```
aws glue create-integration-table-property
  --resource-arn "arn:aws:glue:us-east-1:123456789012:integration/my-integration"
  --table-name "my-table"
  --cli-input-json '{
    "TargetTableConfig": {
      "UnnestSpec": "FULL",
```

```
        "TargetTableName": "my-target-table",
    }
}'
```

Unnesting examples

Consider a DynamoDB item with the following structure:

```
{
  "ProductId": "P12345",
  "ProductDetails": {
    "Name": "Smartphone",
    "Brand": "TechCo",
    "Specifications": {
      "Color": "Black",
      "Storage": "128GB"
    }
  },
  "Reviews": [
    {
      "Rating": 5,
      "Comment": "Great product!"
    },
    {
      "Rating": 4,
      "Comment": "Good value."
    }
  ]
}
```

No unnesting example

With no unnesting, the target table would have columns:

- ProductId (string)
- ProductDetails (struct)
- Reviews (array of structs)

Queries would need to use struct and array access patterns:

```
SELECT
```

```

ProductId,
ProductDetails.Name,
ProductDetails.Specifications.Color
FROM product_table;

```

Unnest one level example

With one level unnesting, the target table would have columns:

- ProductId (string)
- ProductDetails_Name (string)
- ProductDetails_Brand (string)
- ProductDetails_Specifications (struct)
- Reviews (array of structs)

Queries would be simplified for the first level:

```

SELECT
  ProductId,
  ProductDetails_Name,
  ProductDetails_Specifications.Color
FROM product_table;

```

Unnest all levels example

With all levels unnesting, the target table would have columns and values:

Column Name (Type)	Value
ProductId (string)	P12345
ProductDetails_Name (string)	Smartphone
ProductDetails_Brand (string)	TechCo
ProductDetails_Specifications_Color (string)	Black
ProductDetails_Specifications_Storage (string)	128GB

Column Name (Type)	Value
Reviews_0_Rating (number)	5
Reviews_0_Comment (string)	Great product!
Reviews_1_Rating (number)	4
Reviews_1_Comment (string)	Good value.

Queries would be fully flattened:

```
SELECT
  ProductId,
  ProductDetails_Name,
  ProductDetails_Specifications_Color
FROM product_table;
```

Data partitioning

What is data partitioning?

Data partitioning is a technique that divides large datasets into smaller, more manageable segments called partitions. In the context of Amazon Glue Zero-ETL integrations, partitioning organizes your data in the target location based on specific column values or transformations of those values.

Benefits of data partitioning

Effective data partitioning provides several key benefits for analytics workloads:

- **Improved query performance:** Queries can skip irrelevant partitions (partition pruning), reducing the amount of data that needs to be scanned.
- **Reduced costs:** By scanning less data, you can lower compute and I/O costs for your analytics queries.
- **Better scalability:** Partitioning allows parallel processing of data segments, enabling more efficient scaling of analytics workloads.
- **Simplified data lifecycle management:** You can manage retention policies at the partition level, making it easier to archive or delete older data.

Key partitioning concepts

Partition columns

Columns in your data that are used to determine how records are organized into partitions. Effective partition columns should align with common query patterns and have appropriate cardinality.

Partition functions

Transformations applied to partition column values to create the actual partition boundaries. Examples include identity (using the raw value) and time-based functions (year, month, day, hour).

Partition pruning

The process where the query engine identifies and skips partitions that don't contain relevant data for a query, significantly improving performance.

Partition granularity

The level of detail at which data is partitioned. Finer granularity (more partitions) can improve query performance but may increase metadata overhead. Coarser granularity (fewer partitions) reduces metadata overhead but may result in scanning more data than necessary.

Partitioning in Amazon Glue Zero-ETL integrations

Amazon Glue Zero-ETL integrations use Apache Iceberg table format, which provides advanced partitioning capabilities. When you create a Zero-ETL integration, you can:

- Use default partitioning strategies optimized for your data source
- Define custom partitioning specifications tailored to your query patterns
- Apply transformations to partition columns (especially useful for timestamp-based partitioning)
- Combine multiple partition strategies for multi-level partitioning

Partitioning configurations are specified through the `CreateIntegrationTableProperty` API when setting up your Zero-ETL integration. Once configured, Amazon Glue automatically applies these partitioning strategies to organize your data in the target location.

Partition specification API reference

Use the following parameters in the `CreateIntegrationTableProperties` API to configure partitioning:

PartitionSpec

An array of partition specifications that defines how data is partitioned in the target location.

```
{
  "partitionSpec": [
    {
      "fieldName": "timestamp_col",
      "functionSpec": "month",
      "conversionSpec": "epoch_milli"
    },
    {
      "fieldName": "category",
      "functionSpec": "identity"
    }
  ]
}
```

FieldName

A UTF-8 string (1-128 bytes) specifying the column name to use for partitioning.

FunctionSpec

Specifies the partitioning function. Valid values:

- `identity` - Uses source values directly without transformation
- `year` - Extracts the year from timestamp values (e.g., 2023)
- `month` - Extracts the month from timestamp values (e.g., 2023-01)
- `day` - Extracts the day from timestamp values (e.g., 2023-01-15)
- `hour` - Extracts the hour from timestamp values (e.g., 2023-01-15-14)

Note

Time-based functions (`year`, `month`, `day`, `hour`) require the `ConversionSpec` parameter to specify the source timestamp format.

ConversionSpec

A UTF-8 string that specifies the timestamp format of the source data. Valid values are:

- `epoch_sec` - Unix epoch timestamp in seconds
- `epoch_milli` - Unix epoch timestamp in milliseconds
- `iso` - ISO 8601 formatted timestamp

Partitioning strategies

Default partitioning

When no partition columns are specified, Amazon Glue Zero-ETL applies default partitioning strategies optimized for your data source:

- **Primary key-based partitioning:** For sources with primary keys (like DynamoDB tables), Amazon Glue Zero-ETL automatically partitions data using the primary key with bucketing to prevent partition explosion.

Default partitioning is designed to work well for common query patterns without requiring manual configuration. However, for specific query patterns or performance requirements, you may want to define custom partitioning strategies.

User-defined partitioning strategies

Amazon Glue Zero-ETL allows you to define custom partitioning strategies using the `PartitionSpec` parameter. You can specify one or more partition columns and apply different partitioning functions to each column.

Identity partitioning uses the raw values from a column to create partitions. This strategy is useful for columns with low to medium cardinality, such as category, region, or status fields.

Example Identity partitioning example

```
{
  "partitionSpec": [
    {
      "fieldName": "category",
      "functionSpec": "identity"
    }
  ]
}
```

```
]
}
```

This creates separate partitions for each unique value in the "category" column.

Warning

Avoid using identity partitioning with high-cardinality columns (like primary keys or timestamps) as it can lead to partition explosion, which degrades performance and increases metadata overhead.

Time-based partitioning organizes data based on timestamp values at different granularities (year, month, day, or hour). This strategy is ideal for time-series data and enables efficient time-range queries.

When using time-based partitioning, Amazon Glue Zero-ETL can automatically convert various timestamp formats to a standardized format before applying the partition function. This conversion is specified using the `ConversionSpec` parameter.

Example Time-based partitioning example

```
{
  "partitionSpec": [
    {
      "fieldName": "created_at",
      "functionSpec": "month",
      "conversionSpec": "epoch_milli"
    }
  ]
}
```

This partitions data by month based on the "created_at" column, which contains Unix epoch timestamps in milliseconds.

Amazon Glue Zero-ETL supports the following time-based partition functions:

- **year:** Partitions data by year (e.g., 2023, 2024)
- **month:** Partitions data by month (e.g., 2023-01, 2023-02)
- **day:** Partitions data by day (e.g., 2023-01-01, 2023-01-02)

- **hour:** Partitions data by hour (e.g., 2023-01-01-01, 2023-01-01-02)

Amazon Glue Zero-ETL supports the following timestamp formats through the `ConversionSpec` parameter:

- **epoch_sec:** Unix epoch timestamps in seconds
- **epoch_milli:** Unix epoch timestamps in milliseconds
- **iso:** ISO 8601 formatted timestamps

Note

The original column values remain unchanged in your source data. Amazon Glue only transforms partition column values to Timestamp Type in the target database table. The transformations only apply to the partitioning process.

Multi-level partitioning combines multiple partition strategies to create a hierarchical partitioning scheme. This is useful for optimizing different types of queries against the same dataset.

Example Multi-level partitioning example

```
{
  "partitionSpec": [
    {
      "fieldName": "created_at",
      "functionSpec": "month",
      "conversionSpec": "iso"
    },
    {
      "fieldName": "region",
      "functionSpec": "identity"
    }
  ]
}
```

This creates a two-level partitioning scheme: first by month (from the "created_at" column), then by region. This enables efficient queries that filter by date ranges, specific regions, or a combination of these dimensions.

When designing multi-level partitioning schemes, consider:

- Placing higher-selectivity columns first in the partition hierarchy
- Balancing partition granularity with the number of partitions
- Aligning the partitioning scheme with your most common query patterns

Best practices

Partition column selection

- Do not use high-cardinality columns with the `identity` partition function. Using high-cardinality columns with identity partitioning creates many small partitions, which can significantly degrade ingestion performance. High-cardinality columns may include:
 - Primary keys
 - Timestamp fields (such as `LastModifiedTimestamp`, `CreatedDate`)
 - System-generated timestamps
- Do not select multiple timestamp partitions on same column. For example:

```
"partitionSpec": [  
  {"fieldName": "col1", "functionSpec": "year", "conversionSpec" :  
  "epoch_milli"},  
  {"fieldName": "col1", "functionSpec": "month", "conversionSpec" :  
  "epoch_milli"},  
  {"fieldName": "col1", "functionSpec": "day", "conversionSpec" : "epoch_milli"},  
  {"fieldName": "col1", "functionSpec": "hour", "conversionSpec" : "epoch_milli"}  
]
```

Partition FunctionSpec/ConversionSpec selection

- Specify the correct `ConversionSpec` (`epoch_sec` | `epoch_milli` | `iso`) that represents format of column values chosen for timestamp based partitioning when using timestamp-based partition functions. Amazon Glue Zero-ETL uses this parameter to correctly transform source data into timestamp format before partitioning.
- Use appropriate granularity (year/month/day/hour) based on data volume.
- Consider timezone implications when using ISO timestamps. Amazon Glue Zero-ETL populates all the record values of chosen timestamp column with UTC timezone.

Error handling

NEEDS_ATTENTION State

An integration enters the NEEDS_ATTENTION state when:

- Specified partition columns do not exist in the source
- Timestamp conversion fails for partition columns

Limitations

Partitioning limitations

- Partition specifications cannot be changed after an integration is created. To use a different partitioning strategy, you must create a new integration.
- The maximum number of partition columns is limited to 10.

Cross-account integration limitations

- When creating cross-account integrations, Amazon Glue Console has a limitation where it doesn't invoke CreateIntegrationTableProperty API for configuring UnnestSpec and PartitionSpec for target Amazon Glue tables that are hosted in the account where integration does not exist.

Workaround: The CreateIntegrationTableProperty API must be invoked by CX from the account where the target database exists.

Multiple integrations limitations

- If you need to replicate the same source with different schema unnest/partition configurations, it is required to create a new Amazon Glue database for each integration separately. Later invoke CreateIntegrationTableProperty for each table from individual Amazon Glue Database with desired schema unnesting and partitioning configurations.

Common integration tasks

Creating an integration

This sections describes the general steps to create an integration. This example uses Amazon DynamoDB as a source.

1. On the Amazon Glue console home page, select **Zero-ETL integrations**.
2. You can view all you integrations on the Zero ETL integration home page. To create a new integration, select **Create zero-ETL integration**.

The screenshot displays the AWS Glue console interface for Zero-ETL integrations. The left sidebar contains navigation links for 'AWS Glue', 'Getting started', 'ETL jobs', 'Visual ETL', 'Notebooks', 'Job run monitoring', 'Data Catalog tables', 'Data connections', 'Workflows (orchestration)', 'Zero-ETL integrations', 'Data Catalog', 'Data Integration and ETL', and 'Legacy pages'. The main content area is titled 'Zero-ETL integrations' and features a 'How it works' section with three steps: 'Step 1. Prepare source data', 'Step 2. Prepare target database', and 'Step 3. Set up and launch integration'. Below this is a 'Zero-ETL integrations overview' section with a table showing statistics: Total (0), Active (0), Inactive (0), and In error (0). At the bottom, there is a 'Zero-ETL integrations (0)' section with a search bar and a table header for Name, Status, Source type, and Target type.

3. You are prompted to select a **Source Type**. Select your source and click **Next**. Refer to the the source configuration sections for SaaS integration sources.
4. In the **Configure source and target** page, select the tables or entities to replicate. For Amazon DynamoDB make sure the PITR and RBAC policy is configured.
5. Specify your integration target:
 - For an Amazon Glue Data Catalog target, select the Amazon Glue database you want to replicate the data to.

- For an Amazon Redshift data warehouse target, select the Redshift cluster namespace or Redshift Serverless workgroup namespace.

For more information, see [Configuring the integration with your target](#).

6. Provide the **Target IAM Role** that you created in the prerequisites.
7. If you want to configure an optional **Target KMS Key** for your data being stored in the target, provide an enabled KMS Key. Likewise, if you want to configure a target network connection, select an Amazon Glue connection.
8. The **Fix Target** button configures some of the steps in the Prerequisite section of this documentation. Namely it will 1) provide a Catalog RBAC Policy and 2) if no Amazon S3 URI is provided it will generate one for you, otherwise it will use the provided URI.
9. For integrations with a Redshift data warehouse target:
 - 10 In the **Output setting** section of the **Configure source and target** page, select a schema unnesting option that you want for your data in the target. If you want to use customer partition keys for your data, select **Specify custom partition keys** and provide up to 10 keys. Otherwise, you can simply use the partition keys that are assigned to your DynamoDB table being replicated.
 - 11 In the **Security and data encryption** section, you can provide a KMS key that will be used in the intermediary process of replicating your data to the target. Otherwise, an Amazon managed KMS key will be used. Currently we only support a 15 minute replication setting. Enter a name for the Zero ETL integration in **Integration details**.
 - 12 Review and make sure that all the provided details are correct. Click **Create and launch integration** once everything has been confirmed.
 - 13 In the Zero ETL home page, you can select the integration you created and the details for your integrations will appear. The "Status" indicates the state of your integration.

Modifying an integration

You can modify an existing integration.

1. Select **Edit** in the top right corner of your integration details page.
2. On the **Edit source and target** page you can change the Target IAM role and Target network connection. The other fields are not editable after integration creation. Click **Next**.
3. You can also edit the name and description of the integration in the **Edit integration and configuration** page. Click **Next**.

4. Review your edits and once confirmed, click **Update integration**.

Deleting an integration

Delete is a terminal state for an integration. Once deleted, the integration cannot be revived.

Deleting an integration clears up all internal metadata and any intermediate stored data.

During this process any running tasks which are writing data to a target table are terminated.

Amazon Glue will not delete or cleanup the target Amazon Glue database (in the Data Catalog) and the associated data in the Amazon S3 bucket in your account. You need to explicitly clean those up if required.

To delete an integration:

1. In the integration details page, click **Delete**.
2. Enter "Delete" and click **Delete**. Note: This is an irreversible action.
3. In the integration details page, the status shows "Deleting". Once the integration is actually deleted, it will no longer appear on the the Zero ETL integration home page.

Creating integrations using the APIs

You can use the following APIs to create and manage Zero-ETL integrations in Amazon Glue:

- CreateIntegration
- CreateIntegrationTableProperties
- CreateIntegrationResourceProperty
- UpdateIntegrationTableProperties
- UpdateIntegrationResourceProperty
- ModifyingIntegration
- DeleteIntegration
- DeleteIntegrationTableProperties
- DescribeIntegrations
- DescribeInboundIntegrations
- GetIntegrationTableProperties
- GetIntegrationResourceProperty

For more information, see [Integration APIs in Amazon Glue](#).

Monitoring an integration

Integration states

The following integration states describe the integration:

- **Creating** - The integration is being created.
- **Active** - The integration is sending transactional data to the target.
- **Modifying** - The integration is being modified.
- **Syncing** - The integration has encountered a recoverable error and is re-seeding data.
- **Needs attention** - The integration encountered an event or error that requires manual intervention to resolve it. To fix the issue, follow the instructions in the error message on the integration details.
- **Failed** - The integration encountered an unrecoverable event or error. You must delete and recreate the integration.
- **Deleting** - The integration is being deleted.

Viewing Amazon CloudWatch logs for an integration

Amazon Glue zero-ETL integrations generate Amazon CloudWatch logs for visibility into your data movement. Log events relating to each successful ingestion or any failures experienced due to problematic data records at source, or data write errors due to schema changes or insufficient permissions are emitted to a default log group created in a customer account.

For each integration created, the log events for that integration will be collected under `/aws-glue/zeroETL-integrations/logs/` in Amazon Cloudwatch. Inside the log group, log messages will be split into log streams. Each integration created has a dedicated log stream to where all logs for that integration are written.

For example, logs for an integration with IntegrationArn `arn:aws:glue:us-east-1:123456789012:integration:03cabe77-79e7-4b7a-b3da-8c160bea6bbf` can be found under `/aws-glue/zeroETL-integrations/logs/03cabe77-79e7-4b7a-b3da-8c160bea6bbf`. `{IntegrationId}` can be referenced from the `{integrationArn}` generated when an integration is created.

Note

For a cross-account scenario, source processing Logs are emitted in the source account where the integration exists and target processing logs are emitted in the target account where the target database exists.

IAM permissions required to enable logging

When creating your integration, the following IAM permissions are needed by the source and target roles to enable CloudWatch logging for an integration. Amazon Glue zero-ETL integrations use these permissions provided in the source and target roles to emit CloudWatch logs to customer accounts.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

Log messages

Log format: zero-ETL integrations emit four types of log messages:

```
// Ingestion started
{
```

```
"integrationArn": "arn:aws:glue:us-east-2:123456789012:integration/1a012bba-123a-1bba-
ab1c-173de3b12345",
...
  "messageType": "IngestionStarted",
  "details": {
    "tableName": "testDDBTable",
    "message": "Ingestion Job started"
  }
}
// Data processing stats on successful table ingestion
{
...
  "messageType": "IngestionProcessingStats",
  "details": {
