Amazon ECS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon ECS.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Elastic Load Balancing - Version 2 examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Elastic Load Balancing - Version 2.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Elastic Load Balancing

The following code examples show how to get started using Elastic Load Balancing.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
public class HelloLoadBalancer {

        public static void main(String[] args) {
                ElasticLoadBalancingV2Client loadBalancingV2Client =
 ElasticLoadBalancingV2Client.builder()
                                .region(Region.US_EAST_1)
```

```
                                .build();

                DescribeLoadBalancersResponse loadBalancersResponse =
 loadBalancingV2Client
                                .describeLoadBalancers(r -> r.pageSize(10));
                List<LoadBalancer> loadBalancerList =
 loadBalancersResponse.loadBalancers();
                for (LoadBalancer lb : loadBalancerList)
                        System.out.println("Load Balancer DNS name = " +
 lb.dnsName());
        }
}
```

- For API details, see DescribeLoadBalancers in *Amazon SDK for Java 2.x API Reference*.

`CreateListener`

The following code example shows how to use `CreateListener`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /*
     * Creates an Elastic Load Balancing load balancer that uses the specified
     * subnets
     * and forwards requests to the specified target group.
     */
```

```
   public String createLoadBalancer(List<Subnet> subnetIds, String targetGroupARN,
String lbName, int port,
           String protocol) {
       try {
           List<String> subnetIdStrings = subnetIds.stream()
                   .map(Subnet::subnetId)
                   .collect(Collectors.toList());

           CreateLoadBalancerRequest balancerRequest =
CreateLoadBalancerRequest.builder()
                   .subnets(subnetIdStrings)
                   .name(lbName)
                   .scheme("internet-facing")
                   .build();

           // Create and wait for the load balancer to become available.
           CreateLoadBalancerResponse lsResponse =
getLoadBalancerClient().createLoadBalancer(balancerRequest);
           String lbARN = lsResponse.loadBalancers().get(0).loadBalancerArn();

           ElasticLoadBalancingV2Waiter loadBalancerWaiter =
getLoadBalancerClient().waiter();
           DescribeLoadBalancersRequest request =
DescribeLoadBalancersRequest.builder()
                   .loadBalancerArns(lbARN)
                   .build();

           System.out.println("Waiting for Load Balancer " + lbName + " to become
available.");
           WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
loadBalancerWaiter
                   .waitUntilLoadBalancerAvailable(request);
           waiterResponse.matched().response().ifPresent(System.out::println);
           System.out.println("Load Balancer " + lbName + " is available.");

           // Get the DNS name (endpoint) of the load balancer.
           String lbDNSName = lsResponse.loadBalancers().get(0).dnsName();
           System.out.println("*** Load Balancer DNS Name: " + lbDNSName);

           // Create a listener for the load balance.
           Action action = Action.builder()
                   .targetGroupArn(targetGroupARN)
                   .type("forward")
                   .build();
```

```
            CreateListenerRequest listenerRequest = CreateListenerRequest.builder()

.loadBalancerArn(lsResponse.loadBalancers().get(0).loadBalancerArn())
                    .defaultActions(action)
                    .port(port)
                    .protocol(protocol)
                    .build();

            getLoadBalancerClient().createListener(listenerRequest);
            System.out.println("Created listener to forward traffic from load
balancer " + lbName + " to target group "
                    + targetGroupARN);

            // Return the load balancer DNS name.
            return lbDNSName;

        } catch (ElasticLoadBalancingV2Exception e) {
            e.printStackTrace();
        }
        return "";
    }
```

- For API details, see CreateListener in *Amazon SDK for Java 2.x API Reference*.

`CreateLoadBalancer`

The following code example shows how to use `CreateLoadBalancer`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /*
     * Creates an Elastic Load Balancing load balancer that uses the specified
     * subnets
     * and forwards requests to the specified target group.
```

```
    */
   public String createLoadBalancer(List<Subnet> subnetIds, String targetGroupARN,
String lbName, int port,
           String protocol) {
       try {
           List<String> subnetIdStrings = subnetIds.stream()
                   .map(Subnet::subnetId)
                   .collect(Collectors.toList());

           CreateLoadBalancerRequest balancerRequest =
CreateLoadBalancerRequest.builder()
                   .subnets(subnetIdStrings)
                   .name(lbName)
                   .scheme("internet-facing")
                   .build();

           // Create and wait for the load balancer to become available.
           CreateLoadBalancerResponse lsResponse =
getLoadBalancerClient().createLoadBalancer(balancerRequest);
           String lbARN = lsResponse.loadBalancers().get(0).loadBalancerArn();

           ElasticLoadBalancingV2Waiter loadBalancerWaiter =
getLoadBalancerClient().waiter();
           DescribeLoadBalancersRequest request =
DescribeLoadBalancersRequest.builder()
                   .loadBalancerArns(lbARN)
                   .build();

           System.out.println("Waiting for Load Balancer " + lbName + " to become
available.");
           WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
loadBalancerWaiter
                   .waitUntilLoadBalancerAvailable(request);
           waiterResponse.matched().response().ifPresent(System.out::println);
           System.out.println("Load Balancer " + lbName + " is available.");

           // Get the DNS name (endpoint) of the load balancer.
           String lbDNSName = lsResponse.loadBalancers().get(0).dnsName();
           System.out.println("*** Load Balancer DNS Name: " + lbDNSName);

           // Create a listener for the load balance.
           Action action = Action.builder()
                   .targetGroupArn(targetGroupARN)
                   .type("forward")
```

```
                    .build();

            CreateListenerRequest listenerRequest = CreateListenerRequest.builder()

.loadBalancerArn(lsResponse.loadBalancers().get(0).loadBalancerArn())
                    .defaultActions(action)
                    .port(port)
                    .protocol(protocol)
                    .build();

            getLoadBalancerClient().createListener(listenerRequest);
            System.out.println("Created listener to forward traffic from load
balancer " + lbName + " to target group "
                    + targetGroupARN);

            // Return the load balancer DNS name.
            return lbDNSName;

        } catch (ElasticLoadBalancingV2Exception e) {
            e.printStackTrace();
        }
        return "";
    }
```

- For API details, see CreateLoadBalancer in *Amazon SDK for Java 2.x API Reference*.

`CreateTargetGroup`

The following code example shows how to use `CreateTargetGroup`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /*
     * Creates an Elastic Load Balancing target group. The target group specifies
     * how
```

```
     * the load balancer forward requests to instances in the group and how instance
     * health is checked.
     */
    public String createTargetGroup(String protocol, int port, String vpcId, String
targetGroupName) {
        CreateTargetGroupRequest targetGroupRequest =
CreateTargetGroupRequest.builder()
                .healthCheckPath("/healthcheck")
                .healthCheckTimeoutSeconds(5)
                .port(port)
                .vpcId(vpcId)
                .name(targetGroupName)
                .protocol(protocol)
                .build();

        CreateTargetGroupResponse targetGroupResponse =
getLoadBalancerClient().createTargetGroup(targetGroupRequest);
        String targetGroupArn =
targetGroupResponse.targetGroups().get(0).targetGroupArn();
        String targetGroup =
targetGroupResponse.targetGroups().get(0).targetGroupName();
        System.out.println("The " + targetGroup + " was created with ARN" +
targetGroupArn);
        return targetGroupArn;
    }
```

- For API details, see CreateTargetGroup in *Amazon SDK for Java 2.x API Reference*.

`DeleteLoadBalancer`

The following code example shows how to use `DeleteLoadBalancer`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    // Deletes a load balancer.
```

```
    public void deleteLoadBalancer(String lbName) {
        try {
            // Use a waiter to delete the Load Balancer.
            DescribeLoadBalancersResponse res = getLoadBalancerClient()
                    .describeLoadBalancers(describe -> describe.names(lbName));
            ElasticLoadBalancingV2Waiter loadBalancerWaiter =
getLoadBalancerClient().waiter();
            DescribeLoadBalancersRequest request =
DescribeLoadBalancersRequest.builder()
                    .loadBalancerArns(res.loadBalancers().get(0).loadBalancerArn())
                    .build();

            getLoadBalancerClient().deleteLoadBalancer(
                    builder ->
builder.loadBalancerArn(res.loadBalancers().get(0).loadBalancerArn()));
            WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
loadBalancerWaiter
                    .waitUntilLoadBalancersDeleted(request);
            waiterResponse.matched().response().ifPresent(System.out::println);

        } catch (ElasticLoadBalancingV2Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
        }
        System.out.println(lbName + " was deleted.");
    }
```

- For API details, see DeleteLoadBalancer in *Amazon SDK for Java 2.x API Reference*.

`DeleteTargetGroup`

The following code example shows how to use `DeleteTargetGroup`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    // Deletes the target group.
```

```
    public void deleteTargetGroup(String targetGroupName) {
        try {
            DescribeTargetGroupsResponse res = getLoadBalancerClient()
                    .describeTargetGroups(describe ->
describe.names(targetGroupName));
            getLoadBalancerClient()
                    .deleteTargetGroup(builder ->
builder.targetGroupArn(res.targetGroups().get(0).targetGroupArn()));
        } catch (ElasticLoadBalancingV2Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
        }
        System.out.println(targetGroupName + " was deleted.");
    }
```

- For API details, see DeleteTargetGroup in *Amazon SDK for Java 2.x API Reference*.

`DescribeTargetHealth`

The following code example shows how to use `DescribeTargetHealth`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    // Checks the health of the instances in the target group.
    public List<TargetHealthDescription> checkTargetHealth(String targetGroupName) {
        DescribeTargetGroupsRequest targetGroupsRequest =
DescribeTargetGroupsRequest.builder()
                .names(targetGroupName)
                .build();

        DescribeTargetGroupsResponse tgResponse =
getLoadBalancerClient().describeTargetGroups(targetGroupsRequest);

        DescribeTargetHealthRequest healthRequest =
DescribeTargetHealthRequest.builder()
```

```
                .targetGroupArn(tgResponse.targetGroups().get(0).targetGroupArn())
                .build();

        DescribeTargetHealthResponse healthResponse =
getLoadBalancerClient().describeTargetHealth(healthRequest);
        return healthResponse.targetHealthDescriptions();
    }
```

- For API details, see DescribeTargetHealth in *Amazon SDK for Java 2.x API Reference*.

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating Amazon Systems Manager parameters.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Run the interactive scenario at a command prompt.

```

                        For this demo, we'll use the AWS SDK for Java (v2) to create
several AWS resources
                        to set up a load-balanced web service endpoint and explore
some ways to make it resilient
                        against various kinds of failures.

                        Some of the resources create by this demo are:
                        \t* A DynamoDB table that the web service depends on to
provide book, movie, and song recommendations.
                        \t* An EC2 launch template that defines EC2 instances that
each contain a Python web server.
                        \t* An EC2 Auto Scaling group that manages EC2 instances
across several Availability Zones.
                        \t* An Elastic Load Balancing (ELB) load balancer that
targets the Auto Scaling group to distribute requests.
                        """);

        System.out.println("Press Enter when you're ready.");
        in.nextLine();

MediaStore examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with MediaStore.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`CreateContainer`

The following code example shows how to use `CreateContainer`.

SDK for Java 2.x

Amazon Entity Resolution examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Entity Resolution.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Entity Resolution

The following code example shows how to get started using Amazon Entity Resolution.

SDK for Java 2.x

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloEntityResoultion {

    private static final Logger logger =
 LoggerFactory.getLogger(HelloEntityResoultion.class);

    private static EntityResolutionAsyncClient entityResolutionAsyncClient;
    public static void main(String[] args) {
        listMatchingWorkflows();
    }

    public static EntityResolutionAsyncClient getResolutionAsyncClient() {
        if (entityResolutionAsyncClient == null) {
            /*
            The `NettyNioAsyncHttpClient` class is part of the AWS SDK for Java,
 version 2,
```

```
            and it is designed to provide a high-performance, asynchronous HTTP
client for interacting with AWS services.
             It uses the Netty framework to handle the underlying network
communication and the Java NIO API to
             provide a non-blocking, event-driven approach to HTTP requests and
responses.
             */

            SdkAsyncHttpClient httpClient = NettyNioAsyncHttpClient.builder()
                .maxConcurrency(50)  // Adjust as needed.
                .connectionTimeout(Duration.ofSeconds(60))  // Set the connection
timeout.
                .readTimeout(Duration.ofSeconds(60))  // Set the read timeout.
                .writeTimeout(Duration.ofSeconds(60))  // Set the write timeout.
                .build();

            ClientOverrideConfiguration overrideConfig =
ClientOverrideConfiguration.builder()
                .apiCallTimeout(Duration.ofMinutes(2))  // Set the overall API call
timeout.
                .apiCallAttemptTimeout(Duration.ofSeconds(90))  // Set the
individual call attempt timeout.
                .retryStrategy(RetryMode.STANDARD)
                .build();

            entityResolutionAsyncClient = EntityResolutionAsyncClient.builder()
                .httpClient(httpClient)
                .overrideConfiguration(overrideConfig)
                .build();
        }
        return entityResolutionAsyncClient;
    }

    /**
     * Lists all matching workflows using an asynchronous paginator.
     * <p>
     * This method requests a paginated list of matching workflows from the
     * AWS Entity Resolution service and logs the names of the retrieved workflows.
     * It uses an asynchronous approach with a paginator and waits for the operation
     * to complete using {@code CompletableFuture#join()}.
     * </p>
     */
    public static void listMatchingWorkflows() {
```

```
        ListMatchingWorkflowsRequest request =
 ListMatchingWorkflowsRequest.builder().build();

        ListMatchingWorkflowsPublisher paginator =
            getResolutionAsyncClient().listMatchingWorkflowsPaginator(request);

        // Iterate through the paginated results asynchronously
        CompletableFuture<Void> future = paginator.subscribe(response -> {
            response.workflowSummaries().forEach(workflow ->
                logger.info("Matching Workflow Name: " + workflow.workflowName())
            );
        });

        // Wait for the asynchronous operation to complete
        future.join();
    }
}
```

- For API details, see listMatchingWorkflows in *Amazon SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create Schema Mapping.
- Create an Amazon Entity Resolution workflow.
- Start the matching job for the workflow.
- Get details for the matching job.
- Get Schema Mapping.
- List all Schema Mappings.
- Tag the Schema Mapping resource.

- Delete the Amazon Entity Resolution Assets.

Run an interactive scenario demonstrating Amazon Entity Resolution features.

```
public class EntityResScenario {
    private static final Logger logger =
 LoggerFactory.getLogger(EntityResScenario.class);
    public static final String DASHES = new String(new char[80]).replace("\0", "-");
    private static final String STACK_NAME = "EntityResolutionCdkStack";
    private static final String ENTITY_RESOLUTION_ROLE_ARN_KEY =
 "EntityResolutionRoleArn";
    private static final String GLUE_DATA_BUCKET_NAME_KEY = "GlueDataBucketName";
    private static final String JSON_GLUE_TABLE_ARN_KEY = "JsonErGlueTableArn";
    private static final String CSV_GLUE_TABLE_ARN_KEY = "CsvErGlueTableArn";
    private static String glueBucketName;
    private static String workflowName = "workflow-" + UUID.randomUUID();

    private static String jsonSchemaMappingName = "jsonschema-" + UUID.randomUUID();
    private static String jsonSchemaMappingArn = null;
    private static String csvSchemaMappingName = "csv-" + UUID.randomUUID();
    private static String roleARN;
    private static String csvGlueTableArn;
    private static String jsonGlueTableArn;
    private static Scanner scanner = new Scanner(System.in);

    private static EntityResActions actions = new EntityResActions();

    public static void main(String[] args) throws InterruptedException {

        logger.info("Welcome to the AWS Entity Resolution Scenario.");
        logger.info("""
            AWS Entity Resolution is a fully-managed machine learning service
 provided by
            Amazon Web Services (AWS) that helps organizations extract, link, and
```

```
            organize information from multiple data sources. It leverages natural
            language processing and deep learning models to identify and resolve
            entities, such as people, places, organizations, and products,
            across structured and unstructured data.

            With Entity Resolution, customers can build robust data integration
            pipelines to combine and reconcile data from multiple systems,
databases,
            and documents. The service can handle ambiguous, incomplete, or
conflicting
            information, and provide a unified view of entities and their
relationships.
            This can be particularly valuable in applications such as customer 360,
            fraud detection, supply chain management, and knowledge management,
where
            accurate entity identification is crucial.

            The `EntityResolutionAsyncClient` interface in the AWS SDK for Java 2.x
            provides a set of methods to programmatically interact with the AWS
Entity
            Resolution service. This allows developers to automate the entity
extraction,
            linking, and deduplication process as part of their data processing
workflows.
            With Entity Resolution, organizations can unlock the value of their
data,
            improve decision-making, and enhance customer experiences by having a
reliable,
            comprehensive view of their key entities.
            """);

        waitForInputToContinue(scanner);
        logger.info(DASHES);

        logger.info(DASHES);
        logger.info("""
            To prepare the AWS resources needed for this scenario application, the
next step uploads
            a CloudFormation template whose resulting stack creates the following
resources:
            - An AWS Glue Data Catalog table
            - An AWS IAM role
            - An AWS S3 bucket
            - An AWS Entity Resolution Schema
```

```
            It can take a couple minutes for the Stack to finish creating the
resources.

OpenSearch Service examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with OpenSearch Service.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello OpenSearch Service

The following code example shows how to get started using OpenSearch Service.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
import software.amazon.awssdk.services.opensearch.OpenSearchAsyncClient;
import software.amazon.awssdk.services.opensearch.model.ListVersionsRequest;
import java.util.List;
import java.util.concurrent.CompletableFuture;

/**
 * Before running this Java V2 code example, set up your development
```

```
 * environment, including your credentials.

- Basics
- Actions

Basics

Learn OpenSearch Service core operations

The following code example shows how to:

- Create an OpenSearch Service domain.
- Provides detailed information about a specific OpenSearch Service domain.
- Lists all the OpenSearch Service domains owned by the account.
- Waits until the OpenSearch Service domain's change status reaches a completed state.
- Modifies the configuration of an existing OpenSearch Service domain.
- Add a tag to the OpenSearch Service domain.
- Lists the tags associated with an OpenSearch Service domain.
- Removes tags from an OpenSearch Service domain.
- Deletes the OpenSearch Service domain.

SDK for Java 2.x

configuration", exception);
               }
               // Handle success if needed (e.g., logging or additional actions)
           });
   }
```

- For API details, see [UpdateDomainConfig](#) in *Amazon SDK for Java 2.x API Reference*.

EventBridge examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with EventBridge.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello EventBridge

The following code examples show how to get started using EventBridge.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 */
public class HelloEventBridge {
    public static void main(String[] args) {
        Region region = Region.US_WEST_2;
        EventBridgeClient eventBrClient = EventBridgeClient.builder()
                .region(region)
                .build();

        listBuses(eventBrClient);
        eventBrClient.close();
    }

    public static void listBuses(EventBridgeClient eventBrClient) {
        try {
            ListEventBusesRequest busesRequest = ListEventBusesRequest.builder()
                    .limit(10)
                    .build();
```

```
            ListEventBusesResponse response =
 eventBrClient.listEventBuses(busesRequest);
            List<EventBus> buses = response.eventBuses();
            for (EventBus bus : buses) {
                System.out.println("The name of the event bus is: " + bus.name());
                System.out.println("The ARN of the event bus is: " + bus.arn());
            }

        } catch (EventBridgeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
```

- For API details, see ListEventBuses in *Amazon SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions
- Scenarios

Basics

Learn the basics

The following code example shows how to:

- Create a rule and add a target to it.
- Enable and disable rules.
- List and update rules and targets.
- Send events, then clean up resources.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java code example performs the following tasks:
 *
 * This Java V2 example performs the following tasks with Amazon EventBridge:
 *
 * 1. Creates an AWS Identity and Access Management (IAM) role to use with
 * Amazon EventBridge.
 * 2. Amazon Simple Storage Service (Amazon S3) bucket with EventBridge events
 * enabled.
 * 3. Creates a rule that triggers when an object is uploaded to Amazon S3.
 * 4. Lists rules on the event bus.
 * 5. Creates a new Amazon Simple Notification Service (Amazon SNS) topic and
 * lets the user subscribe to it.
 * 6. Adds a target to the rule that sends an email to the specified topic.
 * 7. Creates an EventBridge event that sends an email when an Amazon S3 object
 * is created.
 * 8. Lists Targets.
 * 9. Lists the rules for the same target.
 * 10. Triggers the rule by uploading a file to the Amazon S3 bucket.
 * 11. Disables a specific rule.
 * 12. Checks and print the state of the rule.
 * 13. Adds a transform to the rule to change the text of the email.
 * 14. Enables a specific rule.
 * 15. Triggers the updated rule by uploading a file to the Amazon S3 bucket.
 * 16. Updates the rule to be a custom rule pattern.
 * 17. Sending an event to trigger the rule.
 * 18. Cleans up resources.
```

```
 *
 */

Actions

`DeleteRule`

The following code example shows how to use `DeleteRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void deleteRuleByName(EventBridgeClient eventBrClient, String
ruleName) {
       DeleteRuleRequest ruleRequest = DeleteRuleRequest.builder()
               .name(ruleName)
               .build();

       eventBrClient.deleteRule(ruleRequest);
       System.out.println("Successfully deleted the rule");
```

```
    }
```

- For API details, see DeleteRule in *Amazon SDK for Java 2.x API Reference*.

`DescribeRule`

The following code example shows how to use `DescribeRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void checkRule(EventBridgeClient eventBrClient, String
eventRuleName) {
       try {
           DescribeRuleRequest ruleRequest = DescribeRuleRequest.builder()
                   .name(eventRuleName)
                   .build();

           DescribeRuleResponse response = eventBrClient.describeRule(ruleRequest);
           System.out.println("The state of the rule is " +
response.stateAsString());

       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DescribeRule in *Amazon SDK for Java 2.x API Reference*.

`DisableRule`

The following code example shows how to use `DisableRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Disable a rule by using its rule name.

```
   public static void changeRuleState(EventBridgeClient eventBrClient, String
eventRuleName, Boolean isEnabled) {
       try {
           if (!isEnabled) {
               System.out.println("Disabling the rule: " + eventRuleName);
               DisableRuleRequest ruleRequest = DisableRuleRequest.builder()
                       .name(eventRuleName)
                       .build();

               eventBrClient.disableRule(ruleRequest);
           } else {
               System.out.println("Enabling the rule: " + eventRuleName);
               EnableRuleRequest ruleRequest = EnableRuleRequest.builder()
                       .name(eventRuleName)
                       .build();
               eventBrClient.enableRule(ruleRequest);
           }

       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DisableRule in *Amazon SDK for Java 2.x API Reference*.

`EnableRule`

The following code example shows how to use `EnableRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Enable a rule by using its rule name.

```
   public static void changeRuleState(EventBridgeClient eventBrClient, String
eventRuleName, Boolean isEnabled) {
       try {
           if (!isEnabled) {
               System.out.println("Disabling the rule: " + eventRuleName);
               DisableRuleRequest ruleRequest = DisableRuleRequest.builder()
                       .name(eventRuleName)
                       .build();

               eventBrClient.disableRule(ruleRequest);
           } else {
               System.out.println("Enabling the rule: " + eventRuleName);
               EnableRuleRequest ruleRequest = EnableRuleRequest.builder()
                       .name(eventRuleName)
                       .build();
               eventBrClient.enableRule(ruleRequest);
           }

       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see EnableRule in *Amazon SDK for Java 2.x API Reference*.

`ListRuleNamesByTarget`

The following code example shows how to use `ListRuleNamesByTarget`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

List all of the rule names by using the target.

```
   public static void listTargetRules(EventBridgeClient eventBrClient, String
topicArn) {
       ListRuleNamesByTargetRequest ruleNamesByTargetRequest =
ListRuleNamesByTargetRequest.builder()
               .targetArn(topicArn)
               .build();

       ListRuleNamesByTargetResponse response =
eventBrClient.listRuleNamesByTarget(ruleNamesByTargetRequest);
       List<String> rules = response.ruleNames();
       for (String rule : rules) {
           System.out.println("The rule name is " + rule);
       }
   }
```

- For API details, see ListRuleNamesByTarget in *Amazon SDK for Java 2.x API Reference*.

`ListRules`

The following code example shows how to use `ListRules`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Enable a rule by using its rule name.

```
    public static void listRules(EventBridgeClient eventBrClient) {
        try {
            ListRulesRequest rulesRequest = ListRulesRequest.builder()
                    .eventBusName("default")
                    .limit(10)
                    .build();

            ListRulesResponse response = eventBrClient.listRules(rulesRequest);
            List<Rule> rules = response.rules();
            for (Rule rule : rules) {
                System.out.println("The rule name is : " + rule.name());
                System.out.println("The rule description is : " +
rule.description());
                System.out.println("The rule state is : " + rule.stateAsString());
            }

        } catch (EventBridgeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListRules in *Amazon SDK for Java 2.x API Reference*.

`ListTargetsByRule`

The following code example shows how to use `ListTargetsByRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

List all of the targets for a rule by using the rule name.

```
    public static void listTargets(EventBridgeClient eventBrClient, String ruleName)
{
```

```
        ListTargetsByRuleRequest ruleRequest = ListTargetsByRuleRequest.builder()
                .rule(ruleName)
                .build();

        ListTargetsByRuleResponse res =
eventBrClient.listTargetsByRule(ruleRequest);
        List<Target> targetsList = res.targets();
        for (Target target: targetsList) {
            System.out.println("Target ARN: "+target.arn());
        }
    }
```

- For API details, see ListTargetsByRule in *Amazon SDK for Java 2.x API Reference*.

`PutEvents`

The following code example shows how to use `PutEvents`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    public static void triggerCustomRule(EventBridgeClient eventBrClient, String
email) {
        String json = "{" +
                "\"UserEmail\": \"" + email + "\"," +
                "\"Message\": \"This event was generated by example code.\"," +
                "\"UtcTime\": \"Now.\"" +
                "}";

        PutEventsRequestEntry entry = PutEventsRequestEntry.builder()
                .source("ExampleSource")
                .detail(json)
                .detailType("ExampleType")
                .build();
```

```
        PutEventsRequest eventsRequest = PutEventsRequest.builder()
                .entries(entry)
                .build();

        eventBrClient.putEvents(eventsRequest);
    }
```

- For API details, see PutEvents in *Amazon SDK for Java 2.x API Reference*.

`PutRule`

The following code example shows how to use `PutRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Create a scheduled rule.

```
   public static void createEBRule(EventBridgeClient eventBrClient, String
ruleName, String cronExpression) {
       try {
           PutRuleRequest ruleRequest = PutRuleRequest.builder()
                   .name(ruleName)
                   .eventBusName("default")
                   .scheduleExpression(cronExpression)
                   .state("ENABLED")
                   .description("A test rule that runs on a schedule created by the
Java API")
                   .build();

           PutRuleResponse ruleResponse = eventBrClient.putRule(ruleRequest);
           System.out.println("The ARN of the new rule is " +
ruleResponse.ruleArn());

       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
```

```
            System.exit(1);
        }
    }
```

Create a rule that triggers when an object is added to an Amazon Simple Storage Service bucket.

```
    // Create a new event rule that triggers when an Amazon S3 object is created in
    // a bucket.
    public static void addEventRule(EventBridgeClient eventBrClient, String roleArn,
String bucketName,
            String eventRuleName) {
        String pattern = "{\n" +
                "  \"source\": [\"aws.s3\"],\n" +
                "  \"detail-type\": [\"Object Created\"],\n" +
                "  \"detail\": {\n" +
                "    \"bucket\": {\n" +
                "      \"name\": [\"" + bucketName + "\"]\n" +
                "    }\n" +
                "  }\n" +
                "}";

        try {
            PutRuleRequest ruleRequest = PutRuleRequest.builder()
                    .description("Created by using the AWS SDK for Java v2")
                    .name(eventRuleName)
                    .eventPattern(pattern)
                    .roleArn(roleArn)
                    .build();

            PutRuleResponse ruleResponse = eventBrClient.putRule(ruleRequest);
            System.out.println("The ARN of the new rule is " +
ruleResponse.ruleArn());

        } catch (EventBridgeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see PutRule in *Amazon SDK for Java 2.x API Reference*.

`PutTargets`

The following code example shows how to use `PutTargets`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Add an Amazon SNS topic as a target for a rule.

```
   // Add a rule which triggers an SNS target when a file is uploaded to an S3
   // bucket.
   public static void addSnsEventRule(EventBridgeClient eventBrClient, String
ruleName, String topicArn,
           String topicName, String eventRuleName, String bucketName) {
       String targetID = java.util.UUID.randomUUID().toString();
       Target myTarget = Target.builder()
               .id(targetID)
               .arn(topicArn)
               .build();

       List<Target> targets = new ArrayList<>();
       targets.add(myTarget);
       PutTargetsRequest request = PutTargetsRequest.builder()
               .eventBusName(null)
               .targets(targets)
               .rule(ruleName)
               .build();

       eventBrClient.putTargets(request);
       System.out.println("Added event rule " + eventRuleName + " with Amazon SNS
target " + topicName + " for bucket "
               + bucketName + ".");
   }
```

Add an input transformer to a target for a rule.

```
   public static void updateCustomRuleTargetWithTransform(EventBridgeClient
eventBrClient, String topicArn,
           String ruleName) {
       String targetId = java.util.UUID.randomUUID().toString();
       InputTransformer inputTransformer = InputTransformer.builder()
               .inputTemplate("\"Notification: sample event was received.\"")
               .build();

       Target target = Target.builder()
               .id(targetId)
               .arn(topicArn)
               .inputTransformer(inputTransformer)
               .build();

       try {
           PutTargetsRequest targetsRequest = PutTargetsRequest.builder()
                   .rule(ruleName)
                   .targets(target)
                   .eventBusName(null)
                   .build();

           eventBrClient.putTargets(targetsRequest);
       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see PutTargets in *Amazon SDK for Java 2.x API Reference*.

`RemoveTargets`

The following code example shows how to use `RemoveTargets`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Remove all of the targets for a rule by using the rule name.

```
   public static void deleteTargetsFromRule(EventBridgeClient eventBrClient, String
eventRuleName) {
       // First, get all targets that will be deleted.
       ListTargetsByRuleRequest request = ListTargetsByRuleRequest.builder()
               .rule(eventRuleName)
               .build();

       ListTargetsByRuleResponse response =
eventBrClient.listTargetsByRule(request);
       List<Target> allTargets = response.targets();

       // Get all targets and delete them.
       for (Target myTarget : allTargets) {
           RemoveTargetsRequest removeTargetsRequest =
RemoveTargetsRequest.builder()
                   .rule(eventRuleName)
                   .ids(myTarget.id())
                   .build();

           eventBrClient.removeTargets(removeTargetsRequest);
           System.out.println("Successfully removed the target");
       }
   }
```

- For API details, see RemoveTargets in *Amazon SDK for Java 2.x API Reference*.

Scenarios

Send event notifications to EventBridge

The following code example shows how to enable a bucket to send S3 event notifications to EventBridge and route notifications to an Amazon SNS topic and Amazon SQS queue.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   /** This method configures a bucket to send events to AWS EventBridge and
creates a rule
    * to route the S3 object created events to a topic and a queue.
    *
    * @param bucketName Name of existing bucket
    * @param topicArn ARN of existing topic to receive S3 event notifications
    * @param queueArn ARN of existing queue to receive S3 event notifications
    *
    *  An AWS CloudFormation stack sets up the bucket, queue, topic before the
method runs.
    */
   public static String setBucketNotificationToEventBridge(String bucketName,
String topicArn, String queueArn) {
       try {
           // Enable bucket to emit S3 Event notifications to EventBridge.
           s3Client.putBucketNotificationConfiguration(b -> b
                   .bucket(bucketName)
                   .notificationConfiguration(b1 -> b1
                           .eventBridgeConfiguration(
                                   SdkBuilder::build)
                   ).build()).join();

           // Create an EventBridge rule to route Object Created notifications.
           PutRuleRequest putRuleRequest = PutRuleRequest.builder()
                   .name(RULE_NAME)
                   .eventPattern("""
                           {
                             "source": ["aws.s3"],
                             "detail-type": ["Object Created"],
                             "detail": {
                               "bucket": {
                                 "name": ["%s"]
                               }
                             }
```

```
                            }
                            """.formatted(bucketName))
                    .build();

            // Add the rule to the default event bus.
            PutRuleResponse putRuleResponse =
eventBridgeClient.putRule(putRuleRequest)
                    .whenComplete((r, t) -> {
                        if (t != null) {
                            logger.error("Error creating event bus rule: " +
t.getMessage(), t);
                            throw new RuntimeException(t.getCause().getMessage(),
t);
                        }
                        logger.info("Event bus rule creation request sent
successfully. ARN is: {}", r.ruleArn());
                    }).join();

            // Add the existing SNS topic and SQS queue as targets to the rule.
            eventBridgeClient.putTargets(b -> b
                    .eventBusName("default")
                    .rule(RULE_NAME)
                    .targets(List.of (
                            Target.builder()
                                    .arn(queueArn)
                                    .id("Queue")
                                    .build(),
                            Target.builder()
                                    .arn(topicArn)
                                    .id("Topic")
                                    .build())
                            )
                    ).join();
            return putRuleResponse.ruleArn();
        } catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
        return null;
    }
```

Use scheduled events to invoke a Lambda function

The following code example shows how to create an Amazon Lambda function invoked by an Amazon EventBridge scheduled event.

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an Amazon Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different Amazon services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch Logs
- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

EventBridge Scheduler examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with EventBridge Scheduler.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello EventBridge Scheduler

The following code examples show how to get started using EventBridge Scheduler.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
import software.amazon.awssdk.services.scheduler.SchedulerAsyncClient;

Scenarios

Scheduled Events

The following code example shows how to:

- Deploy a Amazon CloudFormation stack with required resources.
- Create a EventBridge Scheduler schedule group.
- Create a one-time EventBridge Scheduler schedule with a flexible time window.
- Create a recurring EventBridge Scheduler schedule with a specified rate.
- Delete EventBridge Scheduler the schedule and schedule group.
- Clean up resources and delete the stack.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Run the scenario.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

import javax.mail.internet.AddressException;
import javax.mail.internet.InternetAddress;
import java.time.LocalDateTime;
import java.time.format.DateTimeFormatter;
import java.util.Map;
import java.util.Scanner;
import java.util.concurrent.CompletableFuture;
import java.util.concurrent.CompletionException;

/**
 * This Java code example performs the following tasks for the Amazon EventBridge
 Scheduler workflow:
 * <p>
 * 1. Prepare the Application:
```

```
 * - Prompt the user for an email address to use for the subscription for the SNS
 topic subscription.
 * - Deploy the Cloud Formation template in resources/cfn_template.yaml for resource
 creation.
 * - Store the outputs of the stack into variables for use in the workflow.
 * - Create a schedule group for all workflow schedules.
 * <p>
 * 2. Create one-time Schedule:
 * - Create a one-time schedule to send an initial event.
 * - Use a Flexible Time Window and set the schedule to delete after completion.
 * - Wait for the user to receive the event email from SNS.
 * <p>
 * 3. Create a time-based schedule:
 * - Prompt the user for how many X times per Y hours a recurring event should be
 scheduled.
 * - Create the scheduled event for X times per hour for Y hours.
 * - Wait for the user to receive the event email from SNS.
 * - Delete the schedule when the user is finished.
 * <p>
 * 4. Clean up:
 * - Prompt the user for y/n answer if they want to destroy the stack and clean up
 all resources.
 * - Delete the schedule group.
 * - Destroy the Cloud Formation stack and wait until the stack has been removed.

       logger.info("""
           Amazon EventBridge Scheduler is a fully managed service that helps you
schedule and execute
           a wide range of tasks and events in the cloud. It's designed to simplify
the process of
           scheduling and managing recurring or one-time events, making it easier
for developers and
           businesses to automate various workflows and processes.

           One of the key features of Amazon EventBridge Scheduler is its ability
to schedule events
           based on a variety of triggers, including time-based schedules, custom
event patterns, or
           even integration with other AWS services. For example, you can use
EventBridge Scheduler
           to schedule a report generation task to run every weekday at 9 AM, or to
trigger a
           Lambda function when a specific Amazon S3 object is created.

           This flexibility allows you to build complex and dynamic event-driven
architectures
           that adapt to your business needs.

           Lets get started...

Forecast examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Forecast.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Amazon Glue examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Glue.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Glue

The following code examples show how to get started using Amazon Glue.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
package com.example.glue;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.glue.GlueClient;
import software.amazon.awssdk.services.glue.model.ListJobsRequest;
import software.amazon.awssdk.services.glue.model.ListJobsResponse;
import java.util.List;

public class HelloGlue {
    public static void main(String[] args) {
        GlueClient glueClient = GlueClient.builder()
                .region(Region.US_EAST_1)
                .build();

        listJobs(glueClient);
    }

    public static void listJobs(GlueClient glueClient) {
        ListJobsRequest request = ListJobsRequest.builder()
                .maxResults(10)
                .build();
        ListJobsResponse response = glueClient.listJobs(request);
        List<String> jobList = response.jobNames();
        jobList.forEach(job -> {
            System.out.println("Job Name: " + job);
        });
    }
}
```

- For API details, see ListJobs in *Amazon SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create a crawler that crawls a public Amazon S3 bucket and generates a database of CSV-formatted metadata.
- List information about databases and tables in your Amazon Glue Data Catalog.
- Create a job to extract CSV data from the S3 bucket, transform the data, and load JSON-formatted output into another S3 bucket.
- List information about job runs, view transformed data, and clean up resources.

For more information, see Tutorial: Getting started with Amazon Glue Studio.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * <p>
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * To set up the resources, see this documentation topic:
 *
 * https://docs.aws.amazon.com/glue/latest/ug/tutorial-add-crawler.html
 *
```

```
 * This example performs the following tasks:
 *
 * 1. Create a database.
 * 2. Create a crawler.
 * 3. Get a crawler.
 * 4. Start a crawler.
 * 5. Get a database.
 * 6. Get tables.
 * 7. Create a job.
 * 8. Start a job run.
 * 9. List all jobs.
 * 10. Get job runs.
 * 11. Delete a job.
 * 12. Delete a database.
 * 13. Delete a crawler.
 */

public class GlueScenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

        System.out.println(DASHES);
        System.out.println("Welcome to the AWS Glue scenario.");
        System.out.println("""
            AWS Glue is a fully managed extract, transform, and load (ETL) service
provided by Amazon
            Web Services (AWS). It is designed to simplify the process of building,
running, and maintaining
            ETL pipelines, which are essential for data integration and data
warehousing tasks.

            One of the key features of AWS Glue is its ability to automatically
discover and catalog data
            stored in various sources, such as Amazon S3, Amazon RDS, Amazon
Redshift, and other databases.
            This cataloging process creates a central metadata repository, known as
the AWS Glue Data Catalog,
            which provides a unified view of an organization's data assets. This
metadata can then be used to
            create ETL jobs, which can be scheduled and run on-demand or on a
regular basis.

            Lets get started.

            """);

HealthImaging examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with HealthImaging.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

`CreateDatastore`

The following code example shows how to use `CreateDatastore`.

SDK for Java 2.x

```
   public static String createMedicalImageDatastore(MedicalImagingClient
medicalImagingClient,
            String datastoreName) {
        try {
```

```
            CreateDatastoreRequest datastoreRequest =
CreateDatastoreRequest.builder()
                    .datastoreName(datastoreName)
                    .build();
            CreateDatastoreResponse response =
medicalImagingClient.createDatastore(datastoreRequest);
            return response.datastoreId();
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }

        return "";
    }
```

- For API details, see CreateDatastore in *Amazon SDK for Java 2.x API Reference*.

`GetImageSetMetadata`

The following code example shows how to use `GetImageSetMetadata`.

SDK for Java 2.x

```
   public static void getMedicalImageSetMetadata(MedicalImagingClient
medicalImagingClient,
           String destinationPath,
           String datastoreId,
           String imagesetId,
           String versionId) {

       try {
           GetImageSetMetadataRequest.Builder getImageSetMetadataRequestBuilder =
GetImageSetMetadataRequest.builder()
                   .datastoreId(datastoreId)
                   .imageSetId(imagesetId);

           if (versionId != null) {
               getImageSetMetadataRequestBuilder =
getImageSetMetadataRequestBuilder.versionId(versionId);
           }

medicalImagingClient.getImageSetMetadata(getImageSetMetadataRequestBuilder.build(),
                   FileSystems.getDefault().getPath(destinationPath));

           System.out.println("Metadata downloaded to " + destinationPath);
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see GetImageSetMetadata in *Amazon SDK for Java 2.x API Reference*.

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

`ListDICOMImportJobs`

The following code example shows how to use `ListDICOMImportJobs`.

SDK for Java 2.x

```
   public static List<DICOMImportJobSummary>
listDicomImportJobs(MedicalImagingClient medicalImagingClient,
           String datastoreId) {

       try {
           ListDicomImportJobsRequest listDicomImportJobsRequest =
ListDicomImportJobsRequest.builder()
                   .datastoreId(datastoreId)
                   .build();
           ListDicomImportJobsResponse response =
medicalImagingClient.listDICOMImportJobs(listDicomImportJobsRequest);
           return response.jobSummaries();
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }

       return new ArrayList<>();
   }
```

- For API details, see ListDICOMImportJobs in *Amazon SDK for Java 2.x API Reference*.

> **Note**

>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

`SearchImageSets`

The following code example shows how to use `SearchImageSets`.

SDK for Java 2.x

The utility function for searching image sets.

```
    public static List<ImageSetsMetadataSummary> searchMedicalImagingImageSets(
            MedicalImagingClient medicalImagingClient,
            String datastoreId, SearchCriteria searchCriteria) {
        try {
            SearchImageSetsRequest datastoreRequest =
SearchImageSetsRequest.builder()
                    .datastoreId(datastoreId)
                    .searchCriteria(searchCriteria)
                    .build();
            SearchImageSetsIterable responses = medicalImagingClient
                    .searchImageSetsPaginator(datastoreRequest);
            List<ImageSetsMetadataSummary> imageSetsMetadataSummaries = new
ArrayList<>();
```

```
            responses.stream().forEach(response -> imageSetsMetadataSummaries
                    .addAll(response.imageSetsMetadataSummaries()));

            return imageSetsMetadataSummaries;
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }

        return null;
    }
```

Use case #1: EQUAL operator.

```
        List<SearchFilter> searchFilters =
Collections.singletonList(SearchFilter.builder()
                .operator(Operator.EQUAL)
                .values(SearchByAttributeValue.builder()
                        .dicomPatientId(patientId)
                        .build())
                .build());

        SearchCriteria searchCriteria = SearchCriteria.builder()
                .filters(searchFilters)
                .build();

        List<ImageSetsMetadataSummary> imageSetsMetadataSummaries =
searchMedicalImagingImageSets(
                medicalImagingClient,
                datastoreId, searchCriteria);
        if (imageSetsMetadataSummaries != null) {
            System.out.println("The image sets for patient " + patientId + " are:\n"
                    + imageSetsMetadataSummaries);
            System.out.println();
        }
```

Use case #2: BETWEEN operator using DICOMStudyDate and DICOMStudyTime.

```
        DateTimeFormatter formatter = DateTimeFormatter.ofPattern("yyyyMMdd");
        searchFilters = Collections.singletonList(SearchFilter.builder()
```

```
                .operator(Operator.BETWEEN)
                .values(SearchByAttributeValue.builder()

.dicomStudyDateAndTime(DICOMStudyDateAndTime.builder()
                                        .dicomStudyDate("19990101")
                                        .dicomStudyTime("000000.000")
                                        .build())
                                .build(),
                        SearchByAttributeValue.builder()

.dicomStudyDateAndTime(DICOMStudyDateAndTime.builder()
                                        .dicomStudyDate((LocalDate.now()
                                                .format(formatter)))
                                        .dicomStudyTime("000000.000")
                                        .build())
                                .build())
                .build());

        searchCriteria = SearchCriteria.builder()
                .filters(searchFilters)
                .build();

        imageSetsMetadataSummaries =
searchMedicalImagingImageSets(medicalImagingClient,
                datastoreId, searchCriteria);
        if (imageSetsMetadataSummaries != null) {
            System.out.println(
                    "The image sets searched with BETWEEN operator using
DICOMStudyDate and DICOMStudyTime are:\n"
                            +
                            imageSetsMetadataSummaries);
            System.out.println();
        }
```

Use case #3: BETWEEN operator using createdAt. Time studies were previously persisted.

```
        searchFilters = Collections.singletonList(SearchFilter.builder()
                .operator(Operator.BETWEEN)
                .values(SearchByAttributeValue.builder()
                                .createdAt(Instant.parse("1985-04-12T23:20:50.52Z"))
                                .build(),
                        SearchByAttributeValue.builder()
```

```
                                .createdAt(Instant.now())
                                .build())
                .build());

        searchCriteria = SearchCriteria.builder()
                .filters(searchFilters)
                .build();
        imageSetsMetadataSummaries =
searchMedicalImagingImageSets(medicalImagingClient,
                datastoreId, searchCriteria);
        if (imageSetsMetadataSummaries != null) {
            System.out.println("The image sets searched with BETWEEN operator using
createdAt are:\n "
                    + imageSetsMetadataSummaries);
            System.out.println();
        }
```

Use case #4: EQUAL operator on DICOMSeriesInstanceUID and BETWEEN on updatedAt and sort response in ASC order on updatedAt field.

```
        Instant startDate = Instant.parse("1985-04-12T23:20:50.52Z");
        Instant endDate = Instant.now();

        searchFilters = Arrays.asList(
                SearchFilter.builder()
                        .operator(Operator.EQUAL)
                        .values(SearchByAttributeValue.builder()
                                .dicomSeriesInstanceUID(seriesInstanceUID)
                                .build())
                        .build(),
                SearchFilter.builder()
                        .operator(Operator.BETWEEN)
                        .values(

SearchByAttributeValue.builder().updatedAt(startDate).build(),

SearchByAttributeValue.builder().updatedAt(endDate).build()
                        ).build());

        Sort sort =
Sort.builder().sortOrder(SortOrder.ASC).sortField(SortField.UPDATED_AT).build();
```

```
        searchCriteria = SearchCriteria.builder()
                .filters(searchFilters)
                .sort(sort)
                .build();

        imageSetsMetadataSummaries =
searchMedicalImagingImageSets(medicalImagingClient,
                datastoreId, searchCriteria);
        if (imageSetsMetadataSummaries != null) {
            System.out.println("The image sets searched with EQUAL operator on
DICOMSeriesInstanceUID and BETWEEN on updatedAt and sort response\n" +
                    "in ASC order on updatedAt field are:\n "
                    + imageSetsMetadataSummaries);
            System.out.println();
        }
```

`StartDICOMImportJob`

The following code example shows how to use `StartDICOMImportJob`.

SDK for Java 2.x

```
   public static String startDicomImportJob(MedicalImagingClient
medicalImagingClient,
            String jobName,
            String datastoreId,
            String dataAccessRoleArn,
            String inputS3Uri,
            String outputS3Uri) {

        try {
            StartDicomImportJobRequest startDicomImportJobRequest =
StartDicomImportJobRequest.builder()
```

```
                    .jobName(jobName)
                    .datastoreId(datastoreId)
                    .dataAccessRoleArn(dataAccessRoleArn)
                    .inputS3Uri(inputS3Uri)
                    .outputS3Uri(outputS3Uri)
                    .build();
            StartDicomImportJobResponse response =
medicalImagingClient.startDICOMImportJob(startDicomImportJobRequest);
            return response.jobId();
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }

        return "";
    }
```

- For API details, see StartDICOMImportJob in *Amazon SDK for Java 2.x API Reference*.

Scenarios

Tagging a data store

The following code example shows how to tag a HealthImaging data store.

SDK for Java 2.x

To tag a data store.

```
                final String datastoreArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012";

                TagResource.tagMedicalImagingResource(medicalImagingClient,
 datastoreArn,
                                ImmutableMap.of("Deployment", "Development"));
```

The utility function for tagging a resource.

```
   public static void tagMedicalImagingResource(MedicalImagingClient
 medicalImagingClient,
            String resourceArn,
            Map<String, String> tags) {
        try {
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                    .resourceArn(resourceArn)
                    .tags(tags)
                    .build();

            medicalImagingClient.tagResource(tagResourceRequest);

            System.out.println("Tags have been added to the resource.");
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

To list tags for a data store.

```
                final String datastoreArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012";

                ListTagsForResourceResponse result =
 ListTagsForResource.listMedicalImagingResourceTags(
                                medicalImagingClient,
                                datastoreArn);
                if (result != null) {
                        System.out.println("Tags for resource: " + result.tags());
                }
```

The utility function for listing a resource's tags.

```
   public static ListTagsForResourceResponse
listMedicalImagingResourceTags(MedicalImagingClient medicalImagingClient,
           String resourceArn) {
       try {
           ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
                   .resourceArn(resourceArn)
                   .build();

           return
medicalImagingClient.listTagsForResource(listTagsForResourceRequest);
       } catch (MedicalImagingException e) {

Tagging an image set

The following code example shows how to tag a HealthImaging image set.

SDK for Java 2.x

To tag an image set.

```
                final String imageSetArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012/
imageset/12345678901234567890123456789012";

                TagResource.tagMedicalImagingResource(medicalImagingClient,
 imageSetArn,
```

```
                                ImmutableMap.of("Deployment", "Development"));
```

The utility function for tagging a resource.

```
   public static void tagMedicalImagingResource(MedicalImagingClient
medicalImagingClient,
           String resourceArn,
           Map<String, String> tags) {
       try {
           TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                   .resourceArn(resourceArn)
                   .tags(tags)
                   .build();

           medicalImagingClient.tagResource(tagResourceRequest);

           System.out.println("Tags have been added to the resource.");
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

To list tags for an image set.

```
               final String imageSetArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012/
imageset/12345678901234567890123456789012";

               ListTagsForResourceResponse result =
ListTagsForResource.listMedicalImagingResourceTags(
                               medicalImagingClient,
                               imageSetArn);
               if (result != null) {
                       System.out.println("Tags for resource: " + result.tags());
               }
```

The utility function for listing a resource's tags.

```
   public static ListTagsForResourceResponse
listMedicalImagingResourceTags(MedicalImagingClient medicalImagingClient,
           String resourceArn) {
       try {
           ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
                   .resourceArn(resourceArn)
                   .build();

           return
medicalImagingClient.listTagsForResource(listTagsForResourceRequest);
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }

       return null;
   }
```

To untag an image set.

```
               final String imageSetArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012/
imageset/12345678901234567890123456789012";

               UntagResource.untagMedicalImagingResource(medicalImagingClient,
 imageSetArn,
                               Collections.singletonList("Deployment"));
```

The utility function for untagging a resource.

```
   public static void untagMedicalImagingResource(MedicalImagingClient
medicalImagingClient,
           String resourceArn,
           Collection<String> tagKeys) {
       try {
           UntagResourceRequest untagResourceRequest =
UntagResourceRequest.builder()
                   .resourceArn(resourceArn)
                   .tagKeys(tagKeys)
```

```
                .build();

        medicalImagingClient.untagResource(untagResourceRequest);

        System.out.println("Tags have been removed from the resource.");
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

IAM examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with IAM.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello IAM

The following code examples show how to get started using IAM.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.ListPoliciesResponse;
import software.amazon.awssdk.services.iam.model.Policy;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloIAM {
    public static void main(String[] args) {
        Region region = Region.AWS_GLOBAL;
        IamClient iam = IamClient.builder()
                .region(region)
                .build();

        listPolicies(iam);
    }

    public static void listPolicies(IamClient iam) {
        ListPoliciesResponse response = iam.listPolicies();
        List<Policy> polList = response.policies();
        polList.forEach(policy -> {
            System.out.println("Policy Name: " + policy.policyName());
        });
    }
```

```
}
```

- For API details, see ListPolicies in *Amazon SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions
- Scenarios

Basics

Learn the basics

The following code example shows how to create a user and assume a role.

> **Warning**
>
> To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as Amazon IAM Identity Center.

- Create a user with no permissions.
- Create a role that grants permission to list Amazon S3 buckets for the account.
- Add a policy to let the user assume the role.
- Assume the role and list S3 buckets using temporary credentials, then clean up resources.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Create functions that wrap IAM user actions.

```
/*
  To run this Java V2 code example, set up your development environment, including
 your credentials.

  For information, see this documentation topic:

  https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

  This example performs these operations:

  1. Creates a user that has no permissions.
  2. Creates a role and policy that grants Amazon S3 permissions.
  3. Creates a role.
  4. Grants the user permissions.
  5. Gets temporary credentials by assuming the role.  Creates an Amazon S3 Service
 client object with the temporary credentials.
  6. Deletes the resources.
 */

public class IAMScenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating Amazon Systems Manager parameters.

Work with the IAM Policy Builder API

The following code example shows how to:

- Create IAM policies by using the object-oriented API.
- Use the IAM Policy Builder API with the IAM service.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

The examples use the following imports.

```

Create a time-based policy.

```
        public String timeBasedPolicyExample() {
                IamPolicy policy = IamPolicy.builder()
                                .addStatement(b -> b
                                                .effect(IamEffect.ALLOW)
                                                .addAction("dynamodb:GetItem")
                                                .addResource(IamResource.ALL)
                                                .addCondition(b1 -> b1
```

```
.operator(IamConditionOperator.DATE_GREATER_THAN)

.key("aws:CurrentTime")

.value("2020-04-01T00:00:00Z"))
                                                .addCondition(b1 -> b1

.operator(IamConditionOperator.DATE_LESS_THAN)

.key("aws:CurrentTime")

.value("2020-06-30T23:59:59Z")))
                                .build();

                // Use an IamPolicyWriter to write out the JSON string to a more
readable
                // format.
                return policy.toJson(IamPolicyWriter.builder()
                                .prettyPrint(true)
                                .build());
        }
```

Create a policy with multiple conditions.

```
        public String multipleConditionsExample() {
                IamPolicy policy = IamPolicy.builder()
                                .addStatement(b -> b
                                                .effect(IamEffect.ALLOW)
                                                .addAction("dynamodb:GetItem")
                                                .addAction("dynamodb:BatchGetItem")
                                                .addAction("dynamodb:Query")
                                                .addAction("dynamodb:PutItem")
                                                .addAction("dynamodb:UpdateItem")
                                                .addAction("dynamodb:DeleteItem")

.addAction("dynamodb:BatchWriteItem")

.addResource("arn:aws:dynamodb:*:*:table/table-name")

.addConditions(IamConditionOperator.STRING_EQUALS
```

```
 .addPrefix("ForAllValues:"),

 "dynamodb:Attributes",
                                                                    List.of("column-
name1", "column-name2", "column-name3"))
                                                .addCondition(b1 -> b1

 .operator(IamConditionOperator.STRING_EQUALS

 .addSuffix("IfExists"))

 .key("dynamodb:Select")

 .value("SPECIFIC_ATTRIBUTES")))
                                .build();

                return policy.toJson(IamPolicyWriter.builder()
                                .prettyPrint(true).build());
        }
```

Use principals in a policy.

```
        public String specifyPrincipalsExample() {
                IamPolicy policy = IamPolicy.builder()
                                .addStatement(b -> b
                                                .effect(IamEffect.DENY)
                                                .addAction("s3:*")
                                                .addPrincipal(IamPrincipal.ALL)
                                                .addResource("arn:aws:s3:::amzn-s3-
demo-bucket/*")
                                                .addResource("arn:aws:s3:::amzn-s3-
demo-bucket")
                                                .addCondition(b1 -> b1

 .operator(IamConditionOperator.ARN_NOT_EQUALS)

 .key("aws:PrincipalArn")

 .value("arn:aws:iam::444455556666:user/user-name")))
                                .build();
                return policy.toJson(IamPolicyWriter.builder()
```

```
                                .prettyPrint(true).build());
        }
```

Allow cross-account access.

```

Amazon IoT examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon IoT.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon IoT

The following code examples show how to get started using Amazon IoT.

SDK for Java 2.x

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iot.IotClient;
import software.amazon.awssdk.services.iot.model.ListThingsRequest;
import software.amazon.awssdk.services.iot.model.ListThingsResponse;
import software.amazon.awssdk.services.iot.model.ThingAttribute;
import software.amazon.awssdk.services.iot.paginators.ListThingsIterable;

import java.util.List;

public class HelloIoT {
    public static void main(String[] args) {
        System.out.println("Hello AWS IoT. Here is a listing of your AWS IoT
 Things:");
        IotClient iotClient = IotClient.builder()
            .region(Region.US_EAST_1)
            .build();

        listAllThings(iotClient);
    }

    public static void listAllThings(IotClient iotClient) {
        iotClient.listThingsPaginator(ListThingsRequest.builder()
                .maxResults(10)
                .build())
            .stream()
            .flatMap(response -> response.things().stream())
            .forEach(attribute -> {
                System.out.println("Thing name: " + attribute.thingName());
                System.out.println("Thing ARN: " + attribute.thingArn());
            });
    }
}
```

- For API details, see listThings in *Amazon SDK for Java 2.x API Reference*.

- Actions

Basics

Learn the basics

The following code example shows how to:

- Create an Amazon IoT Thing.
- Generate a device certificate.
- Update an Amazon IoT Thing with Attributes.
- Return a unique endpoint.
- List your Amazon IoT certificates.
- Create an Amazon IoT shadow.
- Write out state information.
- Creates a rule.
- List your rules.
- Search things using the Thing name.
- Delete an Amazon IoT Thing.

Run an interactive scenario demonstrating Amazon IoT features.

```
import java.util.Scanner;
```

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java example performs these tasks:
 *
 * 1. Creates an AWS IoT Thing.
 * 2. Generate and attach a device certificate.
 * 3. Update an AWS IoT Thing with Attributes.
 * 4. Get an AWS IoT Endpoint.
 * 5. List your certificates.
 * 6. Updates the shadow for the specified thing..
 * 7. Write out the state information, in JSON format
 * 8. Creates a rule
 * 9. List rules
 * 10. Search things
 * 11. Detach amd delete the certificate.
 * 12. Delete Thing.
 */

Amazon IoT FleetWise examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon IoT FleetWise.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon IoT FleetWise

The following code examples show how to get started using Amazon IoT FleetWise.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
public class HelloFleetwise {

        public static void main(String[] args) {
            ListSignalCatalogs();
        }

        public static void  ListSignalCatalogs() {
            try (IoTFleetWiseClient fleetWiseClient = IoTFleetWiseClient.builder()
                    .region(Region.US_EAST_1)
                    .credentialsProvider(DefaultCredentialsProvider.create())
                    .build()) {

                ListSignalCatalogsRequest request =
 ListSignalCatalogsRequest.builder()
                        .maxResults(10) // Optional: limit per page
                        .build();

                ListSignalCatalogsIterable paginator =
 fleetWiseClient.listSignalCatalogsPaginator(request);
                boolean found = false;
```

```
                for (ListSignalCatalogsResponse response : paginator) {
                    for (SignalCatalogSummary summary : response.summaries()) {
                        found = true;
                        System.out.println("Catalog Name: " + summary.name());
                        System.out.println("ARN: " + summary.arn());
                        System.out.println("Created: " + summary.creationTime());
                        System.out.println("Last Modified: " +
summary.lastModificationTime());
                        System.out.println("---------------");
                    }
                }

                if (!found) {
                    System.out.println("No AWS Fleetwise Signal Catalogs were
found.");
                }

            } catch (IoTFleetWiseException e) {
                System.err.println("Error listing signal catalogs: " +
e.awsErrorDetails().errorMessage());
                throw new RuntimeException(e);
            }
        }
    }
```

- For API details, see listSignalCatalogsPaginator in *Amazon SDK for Java 2.x API Reference*.

Basics

Learn the basics

The following code example shows how to:

- Create a collection of standardized signals.
- Create a fleet that represents a group of vehicles.

- Create a model manifest.
- Create a decoder manifest.
- Check the status of the model manifest.
- Check the status of the decoder.
- Create an IoT Thing.
- Create a vehicle.
- Display vehicle details.
- Delete the Amazon IoT FleetWise Assets.

SDK for Java 2.x

        String fleetId = args[2];
        String vecName = args[3];
        String decName = args[4];

        logger.info(
                """
                 AWS IoT FleetWise is a managed service that simplifies the
                 process of collecting, organizing, and transmitting vehicle
                 data to the cloud in near real-time. Designed for automakers
                 and fleet operators, it allows you to define vehicle models,
                 specify the exact data you want to collect (such as engine
                 temperature, speed, or battery status), and send this data to
                 AWS for analysis. By using intelligent data collection
                 techniques, IoT FleetWise reduces the volume of data
                 transmitted by filtering and transforming it at the edge,
                 helping to minimize bandwidth usage and costs.

                At its core, AWS IoT FleetWise helps organizations build
                scalable systems for vehicle data management and analytics,
                supporting a wide variety of vehicles and sensor configurations.
                You can define signal catalogs and decoder manifests that describe
                how raw CAN bus signals are translated into readable data, making
                the platform highly flexible and extensible. This allows
                manufacturers to optimize vehicle performance, improve safety,
                and reduce maintenance costs by gaining real-time visibility
                into fleet operations.
                """);

    }
```

- For API details, see updateModelManifest in *Amazon SDK for Java 2.x API Reference*.

Amazon IoT SiteWise examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon IoT SiteWise.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon IoT SiteWise

The following code examples show how to get started using Amazon IoT SiteWise.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
public class HelloSitewise {
    private static final Logger logger =
 LoggerFactory.getLogger(HelloSitewise.class);
    public static void main(String[] args) {
         fetchAssetModels();
    }

    /**
     * Fetches asset models using the provided {@link IoTSiteWiseAsyncClient}.
     */
    public static void fetchAssetModels() {
        IoTSiteWiseAsyncClient siteWiseAsyncClient =
 IoTSiteWiseAsyncClient.create();
        ListAssetModelsRequest assetModelsRequest = ListAssetModelsRequest.builder()
```

```
            .assetModelTypes(AssetModelType.ASSET_MODEL)
            .build();

        // Asynchronous paginator - process paginated results.
        ListAssetModelsPublisher listModelsPaginator =
 siteWiseAsyncClient.listAssetModelsPaginator(assetModelsRequest);
        CompletableFuture<Void> future = listModelsPaginator.subscribe(response -> {
            response.assetModelSummaries().forEach(assetSummary ->
                logger.info("Asset Model Name: {} ", assetSummary.name())
            );
        });

        // Wait for the asynchronous operation to complete
        future.join();
    }
}
```

- For API details, see ListAssetModels in *Amazon SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create an Amazon IoT SiteWise Asset Model.
- Create an Amazon IoT SiteWise Asset.
- Retrieve the property ID values.
- Send data to an Amazon IoT SiteWise Asset.
- Retrieve the value of the Amazon IoT SiteWise Asset property.
- Create an Amazon IoT SiteWise Portal.
- Create an Amazon IoT SiteWise Gateway.
- Describe the Amazon IoT SiteWise Gateway.

- Delete the Amazon IoT SiteWise Assets.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Run an interactive scenario demonstrating Amazon IoT SiteWise features.

```
public class SitewiseScenario {

    public static final String DASHES = new String(new char[80]).replace("\0", "-");

    private static final Logger logger =
 LoggerFactory.getLogger(SitewiseScenario.class);
    static Scanner scanner = new Scanner(System.in);

    private static final String ROLES_STACK = "RoleSitewise";

    static SitewiseActions sitewiseActions = new SitewiseActions();

    public static void main(String[] args) throws Throwable {
        Scanner scanner = new Scanner(System.in);
        String contactEmail = "user@mydomain.com"; // Change email address.
        String assetModelName = "MyAssetModel1";
        String assetName = "MyAsset1" ;
        String portalName = "MyPortal1" ;
        String gatewayName = "MyGateway1" ;
        String myThing =  "MyThing1" ;

        logger.info("""
            AWS IoT SiteWise is a fully managed software-as-a-service (SaaS) that
            makes it easy to collect, store, organize, and monitor data from
 industrial equipment and processes.
            It is designed to help industrial and manufacturing organizations
 collect data from their equipment and
            processes, and use that data to make informed decisions about their
 operations.
```

```
            One of the key features of AWS IoT SiteWise is its ability to connect to
a wide range of industrial
            equipment and systems, including programmable logic controllers (PLCs),
sensors, and other
            industrial devices. It can collect data from these devices and organize
it into a unified data model,
            making it easier to analyze and gain insights from the data. AWS IoT
SiteWise also provides tools for
            visualizing the data, setting up alarms and alerts, and generating
reports.

            Another key feature of AWS IoT SiteWise is its ability to scale to
handle large volumes of data.
            It can collect and store data from thousands of devices and process
millions of data points per second,
            making it suitable for large-scale industrial operations. Additionally,
AWS IoT SiteWise is designed
            to be secure and compliant, with features like role-based access
controls, data encryption,
            and integration with other AWS services for additional security and
compliance features.

            Let's get started...
            """);

```

```
            });
    }
```

- For API details, see DescribePortal in *Amazon SDK for Java 2.x API Reference*.

`GetAssetPropertyValue`

The following code example shows how to use `GetAssetPropertyValue`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /**
     * Fetches the value of an asset property.
     *
     * @param propId  the ID of the asset property to fetch.
     * @param assetId the ID of the asset to fetch the property value for.
     * @return a {@link CompletableFuture} that represents a {@link Double} result.
The calling code can attach
     *         callbacks, then handle the result or exception by calling {@link
CompletableFuture#join()} or
     *         {@link CompletableFuture#get()}.
     *         <p>
     *         If any completion stage in this method throws an exception, the
method logs the exception cause and keeps
     *         it available to the calling code as a {@link CompletionException}. By
calling
     *         {@link CompletionException#getCause()}, the calling code can access
the original exception.
     */
    public CompletableFuture<Double> getAssetPropValueAsync(String propId, String
assetId) {
        GetAssetPropertyValueRequest assetPropertyValueRequest =
GetAssetPropertyValueRequest.builder()
                .propertyId(propId)
                .assetId(assetId)
```

```
                .build();

        return getAsyncClient().getAssetPropertyValue(assetPropertyValueRequest)
                .handle((response, exception) -> {
                    if (exception != null) {
                        logger.error("Error occurred while fetching property value:
{}.", exception.getCause().getMessage());
                        throw (CompletionException) exception;
                    }
                    return response.propertyValue().value().doubleValue();
                });
    }
```

- For API details, see GetAssetPropertyValue in *Amazon SDK for Java 2.x API Reference*.

`ListAssetModels`

The following code example shows how to use `ListAssetModels`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /**
     * Retrieves the asset model ID for the given asset model name.
     *
     * @param assetModelName the name of the asset model for the ID.
     * @return a {@link CompletableFuture} that represents a {@link String} result
of the asset model ID or null if the
     *         asset model cannot be found. The calling code can attach callbacks,
then handle the result or exception
     *         by calling {@link CompletableFuture#join()} or {@link
CompletableFuture#get()}.
     *         <p>
     *         If any completion stage in this method throws an exception, the
method logs the exception cause and keeps
```

```
     *         it available to the calling code as a {@link CompletionException}. By
calling
     *         {@link CompletionException#getCause()}, the calling code can access
the original exception.
     */
    public CompletableFuture<String> getAssetModelIdAsync(String assetModelName) {
        ListAssetModelsRequest listAssetModelsRequest =
ListAssetModelsRequest.builder().build();
        return getAsyncClient().listAssetModels(listAssetModelsRequest)
                .handle((listAssetModelsResponse, exception) -> {
                    if (exception != null) {
                        logger.error("Failed to retrieve Asset Model ID: {}",
exception.getCause().getMessage());

Amazon Keyspaces examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Keyspaces.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Keyspaces

The following code examples show how to get started using Amazon Keyspaces.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.keyspaces.KeyspacesClient;
import software.amazon.awssdk.services.keyspaces.model.KeyspaceSummary;
import software.amazon.awssdk.services.keyspaces.model.KeyspacesException;
import software.amazon.awssdk.services.keyspaces.model.ListKeyspacesRequest;
import software.amazon.awssdk.services.keyspaces.model.ListKeyspacesResponse;
import java.util.List;

/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloKeyspaces {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        KeyspacesClient keyClient = KeyspacesClient.builder()
                .region(region)
                .build();

        listKeyspaces(keyClient);
    }

    public static void listKeyspaces(KeyspacesClient keyClient) {
        try {
            ListKeyspacesRequest keyspacesRequest = ListKeyspacesRequest.builder()
                    .maxResults(10)
                    .build();
```

```
            ListKeyspacesResponse response =
 keyClient.listKeyspaces(keyspacesRequest);
            List<KeyspaceSummary> keyspaces = response.keyspaces();
            for (KeyspaceSummary keyspace : keyspaces) {
                System.out.println("The name of the keyspace is " +
 keyspace.keyspaceName());
            }

        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
```

- For API details, see ListKeyspaces in *Amazon SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create a keyspace and table. The table schema holds movie data and has point-in-time recovery enabled.
- Connect to the keyspace using a secure TLS connection with SigV4 authentication.
- Query the table. Add, retrieve, and update movie data.
- Update the table. Add a column to track watched movies.
- Restore the table to its previous state and clean up resources.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * Before running this Java code example, you must create a
 * Java keystore (JKS) file and place it in your project's resources folder.
 *
 * This file is a secure file format used to hold certificate information for
 * Java applications. This is required to make a connection to Amazon Keyspaces.
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/keyspaces/latest/devguide/using_java_driver.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Create a keyspace.
 * 2. Check for keyspace existence.
 * 3. List keyspaces using a paginator.
 * 4. Create a table with a simple movie data schema and enable point-in-time
 * recovery.
 * 5. Check for the table to be in an Active state.
 * 6. List all tables in the keyspace.
 * 7. Use a Cassandra driver to insert some records into the Movie table.
 * 8. Get all records from the Movie table.
 * 9. Get a specific Movie.
 * 10. Get a UTC timestamp for the current time.
 * 11. Update the table schema to add a ‘watched’ Boolean column.
 * 12. Update an item as watched.
 * 13. Query for items with watched = True.
 * 14. Restore the table back to the previous state using the timestamp.
```

```
 * 15. Check for completion of the restore action.
 * 16. Delete the table.
 * 17. Confirm that both tables are deleted.
 * 18. Delete the keyspace.
 */

public class ScenarioKeyspaces {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

Actions

`CreateKeyspace`

The following code example shows how to use `CreateKeyspace`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void createKeySpace(KeyspacesClient keyClient, String
keyspaceName) {
       try {
           CreateKeyspaceRequest keyspaceRequest = CreateKeyspaceRequest.builder()
                   .keyspaceName(keyspaceName)
                   .build();

           CreateKeyspaceResponse response =
keyClient.createKeyspace(keyspaceRequest);
           System.out.println("The ARN of the KeySpace is " +
response.resourceArn());

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see CreateKeyspace in *Amazon SDK for Java 2.x API Reference*.

`CreateTable`

The following code example shows how to use `CreateTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void createTable(KeyspacesClient keyClient, String keySpace,
String tableName) {
       try {
           // Set the columns.
           ColumnDefinition defTitle = ColumnDefinition.builder()
                   .name("title")
                   .type("text")
                   .build();

           ColumnDefinition defYear = ColumnDefinition.builder()
                   .name("year")
                   .type("int")
                   .build();

           ColumnDefinition defReleaseDate = ColumnDefinition.builder()
                   .name("release_date")
                   .type("timestamp")
                   .build();

           ColumnDefinition defPlot = ColumnDefinition.builder()
                   .name("plot")
                   .type("text")
                   .build();

           List<ColumnDefinition> colList = new ArrayList<>();
           colList.add(defTitle);
           colList.add(defYear);
           colList.add(defReleaseDate);
           colList.add(defPlot);

           // Set the keys.
           PartitionKey yearKey = PartitionKey.builder()
                   .name("year")
                   .build();
```

```
            PartitionKey titleKey = PartitionKey.builder()
                    .name("title")
                    .build();

            List<PartitionKey> keyList = new ArrayList<>();
            keyList.add(yearKey);
            keyList.add(titleKey);

            SchemaDefinition schemaDefinition = SchemaDefinition.builder()
                    .partitionKeys(keyList)
                    .allColumns(colList)
                    .build();

            PointInTimeRecovery timeRecovery = PointInTimeRecovery.builder()
                    .status(PointInTimeRecoveryStatus.ENABLED)
                    .build();

            CreateTableRequest tableRequest = CreateTableRequest.builder()
                    .keyspaceName(keySpace)
                    .tableName(tableName)
                    .schemaDefinition(schemaDefinition)
                    .pointInTimeRecovery(timeRecovery)
                    .build();

            CreateTableResponse response = keyClient.createTable(tableRequest);
            System.out.println("The table ARN is " + response.resourceArn());

        } catch (KeyspacesException e) {

            System.exit(1);
        }
    }
```

- For API details, see CreateTable in *Amazon SDK for Java 2.x API Reference*.

`DeleteKeyspace`

The following code example shows how to use `DeleteKeyspace`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void deleteKeyspace(KeyspacesClient keyClient, String
keyspaceName) {
       try {
           DeleteKeyspaceRequest deleteKeyspaceRequest =
DeleteKeyspaceRequest.builder()
                   .keyspaceName(keyspaceName)
                   .build();

           keyClient.deleteKeyspace(deleteKeyspaceRequest);

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DeleteKeyspace in *Amazon SDK for Java 2.x API Reference*.

`DeleteTable`

The following code example shows how to use `DeleteTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void deleteTable(KeyspacesClient keyClient, String keyspaceName,
String tableName) {
       try {
           DeleteTableRequest tableRequest = DeleteTableRequest.builder()
                   .keyspaceName(keyspaceName)
                   .tableName(tableName)
                   .build();

           keyClient.deleteTable(tableRequest);

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DeleteTable in *Amazon SDK for Java 2.x API Reference*.

`GetKeyspace`

The following code example shows how to use `GetKeyspace`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void checkKeyspaceExistence(KeyspacesClient keyClient, String
keyspaceName) {
       try {
           GetKeyspaceRequest keyspaceRequest = GetKeyspaceRequest.builder()
                   .keyspaceName(keyspaceName)
                   .build();

           GetKeyspaceResponse response = keyClient.getKeyspace(keyspaceRequest);
           String name = response.keyspaceName();
           System.out.println("The " + name + " KeySpace is ready");
```

```
        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see GetKeyspace in *Amazon SDK for Java 2.x API Reference*.

`GetTable`

The following code example shows how to use `GetTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void checkTable(KeyspacesClient keyClient, String keyspaceName,
String tableName)
            throws InterruptedException {
        try {
            boolean tableStatus = false;
            String status;
            GetTableResponse response = null;
            GetTableRequest tableRequest = GetTableRequest.builder()
                    .keyspaceName(keyspaceName)
                    .tableName(tableName)
                    .build();

            while (!tableStatus) {
                response = keyClient.getTable(tableRequest);
                status = response.statusAsString();
                System.out.println(". The table status is " + status);

                if (status.compareTo("ACTIVE") == 0) {
                    tableStatus = true;
                }
```

```
                Thread.sleep(500);
            }

            List<ColumnDefinition> cols = response.schemaDefinition().allColumns();
            for (ColumnDefinition def : cols) {
                System.out.println("The column name is " + def.name());
                System.out.println("The column type is " + def.type());
            }

        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see GetTable in *Amazon SDK for Java 2.x API Reference*.

`ListKeyspaces`

The following code example shows how to use `ListKeyspaces`.

SDK for Java 2.x

```
    public static void listKeyspacesPaginator(KeyspacesClient keyClient) {
        try {
            ListKeyspacesRequest keyspacesRequest = ListKeyspacesRequest.builder()
                    .maxResults(10)
                    .build();

            ListKeyspacesIterable listRes =
keyClient.listKeyspacesPaginator(keyspacesRequest);
            listRes.stream()
                    .flatMap(r -> r.keyspaces().stream())
                    .forEach(content -> System.out.println(" Name: " +
content.keyspaceName()));
```

```
        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListKeyspaces in *Amazon SDK for Java 2.x API Reference*.

`ListTables`

The following code example shows how to use `ListTables`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    public static void listTables(KeyspacesClient keyClient, String keyspaceName) {
        try {
            ListTablesRequest tablesRequest = ListTablesRequest.builder()
                    .keyspaceName(keyspaceName)
                    .build();

            ListTablesIterable listRes =
keyClient.listTablesPaginator(tablesRequest);
            listRes.stream()
                    .flatMap(r -> r.tables().stream())
                    .forEach(content -> System.out.println(" ARN: " +
content.resourceArn() +
                            " Table name: " + content.tableName()));

        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListTables in *Amazon SDK for Java 2.x API Reference*.

`RestoreTable`

The following code example shows how to use `RestoreTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void restoreTable(KeyspacesClient keyClient, String keyspaceName,
ZonedDateTime utc) {
       try {
           Instant myTime = utc.toInstant();
           RestoreTableRequest restoreTableRequest = RestoreTableRequest.builder()
                   .restoreTimestamp(myTime)
                   .sourceTableName("Movie")
                   .targetKeyspaceName(keyspaceName)
                   .targetTableName("MovieRestore")
                   .sourceKeyspaceName(keyspaceName)
                   .build();

           RestoreTableResponse response =
keyClient.restoreTable(restoreTableRequest);
           System.out.println("The ARN of the restored table is " +
response.restoredTableARN());

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see RestoreTable in *Amazon SDK for Java 2.x API Reference*.

`UpdateTable`

The following code example shows how to use `UpdateTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void updateTable(KeyspacesClient keyClient, String keySpace,
String tableName) {
       try {
           ColumnDefinition def = ColumnDefinition.builder()
                   .name("watched")
                   .type("boolean")
                   .build();

           UpdateTableRequest tableRequest = UpdateTableRequest.builder()
                   .keyspaceName(keySpace)
                   .tableName(tableName)
                   .addColumns(def)
                   .build();

           keyClient.updateTable(tableRequest);

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see UpdateTable in *Amazon SDK for Java 2.x API Reference*.

Kinesis examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Kinesis.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions
- Serverless examples

Actions

`CreateStream`

The following code example shows how to use `CreateStream`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisClient;
import software.amazon.awssdk.services.kinesis.model.CreateStreamRequest;
import software.amazon.awssdk.services.kinesis.model.KinesisException;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class CreateDataStream {
    public static void main(String[] args) {
```

```
        final String usage = """

                Usage:
                    <streamName>

                Where:
                    streamName - The Amazon Kinesis data stream (for example,
 StockTradeStream).
                """;

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String streamName = args[0];
        Region region = Region.US_EAST_1;
        KinesisClient kinesisClient = KinesisClient.builder()
                .region(region)
                .build();
        createStream(kinesisClient, streamName);
        System.out.println("Done");
        kinesisClient.close();
    }

    public static void createStream(KinesisClient kinesisClient, String streamName)
 {
        try {
            CreateStreamRequest streamReq = CreateStreamRequest.builder()
                    .streamName(streamName)
                    .shardCount(1)

Serverless examples

Invoke a Lambda function from a Kinesis trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a Kinesis stream. The function retrieves the Kinesis payload, decodes from Base64, and logs the record contents.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming a Kinesis event with Lambda using Java.

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.LambdaLogger;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KinesisEvent;

public class Handler implements RequestHandler<KinesisEvent, Void> {
    @Override
    public Void handleRequest(final KinesisEvent event, final Context context) {
        LambdaLogger logger = context.getLogger();
        if (event.getRecords().isEmpty()) {
            logger.log("Empty Kinesis Event received");
            return null;
        }
        for (KinesisEvent.KinesisEventRecord record : event.getRecords()) {
            try {
                logger.log("Processed Event with EventId: "+record.getEventID());
                String data = new String(record.getKinesis().getData().array());
                logger.log("Data:"+ data);
                // TODO: Do interesting work based on the new data
            }
            catch (Exception ex) {
                logger.log("An error occurred:"+ex.getMessage());
                throw ex;
            }
        }
        logger.log("Successfully processed:"+event.getRecords().size()+" records");
        return null;
    }
```

```
}
```

Reporting batch item failures for Lambda functions with a Kinesis trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from a Kinesis stream. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Amazon KMS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon KMS.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Key Management Service

The following code examples show how to get started using Amazon Key Management Service.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
import software.amazon.awssdk.services.kms.KmsAsyncClient;
import software.amazon.awssdk.services.kms.model.ListKeysRequest;
import software.amazon.awssdk.services.kms.paginators.ListKeysPublisher;
import java.util.concurrent.CompletableFuture;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloKMS {
    public static void main(String[] args) {
        listAllKeys();
    }

    public static void listAllKeys() {
        KmsAsyncClient kmsAsyncClient = KmsAsyncClient.builder()
            .build();
        ListKeysRequest listKeysRequest = ListKeysRequest.builder()
            .limit(15)
            .build();

        /*
         * The `subscribe` method is required when using paginator methods in the
 AWS SDK
         * because paginator methods return an instance of a `ListKeysPublisher`,
 which is
         * based on a reactive stream. This allows asynchronous retrieval of
 paginated
         * results as they become available. By subscribing to the stream, we can
 process
```

```
         * each page of results as they are emitted.
         */
        ListKeysPublisher keysPublisher =
 kmsAsyncClient.listKeysPaginator(listKeysRequest);
        CompletableFuture<Void> future = keysPublisher
            .subscribe(r -> r.keys().forEach(key ->
                System.out.println("The key ARN is: " + key.keyArn() + ". The key Id
 is: " + key.keyId())))
            .whenComplete((result, exception) -> {
                if (exception != null) {
                    System.err.println("Error occurred: " + exception.getMessage());
                } else {
                    System.out.println("Successfully listed all keys.");
                }
            });

        try {
            future.join();
        } catch (Exception e) {
            System.err.println("Failed to list keys: " + e.getMessage());
        }
    }
}
```

- For API details, see ListKeys in *Amazon SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create a KMS key.
- List KMS keys for your account and get details about them.
- Enable and disable KMS keys.

- Generate a symmetric data key that can be used for client-side encryption.
- Generate an asymmetric key used to digitally sign data.
- Tag keys.
- Delete KMS keys.

SDK for Java 2.x

           Welcome to the AWS Key Management SDK Basics scenario.

           This program demonstrates how to interact with AWS Key Management using
the AWS SDK for Java (v2).
           The AWS Key Management Service (KMS) is a secure and highly available
service that allows you to create
           and manage AWS KMS keys and control their use across a wide range of AWS
services and applications.
           KMS provides a centralized and unified approach to managing encryption
keys, making it easier to meet your
           data protection and regulatory compliance requirements.

           This Basics scenario creates two key types:
```

```
            - A symmetric encryption key is used to encrypt and decrypt data.
            - An asymmetric key used to digitally sign data.

            Let's get started...

        logger.info("""
            A key policy is a resource policy for a KMS key. Key policies are the
primary way to control
            access to KMS keys. Every KMS key must have exactly one key policy. The
statements in the key policy
            determine who has permission to use the KMS key and how they can use
it.
            You can also use IAM policies and grants to control access to the KMS
key, but every KMS key
            must have a key policy.

            By default, when you create a key by using the SDK, a policy is created
that
            gives the AWS account that owns the KMS key full access to the KMS key.

            Let's try to replace the automatically created policy with the following
policy.

                "Version": "2012-10-17",
                "Statement": [{
                "Effect": "Allow",
                "Principal": {"AWS": "arn:aws:iam::0000000000:root"},
```

```
                "Action": "kms:*",
                "Resource": "*"
                }]
            """);

`CreateAlias`

The following code example shows how to use `CreateAlias`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   /**
    * Creates a custom alias for the specified target key asynchronously.
    *
    * @param targetKeyId the ID of the target key for the alias
    * @param aliasName   the name of the alias to create
    * @return a {@link CompletableFuture} that completes when the alias creation
operation is finished
    */
   public CompletableFuture<Void> createCustomAliasAsync(String targetKeyId, String
aliasName) {
       CreateAliasRequest aliasRequest = CreateAliasRequest.builder()
           .aliasName(aliasName)
           .targetKeyId(targetKeyId)
           .build();

       CompletableFuture<CreateAliasResponse> responseFuture =
getAsyncClient().createAlias(aliasRequest);
       responseFuture.whenComplete((response, exception) -> {
           if (exception == null) {
               logger.info("{} was successfully created.", aliasName);
           } else {
               if (exception instanceof ResourceExistsException) {
                   logger.info("Alias [{}] already exists. Moving on...",
aliasName);
               } else if (exception instanceof KmsException kmsEx) {
                   throw new RuntimeException("KMS error occurred while creating
alias: " + kmsEx.getMessage(), kmsEx);
               } else {
                   throw new RuntimeException("An unexpected error occurred while
creating alias: " + exception.getMessage(), exception);
               }
           }
       });

       return responseFuture.thenApply(response -> null);
   }
```

- For API details, see CreateAlias in *Amazon SDK for Java 2.x API Reference*.

`CreateGrant`

The following code example shows how to use `CreateGrant`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   /**
    * Grants permissions to a specified principal on a customer master key (CMK)
asynchronously.
    *
    * @param keyId             The unique identifier for the customer master key
(CMK) that the grant applies to.
    * @param granteePrincipal  The principal that is given permission to perform
the operations that the grant permits on the CMK.
    * @return A {@link CompletableFuture} that, when completed, contains the ID of
the created grant.
    * @throws RuntimeException If an error occurs during the grant creation
process.
    */
   public CompletableFuture<String> grantKeyAsync(String keyId, String
granteePrincipal) {
       List<GrantOperation> grantPermissions = List.of(
           GrantOperation.ENCRYPT,
           GrantOperation.DECRYPT,
           GrantOperation.DESCRIBE_KEY
       );

       CreateGrantRequest grantRequest = CreateGrantRequest.builder()
           .keyId(keyId)
           .name("grant1")
           .granteePrincipal(granteePrincipal)
           .operations(grantPermissions)
           .build();

       CompletableFuture<CreateGrantResponse> responseFuture =
getAsyncClient().createGrant(grantRequest);
       responseFuture.whenComplete((response, ex) -> {
```

```
            if (ex == null) {
                logger.info("Grant created successfully with ID: " +
response.grantId());
            } else {
                if (ex instanceof KmsException kmsEx) {
                    throw new RuntimeException("Failed to create grant: " +
kmsEx.getMessage(), kmsEx);
                } else {
                    throw new RuntimeException("An unexpected error occurred: " +
ex.getMessage(), ex);
                }
            }
        });

        return responseFuture.thenApply(CreateGrantResponse::grantId);
    }
```

- For API details, see CreateGrant in *Amazon SDK for Java 2.x API Reference*.

`CreateKey`

The following code example shows how to use `CreateKey`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /**
     * Creates a new symmetric encryption key asynchronously.
     *
     * @param keyDesc the description of the key to be created
     * @return a {@link CompletableFuture} that completes with the ID of the newly
created key
     * @throws RuntimeException if an error occurs while creating the key
     */
    public CompletableFuture<String> createKeyAsync(String keyDesc) {
        CreateKeyRequest keyRequest = CreateKeyRequest.builder()
```

```
            .description(keyDesc)
            .keySpec(KeySpec.SYMMETRIC_DEFAULT)
            .keyUsage(KeyUsageType.ENCRYPT_DECRYPT)
            .build();

        return getAsyncClient().createKey(keyRequest)
            .thenApply(resp -> resp.keyMetadata().keyId())
            .exceptionally(ex -> {
                throw new RuntimeException("An error occurred while creating the
key: " + ex.getMessage(), ex);
            });
    }
```

`ScheduleKeyDeletion`

The following code example shows how to use `ScheduleKeyDeletion`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /**
     * Deletes a KMS key asynchronously.
     *
     * <p><strong>Warning:</strong> Deleting a KMS key is a destructive and
potentially dangerous operation.
     * When a KMS key is deleted, all data that was encrypted under the KMS key
becomes unrecoverable.
     * This means that any files, databases, or other data that were encrypted using
the deleted KMS key
     * will become permanently inaccessible. Exercise extreme caution when deleting
KMS keys.</p>
     *
     * @param keyId the ID of the KMS key to delete
     * @return a {@link CompletableFuture} that completes when the key deletion is
scheduled
     */
```

```
    public CompletableFuture<Void> deleteKeyAsync(String keyId) {
        ScheduleKeyDeletionRequest deletionRequest =
 ScheduleKeyDeletionRequest.builder()
            .keyId(keyId)
            .pendingWindowInDays(7)
            .build();

        return getAsyncClient().scheduleKeyDeletion(deletionRequest)
            .thenRun(() -> {
                logger.info("Key {} will be deleted in 7 days", keyId);
            })
            .exceptionally(throwable -> {
                throw new RuntimeException("Failed to schedule key deletion for key
 ID: " + keyId, throwable);
            });

            });
    }
```

- For API details, see TagResource in *Amazon SDK for Java 2.x API Reference*.

Lambda examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Lambda.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Amazon community contributions are examples that were created and are maintained by multiple teams across Amazon. To provide feedback, use the mechanism provided in the linked repositories.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Lambda

The following code examples show how to get started using Lambda.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /**
     * Lists the AWS Lambda functions associated with the current AWS account.
     *
     * @param awsLambda an instance of the {@link LambdaClient} class, which is used
to interact with the AWS Lambda service
     *
     * @throws LambdaException if an error occurs while interacting with the AWS
Lambda service
     */
    public static void listFunctions(LambdaClient awsLambda) {
        try {
            ListFunctionsResponse functionResult = awsLambda.listFunctions();
            List<FunctionConfiguration> list = functionResult.functions();
            for (FunctionConfiguration config : list) {
                System.out.println("The function name is " + config.functionName());
            }

        } catch (LambdaException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListFunctions in *Amazon SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions
- Scenarios
- Serverless examples

- Amazon community contributions

Basics

Learn the basics

The following code example shows how to:

- Create an IAM role and Lambda function, then upload handler code.
- Invoke the function with a single parameter and get results.
- Update the function code and configure with an environment variable.
- Invoke the function with new parameters and get results. Display the returned execution log.
- List the functions for your account, then clean up resources.

For more information, see Create a Lambda function with the console.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
/*
 *  Lambda function names appear as:
 *
 *  arn:aws:lambda:us-west-2:335556666777:function:HelloFunction
 *
 *  To find this value, look at the function in the AWS Management Console.
 *
 *  Before running this Java code example, set up your development environment,
including your credentials.
 *
 *  For more information, see this documentation topic:
 *
 *  https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 *  This example performs the following tasks:
```

```
 *
 * 1. Creates an AWS Lambda function.
 * 2. Gets a specific AWS Lambda function.
 * 3. Lists all Lambda functions.
 * 4. Invokes a Lambda function.
 * 5. Updates the Lambda function code and invokes it again.
 * 6. Updates a Lambda function's configuration value.
 * 7. Deletes a Lambda function.
 */

public class LambdaScenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

`DeleteFunction`

The following code example shows how to use `DeleteFunction`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /**
     * Deletes an AWS Lambda function.
     *
     * @param awsLambda     an instance of the {@link LambdaClient} class, which is
used to interact with the AWS Lambda service
     * @param functionName  the name of the Lambda function to be deleted
     *
```

```
    * @throws LambdaException if an error occurs while deleting the Lambda function
    */
   public static void deleteLambdaFunction(LambdaClient awsLambda, String
functionName) {
       try {
           DeleteFunctionRequest request = DeleteFunctionRequest.builder()
               .functionName(functionName)
               .build();

           awsLambda.deleteFunction(request);
           System.out.println("The " + functionName + " function was deleted");

       } catch (LambdaException e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
   }
```

- For API details, see DeleteFunction in *Amazon SDK for Java 2.x API Reference*.

`GetFunction`

The following code example shows how to use `GetFunction`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   /**
    * Retrieves information about an AWS Lambda function.
    *
    * @param awsLambda    an instance of the {@link LambdaClient} class, which is
used to interact with the AWS Lambda service
    * @param functionName the name of the AWS Lambda function to retrieve
information about
    */
```

```
    public static void getFunction(LambdaClient awsLambda, String functionName) {
        try {
            GetFunctionRequest functionRequest = GetFunctionRequest.builder()
                .functionName(functionName)
                .build();

            GetFunctionResponse response = awsLambda.getFunction(functionRequest);
            System.out.println("The runtime of this Lambda function is " +
response.configuration().runtime());

        } catch (LambdaException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see GetFunction in *Amazon SDK for Java 2.x API Reference*.

Invoke

The following code example shows how to use `Invoke`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /**
     * Invokes a specific AWS Lambda function.
     *
     * @param awsLambda    an instance of {@link LambdaClient} to interact with the
AWS Lambda service
     * @param functionName the name of the AWS Lambda function to be invoked
     */
    public static void invokeFunction(LambdaClient awsLambda, String functionName) {
        InvokeResponse res;
        try {
```

```
            // Need a SdkBytes instance for the payload.
            JSONObject jsonObj = new JSONObject();
            jsonObj.put("inputValue", "2000");
            String json = jsonObj.toString();
            SdkBytes payload = SdkBytes.fromUtf8String(json);

            InvokeRequest request = InvokeRequest.builder()
                .functionName(functionName)
                .payload(payload)
                .build();

            res = awsLambda.invoke(request);
            String value = res.payload().asUtf8String();
            System.out.println(value);

        } catch (LambdaException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see Invoke in *Amazon SDK for Java 2.x API Reference*.

`UpdateFunctionCode`

The following code example shows how to use `UpdateFunctionCode`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /**
     * Updates the code for an AWS Lambda function.
     *
     * @param awsLambda  the AWS Lambda client
     * @param functionName the name of the Lambda function to update
```

```
    * @param bucketName the name of the S3 bucket where the function code is
located
    * @param key the key (file name) of the function code in the S3 bucket
    * @throws LambdaException if there is an error updating the function code
    */
   public static void updateFunctionCode(LambdaClient awsLambda, String
functionName, String bucketName, String key) {
       try {
           LambdaWaiter waiter = awsLambda.waiter();
           UpdateFunctionCodeRequest functionCodeRequest =
UpdateFunctionCodeRequest.builder()
                .functionName(functionName)
                .publish(true)
                .s3Bucket(bucketName)
                .s3Key(key)
                .build();

           UpdateFunctionCodeResponse response =
awsLambda.updateFunctionCode(functionCodeRequest);
           GetFunctionConfigurationRequest getFunctionConfigRequest =
GetFunctionConfigurationRequest.builder()
                .functionName(functionName)
                .build();

           WaiterResponse<GetFunctionConfigurationResponse> waiterResponse = waiter
                .waitUntilFunctionUpdated(getFunctionConfigRequest);
           waiterResponse.matched().response().ifPresent(System.out::println);
           System.out.println("The last modified value is " +
response.lastModified());

       } catch (LambdaException e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
   }
```

- For API details, see [UpdateFunctionCode](#) in *Amazon SDK for Java 2.x API Reference*.

`UpdateFunctionConfiguration`

The following code example shows how to use `UpdateFunctionConfiguration`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   /**
    * Updates the configuration of an AWS Lambda function.
    *
    * @param awsLambda     the {@link LambdaClient} instance to use for the AWS
Lambda operation
    * @param functionName  the name of the AWS Lambda function to update
    * @param handler       the new handler for the AWS Lambda function
    *
    * @throws LambdaException if there is an error while updating the function
configuration
    */
   public static void updateFunctionConfiguration(LambdaClient awsLambda, String
functionName, String handler) {
       try {
           UpdateFunctionConfigurationRequest configurationRequest =
UpdateFunctionConfigurationRequest.builder()
               .functionName(functionName)
               .handler(handler)
               .runtime(Runtime.JAVA17)
               .build();

           awsLambda.updateFunctionConfiguration(configurationRequest);

       } catch (LambdaException e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
   }
```

- For API details, see UpdateFunctionConfiguration in *Amazon SDK for Java 2.x API Reference*.

Scenarios

Create a serverless application to manage photos

The following code example shows how to create a serverless application that lets users manage photos using labels.

SDK for Java 2.x

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on Amazon Community.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Create an application to analyze customer feedback

The following code example shows how to create an application that analyzes customer comment cards, translates them from their original language, determines their sentiment, and generates an audio file from the translated text.

SDK for Java 2.x

This example application analyzes and stores customer feedback cards. Specifically, it fulfills the need of a fictitious hotel in New York City. The hotel receives feedback from guests in various languages in the form of physical comment cards. That feedback is uploaded into the app through a web client. After an image of a comment card is uploaded, the following steps occur:

- Text is extracted from the image using Amazon Textract.

- Amazon Comprehend determines the sentiment of the extracted text and its language.
- The extracted text is translated to English using Amazon Translate.
- Amazon Polly synthesizes an audio file from the extracted text.

The full app can be deployed with the Amazon CDK. For source code and deployment instructions, see the project in GitHub.

Services used in this example

- Amazon Comprehend
- Lambda
- Amazon Polly
- Amazon Textract
- Amazon Translate

Use API Gateway to invoke a Lambda function

The following code example shows how to create an Amazon Lambda function invoked by Amazon API Gateway.

SDK for Java 2.x

Shows how to create an Amazon Lambda function by using the Lambda Java runtime API. This example invokes different Amazon services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

Use Step Functions to invoke Lambda functions

The following code example shows how to create an Amazon Step Functions state machine that invokes Amazon Lambda functions in sequence.

SDK for Java 2.x

Shows how to create an Amazon serverless workflow by using Amazon Step Functions and the Amazon SDK for Java 2.x. Each workflow step is implemented using an Amazon Lambda function.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Lambda
- Amazon SES
- Step Functions

Use scheduled events to invoke a Lambda function

The following code example shows how to create an Amazon Lambda function invoked by an Amazon EventBridge scheduled event.

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an Amazon Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different Amazon services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch Logs

- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

Serverless examples

Connecting to an Amazon RDS database in a Lambda function

The following code example shows how to implement a Lambda function that connects to an RDS database. The function makes a simple database request and returns the result.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Connecting to an Amazon RDS database in a Lambda function using Java.

```
import com.amazonaws.services.lambda.runtime.Context;

import software.amazon.awssdk.services.rdsdata.model.ExecuteStatementResponse;
import software.amazon.awssdk.services.rdsdata.model.Field;

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.ResultSet;

public class RdsLambdaHandler implements RequestHandler<APIGatewayProxyRequestEvent,
 APIGatewayProxyResponseEvent> {
```

```
    @Override
    public APIGatewayProxyResponseEvent handleRequest(APIGatewayProxyRequestEvent
 event, Context context) {
        APIGatewayProxyResponseEvent response = new APIGatewayProxyResponseEvent();

        try {
            // Obtain auth token
            String token = createAuthToken();

            // Define connection configuration
            String connectionString = String.format("jdbc:mysql://%s:%s/%s?
useSSL=true&requireSSL=true",
                    System.getenv("ProxyHostName"),
                    System.getenv("Port"),
                    System.getenv("DBName"));

            // Establish a connection to the database
            try (Connection connection =
 DriverManager.getConnection(connectionString, System.getenv("DBUserName"), token);
                 PreparedStatement statement = connection.prepareStatement("SELECT ?
 + ? AS sum")) {

                statement.setInt(1, 3);
                statement.setInt(2, 2);

                try (ResultSet resultSet = statement.executeQuery()) {
                    if (resultSet.next()) {
                        int sum = resultSet.getInt("sum");
                        response.setStatusCode(200);
                        response.setBody("The selected sum is: " + sum);
                    }
                }
            }

        } catch (Exception e) {
            response.setStatusCode(500);
            response.setBody("Error: " + e.getMessage());
        }

        return response;
    }

    private String createAuthToken() {
```

```
        // Create RDS Data Service client
        RdsDataClient rdsDataClient = RdsDataClient.builder()
                .region(Region.of(System.getenv("AWS_REGION")))
                .credentialsProvider(DefaultCredentialsProvider.create())
                .build();

        // Define authentication request
        ExecuteStatementRequest request = ExecuteStatementRequest.builder()
                .resourceArn(System.getenv("ProxyHostName"))
                .secretArn(System.getenv("DBUserName"))
                .database(System.getenv("DBName"))
                .sql("SELECT 'RDS IAM Authentication'")
                .build();

        // Execute request and obtain authentication token
        ExecuteStatementResponse response = rdsDataClient.executeStatement(request);
        Field tokenField = response.records().get(0).get(0);

        return tokenField.stringValue();
    }
}
```

Invoke a Lambda function from a Kinesis trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a Kinesis stream. The function retrieves the Kinesis payload, decodes from Base64, and logs the record contents.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming a Kinesis event with Lambda using Java.

Consuming a DynamoDB event with Lambda using Java.

```
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.DynamodbEvent;
import
 com.amazonaws.services.lambda.runtime.events.DynamodbEvent.DynamodbStreamRecord;
import com.google.gson.Gson;
import com.google.gson.GsonBuilder;

public class example implements RequestHandler<DynamodbEvent, Void> {

    private static final Gson GSON = new GsonBuilder().setPrettyPrinting().create();

    @Override
    public Void handleRequest(DynamodbEvent event, Context context) {
        System.out.println(GSON.toJson(event));
        event.getRecords().forEach(this::logDynamoDBRecord);
        return null;
    }

    private void logDynamoDBRecord(DynamodbStreamRecord record) {
        System.out.println(record.getEventID());
        System.out.println(record.getEventName());
        System.out.println("DynamoDB Record: " + GSON.toJson(record.getDynamodb()));
    }
}
```

Invoke a Lambda function from a Amazon DocumentDB trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a DocumentDB change stream. The function retrieves the DocumentDB payload and logs the record contents.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming a Amazon DocumentDB event with Lambda using Java.

```
import java.util.List;
import java.util.Map;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;

public class Example implements RequestHandler<Map<String, Object>, String> {

    @SuppressWarnings("unchecked")
    @Override
    public String handleRequest(Map<String, Object> event, Context context) {
        List<Map<String, Object>> events = (List<Map<String, Object>>)
 event.get("events");
        for (Map<String, Object> record : events) {
            Map<String, Object> eventData = (Map<String, Object>)
 record.get("event");
            processEventData(eventData);
        }

        return "OK";
    }

    @SuppressWarnings("unchecked")
    private void processEventData(Map<String, Object> eventData) {
        String operationType = (String) eventData.get("operationType");
        System.out.println("operationType: %s".formatted(operationType));

        Map<String, Object> ns = (Map<String, Object>) eventData.get("ns");

        String db = (String) ns.get("db");
        System.out.println("db: %s".formatted(db));
        String coll = (String) ns.get("coll");
        System.out.println("coll: %s".formatted(coll));
```

```
        Map<String, Object> fullDocument = (Map<String, Object>)
 eventData.get("fullDocument");
        System.out.println("fullDocument: %s".formatted(fullDocument));
    }

}
```

Invoke a Lambda function from an Amazon MSK trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from an Amazon MSK cluster. The function retrieves the MSK payload and logs the record contents.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an Amazon MSK event with Lambda using Java.

```
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KafkaEvent;
import com.amazonaws.services.lambda.runtime.events.KafkaEvent.KafkaEventRecord;

import java.util.Base64;
import java.util.Map;

public class Example implements RequestHandler<KafkaEvent, Void> {

    @Override
    public Void handleRequest(KafkaEvent event, Context context) {
        for (Map.Entry<String, java.util.List<KafkaEventRecord>> entry :
 event.getRecords().entrySet()) {
            String key = entry.getKey();
```

```
            System.out.println("Key: " + key);

            for (KafkaEventRecord record : entry.getValue()) {
                System.out.println("Record: " + record);

                byte[] value = Base64.getDecoder().decode(record.getValue());
                String message = new String(value);
                System.out.println("Message: " + message);
            }
        }

        return null;
    }
}
```

Invoke a Lambda function from an Amazon S3 trigger

The following code example shows how to implement a Lambda function that receives an event triggered by uploading an object to an S3 bucket. The function retrieves the S3 bucket name and object key from the event parameter and calls the Amazon S3 API to retrieve and log the content type of the object.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an S3 event with Lambda using Java.

Build and test a serverless application

The following code example shows how to build and test a serverless application using API Gateway with Lambda and DynamoDB

SDK for Java 2.x

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Java SDK.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway

- DynamoDB
- Lambda

Amazon Lex examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Lex.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Building an Amazon Lex chatbot

The following code example shows how to create a chatbot to engage your website visitors.

SDK for Java 2.x

Shows how to use the Amazon Lex API to create a Chatbot within a web application to engage your web site visitors.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Amazon Comprehend
- Amazon Lex
- Amazon Translate

Amazon Location examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Location.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Location Service

The following code examples show how to get started using Amazon Location Service.

Basics

Learn the basics

The following code example shows how to:

- Create an Amazon Location map.
- Create an Amazon Location API key.
- Display Map URL.
- Create a geofence collection.
- Store a geofence geometry.
- Create a tracker resource.
- Update the position of a device.
- Retrieve the most recent position update for a specified device.
- Create a route calculator.
- Determine the distance between Seattle and Vancouver.
- Use Amazon Location higher level APIs.
- Delete the Amazon Location Assets.

```

```
            AWS Location Service is a fully managed service offered by Amazon Web
Services (AWS) that
            provides location-based services for developers. This service simplifies
            the integration of location-based features into applications, making it
            easier to build and deploy location-aware applications.

            The AWS Location Service offers a range of location-based services,
            including:

            Maps: The service provides access to high-quality maps, satellite
imagery,\s
            and geospatial data from various providers, allowing developers to\s
            easily embed maps into their applications.

            Tracking: The Location Service enables real-time tracking of mobile
devices,\s
            assets, or other entities, allowing developers to build applications\s
            that can monitor the location of people, vehicles, or other objects.

            Geocoding: The service provides the ability to convert addresses or\s
            location names into geographic coordinates (latitude and longitude),\s
            and vice versa, enabling developers to integrate location-based search\s
            and routing functionality into their applications.

            An AWS Location geofence is a virtual boundary that defines a geographic
area
            on a map. It is a useful feature for tracking the location of
            assets or monitoring the movement of objects within a specific region.

            To define a geofence, you need to specify the coordinates of a
            polygon that represents the area of interest. The polygon must be
            defined in a counter-clockwise direction, meaning that the points of
            the polygon must be listed in a counter-clockwise order.

            This is a requirement for the AWS Location service to correctly
            interpret the geofence and ensure that the location data is
            accurately processed within the defined area.

- For API details, see StartChangeSet in *Amazon SDK for Java 2.x API Reference*.

Create a public or limited AMI product and public offer with hourly pricing

The following code example shows how to create a public or limited AMI product and public offer with hourly pricing. This example creates either and standard or custom EULA.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to `RunChangesets` in *Utilities to start a changeset* from the **Utilities** section.

```

Create an draft AMI product with a draft public offer

The following code example shows how to create an draft AMI product with a draft public offer.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "CreateProduct",
            "ChangeName": "CreateProductChange",
            "Entity": {
                "Type": "AmiProduct@1.0"
            },
```

```
            "DetailsDocument": {
                "ProductTitle": "Sample product"
            }
        },
        {
            "ChangeType": "CreateOffer",
            "ChangeName": "CreateOfferChange",
            "Entity": {
                "Type": "Offer@1.0"
            },
            "DetailsDocument": {
                "ProductId": "$CreateProductChange.Entity.Identifier",
                "Name": "Test Offer"
            }
        }
    ]
}
```

- For API details, see StartChangeSet in *Amazon SDK for Java 2.x API Reference*.

Restrict a region where an AMI product is deployed

The following code example shows how to restrict a region where an AMI product is deployed.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to `RunChangesets` in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "RestrictRegions",
            "Entity": {
```

```
                "Type": "AmiProduct@1.0",
                "Identifier": "prod-1111111111111"
            },
            "DetailsDocument": {
                "Regions": [
                    "us-west-2"
                ]
            }
        }
    ]
}
```

- For API details, see StartChangeSet in *Amazon SDK for Java 2.x API Reference*.

Restrict product visibility

The following code example shows how to restrict product visibility.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to `RunChangesets` in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "UpdateVisibility",
            "Entity": {
                "Type": "AmiProduct@1.0",
                "Identifier": "prod-1111111111111"
            },
            "DetailsDocument": {
                "TargetVisibility": "Restricted"
```

```
            }
        }
    ]
}
```

- For API details, see StartChangeSet in *Amazon SDK for Java 2.x API Reference*.

Specify whether AMI assets are deployed in new regions

The following code example shows how to specify whether AMI assets are deployed in new regions built by Amazon to support future regions.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "UpdateFutureRegionSupport",
            "Entity": {
                "Type": "AmiProduct@1.0",
                "Identifier": "prod-1111111111111"
            },
            "DetailsDocument": {
                "FutureRegionSupport": {
                    "SupportedRegions": [
                        "All"
                    ]
                }
            }
        }
    ]
```

```
}
```

- For API details, see StartChangeSet in *Amazon SDK for Java 2.x API Reference*.

Channel partner offers

Create a draft CPPO for any product type

The following code example shows how to create a draft CPPO for any product type so you can review them internally before publishing to buyers.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "CreateOfferUsingResaleAuthorization",
            "Entity": {
                "Type": "Offer@1.0"
            },
            "DetailsDocument": {
                "ResaleAuthorizationId": "11111111-1111-1111-1111-111111111111",
                "Name": "Test Offer",
                "Description": "Test product"
            }
        }
    ]
}
```

- For API details, see StartChangeSet in *Amazon SDK for Java 2.x API Reference*.

Create a resale authorization replacement private offer with contract pricing

The following code example shows how to create a resale authorization replacement private offer from an existing agreement with contract pricing.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType" : "CreateReplacementOfferUsingResaleAuthorization",
            "Entity": {
                "Type": "Offer@1.0"
            },

Publish multi-use resale authorization with an expiration date

The following code example shows how to publish multi-use resale authorization with an expiration date for an AMI product with hourly annual pricing so a Channel Partner can use it to create a CPPO.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {

Create a public or limited SaaS product and public offer with contract with Pay-As-You-Go pricing

The following code example shows how to create a public or limited SaaS product and public offer with a contract with Pay-As-You-Go pricing. This example creates either a standard or custom EULA.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to `RunChangesets` in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "CreateProduct",
            "Entity": {
                "Type": "SaaSProduct@1.0"
```

```
            },
            "ChangeName": "CreateProductChange",
            "DetailsDocument": {}
        },
        {
            "ChangeType": "UpdateInformation",
            "Entity": {
                "Type": "SaaSProduct@1.0",
                "Identifier": "$CreateProductChange.Entity.Identifier"
            },
            "DetailsDocument": {
                "ProductTitle": "Sample product",

Create a public or limited SaaS product and public offer with subscription pricing

The following code example shows how to create a public or limited SaaS product and public offer with subscription pricing. This examples creates either a standard or custom EULA.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to `RunChangesets` in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
```

```

Publish a SaaS product and associated public offer

The following code example shows how to publish a SaaS product and associated public offer. The product will be in a limited state by default.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog":"AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "CreateProduct",
            "ChangeName": "CreateProductChange",
            "Entity": {
                "Type": "SaaSProduct@1.0"
            },
            "DetailsDocument": {}
        },
        {
            "ChangeType": "UpdateInformation",

Update dimensions on an AMI or SaaS product

The following code example shows how to update dimensions on an AMI or SaaS product.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Web Services Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "UpdateDimensions",
            "Entity": {
                "Type": "SaaSProduct@1.0",
                "Identifier": "prod-111111111111"
            },
            "DetailsDocument": [
                {
                    "Key": "BasicService",
                    "Types": [
                        "Entitled"
                    ],
                    "Name": "Some new name",
                    "Description": "Some new description"
                }
            ]
```

```
        }
    ]
}
```

Amazon Web Services Marketplace Agreement API examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Web Services Marketplace Agreement API.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Agreements

Agreements

Get all agreement IDs

The following code example shows how to get all agreement IDs.

MediaConvert examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with MediaConvert.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`CreateJob`

The following code example shows how to use `CreateJob`.

Migration Hub examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Migration Hub.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`DeleteProgressUpdateStream`

The following code example shows how to use `DeleteProgressUpdateStream`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.migrationhub.MigrationHubClient;

Amazon MSK examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon MSK.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Serverless examples

Serverless examples

Invoke a Lambda function from an Amazon MSK trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from an Amazon MSK cluster. The function retrieves the MSK payload and logs the record contents.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an Amazon MSK event with Lambda using Java.

```
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KafkaEvent;
import com.amazonaws.services.lambda.runtime.events.KafkaEvent.KafkaEventRecord;

import java.util.Base64;
import java.util.Map;

public class Example implements RequestHandler<KafkaEvent, Void> {

    @Override
    public Void handleRequest(KafkaEvent event, Context context) {
        for (Map.Entry<String, java.util.List<KafkaEventRecord>> entry :
 event.getRecords().entrySet()) {
            String key = entry.getKey();
            System.out.println("Key: " + key);

            for (KafkaEventRecord record : entry.getValue()) {
                System.out.println("Record: " + record);

                byte[] value = Base64.getDecoder().decode(record.getValue());
                String message = new String(value);
                System.out.println("Message: " + message);
```

```
            }
        }

        return null;
    }
}
```

Partner Central examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Partner Central.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

`StartEngagementFromOpportunityTask`

The following code example shows how to use `StartEngagementFromOpportunityTask`.

SDK for Java 2.x

Initiates the engagement process from an existing opportunity by accepting the engagement invitation and creating a corresponding opportunity in the partner's system.

```
package org.example;

import static org.example.utils.Constants.*;

import org.example.utils.Constants;
import org.example.utils.ReferenceCodesUtils;

Amazon Personalize examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Personalize.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

`DeleteCampaign`

The following code example shows how to use `DeleteCampaign`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    public static void deleteSpecificCampaign(PersonalizeClient personalizeClient,
 String campaignArn) {
        try {
            DeleteCampaignRequest campaignRequest = DeleteCampaignRequest.builder()
                    .campaignArn(campaignArn)
                    .build();

            personalizeClient.deleteCampaign(campaignRequest);
            System.out.println("Delete request sent successfully.");
        } catch (PersonalizeException e) {
            System.err.println("Error deleting campaign: " +
 e.awsErrorDetails().errorMessage());
            throw new RuntimeException(e);
        }
    }
}
```

- For API details, see DeleteCampaign in *Amazon SDK for Java 2.x API Reference*.

`DeleteEventTracker`

The following code example shows how to use `DeleteEventTracker`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void deleteEventTracker(PersonalizeClient personalizeClient,
String eventTrackerArn) {
       try {
           DeleteEventTrackerRequest deleteEventTrackerRequest =
DeleteEventTrackerRequest.builder()
                   .eventTrackerArn(eventTrackerArn)
                   .build();

           int status =
personalizeClient.deleteEventTracker(deleteEventTrackerRequest).sdkHttpResponse().statusCod

           System.out.println("Status code:" + status);

       } catch (PersonalizeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DeleteEventTracker in *Amazon SDK for Java 2.x API Reference*.

`DeleteSolution`

The following code example shows how to use `DeleteSolution`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void deleteGivenSolution(PersonalizeClient personalizeClient,
String solutionArn) {

       try {
           DeleteSolutionRequest solutionRequest = DeleteSolutionRequest.builder()
                   .solutionArn(solutionArn)
                   .build();

           personalizeClient.deleteSolution(solutionRequest);
           System.out.println("Done");

       } catch (PersonalizeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DeleteSolution in *Amazon SDK for Java 2.x API Reference*.

`DescribeCampaign`

The following code example shows how to use `DescribeCampaign`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void describeSpecificCampaign(PersonalizeClient personalizeClient,
String campaignArn) {

       try {
           DescribeCampaignRequest campaignRequest =
DescribeCampaignRequest.builder()
                   .campaignArn(campaignArn)
                   .build();
```

```
            DescribeCampaignResponse campaignResponse =
personalizeClient.describeCampaign(campaignRequest);
            Campaign myCampaign = campaignResponse.campaign();
            System.out.println("The Campaign name is " + myCampaign.name());
            System.out.println("The Campaign status is " + myCampaign.status());

        } catch (PersonalizeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see [DescribeCampaign](#) in *Amazon SDK for Java 2.x API Reference*.

`DescribeRecipe`

The following code example shows how to use `DescribeRecipe`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
    public static void describeSpecificRecipe(PersonalizeClient personalizeClient,
String recipeArn) {

        try {
            DescribeRecipeRequest recipeRequest = DescribeRecipeRequest.builder()
                    .recipeArn(recipeArn)
                    .build();

            DescribeRecipeResponse recipeResponse =
personalizeClient.describeRecipe(recipeRequest);
            System.out.println("The recipe name is " +
recipeResponse.recipe().name());

        } catch (PersonalizeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
```

```
            System.exit(1);
        }
    }
```

- For API details, see DescribeRecipe in *Amazon SDK for Java 2.x API Reference*.

`DescribeSolution`

The following code example shows how to use `DescribeSolution`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void describeSpecificSolution(PersonalizeClient personalizeClient,
String solutionArn) {

        try {
            DescribeSolutionRequest solutionRequest =
DescribeSolutionRequest.builder()
                    .solutionArn(solutionArn)
                    .build();

            DescribeSolutionResponse response =
personalizeClient.describeSolution(solutionRequest);
            System.out.println("The Solution name is " +
response.solution().name());

        } catch (PersonalizeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see DescribeSolution in *Amazon SDK for Java 2.x API Reference*.

`ListCampaigns`

The following code example shows how to use `ListCampaigns`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void listAllCampaigns(PersonalizeClient personalizeClient, String
solutionArn) {

       try {
           ListCampaignsRequest campaignsRequest = ListCampaignsRequest.builder()
                   .maxResults(10)
                   .solutionArn(solutionArn)
                   .build();

           ListCampaignsResponse response =
personalizeClient.listCampaigns(campaignsRequest);
           List<CampaignSummary> campaigns = response.campaigns();
           for (CampaignSummary campaign : campaigns) {
               System.out.println("Campaign name is : " + campaign.name());
               System.out.println("Campaign ARN is : " + campaign.campaignArn());
           }

       } catch (PersonalizeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see ListCampaigns in *Amazon SDK for Java 2.x API Reference*.

`ListDatasetGroups`

The following code example shows how to use `ListDatasetGroups`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void listDSGroups(PersonalizeClient personalizeClient) {

       try {
           ListDatasetGroupsRequest groupsRequest =
ListDatasetGroupsRequest.builder()
                   .maxResults(15)
                   .build();

           ListDatasetGroupsResponse groupsResponse =
personalizeClient.listDatasetGroups(groupsRequest);
           List<DatasetGroupSummary> groups = groupsResponse.datasetGroups();
           for (DatasetGroupSummary group : groups) {
               System.out.println("The DataSet name is : " + group.name());
               System.out.println("The DataSet ARN is : " +
group.datasetGroupArn());
           }

       } catch (PersonalizeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see ListDatasetGroups in *Amazon SDK for Java 2.x API Reference*.

`ListRecipes`

The following code example shows how to use `ListRecipes`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    public static void listAllRecipes(PersonalizeClient personalizeClient) {

        try {
            ListRecipesRequest recipesRequest = ListRecipesRequest.builder()
                    .maxResults(15)
                    .build();

            ListRecipesResponse response =
personalizeClient.listRecipes(recipesRequest);
            List<RecipeSummary> recipes = response.recipes();
            for (RecipeSummary recipe : recipes) {
                System.out.println("The recipe ARN is: " + recipe.recipeArn());
                System.out.println("The recipe name is: " + recipe.name());
            }

        } catch (PersonalizeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListRecipes in *Amazon SDK for Java 2.x API Reference*.

`ListSolutions`

The following code example shows how to use `ListSolutions`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void listAllSolutions(PersonalizeClient personalizeClient, String
datasetGroupArn) {

       try {
           ListSolutionsRequest solutionsRequest = ListSolutionsRequest.builder()
                   .maxResults(10)
                   .datasetGroupArn(datasetGroupArn)
                   .build();

           ListSolutionsResponse response =
personalizeClient.listSolutions(solutionsRequest);
           List<SolutionSummary> solutions = response.solutions();
           for (SolutionSummary solution : solutions) {

       }
```

```
        return "";
    }
```

- For API details, see UpdateCampaign in *Amazon SDK for Java 2.x API Reference*.

Amazon Personalize Events examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Personalize Events.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`PutEvents`

The following code example shows how to use `PutEvents`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    public static int putItems(PersonalizeEventsClient personalizeEventsClient,
                               String datasetArn,
                               String item1Id,
                               String item1PropertyName,
                               String item1PropertyValue,
```

```
                        String item2Id,
                        String item2PropertyName,
                        String item2PropertyValue) {

                int responseCode = 0;
                ArrayList<Item> items = new ArrayList<>();

                try {
                        Item item1 = Item.builder()
                                        .itemId(item1Id)
                                        .properties(String.format("{\"%1$s\": \"%2$s
\"}",
                                                                item1PropertyName,
 item1PropertyValue))
                                        .build();

                        items.add(item1);

                        Item item2 = Item.builder()
                                        .itemId(item2Id)
                                        .properties(String.format("{\"%1$s\": \"%2$s
\"}",
                                                                item2PropertyName,
 item2PropertyValue))
                                        .build();

                        items.add(item2);

                        PutItemsRequest putItemsRequest = PutItemsRequest.builder()
                                        .datasetArn(datasetArn)
                                        .items(items)
                                        .build();

                        responseCode =
 personalizeEventsClient.putItems(putItemsRequest).sdkHttpResponse().statusCode();
                        System.out.println("Response code: " + responseCode);
                        return responseCode;

                } catch (PersonalizeEventsException e) {
                        System.out.println(e.awsErrorDetails().errorMessage());
                }
                return responseCode;
        }
```

Amazon Personalize Runtime examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Personalize Runtime.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

`GetPersonalizedRanking`

The following code example shows how to use `GetPersonalizedRanking`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static List<PredictedItem> getRankedRecs(PersonalizeRuntimeClient
personalizeRuntimeClient,
           String campaignArn,
           String userId,
           ArrayList<String> items) {

       try {
           GetPersonalizedRankingRequest rankingRecommendationsRequest =
GetPersonalizedRankingRequest.builder()
                   .campaignArn(campaignArn)
                   .userId(userId)
                   .inputList(items)
                   .build();

           GetPersonalizedRankingResponse recommendationsResponse =
personalizeRuntimeClient
                   .getPersonalizedRanking(rankingRecommendationsRequest);
           List<PredictedItem> rankedItems =
recommendationsResponse.personalizedRanking();
           int rank = 1;
           for (PredictedItem item : rankedItems) {
               System.out.println("Item ranked at position " + rank + " details");
               System.out.println("Item Id is : " + item.itemId());
               System.out.println("Item score is : " + item.score());
               System.out.println("-----------------------------------------");
               rank++;
           }
           return rankedItems;
```

```
        } catch (PersonalizeRuntimeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
        return null;
    }
```

- For API details, see GetPersonalizedRanking in *Amazon SDK for Java 2.x API Reference*.

`GetRecommendations`

The following code example shows how to use `GetRecommendations`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Get a list of recommended items.

```
   public static void getRecs(PersonalizeRuntimeClient personalizeRuntimeClient,
String campaignArn, String userId) {

        try {
            GetRecommendationsRequest recommendationsRequest =
GetRecommendationsRequest.builder()
                    .campaignArn(campaignArn)
                    .numResults(20)
                    .userId(userId)
                    .build();

            GetRecommendationsResponse recommendationsResponse =
personalizeRuntimeClient
                    .getRecommendations(recommendationsRequest);
            List<PredictedItem> items = recommendationsResponse.itemList();
            for (PredictedItem item : items) {
                System.out.println("Item Id is : " + item.itemId());
                System.out.println("Item score is : " + item.score());
```

```
            }

        } catch (AwsServiceException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

Get a list of recommended items from a recommender created in a domain dataset group.

```
    public static void getRecs(PersonalizeRuntimeClient personalizeRuntimeClient,
String recommenderArn,
            String userId) {

        try {
            GetRecommendationsRequest recommendationsRequest =
GetRecommendationsRequest.builder()
                    .recommenderArn(recommenderArn)
                    .numResults(20)
                    .userId(userId)
                    .build();

            GetRecommendationsResponse recommendationsResponse =
personalizeRuntimeClient
                    .getRecommendations(recommendationsRequest);
            List<PredictedItem> items = recommendationsResponse.itemList();

            for (PredictedItem item : items) {
                System.out.println("Item Id is : " + item.itemId());
                System.out.println("Item score is : " + item.score());
            }
        } catch (AwsServiceException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

Use a filter when requesting recommendations.

```
    public static void getFilteredRecs(PersonalizeRuntimeClient
personalizeRuntimeClient,
```

```
            String campaignArn,
            String userId,
            String filterArn,
            String parameter1Name,
            String parameter1Value1,
            String parameter1Value2,
            String parameter2Name,
            String parameter2Value) {

        try {

            Map<String, String> filterValues = new HashMap<>();

            filterValues.put(parameter1Name, String.format("\"%1$s\",\"%2$s\"",
                    parameter1Value1, parameter1Value2));
            filterValues.put(parameter2Name, String.format("\"%1$s\"",
                    parameter2Value));

            GetRecommendationsRequest recommendationsRequest =
GetRecommendationsRequest.builder()
                    .campaignArn(campaignArn)
                    .numResults(20)
                    .userId(userId)
                    .filterArn(filterArn)
                    .filterValues(filterValues)
                    .build();

            GetRecommendationsResponse recommendationsResponse =
personalizeRuntimeClient
                    .getRecommendations(recommendationsRequest);
            List<PredictedItem> items = recommendationsResponse.itemList();

            for (PredictedItem item : items) {
                System.out.println("Item Id is : " + item.itemId());
                System.out.println("Item score is : " + item.score());
            }
        } catch (PersonalizeRuntimeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

Amazon Pinpoint SMS and Voice API examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Pinpoint SMS and Voice API.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Amazon Polly examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Polly.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

        return synthRes;
    }
}
```

- For API details, see SynthesizeSpeech in *Amazon SDK for Java 2.x API Reference*.

Scenarios

Create an application to analyze customer feedback

The following code example shows how to create an application that analyzes customer comment cards, translates them from their original language, determines their sentiment, and generates an audio file from the translated text.

SDK for Java 2.x

This example application analyzes and stores customer feedback cards. Specifically, it fulfills the need of a fictitious hotel in New York City. The hotel receives feedback from guests in various languages in the form of physical comment cards. That feedback is uploaded into the app through a web client. After an image of a comment card is uploaded, the following steps occur:

- Text is extracted from the image using Amazon Textract.
- Amazon Comprehend determines the sentiment of the extracted text and its language.
- The extracted text is translated to English using Amazon Translate.
- Amazon Polly synthesizes an audio file from the extracted text.

The full app can be deployed with the Amazon CDK. For source code and deployment instructions, see the project in GitHub.

Services used in this example

- Amazon Comprehend
- Lambda
- Amazon Polly
- Amazon Textract
- Amazon Translate

Amazon RDS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon RDS.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon RDS

The following code examples show how to get started using Amazon RDS.

SDK for Java 2.x

Basics

Learn the basics

The following code example shows how to:

- Create a custom DB parameter group and set parameter values.
- Create a DB instance that's configured to use the parameter group. The DB instance also contains a database.
- Take a snapshot of the instance.
- Delete the instance and parameter group.

SDK for Java 2.x

/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html
 *
 * This Java example performs these tasks:
 *
 * 1. Returns a list of the available DB engines.
 * 2. Selects an engine family and create a custom DB parameter group.
 * 3. Gets the parameter groups.
 * 4. Gets parameters in the group.
 * 5. Modifies the auto_increment_offset parameter.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions.
 * 8. Gets a list of micro instance classes available for the selected engine.
 * 9. Creates an RDS database instance that contains a MySql database and uses
 * the parameter group.
 * 10. Waits for the DB instance to be ready and prints out the connection
 * endpoint value.
 * 11. Creates a snapshot of the DB instance.
 * 12. Waits for an RDS DB snapshot to be ready.
 * 13. Deletes the RDS DB instance.
 * 14. Deletes the parameter group.
 */

`DescribeDBParameterGroups`

The following code example shows how to use `DescribeDBParameterGroups`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void describeDbParameterGroups(RdsClient rdsClient, String
 dbGroupName) {
        try {
            DescribeDbParameterGroupsRequest groupsRequest =
 DescribeDbParameterGroupsRequest.builder()
                    .dbParameterGroupName(dbGroupName)
                    .maxRecords(20)
                    .build();

            DescribeDbParameterGroupsResponse response =
 rdsClient.describeDBParameterGroups(groupsRequest);
            List<DBParameterGroup> groups = response.dbParameterGroups();
            for (DBParameterGroup group : groups) {
```

```
                System.out.println("The group name is " +
group.dbParameterGroupName());
                System.out.println("The group description is " +
group.description());
            }

        } catch (RdsException e) {
            System.out.println(e.getLocalizedMessage());
            System.exit(1);
        }
    }
```

- For API details, see DescribeDBParameterGroups in *Amazon SDK for Java 2.x API Reference*.

`DescribeDBParameters`

The following code example shows how to use `DescribeDBParameters`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    // Retrieve parameters in the group.
    public static void describeDbParameters(RdsClient rdsClient, String dbGroupName,
int flag) {
        try {
            DescribeDbParametersRequest dbParameterGroupsRequest;
            if (flag == 0) {
                dbParameterGroupsRequest = DescribeDbParametersRequest.builder()
                        .dbParameterGroupName(dbGroupName)
                        .build();
            } else {
                dbParameterGroupsRequest = DescribeDbParametersRequest.builder()
                        .dbParameterGroupName(dbGroupName)
                        .source("user")
                        .build();
            }
```

```
            DescribeDbParametersResponse response =
rdsClient.describeDBParameters(dbParameterGroupsRequest);
            List<Parameter> dbParameters = response.parameters();
            String paraName;
            for (Parameter para : dbParameters) {
                // Only print out information about either auto_increment_offset or
                // auto_increment_increment.
                paraName = para.parameterName();
                if ((paraName.compareTo("auto_increment_offset") == 0)
                        || (paraName.compareTo("auto_increment_increment ") == 0)) {
                    System.out.println("*** The parameter name is  " + paraName);
                    System.out.println("*** The parameter value is  " +
para.parameterValue());

`GenerateRDSAuthToken`

The following code example shows how to use `GenerateRDSAuthToken`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Use the RdsUtilities class to generate an authentication token.

```
public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        final String usage = """

                Usage:
                    <dbInstanceIdentifier> <masterUsername>

                Where:
                    dbInstanceIdentifier - The database instance identifier.\s
                    masterUsername - The master user name.\s
                """;

        if (args.length != 2) {
            System.out.println(usage);
            System.exit(1);
        }

        String dbInstanceIdentifier = args[0];
        String masterUsername = args[1];
        Region region = Region.US_WEST_2;
        RdsClient rdsClient = RdsClient.builder()
                .region(region)
                .build();

        String token = getAuthToken(rdsClient, dbInstanceIdentifier,
masterUsername);
        System.out.println("The token response is " + token);
    }

    public static String getAuthToken(RdsClient rdsClient, String
dbInstanceIdentifier, String masterUsername) {

        RdsUtilities utilities = rdsClient.utilities();
        try {
            GenerateAuthenticationTokenRequest tokenRequest =
GenerateAuthenticationTokenRequest.builder()
                    .credentialsProvider(ProfileCredentialsProvider.create())
                    .username(masterUsername)
                    .port(3306)
                    .hostname(dbInstanceIdentifier)
                    .build();
```

```
            return utilities.generateAuthenticationToken(tokenRequest);

        } catch (RdsException e) {
            System.out.println(e.getLocalizedMessage());
            System.exit(1);
        }
        return "";
    }
}
```

Scenarios

Create an Aurora Serverless work item tracker

The following code example shows how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Serverless examples

Connecting to an Amazon RDS database in a Lambda function

The following code example shows how to implement a Lambda function that connects to an RDS database. The function makes a simple database request and returns the result.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Connecting to an Amazon RDS database in a Lambda function using Java.

        return tokenField.stringValue();
    }
}
```

Amazon RDS Data Service examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon RDS Data Service.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Create an Aurora Serverless work item tracker

The following code example shows how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

- Amazon SES

Amazon Redshift examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Redshift.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Redshift

The following code examples show how to get started using Amazon Redshift.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.redshift.RedshiftClient;
import software.amazon.awssdk.services.redshift.paginators.DescribeClustersIterable;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
```

```
public class HelloRedshift {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        RedshiftClient redshiftClient = RedshiftClient.builder()
            .region(region)
            .build();

        listClustersPaginator(redshiftClient);
    }

    public static void listClustersPaginator(RedshiftClient redshiftClient) {
        DescribeClustersIterable clustersIterable =
 redshiftClient.describeClustersPaginator();
        clustersIterable.stream()
            .flatMap(r -> r.clusters().stream())
            .forEach(cluster -> System.out
                .println(" Cluster identifier: " + cluster.clusterIdentifier() + "
 status = " + cluster.clusterStatus()));
    }
}
```

- For API details, see DescribeClusters in *Amazon SDK for Java 2.x API Reference*.

Topics

Basics

Learn the basics

The following code example shows how to:

- Create a Redshift cluster.
- List databases in the cluster.
- Create a table named Movies.
- Populate the Movies table.

- Query the Movies table by year.
- Modify the Redshift cluster.
- Delete the Amazon Redshift cluster.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Run an interactive scenario demonstrating Amazon Redshift features.

```
import com.example.redshift.User;
import com.google.gson.Gson;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 *
```

```
 *  This example requires an AWS Secrets Manager secret that contains the
 *  database credentials. If you do not create a
 *  secret that specifies user name and password, this example will not work. For
 details, see:
 *
 *  https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html
 *
 This Java example performs these tasks:
 *
 * 1. Prompts the user for a unique cluster ID or use the default value.
 * 2. Creates a Redshift cluster with the specified or default cluster Id value.
 * 3. Waits until the Redshift cluster is available for use.
 * 4. Lists all databases using a pagination API call.
 * 5. Creates a table named "Movies" with fields ID, title, and year.
 * 6. Inserts a specified number of records into the "Movies" table by reading the
 Movies JSON file.
 * 7. Prompts the user for a movie release year.
 * 8. Runs a SQL query to retrieve movies released in the specified year.
 * 9. Modifies the Redshift cluster.
 * 10. Prompts the user for confirmation to delete the Redshift cluster.
 * 11. If confirmed, deletes the specified Redshift cluster.
 */

           });
   }
```

- For API details, see ModifyCluster in *Amazon SDK for Java 2.x API Reference*.

Scenarios

Create a web application to track Amazon Redshift data

The following code example shows how to create a web application that tracks and reports on work items using an Amazon Redshift database.

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon Redshift database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Redshift data and for use by a React application, see the full example on GitHub.

Services used in this example

- Amazon Redshift
- Amazon SES

Amazon Rekognition examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon Rekognition.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Scenarios

Create a serverless application to manage photos

The following code example shows how to create a serverless application that lets users manage photos using labels.

SDK for Java 2.x

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on Amazon Community.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Detect PPE in images

The following code example shows how to build an app that uses Amazon Rekognition to detect Personal Protective Equipment (PPE) in images.

SDK for Java 2.x

Shows how to create an Amazon Lambda function that detects images with Personal Protective Equipment.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3
- Amazon SES

Detect information in videos

The following code example shows how to:

- Start Amazon Rekognition jobs to detect elements like people, objects, and text in videos.
- Check job status until jobs finish.
- Output the list of elements detected by each job.

SDK for Java 2.x

Detect objects in images

The following code example shows how to build an app that uses Amazon Rekognition to detect objects by category in images.

SDK for Java 2.x

Shows how to use Amazon Rekognition Java API to create an app that uses Amazon Rekognition to identify objects by category in images located in an Amazon Simple Storage Service (Amazon S3) bucket. The app sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Amazon Rekognition
- Amazon S3
- Amazon SES

Detect people and objects in a video

The following code example shows how to detect people and objects in a video with Amazon Rekognition.

SDK for Java 2.x

Shows how to use Amazon Rekognition Java API to create an app to detect faces and objects in videos located in an Amazon Simple Storage Service (Amazon S3) bucket. The app sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Amazon Rekognition
- Amazon S3
- Amazon SES
- Amazon SNS
- Amazon SQS

Route 53 domain registration examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Route 53 domain registration.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Route 53 domain registration

The following code examples show how to get started using Route 53 domain registration.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Basics

Learn the basics

The following code example shows how to:

- List current domains, and list operations in the past year.
- View billing for the past year, and view prices for domain types.
- Get domain suggestions.
- Check domain availability and transferability.
- Optionally, request a domain registration.
- Get an operation detail.
- Optionally, get a domain detail.

SDK for Java 2.x

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This example uses pagination methods where applicable. For example, to list
 * domains, the
 * listDomainsPaginator method is used. For more information about pagination,
 * see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/pagination.html
 *
 * This Java code example performs the following operations:
 *
 * 1. List current domains.
 * 2. List operations in the past year.
 * 3. View billing for the account in the past year.
 * 4. View prices for domain types.
 * 5. Get domain suggestions.
 * 6. Check domain availability.
```

```
 * 7. Check domain transferability.
 * 8. Request a domain registration.
 * 9. Get operation details.
 * 10. Optionally, get domain details.

```

```
        } catch (Route53Exception e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see CheckDomainTransferability in *Amazon SDK for Java 2.x API Reference*.

`GetDomainDetail`

The following code example shows how to use `GetDomainDetail`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void getDomainDetails(Route53DomainsClient route53DomainsClient,
String domainSuggestion) {
        try {
            GetDomainDetailRequest detailRequest = GetDomainDetailRequest.builder()
                    .domainName(domainSuggestion)
                    .build();

            GetDomainDetailResponse response =
route53DomainsClient.getDomainDetail(detailRequest);
            System.out.println("The contact first name is " +
response.registrantContact().firstName());
            System.out.println("The contact last name is " +
response.registrantContact().lastName());
            System.out.println("The contact org name is " +
response.registrantContact().organizationName());

        } catch (Route53Exception e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
```

```
    }
```

- For API details, see GetDomainDetail in *Amazon SDK for Java 2.x API Reference*.

`GetDomainSuggestions`

The following code example shows how to use `GetDomainSuggestions`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void listDomainSuggestions(Route53DomainsClient
route53DomainsClient, String domainSuggestion) {
       try {
           GetDomainSuggestionsRequest suggestionsRequest =
GetDomainSuggestionsRequest.builder()
                   .domainName(domainSuggestion)
                   .suggestionCount(5)
                   .onlyAvailable(true)
                   .build();

           GetDomainSuggestionsResponse response =
route53DomainsClient.getDomainSuggestions(suggestionsRequest);
           List<DomainSuggestion> suggestions = response.suggestionsList();
           for (DomainSuggestion suggestion : suggestions) {
               System.out.println("Suggestion Name: " + suggestion.domainName());
               System.out.println("Availability: " + suggestion.availability());
               System.out.println(" ");
           }

       } catch (Route53Exception e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
   }
```

- For API details, see GetDomainSuggestions in *Amazon SDK for Java 2.x API Reference*.

`GetOperationDetail`

The following code example shows how to use `GetOperationDetail`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void getOperationalDetail(Route53DomainsClient
route53DomainsClient, String operationId) {
       try {
           GetOperationDetailRequest detailRequest =
GetOperationDetailRequest.builder()
                   .operationId(operationId)
                   .build();

           GetOperationDetailResponse response =
route53DomainsClient.getOperationDetail(detailRequest);
           System.out.println("Operation detail message is " + response.message());

       } catch (Route53Exception e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
   }
```

- For API details, see GetOperationDetail in *Amazon SDK for Java 2.x API Reference*.

`ListDomains`

The following code example shows how to use `ListDomains`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    public static void listDomains(Route53DomainsClient route53DomainsClient) {
        try {
            ListDomainsIterable listRes =
route53DomainsClient.listDomainsPaginator();
            listRes.stream()
                    .flatMap(r -> r.domains().stream())
                    .forEach(content -> System.out.println("The domain name is " +
content.domainName()));

        } catch (Route53Exception e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListDomains in *Amazon SDK for Java 2.x API Reference*.

`ListOperations`

The following code example shows how to use `ListOperations`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    public static void listOperations(Route53DomainsClient route53DomainsClient) {
```

```
        try {
            Date currentDate = new Date();
            LocalDateTime localDateTime =
currentDate.toInstant().atZone(ZoneId.systemDefault()).toLocalDateTime();
            ZoneOffset zoneOffset = ZoneOffset.of("+01:00");
            localDateTime = localDateTime.minusYears(1);
            Instant myTime = localDateTime.toInstant(zoneOffset);

            ListOperationsRequest operationsRequest =
ListOperationsRequest.builder()
                    .submittedSince(myTime)
                    .build();

            ListOperationsIterable listRes =
route53DomainsClient.listOperationsPaginator(operationsRequest);
            listRes.stream()
                    .flatMap(r -> r.operations().stream())
                    .forEach(content -> System.out.println(" Operation Id: " +
content.operationId() +
                            " Status: " + content.statusAsString() +
                            " Date: " + content.submittedDate()));

        } catch (Route53Exception e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListOperations in *Amazon SDK for Java 2.x API Reference*.

`ListPrices`

The following code example shows how to use `ListPrices`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void listPrices(Route53DomainsClient route53DomainsClient, String
domainType) {
       try {
           ListPricesRequest pricesRequest = ListPricesRequest.builder()
                   .tld(domainType)
                   .build();

           ListPricesIterable listRes =
route53DomainsClient.listPricesPaginator(pricesRequest);
           listRes.stream()
                   .flatMap(r -> r.prices().stream())
                   .forEach(content -> System.out.println(" Name: " +
content.name() +
                           " Registration: " + content.registrationPrice().price()
+ " "
                           + content.registrationPrice().currency() +
                           " Renewal: " + content.renewalPrice().price() + " " +
content.renewalPrice().currency()));

       } catch (Route53Exception e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
   }
```

- For API details, see ListPrices in *Amazon SDK for Java 2.x API Reference*.

`RegisterDomain`

The following code example shows how to use `RegisterDomain`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static String requestDomainRegistration(Route53DomainsClient
route53DomainsClient,
           String domainSuggestion,
           String phoneNumber,
           String email,
           String firstName,
           String lastName,
           String city) {

       try {
           ContactDetail contactDetail = ContactDetail.builder()
                   .contactType(ContactType.COMPANY)
                   .state("LA")
                   .countryCode(CountryCode.IN)
                   .email(email)
                   .firstName(firstName)
                   .lastName(lastName)
                   .city(city)
                   .phoneNumber(phoneNumber)
                   .organizationName("My Org")
                   .addressLine1("My Address")
                   .zipCode("123 123")
                   .build();

           RegisterDomainRequest domainRequest = RegisterDomainRequest.builder()
                   .adminContact(contactDetail)
                   .registrantContact(contactDetail)
                   .techContact(contactDetail)
                   .domainName(domainSuggestion)
                   .autoRenew(true)
                   .durationInYears(1)
                   .build();

           RegisterDomainResponse response =
route53DomainsClient.registerDomain(domainRequest);
           System.out.println("Registration requested. Operation Id: " +
response.operationId());
           return response.operationId();

       } catch (Route53Exception e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
```

```
        return "";
    }
```

- For API details, see RegisterDomain in *Amazon SDK for Java 2.x API Reference*.

`ViewBilling`

The following code example shows how to use `ViewBilling`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   public static void listBillingRecords(Route53DomainsClient route53DomainsClient)
{
       try {
           Date currentDate = new Date();
           LocalDateTime localDateTime =
currentDate.toInstant().atZone(ZoneId.systemDefault()).toLocalDateTime();
           ZoneOffset zoneOffset = ZoneOffset.of("+01:00");
           LocalDateTime localDateTime2 = localDateTime.minusYears(1);
           Instant myStartTime = localDateTime2.toInstant(zoneOffset);
           Instant myEndTime = localDateTime.toInstant(zoneOffset);

           ViewBillingRequest viewBillingRequest = ViewBillingRequest.builder()
                   .start(myStartTime)
                   .end(myEndTime)
                   .build();

           ViewBillingIterable listRes =
route53DomainsClient.viewBillingPaginator(viewBillingRequest);
           listRes.stream()
                   .flatMap(r -> r.billingRecords().stream())
                   .forEach(content -> System.out.println(" Bill Date:: " +
content.billDate() +
                           " Operation: " + content.operationAsString() +
                           " Price: " + content.price()));
```

```
        } catch (Route53Exception e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see ViewBilling in *Amazon SDK for Java 2.x API Reference*.

Amazon S3 examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the Amazon SDK for Java 2.x with Amazon S3.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon S3

The following code examples show how to get started using Amazon S3.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.Bucket;
import software.amazon.awssdk.services.s3.model.ListBucketsResponse;
import software.amazon.awssdk.services.s3.model.S3Exception;
import java.util.List;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * <p>
 * For more information, see the following documentation topic:
 * <p>
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloS3 {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        S3Client s3 = S3Client.builder()
            .region(region)
            .build();

        listBuckets(s3);
    }

    /**
     * Lists all the S3 buckets associated with the provided AWS S3 client.
     *
     * @param s3 the S3Client instance used to interact with the AWS S3 service
     */
    public static void listBuckets(S3Client s3) {
        try {
            ListBucketsResponse response = s3.listBuckets();
            List<Bucket> bucketList = response.buckets();
            bucketList.forEach(bucket -> {
                System.out.println("Bucket Name: " + bucket.name());
            });

        } catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
```

- For API details, see ListBuckets in *Amazon SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions
- Scenarios
- Serverless examples

Basics

Learn the basics

The following code example shows how to:

- Create a bucket and upload a file to it.
- Download an object from a bucket.
- Copy an object to a subfolder in a bucket.
- List the objects in a bucket.
- Delete the bucket objects and the bucket.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

A scenario example.

```
import java.io.IOException;
import java.util.Scanner;
import java.util.UUID;
import java.util.concurrent.CompletableFuture;
```

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.s3.model.PutObjectResponse;
import software.amazon.awssdk.services.s3.model.S3Exception;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java code example performs the following tasks:
 *
 * 1. Creates an Amazon S3 bucket.
 * 2. Uploads an object to the bucket.
 * 3. Downloads the object to another local file.
 * 4. Uploads an object using multipart upload.
 * 5. List all objects located in the Amazon S3 bucket.
 * 6. Copies the object to another Amazon S3 bucket.
 * 7. Copy the object to another Amazon S3 bucket using multi copy.
 * 8. Deletes the object from the Amazon S3 bucket.
 * 9. Deletes the Amazon S3 bucket.
 */

public class S3Scenario {

    public static Scanner scanner = new Scanner(System.in);

        String toBucket = args[4];

        logger.info(DASHES);
        logger.info("Welcome to the Amazon Simple Storage Service (S3) example
scenario.");
        logger.info("""
            Amazon S3 is a highly scalable and durable object storage
            service provided by Amazon Web Services (AWS). It is designed to store
and retrieve
            any amount of data, from anywhere on the web, at any time.

            The `S3AsyncClient` interface in the AWS SDK for Java 2.x provides a set
of methods to
            programmatically interact with the Amazon S3 (Simple Storage Service)
service. This allows
            developers to automate the management and manipulation of S3 buckets and
objects as
            part of their application deployment pipelines. With S3, teams can focus
on building
            and deploying their applications without having to worry about the
underlying storage
            infrastructure required to host and manage large amounts of data.

            This scenario walks you through how to perform key operations for this
service.
            Let's get started...
            """);

`CreateBucket`

The following code example shows how to use `CreateBucket`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Create a bucket.

```
   /**
    * Creates an S3 bucket asynchronously.
    *
    * @param bucketName the name of the S3 bucket to create
    * @return a {@link CompletableFuture} that completes when the bucket is created
and ready
    * @throws RuntimeException if there is a failure while creating the bucket
    */
   public CompletableFuture<Void> createBucketAsync(String bucketName) {
       CreateBucketRequest bucketRequest = CreateBucketRequest.builder()
           .bucket(bucketName)
           .build();

       CompletableFuture<CreateBucketResponse> response =
getAsyncClient().createBucket(bucketRequest);
       return response.thenCompose(resp -> {
           S3AsyncWaiter s3Waiter = getAsyncClient().waiter();
           HeadBucketRequest bucketRequestWait = HeadBucketRequest.builder()
               .bucket(bucketName)
               .build();

           CompletableFuture<WaiterResponse<HeadBucketResponse>>
waiterResponseFuture =
               s3Waiter.waitUntilBucketExists(bucketRequestWait);
           return waiterResponseFuture.thenAccept(waiterResponse -> {
               waiterResponse.matched().response().ifPresent(headBucketResponse ->
{
                   logger.info(bucketName + " is ready");
```

```
                });
            });
        }).whenComplete((resp, ex) -> {
            if (ex != null) {
                throw new RuntimeException("Failed to create bucket", ex);
            }
        });
    }
```

Create a bucket with object lock enabled.

```
    // Create a new Amazon S3 bucket with object lock options.
    public void createBucketWithLockOptions(boolean enableObjectLock, String
bucketName) {
        S3Waiter s3Waiter = getClient().waiter();
        CreateBucketRequest bucketRequest = CreateBucketRequest.builder()
            .bucket(bucketName)
            .objectLockEnabledForBucket(enableObjectLock)
            .build();

        getClient().createBucket(bucketRequest);
        HeadBucketRequest bucketRequestWait = HeadBucketRequest.builder()
            .bucket(bucketName)
            .build();

        // Wait until the bucket is created and print out the response.
        s3Waiter.waitUntilBucketExists(bucketRequestWait);
        System.out.println(bucketName + " is ready");
    }
```

- For API details, see CreateBucket in *Amazon SDK for Java 2.x API Reference*.

`DeleteBucket`

`GetBucketReplication`

The following code example shows how to use `GetBucketReplication`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
   /**
    * Retrieves the replication details for the specified S3 bucket.
    *
    * @param s3Client           the S3 client used to interact with the S3 service
    * @param sourceBucketName   the name of the S3 bucket to retrieve the
replication details for
    *
    * @throws S3Exception if there is an error retrieving the replication details
    */
   public static void getReplicationDetails(S3Client s3Client, String
sourceBucketName) {
       GetBucketReplicationRequest getRequest =
GetBucketReplicationRequest.builder()
           .bucket(sourceBucketName)
           .build();

       try {
           ReplicationConfiguration replicationConfig =
s3Client.getBucketReplication(getRequest).replicationConfiguration();
           ReplicationRule rule = replicationConfig.rules().get(0);
           System.out.println("Retrieved destination bucket: " +
rule.destination().bucket());
           System.out.println("Retrieved priority: " + rule.priority());
           System.out.println("Retrieved source-bucket replication rule status: " +
rule.status());

       } catch (S3Exception e) {
           System.err.println("Failed to retrieve replication details: " +
e.awsErrorDetails().errorMessage());
       }
   }
```

- For API details, see GetBucketReplication in *Amazon SDK for Java 2.x API Reference*.

`GetObject`

The following code example shows how to use `GetObject`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Read data as a byte array using an S3Client.

```
   /**
    * Asynchronously retrieves the bytes of an object from an Amazon S3 bucket and
writes them to a local file.
    *
    * @param bucketName the name of the S3 bucket containing the object
    * @param keyName    the key (or name) of the S3 object to retrieve
    * @param path       the local file path where the object's bytes will be
written
    * @return a {@link CompletableFuture} that completes when the object bytes have
been written to the local file
    */
   public CompletableFuture<Void> getObjectBytesAsync(String bucketName, String
keyName, String path) {
       GetObjectRequest objectRequest = GetObjectRequest.builder()
           .key(keyName)
           .bucket(bucketName)
           .build();

       CompletableFuture<ResponseBytes<GetObjectResponse>> response =
getAsyncClient().getObject(objectRequest, AsyncResponseTransformer.toBytes());
       return response.thenAccept(objectBytes -> {
           try {
               byte[] data = objectBytes.asByteArray();
```

```
                Path filePath = Paths.get(path);
                Files.write(filePath, data);
                logger.info("Successfully obtained bytes from an S3 object");
            } catch (IOException ex) {
                throw new RuntimeException("Failed to write data to file", ex);
            }
        }).whenComplete((resp, ex) -> {
            if (ex != null) {
                throw new RuntimeException("Failed to get object bytes from S3",
ex);
            }
        });
    }
```

Use an S3TransferManager to download an object in an S3 bucket to a local file. View the complete file and test.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.core.sync.RequestBody;
import software.amazon.awssdk.transfer.s3.S3TransferManager;
import software.amazon.awssdk.transfer.s3.model.CompletedFileDownload;
import software.amazon.awssdk.transfer.s3.model.DownloadFileRequest;
import software.amazon.awssdk.transfer.s3.model.FileDownload;
import software.amazon.awssdk.transfer.s3.progress.LoggingTransferListener;

import java.io.IOException;
import java.net.URISyntaxException;
import java.net.URL;
import java.nio.file.Files;
import java.nio.file.Path;
import java.nio.file.Paths;
import java.util.UUID;

    public Long downloadFile(S3TransferManager transferManager, String bucketName,
                             String key, String downloadedFileWithPath) {
        DownloadFileRequest downloadFileRequest = DownloadFileRequest.builder()
                .getObjectRequest(b -> b.bucket(bucketName).key(key))
                .destination(Paths.get(downloadedFileWithPath))
                .build();
```

```
        FileDownload downloadFile =
 transferManager.downloadFile(downloadFileRequest);

        CompletedFileDownload downloadResult =
 downloadFile.completionFuture().join();
        logger.info("Content length [{}]",
 downloadResult.response().contentLength());
        return downloadResult.response().contentLength();
    }
```

Read tags that belong to an object using an S3Client.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.s3.S3Client;
import software.amazon.awssdk.services.s3.model.GetObjectTaggingRequest;
